Table of Contents

Preface **29**
About This Guide 29

Basic System **33**

IEEE 1588 for Frequency, Phase, and Time Distribution **35**
Applicability 35
Overview 35
Configuration 48
Conclusion 68

Synchronous Ethernet **69**
Applicability 69
Summary 69
Overview 70
Configuration 76
Conclusion 82

System Management **83**

Distributed CPU Protection **85**
Applicability 85
Overview 85
Configuration 86
Conclusion 107

Event Handling System **109**
Applicability 109
Overview 109
Configuration 110
Conclusion 122

Interface Configuration **123**

Multi-Chassis APS and Pseudowire Redundancy Interworking **125**
Applicability 125
Overview 125
Configuration 128
Conclusion 143

Multi-Chassis LAG and Pseudowire Redundancy Interworking **145**
Applicability 145
Overview 145

Configuration 147
Conclusion 165

Router Configuration 167

Aggregate Route Indirect Next-Hop Option 169
Applicability 169
Overview 169
Configuration 170
Conclusion 177

Bi-Directional Forwarding Detection 179
Applicability 179
Overview 179
Configuration 181
Conclusion 220

LFA Policies Using OSPF as IGP 223
Applicability 223
Overview 223
Configuration 225
Conclusion 242

Unicast Routing Protocols 243

Associating Communities with Static and Aggregate Routes 245
Applicability 245
Overview 246
Configuration 247
Conclusion 272

BGP FlowSpec for IPv4 and IPv6 273
Applicability 273
Overview 273
Configuration 277
Conclusion 292

BGP Multipath 293
Applicability 293
Overview 293
Configuration 295
Conclusion 316

BGP Route Leaking 317
Applicability 317
Overview 317
Configuration 319

Conclusion 351

IS-IS Link Bundling 353
Applicability 353
Overview 353
Configuration 357
Conclusion 369

Policy Chaining and Logical Expressions 371
Applicability 371
Overview 371
Configuration 375
Conclusion 392

Separate BGP RIBs for Labeled Routes 393
Applicability 393
Overview 393
Configuration 399
Conclusion 419

MPLS 421

Automatic Bandwidth Adjustment in P2P LSPs 423
Applicability 423
Overview 423
Configuration 434
Conclusion 458

Automatic Creation of RSVP-TE LSPs 459
Applicability 459
Overview 459
Configuration 460
Conclusion 477

Class-Based Forwarding 479
Applicability 479
Overview 479
Configuration 480
Conclusion 514

DiffServ Traffic Engineering 515
Applicability 515
Overview 515
Configuration 527
Conclusion 551

Entropy Label 553
Applicability 553

Overview 553
Configuration 556
Conclusion 567

IGP Shortcuts 569
Applicability 569
Overview 569
Configuration 571
Conclusion 620

Inter-Area TE Point-to-Point LSPs 621
Applicability 621
Summary 621
Overview 623
Configuration 624
Conclusion 642

LDP FEC to BGP Label Route Stitching 643
Applicability 643
Overview 643
Configuration 646
Conclusion 671

LDP over RSVP Using OSPF as IGP 673
Applicability 673
Overview 673
Configuration 675
Conclusion 708

LDP Point-to-Point LSPs 709
Applicability 709
Overview 709
Configuration 713
Conclusion 725

LDP-SR Stitching for IPv4 Prefixes (IS-IS) 727
Applicability 727
Overview 727
Configuration 728
Conclusion 742

MPLS LDP FRR using ISIS as IGP 743
Applicability 743
Overview 743
Configuration 744
Conclusion 767

MPLS Transport Profile 769
Applicability 769
Summary 769
Overview 770
Configuration 771
Conclusion 794

Multicast Label Distribution Protocol 795
Applicability 795
Overview 795
Configuration 797
Conclusion 826

RSVP Point-to-Point LSPs 827
Applicability 827
Overview 827
Configuration 831
Conclusion 867

RSVP Signaled Point-to-Multipoint LSPs 869
Applicability 869
Overview 869
Configuration 870
Conclusion 911

Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP 913
Applicability 913
Overview 913
Configuration 915
Conclusion 933

Segment Routing with IS-IS Control Plane 935
Applicability 935
Overview 935
Configuration 937
Conclusion 957

Shared Risk Link Groups for RSVP-Based LSP 959
Applicability 959
Overview 959
Configuration 961
Conclusion 978

Static Point-to-Point LSPs 979
Applicability 979
Overview 979
Configuration 983
Conclusion 989

Tunneling of ICMP Reply Packets over MPLS LSPs 991
Applicability 991
Overview 991
Configuration 1002
Conclusion 1014

Unnumbered Interfaces in RSVP-TE and LDP 1015
Applicability 1015
Overview 1015
Configuration 1024
Conclusion 1060

Services Overview 1061

G.8032 Ethernet Ring Protection Multiple Ring Topology 1063
Applicability 1063
Overview 1063
Configuration 1071
Conclusion 1106

G.8032 Ethernet Ring Protection Single Ring Topology 1107
Applicability 1107
Overview 1107
Configuration 1110
Conclusion 1127

Layer 2 Services and EVPN 1129

BGP Multi-Homing for VPLS Networks 1131
Applicability 1131
Summary 1131
Overview 1133
Configuration 1135
Conclusion 1164

BGP Virtual Private Wire Services 1165
Applicability 1165
Overview 1166
Configuration 1169
Conclusion 1194

BGP VPLS 1195
Applicability 1195
Summary 1195
Overview 1196
Configuration 1197
Conclusion 1228

EVPN for MPLS Tunnels 1229
Applicability 1229
Overview 1229
Configuration 1231
Conclusion 1281

EVPN for MPLS Tunnels in Epipe Services (EVPN-VPWS) 1283
Applicability 1283
Overview 1283
Configuration 1285
Conclusion 1311

EVPN for PBB over MPLS (PBB-EVPN) 1313
Applicability 1313
Overview 1313
Configuration 1316
Conclusion 1350

EVPN for VXLAN Tunnels (Layer 2) 1351
Applicability 1351
Overview 1351
Configuration 1353
Conclusion 1377

EVPN for VXLAN Tunnels (Layer 3) 1379
Applicability 1379
Overview 1379
Configuration 1380
Conclusion 1418

EVPN-MPLS Interconnect for EVPN-VXLAN VPLS Services 1419
Applicability 1419
Overview 1419
Configuration 1421
Conclusion 1444

Fully Dynamic VSD Integration Model 1445
Applicability 1445
Overview 1446
Configuration 1453
Conclusion 1496

Inter-AS Model C for VLL 1497
Applicability 1497
Overview 1497
Configuration 1499
Conclusion 1515

LDP VPLS using BGP-Auto Discovery 1517
Applicability 1517
Summary 1517
Overview 1518
Configuration 1520
Conclusion 1542

Multi-Chassis Endpoint for VPLS Active/Standby Pseudowire 1543
Applicability 1543
Overview 1543
Configuration 1547
Conclusion 1567

Multi-Segment Pseudowire Routing 1569
Applicability 1569
Summary 1569
Overview 1570
Configuration 1573
Conclusion 1617

P2MP mLDP Tunnels for BUM Traffic in EVPN-MPLS Services 1619
Applicability 1619
Overview 1619
Configuration 1624
Conclusion 1643

PBB-Epipe 1645
Applicability 1645
Overview 1645
Configuration 1647
Conclusion 1664

PBB-VPLS 1665
Applicability 1665
Summary 1665
Overview 1666
Configuration 1667
Conclusion 1700

Shortest Path Bridging for MAC 1701
Applicability 1701
Overview 1701
Configuration 1703
Conclusion 1730

Layer 3 Services 1731

Carrier Supporting Carrier IP VPNs 1733
Applicability 1733
Overview 1733
Configuration 1736
Conclusion 1756

Layer 3 VPN: VPRN Type Spoke 1757
Applicability 1757
Summary 1757
Overview 1757
Configuration 1760
Conclusion 1770

NG-MVPN Configuration with PIM 1771
Applicability 1771
Summary 1771
Overview 1774
Configuration 1776
Conclusion 1817

NG-MVPN Configuration with MPLS 1819
Applicability 1819
Summary 1819
Overview 1821
Configuration 1823
Conclusion 1873

Rosen MVPN Core Diversity 1875
Applicability 1875
Overview 1875
Configuration 1881
Conclusion 1900

Rosen MVPN Inter-AS Option B 1901
Applicability 1901
Overview 1901
Configuration 1909
Conclusion 1926

NG-MVPN Sender-Only, Receiver-Only 1927
Applicability 1927
Overview 1927
Configuration 1929
Conclusion 1974

NG-MVPN Wildcard S-PMSI 1975
Applicability 1975
Overview 1975
Configuration 1979
Conclusion 2003

NG-MVPN Source Redundancy 2005
Applicability 2005
Summary 2005
Overview 2006
Configuration 2008
Conclusion 2037

Spoke Termination for IPv6-6VPE 2039
Applicability 2039
Overview 2039
Configuration 2041
Conclusion 2061

Traffic Leaking from VPRN to GRT 2063
Applicability 2063
Overview 2063
Configuration 2064
Conclusion 2084

VPRN Inter-AS VPN Model C 2085
Applicability 2085
Overview 2085
Configuration 2089
Conclusion 2099

Quality of Service 2101

Class Fair Hierarchical Policing for SAPs 2103
Applicability 2103
Summary 2103
Overview 2104
Configuration 2113
Conclusion 2140

FP and Port Queue Groups 2141
Applicability 2141
Overview 2141
Configuration 2143
Conclusion 2181

Pseudowire QoS 2183
Applicability 2183

Overview 2183
Configuration 2188
Conclusion 2204

QoS Architecture and Basic Operation 2205
Applicability 2205
Overview 2205
Configuration 2206
Conclusion 2245

Preface

About This Guide

The Advanced Configuration Guide is divided into two books, the Part I Guide and the Part II Guide.

Part I provides advanced configurations for basic systems, system management, interface configuration, router configuration, unicast routing protocols, MPLS, services overview, Layer 2 and EVPN services, Layer 3 services, and Quality of Service.

Part II provides advanced configurations for Multi-Service Integrated Service Adapter and Triple Play Service Delivery Architecture.

Parts I and II of the Advanced Configuration Guide supplement the user configuration guides listed below.

The guide is organized alphabetically within each chapter and provides feature and configuration explanations, CLI descriptions and overall solutions. The chapters in the Advanced Configuration Guide are written for and based on several releases, up to 14.0.R5. The Applicability section in each chapter specifies on which release the configuration is based.

Audience

This manual is intended for network administrators who are responsible for configuring the routers. It is assumed that the network administrators have a detailed understanding of networking principles and configurations.

List of Technical Publications

The 7x50 series documentation set also includes the following guides:

- Basic System Configuration Guide

  This guide describes CLI usage, file system management, and boot option file (BOF) configuration, as well as how to configure basic system management, node timing, and synchronization functions.

- System Management Guide

  This guide describes system security features, SNMP and NETCONF features, and event and accounting logs. It covers basic tasks such as configuring management access filters, passwords, and user profiles.

- Interface Configuration Guide

  This guide describes how to provision Input/Output Modules (IOMs), XMA Control Modules (XCMs), Media Dependent Adapters (MDAs), XRS Media Adapters (XMAs), and ports.

- Router Configuration Guide

  This guide describes logical IP routing interfaces and associated attributes such as IP addresses, as well as Redundancy Protocol (VRRP), and Cflowd.

- Unicast Routing Protocols Guide

  This guide provides an overview of unicast routing concepts and provides configuration examples for Routing Information Protocol (RIP), Open Shortest Path First (OSPF), Intermediate-system-to-intermediate-system (IS-IS), and Border Gateway Protocol (BGP) routing protocols, and for route policies.

- Multicast Routing Protocols Guide

  This guide provides an overview of multicast routing concepts and provides configuration examples for Internet Group Management Protocol (IGMP), Multicast Listener Discovery (MLD), Protocol Independent Multicast (PIM), Multicast Source Discovery Protocol (MSDP), Multipoint LDP, multicast extensions to BGP, and Multicast Connection Admission Control (MCAC).

- MPLS Guide

  This guide describes how to configure Multiprotocol Label Switching (MPLS), Resource Reservation Protocol (RSVP), Generalized Multiprotocol Label Switching (GMPLS), and Label Distribution Protocol (LDP).

- Services Overview Guide

  This guide provides a general overview of functionality provided by the routers and describes how to configure service parameters such as Service Access Points (SAPs), Service Distribution Points (SDPs), customer information, and user services.

- Layer 2 Services and EVPN Guide: VLL, VPLS, PBB, and EVPN

  This guide describes Layer 2 service and Ethernet Virtual Private Network (EVPN) functionality and provides examples to configure and implement Virtual Leased Lines (VLLs), Virtual Private LAN Service (VPLS), Provider Backbone Bridging (PBB), and EVPN.

- Layer 3 Services Guide: Internet Enhanced Services and Virtual Private Routed Network Services

This guide describes Layer 3 service functionality and provides examples to configure and implement Internet Enhanced Services (IES) and Virtual Private Routed Network (VPRN) services.

- Versatile Service Module Guide (for the 7750 SR)

  This guide describes how to configure service parameters for the Versatile Service Module (VSM).

- OAM and Diagnostics Guide

  This guide describes how to configure features such as service mirroring and Lawful Intercept (LI), and how to use the Operations, Administration and Management (OAM) and diagnostics tools.

- Log Events Guide

  This guide provides general information about log events.

- Triple Play Service Delivery Architecture Guide (for the 7450 ESS and 7750 SR)

  This guide describes the Triple Play Service Delivery Architecture (TPSDA) support and provides examples to configure and implement various protocols and services.

- Quality of Service Guide

  This guide describes how to configure Quality of Service (QoS) policy management.

- RADIUS Attributes Reference Guide (for the 7750 SR)

  This guide describes all supported RADIUS Authentication, Authorization, and Accounting attributes.

- Multiservice Integrated Service Adapter Guide (for the 7450 ESS and 7750 SR)

  This guide describes services provided by integrated service adapters, such as Application Assurance, IPSec, ad insertion (ADI), and Network Address Translation (NAT).

- Gx AVPs Reference Guide (for 7750 SR)

  This guide describes Gx Attribute Value Pairs (AVPs).

- Acronyms Reference Guide

  This guide lists acronyms used in the customer documentation for 7750 SR, 7450 ESS, and 7950 XRS.

Basic System

In this section

This section provides configuration information for the following topics:

- IEEE 1588 for Frequency, Phase, and Time Distribution
- Synchronous Ethernet

IEEE 1588 for Frequency, Phase, and Time Distribution

This chapter provides information about IEEE 1588 for frequency, phase, and time distribution.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This section is applicable to all of the 7750 SR and 7450 ESS series, except for the SR-1, ESS-1, and ESS-6/6v. It is not applicable to t.he 7710 SR nor the 7950 XRS series. Description and examples are based on release 12.0.R2. The only software pre-requisites are IP reachability between the node and neighboring 1588 clocks.

IEEE 1588 has several hardware dependencies both for the basic functionality as well as the 1588 port based timestamping necessary for high accuracy time distribution. Please consult the related Nokia documentation for the details of all the hardware requirements.

Overview

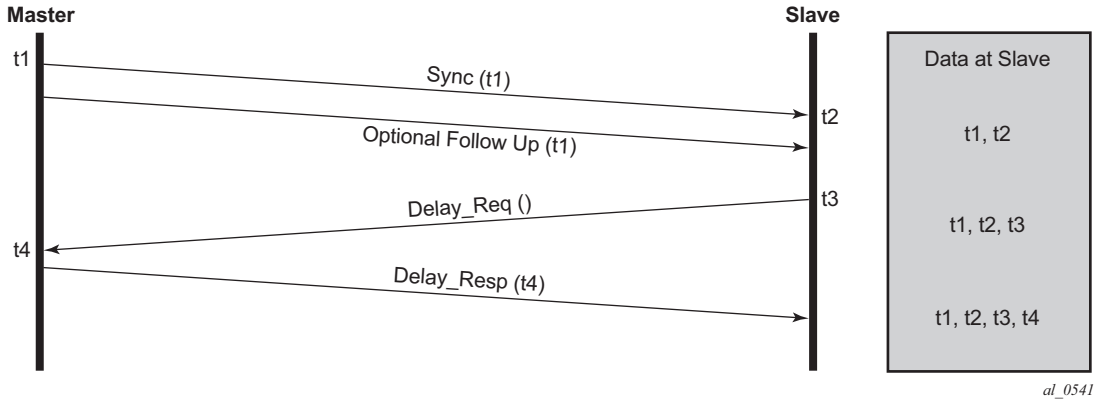
Defined in IEEE Std 1588™-2008 (1588v2), Precision Time Protocol (PTP) is a protocol that distributes frequency, phase and time over packet based networks.

Note: Many applications do not need time alignment but only phase alignment. However, phase is derived from time and so, for the remainder of the document, discussion refers to time but those references imply both time and phase.

The IEEE 1588 protocol has become the standard for distribution of high accuracy time. Following guidelines for specific network architectures allows the delivery of time to accuracies of one microsecond. This level of accuracy is required for mobile base stations using either Time Division Duplex technology and/or advanced LTE functions, as well as in the power industry for intelligent electronic device alignment.

More lenient architectures can still achieve 100 microseconds or better accuracies which can greatly enhance the usefulness of event logging and network one way delay measurements.

In addition, 1588 has been used to deliver a frequency reference for T1/E1 ports or for mobile base station frequency alignment. This is useful in environments where the transport network does not provide physical layer synchronization services.



The following 1588 capabilities are provided within the 7750 SR and 7450 ESS nodes:

- CPM/CFM based 1588 master, boundary, and slave clock functionality
- Transport over Unicast UDP/IPv4 packets
- Access to 1588 process through base routing, IES, and VPRNs
- Port based timestamping of 1588 packets
- IEEE 1588 Profiles: 2008 standard default and ITU-T G.8265.1
- Utilization of 1588 derived time for NTP and System time.

PTP Basics

PTP uses an exchange of four timestamps between a reference clock (master port) and the clock to be synchronized (slave port). A simplified illustration of this mechanism is shown in Figure 1.

Figure 1 **PTP Messages and Timestamp Exchange**

The master sends a PTP Sync message containing a timestamp of when the Sync message is transmitted (t1) to the slave. In a two-step master clock, the t1 timestamp is sent in a Follow_Up message. The slave records the time it receives the Sync message (t2). At some point after receiving the Sync message, the slave sends a Delay_Req message back to the master. The slave records the time of transmission of the Delay_Req message (t3) locally. The master records the time it receives the Delay_Req message (t4) and sends this timestamp back to the slave in a Delay_Resp message.

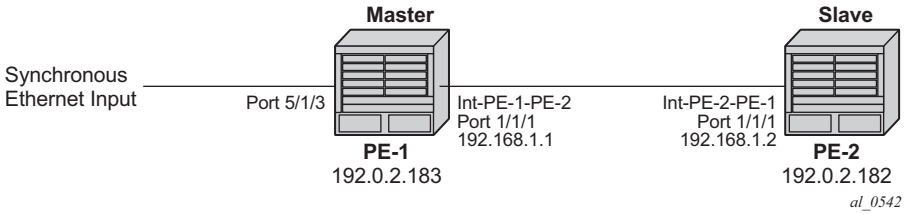
Note: The Follow_Up message was defined to allow for implementations to generate a timestamp for the transmission of the Sync message but not have to try to insert that timestamp into the Sync message and update any frame checksums on the fly as it is in the process of transmission. While many recent implementations can perform the timestamping, update and checksum calculation on the fly, not all devices could perform this three step process with the desired accuracy. By using the Follow_Up message to transmit the timestamp of the Sync message, the master port can still provide extremely accurate timestamps for the transmission of the Sync message to the slave port. Apart from the extra message required, there is no detriment to a master port using one-step clock versus a two-step clock procedures. All PTP clocks that have slave port capability must accept timing information from both types of master port. There is no requirement to force a clock that is a one-step clock to use two-step clock procedures on its master ports. The nodes covered by this example all support one-step clock master port procedures.

After the four timestamp exchange the slave can calculate the mean path delay and the clock offset from master using the following two equations:

- mean_path_delay = [(t4-t1) – (t3-t2)] /2
- offset_from_master = [(t2 –t1) – mean_path_delay]

These calculations can occur on every message exchange or some initial packet selection can be performed so that only optimal message exchanges are used. The latter is useful if there is variable delay between the master and slave ports.

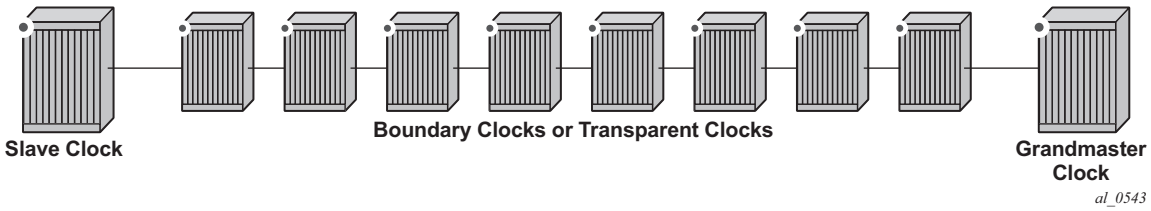
If only frequency is necessary, then the slave may use one or both pairs of timestamps (t1, t2) and (t3, t4). The slave can monitor the change in the perceived delay master-to-slave (t2 - t1) or slave-to-master (t4 - t3) over time. If the delay (t2 – t1) decreases over time, it means the t2 timestamps are not progressing quickly enough and the slave clock frequency needs to be increased.



If time is necessary, then all four timestamps must be used. It is also important to note how the equation for offset uses the mean_path_delay. If the delays in the two directions are actually different, then the equation will introduce an error in the offset_from_master that is half of the difference of the two delays. The IEEE 1588 standard includes procedures to compensate for this asymmetry, if it is known, but if it is uncompensated it does introduce time error.

PTP Deployment Architectures

It is important to understand that there are very different topologies recommended for using 1588 for frequency distribution and using 1588 for time distribution.



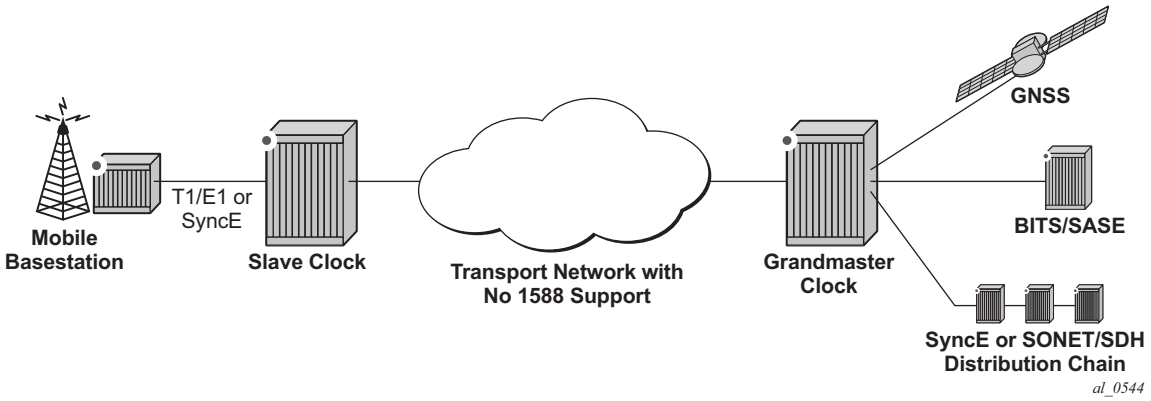
Frequency distribution was developed for an architecture where there are mobile providers who have points of presence at the mobile telephony switching offices (MTSOs) and the cell site locations which depend on other parties for the connectivity between the MTSOs and the cell site locations. The mobile providers wanted a solution that could span the transport networks with minimal dependence on that network. This can be achieved by placing a 1588 grandmaster at the MTSO and a slave in a cell site router or directly in the basestation and distributing the timestamped packets between the two, as shown in Figure 2. The transport network does introduce packet delay variation (PDV) to the 1588 messages which makes it more difficult to track the frequency of the grandmaster’s clock. However, the slaves have been designed to perform packet selection and noise filtering to allow for the recovery of a frequency within the required accuracies of the mobile basestations. This architecture and the performance requirements are covered by the ITU-T G.826x series of recommendations.

Figure 2 **1588 Topology for Frequency Distribution**

For time distribution, it has been recognized that the architecture used above is extremely unlikely to be successful. The fundamental reason is that the performance requirement is much tighter and the network introduces not only PDV but also potentially asymmetric delay which causes time error in the slave. The topology recommended for time distribution is what is sometimes referred to as “Full On-Path Support (OPS)”. Full OPS means that every network element between the grandmaster clock and the slave clock is either a 1588 boundary clock or a 1588 transparent clock, as shown in Figure 3. Boundary clocks and transparent clocks process the 1588 messages and remove the PDV noise that would be present in a non 1588 network element. By using network elements that have very tight constraints on the time error they introduced, the network can be built to guarantee time accuracy under all network traffic conditions. This architecture and the performance requirements are covered by the ITU-T G.827x series of recommendations.

Figure 3 **1588 Topology for Time Distribution**

PTP Profiles



The 1588v2 standard includes the concept of a PTP profile. A PTP profile allows standardization bodies or industry groups to adapt the 1588v2 standard to a particular application. A profile defines which aspects of the 1588v2 standard are included or excluded, along with configurable ranges and defaults necessary for the application.

The 1588 standard itself includes a **default** profile that can be used for either time or frequency distribution. The default profile was defined principally for multicast operation. However, it can be used with the unicast sessions as described below. The default profile supports all 1588 clock types and includes the Best Master Clock Algorithm (BMCA) that automatically builds the synchronization distribution hierarchy amongst the PTP clocks. The SR OS only supports the unicast session version of the default profile.

In the telecommunications industry, the ITU-T is the body that develops these profiles. They have generated a profile for frequency distribution (G.8265.1) and a profile for time distribution (G.8275.1). The frequency profile permits only grandmaster and slave clocks and can be used to extended a traditional physical layer synchronization distribution (SONET/SDH, PDH, or SyncE) with a final leg of 1588 messages. The frequency source of the 1588 grandmaster could be a GPS receiver, a central office BITS or SASE device or it could use the frequency recovered from a Synchronous Ethernet or SONET/SDH interface. This is shown in Figure 4

Because a 1588 distribution system is significantly noisier than a physical layer distribution system, it should only be used as the final segment to connect the end application into the synchronization network. It should not be used to connect two Synchronous Ethernet or SONET/SDH islands.

Figure 4 **Frequency Distribution with 1588 as Last Mile**

The important features defined in the G.8265.1 profile are:

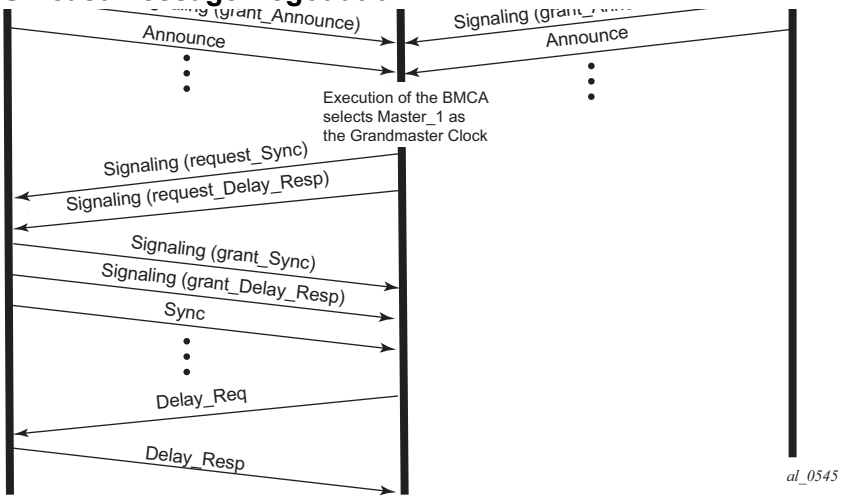
- Only master clocks and slave clocks are allowed.
- Unicast Message Negotiation using Signaling messages from the slave clocks toward the master clocks is used to establish communications.
- PTP messages are encapsulated over UDP over IPv4.

- PTP clock class values are based on a mapping of traditional quality levels from SSM/ESMC.

Note: SSM stands for Synchronization Status Messages and ESMC stands for Ethernet Synchronization Messaging Channel. These are two capabilities in SDH/SONET and Synchronous Ethernet respectively for the relaying of source clock quality information.

The slave clock uses an alternate BMCA to select the grandmaster clock from the available master clocks based on:

- Quality Level.
- Relative Priority.



The ITU-T has defined the first time distribution profile in G.8275.1. It uses an architecture of a Global Navigation Satellite System (GNSS) based grandmaster clock distributing time through a chain of boundary clocks to a final slave device and end application. It includes the use of Synchronous Ethernet and 1588 at the same time for optimal performance. Physical layer Synchronous Ethernet is an excellent tool for the distribution of an accurate and stable frequency. This frequency can be used to advance time between offset adjustments made using the 1588 information.

Unicast Message Negotiation

The initial IEEE 1588-2002 standard defined a multicast messaging model. IEEE 1588-2008 introduced the option of using unicast messaging with unicast discovery to establish a message exchange between a master and slave.

The typical unicast message flow between a master and slave is illustrated in Figure 5.

Figure 5 **Unicast Message Negotiation**

A slave clock initiates unicast discovery by sending a Signaling message to one of its configured master clocks requesting the master send unicast Announce messages to the slave. The request includes the desired rate for the Announce messages and the duration over which the messages should be sent. If the master can support the request it replies with a Signaling message indicating that the session for unicast Announce messages has been granted.

From this point on, the master sends unicast Announce messages to the slave at the rate requested. A slave will generally establish an Announce message session with at least two master clocks.

The slave then uses the Announce messages it receives from all masters as input to the BMCA that determines which master clock is the best source for information. The selected master becomes the grandmaster clock to the slave. The slave then sends additional Signaling messages to the grandmaster to request unicast delivery of Sync and Delay_Resp messages. Assuming the grandmaster clock has sufficient resources, the request is granted and unicast Sync and Delay_Resp messages are sent from the grandmaster to the slave.

As with the Announce messages, the rate at which the Sync and Delay_Resp messages are sent and the duration of the unicast sessions is requested by the slave in the initial Signaling messages.

The unicast sessions for Announce, Sync and Delay Response messages have an expiry time. The slave renews all three sessions before this time is reached.

Network Limits

A common concern around 1588 is whether it will work on or over a specific customer network. For time distribution using full OPS as shown in Figure 3, there are well defined limits on the number of network elements allowed in the distribution chain (see below). However, for the frequency distribution using the architecture shown in Figure 2, it is a more difficult question to answer. There are so many different types of network elements and inter-node links that a simple limit on the number of network elements is not adequate. What has been specified is a limit to the noise that the network can introduce to the 1588 message flow between the grandmaster and slave clocks. This noise occurs as packet delay variation (PDV). The following sections provide some description of this PDV and a new metric that has been defined for PDV as well as the recommended limit to PDV for 1588 deployments.

Packet Delay Variation

If the packet delay through the packet network is constant, then it is relatively easy to use a series of timestamp exchanges to remove the delay as an unknown and track the master clock frequency. However, in most network technologies, the packet delay will be different for each individual packet. This PDV makes it more difficult to track the master clock since observations have both the master information and PDV noise included.

PDV is introduced when packets get placed in queues before they are forwarded. The time each packet sits in any one queue is influenced by multiple factors:

- the speed of the interface toward which the queue drains, for example 100Mbps versus 100Gbps,
- the traffic load on the interface, for example 20% versus 100% of line capacity,
- the distribution of packet sizes and priorities in the traffic load toward the interface, and
- the underlying physical technology used, xPON, xDSL, Ethernet, or microwave.

In addition, the load and packet distribution within the load will vary over time so the distribution of the PDV can shift rapidly such as when a network event triggers congestion or slowly, for example as end customers gradually come online over a period of several hours.

Also there are pipeline effects that can occur in a chain of queuing devices, where the small timing packets can catch up to a large packets moving across the network. Once behind such a packet, the timing packet can remain stuck behind that packet on all subsequent transmit queues.

QoS prioritization of packets helps reduce PDV significantly during congestion periods, but does not remove the PDV effects during lighter loading. This is due to the fact that a timing packet may be delivered to the egress queue for an interface while the interface is busy transmitting a packet. Pre-emption of packet transmissions is not used in today's networks.

Having stated all of the above, most of the time, the network will still present a percentage of packets that get across the network with minimal queuing delays. These are often referred to as 'lucky' or 'fastest' packets. Since these lucky packets are never waiting in queues or have minimal wait times, their transit across the network is relatively consistent. By running a selection filter on all 1588 packets to find these lucky packets, a level of variation of network delay can be removed or reduced significantly. Then the slave clocks have a much easier time determining the frequency of the grandmaster.

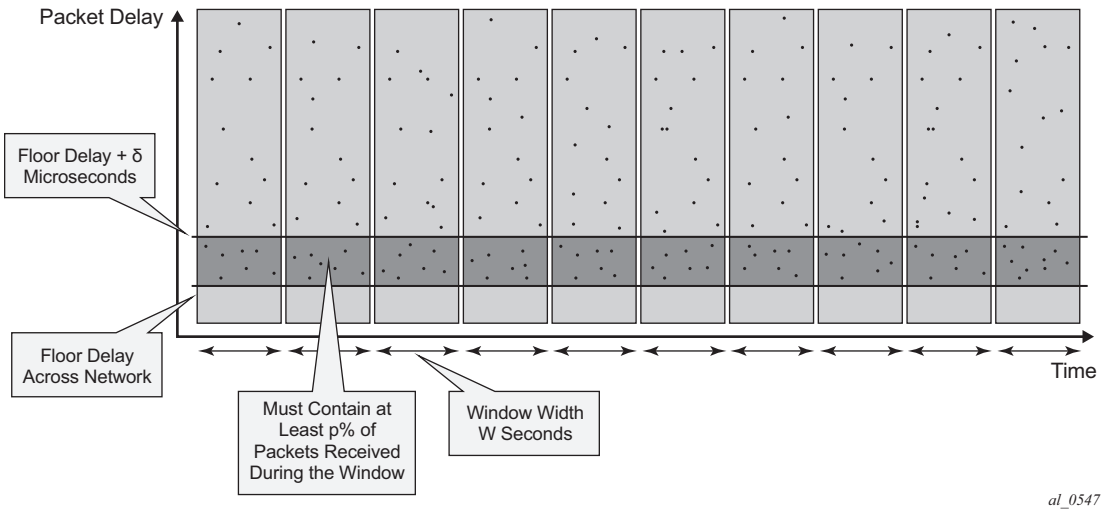
However, there will always be a limit to the amount of PDV that can be tolerated. The ITU has defined a metric to quantify the PDV, the limit of the PDV for a compliant network, and the required tolerance of a slave clock.

PDV Metrics

In order to know whether a particular timing-over-packet implementation will meet the performance targets in a given network deployment, it is desirable to both characterize the limits on the PDV that the implementation can tolerate and to measure the network against these limits. In 2012, the ITU-T published three documents that address these requirements:

- G.8260 defines the Floor Packet Percentage (FPP) metric.
- G.8261.1 defines a network limit for PDV in terms of FPP.
- G.8263 defines the input tolerance expected of a 1588 frequency slave in terms of FPP.

The Floor Packet Percentage (FPP) metric provides an indication of the guarantee that there are packets experiencing minimal delay across the network. The rationale behind this focus on 'fastest' packets is that many networks do provide good consistency of these packets in most operating conditions and because most slave clocks are capable of operating using only the information from these fastest packets.



There are four parameters associated with the metric:

- **W** is the width of the windows used to monitor for the presence of fastest packets.

- **Floor Delay** is a value that is as close as possible to the absolute minimum transit delay across the network. Every actual delay measurement must be equal to or larger than this value.
- δ is the range above the floor to be analyzed for the presence of fastest packets.
- ρ is the percentage of all the packets received in a window whose delay must be within the range floor delay to floor delay + δ.

Figure 6 illustrates how these parameters and the metric work. First the delays of all individual 1588 packets are plotted over the period of observation. Next the observation period is broken down into a series of consecutive windows of width **W** seconds. Then for each window a count is made of all the 1588 packets whose delays are within the range **floor delay** to **floor delay + δ** and this count is compared with all the 1588 packets received during the window to turn the count into a percentage. Finally the percentage of each window is checked against the threshold percentage ρ. For the FPP metric to be met, every window must have a percentage greater or equal to the threshold. If even one single window does not meet this threshold then the metric condition is not met.

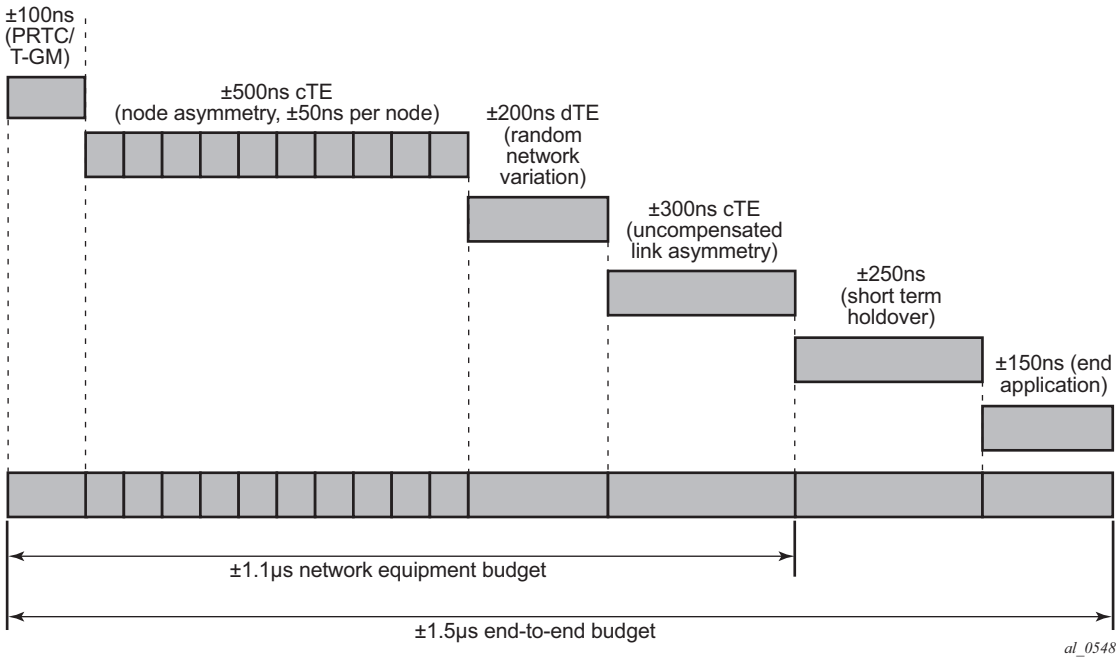
Figure 6 **Floor Packet Counting for FPP (n, W, δ)**

Note: This metric is not perfect as it does not take into account slaves that use other aspects of the packet delay distribution (such as average delay), nor does it discuss the impact of reroutes, nor do the limits discuss how to apply these limits to the forward and backward message exchanges at the same time. However, it was agreed that this metric was a good start for the definitions of the network and slave limits. Expect to see timing test equipment vendors providing the tools to generate 1588 PDV profiles providing FPP based distributions.

ITU-T Budget for Frequency

The network limit on PDV for frequency distribution is defined in G.8271.1 using the FPP metrics defined above.

In general most carrier grade networks with spans of up to 10 nodes and which do not exceed 80% load on their internode links should meet the requirement. However, very low (sub 50 Mbps) shaping or very long networks or last mile technologies such as xDSL or xPON may need to be studied to determine their acceptability.



A general strategy for rolling out 1588 frequency distribution is to evaluate the specific grandmaster and slave pairing in a lab environment using a network emulator to introduce controlled PDV. Once the grandmaster and slave have passed the lab tests, then field trial locations should be identified. Ideally, the sites should include locations where the PDV of the network will likely be at its worst. This would be sites with the most intervening network elements between the grandmasters and the slaves and include segments of the network that have a high load. The slaves' clocks should be deployed and monitored over several days to ensure that their frequency recovery engines can maintain lock with the grandmasters. During the initial field trails, it is beneficial to use external frequency test equipment at the slave locations to accurately monitor the frequency generated out of the slaves and ensure it stays within limits. As more sites are evaluated and confidence in the PDV environment increases, more deployments can be rolled out. In the deployed network, PTP frequency recovery slave states can be monitored to ensure the solution continues to work.

There may be some locations in the network where the PDV will be too large preventing the slaves to achieve or maintain lock. If it is possible to utilize an alternate network interface to obtain a frequency such as a leased T1 or E1 interface then that could be used. A last resort would be the deployment of a GNSS receiver at the location to provide the frequency reference.

ITU-T Budget for Time

The ITU-T has defined a topology for time distribution based on a full OPS environment. This means that every network element in the time distribution chain is a 1588 clock of some type. Currently the work has defined an environment using Boundary Clocks, but this might be modified in the future to include transparent clocks. The ITU-T tackled the time distribution problem in a more traditional way when compared with the frequency distribution. The ITU-T first defined specific network element clock performance constraints and then defined a longest chain network permitted to ensure that the solution meets the end to end budget. The breakdown of the chain and the budget is shown in Figure 7.

Figure 7 **G.8271.1 Time Error Budget**

The overall end to end budget is defined as ±1.5 microseconds. From this the following allocations are made:

- ±100ns Time error due to the GNSS receiver and the 1588 grandmaster.
- ±500ns Constant Time error due to ten Telecom Boundary Clocks (50 ns limit per

  boundary clock).
- ±200ns Dynamic Time error presented at the end of the boundary clock chain into the

  end slave.
- ±300ns Time error due to errors in cable latency asymmetry compensation (see below).
- ±150ns Time error due to the end slave and any internals of the basestation between

  the recovery and the presentation on the air interface.
- ±200ns Time error in the end application during short term holdovers such as

  network topology re-arrangements.

Note there is discussion that some of these elements could be traded-off against each other. For example, if the link asymmetry needs a higher budget then the holdover budget would have to be less – implying a better end device or a shorter duration of holdover.

The link asymmetries are an important aspect of this budget. The network topology not only has to have the network elements that meet the clock specifications but it also needs to have links that meet certain requirements. As explained above, the time offset calculation makes the assumptions that the master–to-slave latency is the same from the slave–to-master latency. When the latency is not equal, an error is introduced. Some analysis of network intersite connections may need to be performed to determine the budget for the link asymmetries.

Configuration

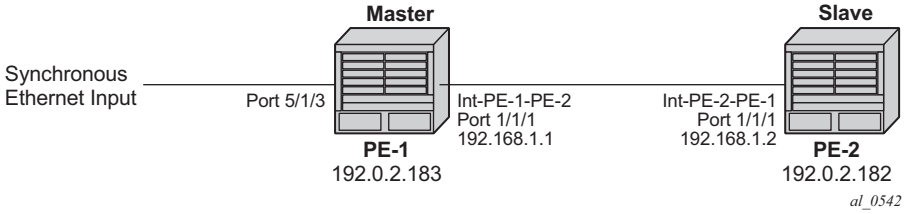
IP Addressing for PTP Communication

The system supports communication to the PTP process on the CPM using any of the IPv4 local interface addresses or an IPv4 local loopback addresses. The system will record both the source and destination address information from the received Signaling message which establishes the unicast session. The system will then swap these addresses for use for the Sync and/or Delay_Req messages generated toward the external clock.

The IP address becomes more significant when 1588 port based timestamping is enabled. The port level functionality will filter received PTP packets for a known IP address. This ensures that only PTP messages intended for the node are modified and not PTP messages merely transiting the node.

If the 1588 nodes are directly connected or it is ensured that the PTP messages for a peer shall always enter/exit the system through a single interface, then the IP address of that interface can be used for the PTP message communication. If the PTP messages from a peer could enter through more than one interface, then it may be easier to utilize a loopback address for the PTP message communication.

If using a loopback address and 1588 port based timestamping is also to be used, then the specific loopback address must be assigned to PTP for use using the source-address command. An example is provided in the “Port Based Timestamping” section below. Note: When a source address is defined for the PTP process within a given routing context, then the source address for all Signaling messages originating out of the node within that routing context shall use that address.



Note: The procedures to establish IP connectivity for the specific addresses used in these examples are not included.

Master and Slave Clocks for Frequency

A typical deployment scenario for a system configured as an ordinary master to distribute frequency to an external slave clock, often a cell site router or a base station, is shown in Figure 8. The central clock of the system is locked via its BITS ports or a Synchronous Ethernet port to an external source that is traceable to a primary reference. The frequency of the central clock is used to generate the timestamps contained in PTP event messages. The timestamps generated do not correlate to any standard epoch and therefore indicate an arbitrary timescale. As such it is only the rate of progression of the timestamps that has meaning.

The 7750 SR and the 7450 ESS can be configured as a 1588 slave clock for frequency recovery. In real deployments, it is more likely for the slave devices to be smaller cell site routers or basestations instead of another 7750 SR or 7450 ESS.

Figure 8 **Master and Slave Clocks for Frequency**

In the topology in Figure 8, the systems will most likely be configured with the ITU-T G.8265.1 Profile.

For this example, a loopback address is used for PTP communication between the nodes.

Ordinary Master Configuration

The steps to configure PE-1 as a PTP ordinary-clock master for frequency distribution using the G.8265.1 Telecom profile are outlined below:

Configure a /32 IPv4 system address on PE-1 and an interface to reach PE-2.

```
*A:PE-1#
        configure
            router
                interface "system"
                    address 192.0.2.183/32
                    no shutdown
                exit
                interface "int-PE-1-PE-2"
                    address 192.168.1.1/30
                    port 1/1/1
                    no shutdown
                exit
            exit
```

Configure an input reference for the central clock on PE-1. In this example, Synchronous Ethernet port 5/1/3 is used as the source for **ref2**.

```
*A:PE-1#
        configure
            port 5/1/3
                description "Sync-E reference for node"
                ethernet
                    ssm
                        code-type sonet
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            system
                sync-if-timing
                    begin
                    ql-selection
                    ref2
                        source-port 5/1/3
                        no shutdown
                    exit
                    commit
                exit
            exit
```

The default clock type is set to ordinary slave so that must be changed to ordinary master. The only other relevant configuration parameter for the master clock running the G.8265.1 profile is the network-type. The coding of the SSM/ESMC Quality Level into PTP clock Class must match the environment. The system supports both SONET and SDH networks. The default network-type is sdh but for this example, the system is configured for the North American market so the network-type is set to sonet.

```
*A:PE-1#
        configure
            system
                ptp
                    clock-type ordinary master
                    network-type sonet
                    no shutdown
                exit
            exit
```

Ordinary Slave Configuration

To configure PE-2 as a PTP ordinary slave for frequency distribution using the G.8265.1 Telecom profile, firstly configure a /32 IPv4 system address on PE-2 and an interface to reach PE-1.

```
*A:PE-2#
        configure
            router
                interface "system"
                    address 192.0.2.182/32
                    no shutdown
                exit
                interface "int-PE-2-PE-1"
                    address 192.168.1.2/30
                    port 1/1/1
                    no shutdown
                exit
            exit
```

As the default clock type is ordinary slave, PE-1 is configured as a peer clock, and the PTP process is enabled. In this example, the Quality Level encoding is also changed to sonet in order to match the North American market

```
*A:PE-1#
        configure
            system
                ptp
                    network-type sonet
                    peer 192.0.2.183 create
                        no shutdown
```

```
                exit
                no shutdown
            exit
        exit
```

Usually a 1588 slave has at least two peers configured in order to provide redundant sources.

Configure PTP as the reference for the central clock on PE-2.

```
*A:PE-2#
        configure
            system
                sync-if-timing
                    begin
                    ql-selection
                    ptp
                        no shutdown
                    exit
                    commit
                exit
            exit
```

Verification of Session Establishment

When PTP is set to no shutdown on PE-2, it initiates a PTP unicast session with PE-1. Correct session establishment can be verified by checking PTP related information as follows:

```
*A:PE-1# show system ptp unicast

```

A **Pending** state indicates the system has sent a Unicast Request toward the peer but has not received a response. If the state remains **Pending**, then the IP connectivity between the systems should be verified.

To verify the slave frequency is operating properly, first check the high level information for PTP on PE-2. Note that the PTP Recovery State initially shows phase-tracking and then changes to locked. The time to achieve locked state varies based on the PDV.

```

Optional Configuration Items for Ordinary Master or Slave Configuration

The G.8265.1 profile is the default PTP profile on the system and it uses domain number value of 4. The domain number must match at both ends of the communication path or the PTP messages will be dropped. Some very old 1588 devices, may have the domain number set to zero which is the value used by the IEEE1588 default profile. In this case, the system would need to have its domain number changed to match that of the external slave.

```
configure
    system
        ptp
            shutdown
            domain 0
            no shutdown
        exit
    exit
```

Note that the domain number can only be adjusted if PTP is shutdown and only one common domain number is allowed for all 1588 messages to and from the system.

When using the system as a 1588 slave for frequency distribution, it is strongly recommended to use the default message rate of 64 pps for Sync and Delay_Resp messages. If for some reason the parent 1588 peer cannot offer this rate, then the rate that the system requests must be adjusted. For example, if the maximum rate supported by the external 1588 grandmaster device (with an IP address of 192.0.2.166) only is 32 pps, then the system can be adjusted to request that rate as follows:

```
configure
    system
        ptp
            peer 192.0.2.166 create
                log-sync-interval -5
                no shutdown
            exit
        exit
    exit
```

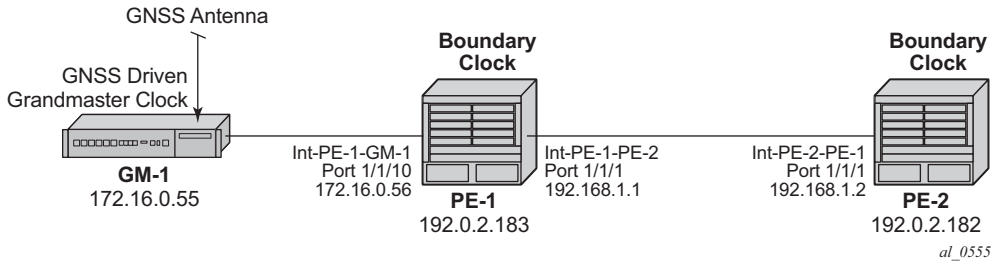
Note that the Sync message rate can only be adjusted if the peer is shutdown.

The message rates are entered as the base 2 logarithm of the inter-message interval. So 32 pps has an inter message interval of 1/32 seconds and a log-sync-interval of -5.

The Announce message rate impact the speed at which PTP can detect communication failures and the speed at which the PTP topology is re-arranged. The default Announce rate is one message every two seconds and this should be adequate for networks with short chains of PTP clocks, for example G.8265.1 architectures. However, in network with longer chains of PTP clocks (for example, more than 5 boundary clocks), it may be desired to use a faster Announce message rate. In the following example, the slave is configured to request two Announce messages per second:

```
configure
    system
        ptp
            shutdown
            log-anno-interval -1
            no shutdown
        exit
    exit
```

Note that the Announce rate can only be adjusted if PTP is shutdown. In addition, there is one common Announce rate for all unicast sessions; it cannot be configured on an individual peer basis.



Boundary Clock

With the increase interest in high accuracy time distribution across networks, the system most likely takes on the role of a 1588 boundary clock. In this role, the system requests time from a GNSS driven grandmaster clock or from a neighboring boundary clock. The system only supports boundary clock configuration when the ptp profile is configured as the default profile.

In this mode of operation, it is strongly recommended to have Synchronous Ethernet physical layer frequency distribution configured at the same time.

The example in Figure 9 shows a boundary clock (PE-1) communicating directly with the GNSS driven grandmaster (GM-1) and a second boundary clock (PE-2) communicating with the first boundary clock.

Figure 9 **Boundary Clock**

The steps to configure the systems as boundary clocks running the IEEE default profile are:

On PE-1, configure a /32 IPv4 system address, an interface to reach PE-2, and an interface to reach GM-1.

```
*A:PE-1#
        configure
            router
                interface "system"
                    address 192.0.2.183/32
                    no shutdown
                exit
                interface "int-PE-1-PE-2"
                    address 192.168.1.1/30
                    port 1/1/1
                    no shutdown
                exit
                interface "int-PE-1-GM-1"
                    address 172.16.0.56/30
                    port 1/1/2
                    no shutdown
                exit
            exit
```

On PE-2, configure a /32 IPv4 system address and an interface to reach PE-1.

```
*A:PE-2#
        configure
            router
                interface "system"
                    address 192.0.2.182/32
                    no shutdown
                exit
                interface "int-PE-2-PE-1"
                    address 192.168.1.2/30
                    port 1/1/1
                    no shutdown
                exit
            exit
```

Configure both PE-1 and PE-2 to have physical layer frequency sources into their central clocks. PE-2 is configured to receive Synchronous Ethernet from PE-1 on the same port as is used for PTP. This commonality is not a requirement but might be common in the network topology.

On PE-1, configure the port toward PE-2 as a Synchronous Ethernet port. This will cause the port transmit timing to be sourced from the node timing. Also configure the port to transmit ssm codes using the sonet codes.

```
*A:PE-1#
        configure card 1 mda 1 sync-e
        configure port 1/1/1 ethernet
            code-type sonet
            no shutdown
        exit
```

On PE-2, configure the port on towards PE-1 as a Synchronous Ethernet port and to use sonet codes and to be the reference into the central clock of PE-2.

```
*A:PE-2#
        configure card 1 mda 1 sync-e
        configure port 1/1/1
            ethernet
                ssm
                    code-type sonet
                    no shutdown
                exit
            exit
        exit
        configure system sync-it-timing
            begin
            ql-selection
            ref1
                source-port 1/1/1
                no shutdown
            exit
            commit
```

```
        exit
```

Next configure PE-1 as a boundary clock requesting service from GM-1 using the default profile. In this example, the interface address of GM-1 is used for the PTP communication.

```
*A:PE-1#
        configure system ptp
            shutdown
            profile ieee1588-2008
            clock-type boundary
            peer 172.16.0.55 create
                no shutdown
            exit
            no shutdown
        exit
```

If it is desired to operate the network at the default for the G.8275.1 profile, then the Announce messages should be set to 8 pps and the Sync and Delay_Resp messages should be set to 16 pps.

```
*A:PE-1#
        configure system ptp
            shutdown
            log-anno-interval -3
            peer 172.16.0.55
                shutdown
                log-sync-interval -4
                no shutdown
            exit
            no shutdown
        exit
```

Configure PE-2 as a boundary clock using PE-1 as its parent clock and the same set of 1588 parameters. In this example, PE-2 uses a loopback address of PE-1 for communication.

```
*A:PE-2#
        configure system ptp
            shutdown
            profile ieee1588-2008
            clock-type boundary
            log-anno-interval -3
            peer 192.0.2.183 create
                shutdown
                log-sync-interval -4
                no shutdown
            exit
            no shutdown
        exit
```

On PE-1, validate the status of the PTP topology by checking the unicast sessions. Also validate the PTP process has elected GM-1 as both the parentClock and the grandmaster clock.

```
*A:PE-1# show system ptp unicast

Boundary Clock with VPRN Access

The system supports access to the 1588 process through Base routing, IES, and VPRN contexts. This permits the system 1588 topology to be created and managed in one context with access for edge distribution through other contexts. For example, building on top of the base routing distribution shown in the previous example, access can be given to the 1588 process on PE-2 via a VPRN existing on that node. This allows the VPRN customer to have access to the high accuracy time available within the system in the customer edge equipment connecting into that node.

Figure 10 **Boundary Clocks with Edge VPRN Access**

For the example shown in Figure 10, it is assumed that a VPRN service is already configured and operational on PE-2 providing connectivity between PE-2 and CE-1:

```
*A:PE-2#
        configure service vprn 10 customer 1 create
            router-id 176.16.1.1
            autonomous-system 64496
            route-distinguisher 64496:10
            interface "int-PE-2-CE-1" create
                address 10.90.97.1/30
                sap 2/1/1 create
                exit
            exit
            no shutdown
        exit
```

To enable access to the PTP process via VPRN 10 in PE-2, PTP must be enabled within the VPRN context. To ensure that no more than 10 external clocks access the system PTP through this VPRN at any one time, a peer-limit may be defined.

```
*A:PE-2#
        configure service vprn 10
            peer-limit 10
            ptp no shutdown
        exit
```

To confirm PTP access with the VPRN, the PTP information with the VPRN context can be queried. Either of the following two commands can be used:

```
*A:PE-2# show system ptp unicast router 10
```

or

```
*A:PE-2# show service id 10 ptp unicast
```

These two commands provide the same information as shown below.

```
*A:PE-2# show system ptp unicast router 10

Port Based Timestamping

As described above, optimal performance is achieved when the 1588 port based timestamping (PBT) feature is used. This feature is not available on all hardware and the interfaces for PTP should be planned in advance if this feature is to be used.

Since 1588 messages ingress and egress the node through router interfaces, the configuration of the 1588 PBT feature is enabled within the router interface context. In the previous examples, if 1588 PBT is to be enabled on all the PTP interfaces the following commands are required.

On PE-1, enable 1588 PBT on the interface toward GM-1 and PE-2.

```
*A:PE-1#
        configure
            router
                interface "int-PE-1-PE-2"
                    ptp-hw-assist
                exit
                interface "int-PE-1-GM-1"
                    ptp-hw-assist
                exit
            exit
```

On PE-2, enable 1588 PBT on the interface toward PE-1 and CE-1.

```
*A:PE-2#
        configure
            router
                interface "int-PE-2-PE-1"
                    ptp-hw-assist
                exit
            exit
        exit
        configure service vprn 10 customer 1
            interface "int-PE-2-CE-1"
                ptp-hw-assist
            exit
        exit
```

To verify 1588 PBT is active on the 1588 messages to the peers, check the timestamp point for the specific peer. It now indicates *port* rather than cpm.

On PE-1 for the CE-1 communication:

```
*A:PE-1# show system ptp peer 172.16.0.55
===============================================================================
IEEE 1588/PTP Peer Information
===============================================================================
Router            : Base
IP Address        : 172.16.0.55        Announce Direction : rx
Admin State       : up                 G.8265.1 Priority  : n/a
Sync Interval     : 16 pkt/s
Local PTP Port    : 2                  PTP Port State     : slave
Clock Id          : 8887868584838281   Remote PTP Port    : 1
GM Clock Id       : 8887868584838281   GM Clock Class     : 7
GM Clock Accuracy : within 250 ns      GM Clock Variance  : 0x6400 (3.7E-09)
GM Clock Priority1: 128                GM Clock Priority2 : 128
Steps Removed     : 0                  Parent Clock       : yes
Tx Timestamp Point: port               Rx Timestamp Point : port
Last Tx Port      : 5/1/1              Last Rx Port       : 5/1/1
===============================================================================
```

On PE-1 the communication with the PE-2 will still be CPM timestamping since the port has not been configured to watch for the ‘system’ loopback address.

```
*A:PE-1# show system ptp peer 192.0.2.182
===============================================================================
IEEE 1588/PTP Peer Information
===============================================================================
Router            : Base
IP Address        : 192.0.2.182        Announce Direction : tx
Admin State       : n/a                G.8265.1 Priority  : n/a
Sync Interval     : n/a
Local PTP Port    : 3                  PTP Port State     : master
Clock Id          : 00233efffe808250   Remote PTP Port    : 4
Tx Timestamp Point: cpm                Rx Timestamp Point : cpm
Last Tx Port      : 5/1/2              Last Rx Port       : 5/1/2
===============================================================================
```

In order to configure the **system** loopback address for PTP, enter the following on PE-1:

```
*A:PE-1#
        configure
            system security
                source-address application ptp "system"
                exit
            exit
```

Now the timestamp point on PE-1 will be the port.

```
*A:PE-1# show system ptp peer 192.0.2.182
===============================================================================
IEEE 1588/PTP Peer Information
===============================================================================
Router            : Base
IP Address        : 192.0.2.182        Announce Direction : tx
Admin State       : n/a                G.8265.1 Priority  : n/a
Sync Interval     : n/a
Local PTP Port    : 3                  PTP Port State     : master
Clock Id          : 00233efffe808250   Remote PTP Port    : 4
Tx Timestamp Point: port               Rx Timestamp Point : port
Last Tx Port      : 5/1/2              Last Rx Port       : 5/1/2
===============================================================================
```

Repeat this configuration of system address for the base routing context on PE-2

```
*A:PE-2#
        configure
            system security
                source-address application ptp "system"
                exit
            exit
```

Now the timestamp point on PE-2 will be the port.

```
*A:PE-2# show system ptp peer 192.0.2.183
===============================================================================
IEEE 1588/PTP Peer Information
===============================================================================
Router            : Base
IP Address        : 192.0.2.183        Announce Direction : rx
Admin State       : up                 G.8265.1 Priority  : n/a
Sync Interval     : 16 pkt/s
Local PTP Port    : 4                  PTP Port State     : slave
Clock Id          : 00233efffe69f250   Remote PTP Port    : 3
GM Clock Id       : 8887868584838281   GM Clock Class     : 6
GM Clock Accuracy : within 100 ns      GM Clock Variance  : 0x6400 (3.7E-09)
GM Clock Priority1: 128                GM Clock Priority2 : 128
Steps Removed     : 1                  Parent Clock       : yes
Tx Timestamp Point: port               Rx Timestamp Point : port
Last Tx Port      : 1/1/2              Last Rx Port       : 1/1/2
===============================================================================
```

On PE-2, a loopback address must assigned for PTP communication as follows:

```
*A:PE-2#
configure service vprn 10
    interface "ptp_loopback"
        address 172.16.1.1/32
        loopback
    exit
    source-address
        application ptp "ptp_loopback"
            exit
        exit
```

1588 as NTP Local Clock (server)

If the system is configured as a boundary clock or slave clock then the time recovered from the 1588 slave port can be used as the source of system time on the node. This allows for higher accuracy and better stability in the timebase when compared to NTP. To enable this, PTP must be made the preferred server in the NTP context in the node.

Note that if the system is acting as an NTP server or peer to other NTP clocks, then turning on this feature will impact the existing NTP topology. The system shall advertise itself as an NTP Stratum 1 server to external clients and peers. Given the much higher accuracies achievable with PTP time distribution, this change in topology does not degrade the time in the clients and peers.

```
*A:PE-1#
        configure system time ntp
            server ptp prefer
        exit
```

To validate PTP is now being used for NTP time and system time, use the following command:

```
*A:PE-1# show system ntp all
===============================================================================

Conclusion

The systems provide support for IEEE 1588 frequency and time distribution for the synchronization applications of the mobile networks. They can be configured as frequency distribution grandmasters and slave clocks or time distribution boundary and slave clocks.

Synchronous Ethernet

This chapter provides information about Synchronous Ethernet (SyncE).

Topics in this chapter include:

- Applicability
- Summary
- Overview
- Configuration
- Conclusion

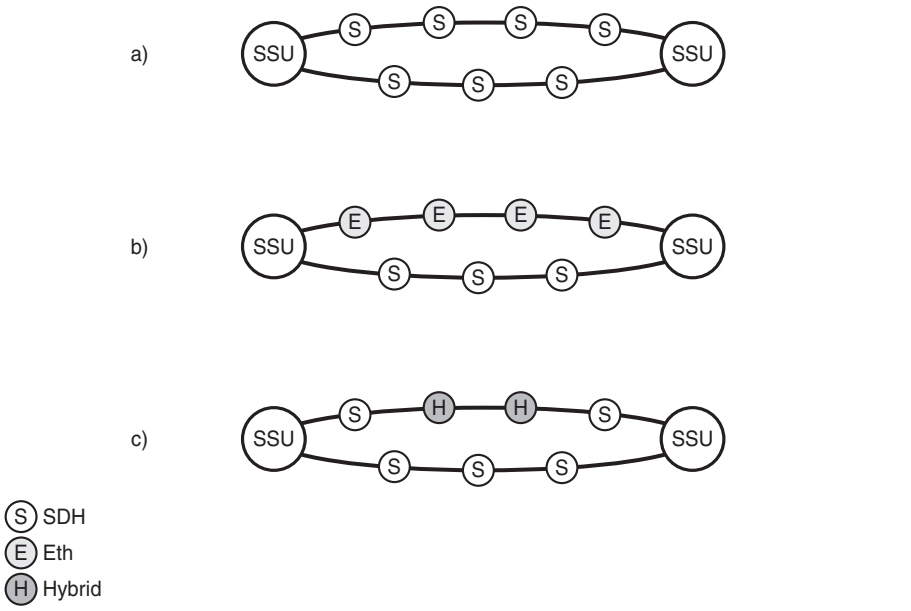
Applicability

This information and configuration in this chapter is based on SR OS release 8.0.R7. There are no software prerequisites for this configuration, however, the hardware requires the use of Synchronous Ethernet capable MDA-XPs/CMA-XPs or the IMMs.

In addition, Synchronous Ethernet is only supported on optical interfaces. It is not supported on 10/100/1000 base copper interfaces.

Summary

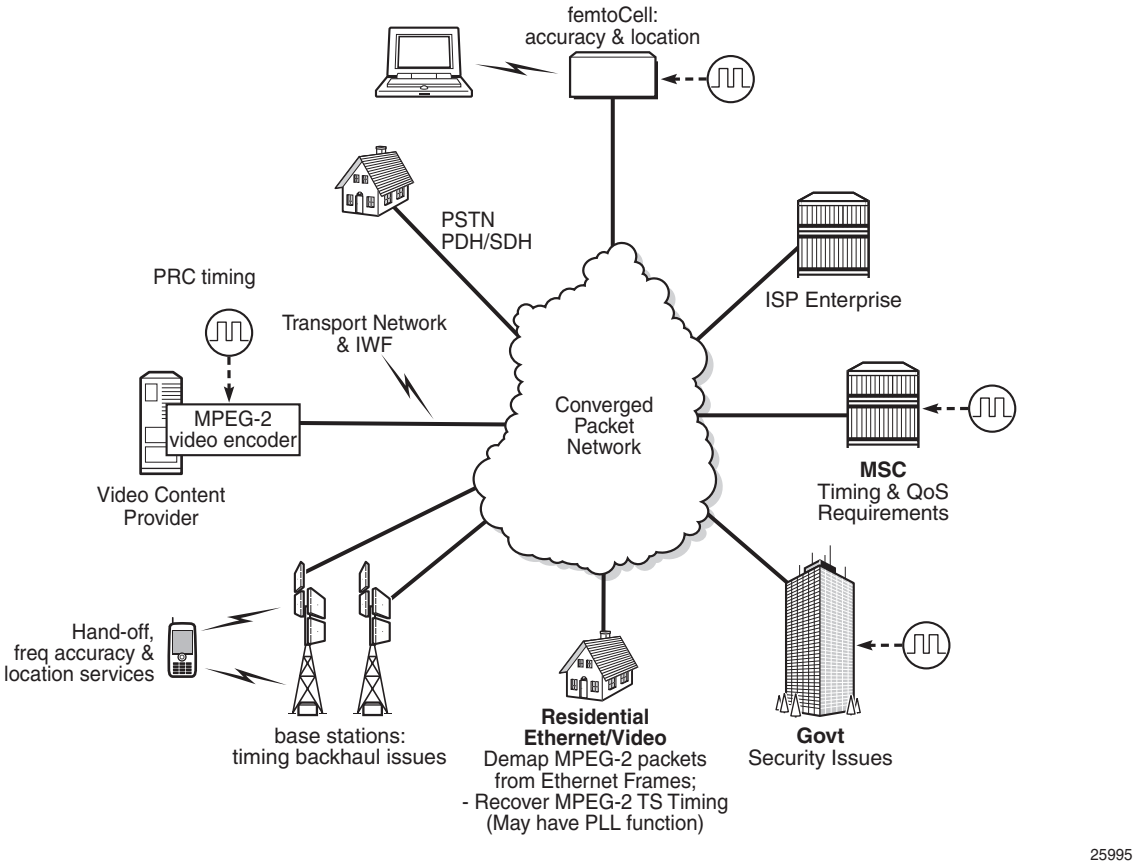
Synchronous Ethernet (SyncE) is the ability to provide PHY-level frequency distribution through an Ethernet port. It is one of the building blocks of Next Generation Networks (NGNs).



Overview

Synchronous Ethernet

Traditionally, Ethernet based networks employ the physical layer transmitter clock to be derived from an inexpensive +/-100ppm crystal oscillator and the receiver locks onto it. There is no need for long term frequency stability as the data is packetized and can be buffered. For the same reason, there is no need for consistency between the frequencies of different links. However, one could elect to derive the physical layer transmitter clock from a high quality frequency reference by replacing the crystal with a frequency source traceable to a primary reference clock. This would not affect the operation of any of the Ethernet layers, for which this change would be transparent. The receiver at the far end of the link would lock onto the physical layer clock of the received signal, and thus itself gain access to a highly accurate and stable frequency reference. Then, in a manner analogous to conventional hierarchical master-slave network synchronization, this receiver could lock the transmission clock of its other ports to this frequency reference and a fully time synchronous network could be established.

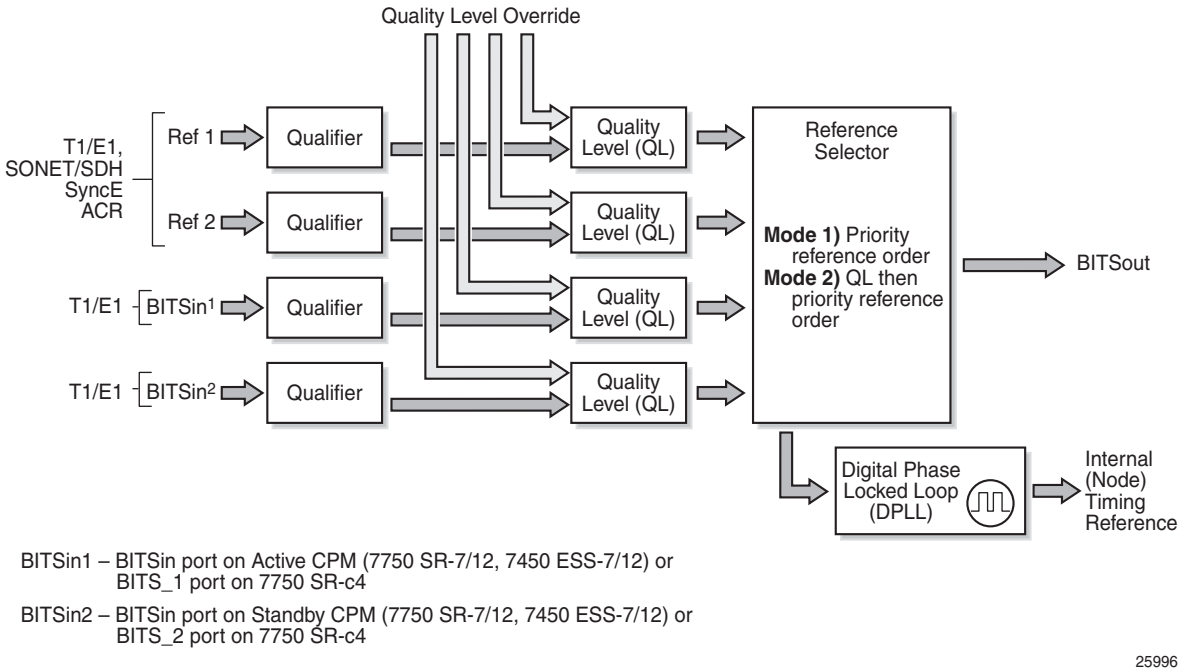


The advantage of using SyncE, as compared to methods relying on sending timing information in packets over an unlocked physical layer, is that SyncE is not influenced by impairments introduced by the higher levels of the networking technology (packet loss, packet delay variation). Therefore, the frequency accuracy and stability may be expected to exceed those of networks with unsynchronized physical layers. In addition, SyncE was designed to integrate into any existing SONET/SDH synchronization distribution architecture to allow for the easy migration from the traditional to the new synchronous interfaces. SyncE includes the concept of a hybrid switch which supports the interworking of synchronization distribution through SONET/SDH and the SyncE interfaces at the same time.

Figure 11 **SyncE Hypothetical Reference Network Architecture**

Many Tier 1 carriers are looking to migrate their synchronization infrastructure to a familiar and manageable model. In order to enable rapid migration of these networks, SyncE may be the easiest to deploy in order to ensure robust frequency synchronization.

Figure 12 **Packet Based Network Timing Infrastructure**



Central Synchronization Sub-System

The timing subsystem for the SR/ESS platforms has a central clock located on the Control Processor Module (CPM). The timing subsystem performs many of the duties of the network element clock as defined by Telcordia (GR-1244) and ITU-T G.781.

The system can select from up to four timing inputs to train the local oscillator. The priority order of these references must be specified. This is a simple ordered list of inputs: {BITS [Building Integrated Timing Source], ref1, ref2}. The CPM clock output has the ability to drive the clocking for all line cards in the system. The SR/ESS supports selection of the node reference using Quality Level (QL) indications.

Figure 13 **Current 7x50 Timing Sub-System Architecture**

The recovered clock is able to derive its timing from any of the following:

- OC3/STM1, OC12/STM4, OC48/STM16, OC192/STM64 ports
- T1/E1 CES channel (adaptive clocking)
- SyncE ports
- T1/E1 ports
- BITS port on a channelized OC3/STM1 CES CMA (7710 SR-c4, 7710 SR-c12, and the 7750 SR-c12)
- BITS port on the CPM or CFM module

On 7750 SR-12 and 7750 SR-7 systems with redundant CPMs, the system has two BITS input ports (one per CPM). On the 7750 SRc-4 systems, there are two BITS input ports on the chassis front plate. These BITS input ports provide redundant synchronization inputs from an external BITS/SSU. Note: the 7750 SR-c12 does not support BITS input port redundancy or BITS out.

All settings of the signal characteristics for the BITS input apply to both ports. When the active CPM considers the BITS input as a possible reference, it will consider first the BITS input port on the active CPM followed the BITS input port on the standby CPM in that relative priority order. This relative priority order is in addition to the user definable ref-order. For example, a ref-order of 'bits-ref1-ref2' would actually be BITS in (active CPM) followed by BITS in (standby CPM) followed by ref1 followed by ref2. When ql-selection is enabled, then the QL of each BITS input port is viewed independently. The higher QL source is chosen.

On the 7750 SR-c4 platform CFM, there are two BITS input ports and two BITS output ports on this one module. These two ports are provided for BITS redundancy for the chassis. All settings of the signal characteristics for the BITS input apply to both ports. This includes the ql-override setting. When the CFM considers the BITS input as a possible reference, it will consider first the BITS input port "bits1" followed the BITS input port "bits2" in that relative priority order. This relative priority order is in addition to the user definable ref-order. For example, a ref-order of 'bits-ref1-ref2' would actually be "bits1" followed by "bits2" followed by ref1 followed by ref2. When ql-selection is enabled, then the QL of each BITS input port is viewed independently. The higher QL source is chosen.

The BITS output ports are provided to deliver a unfiltered recovered line clock from a SR/ESS port directly to a dedicated timing device in the facility (BITS or Standalone Synchronization Equipment (SASE) device). The signal selected will be one of ref1 or ref2. It cannot be the BITS input port signal nor can it be the output of the central clock.

When QL selection mode is disabled, then the reversion setting controls when the central clock can re-select a previously failed reference.

Table 1 **Revertive, Non-Revertive Timing Reference Switching Operation**

Status of Reference A	Status of Reference B	Active Reference Non-revertive Case	Active Reference Revertive Case
OK	OK	A	A
Failed	OK	B	B
OK	OK	B	A
OK	Failed	A	A
OK	OK	A	A
Failed	Failed	holdover	holdover
OK	Failed	A	A
Failed	Failed	holdover	holdover

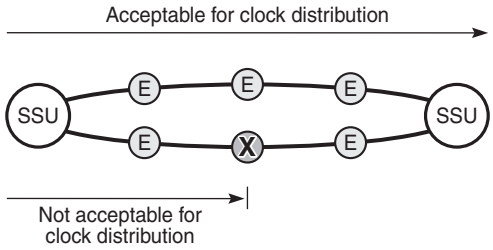
Table 1 **Revertive, Non-Revertive Timing Reference Switching Operation (Continued)**

Status of Reference A	Status of Reference B	Active Reference Non-revertive Case	Active Reference Revertive Case
Failed	OK	B	B
Failed	Failed	holdover	holdover
OK	OK	A or B	A

Synchronization Status Messages (SSM)

SSM provides a mechanism to allow the synchronization distribution network to both determine the quality level of the clock sourcing a given synchronisation trail and to allow a network element to select the best of multiple input synchronization trails. Synchronization Status messages have been defined for various transport protocols including SONET/SDH, T1/E1, and SyncE, for interaction with office clocks, such as BITS or SSUs (synchronisation supply unit) and embedded network element clocks.

SSM allows equipment to autonomously provision and reconfigure (by reference switching) their synchronization references, while helping to avoid the creation of timing loops. These messages are particularly useful to allow synchronization reconfigurations when timing is distributed in both directions around a ring.



In SyncE, the SSM is provided through the Ethernet Synchronization Messaging Channel (ESMC). This mechanism uses Ethernet OAM PDU to exchange the Quality Level values over the SyncE link.

SyncE Chains

Transmission of a reference clock through a chain of Ethernet equipment requires that all of the equipment support SyncE.

A single piece of equipment not capable of SyncE breaks the chain as shown in Figure 14. Ethernet frames will still get through but downstream device will recognize that the signal is out of pull-in range and not use it for reference.

Figure 14 **Network Considerations for Ethernet Timing Distribution**

Configuration

Configuration 1

The following example shows the configuration options for SyncE when ql-selection mode is disabled. Generally, North American SONET networks do not use the automatic reference selection mechanisms. If SyncE is being added into such a network, it would likely have ql-selection set to disabled.

```
A:PE-1>config# card 1 mda 1

Conclusion

With the world rapidly transitioning to IP/MPLS-based NGNs with Ethernet as the transport medium of choice, there is an increasing need to enhance services and capabilities while still leveraging existing infrastructure, thereby easing the transition while continuing to increase revenue and reduce the Total Cost of Ownership (TCO). In areas such as mobile backhaul, TDM CES etc., these requirements create a need for SONET/SDH-like frequency synchronization capability in the inherently asynchronous Ethernet network.

SyncE, natively supported on the Nokia SR OS routers, is an ITU-T standardized PHY-level way of transmitting frequency synchronization across Ethernet packet networks that fulfills that need in a reliable, secure, scalable, efficient, and cost-effective manner. It allows service providers to keep existing revenue streams alive and create new ones while simplifying the network design and reducing TCO.

System Management

In This Section

This section provides configuration information for the following topics:

- Distributed CPU Protection
- Event Handling System

Distributed CPU Protection

This chapter describes Distributed CPU Protection (DCP) configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This Distributed CPU Protection (DCP) configuration example was created using the 7750 SR-c12 platform but is equally applicable to the following platforms: 7750 SR-7/12, 7450 ESS-6/7/12, 7750 SR-c4/c12 and 7950 XRS. DCP is not supported on the 7750 SR-1, 7450 ESS-1 or 7710 SR platforms.

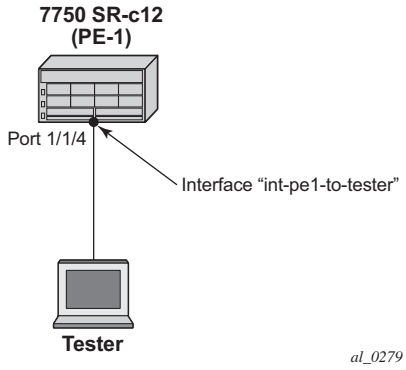
DCP operates on the line cards and requires line cards with the FP2 or greater hardware (for example, IOM3-XP, IMMs and C-XMAs).

The configuration was tested on release 11.0R1.

Overview

SR OS provides several rate limiting mechanisms to protect the CPM/CFM processing resources of the router:

- CPU Protection: A centralized rate limiting function that operates on the CPM to limit traffic destined to the CPUs.
- Distributed CPU Protection: A control traffic rate limiting protection mechanism for the CPM/CFM that operates on the line cards (hence ‘distributed’). CPU protection protects the CPU of the node that it is configured on from a DOS attack by limiting the amount of traffic coming in from one of its ports and destined to the CPM (to be processed by its CPU) using a combination of the configurable limits.



The goal of this example is to familiarize the reader with the configuration and use of Distributed CPU Protection. A simple and controlled setup is used to illustrate how the protection behaves and how to use the tools provided for the feature.

External testing equipment (“tester”) is used to send control traffic of various protocols at various rates to the router in order to exercise DCP. Log events and show routines are examined to explain the indications that the router provides to an operator.

Configuration

The test topology is shown in Figure 15. A Gigabit Ethernet link is used between the Tester and the router.

Figure 15 **Test Topology**

Step 1. The basic configuration of the mda, port, interface and a security event log on the router is shown below.

```
*A:PE-1# configure card 1 mda 1

*A:PE-1>config>log>log-id# info
----------------------------------------------
            from security
            to memory 1024
----------------------------------------------
```

This example was developed on a 7750 SR-c12 platform but it is equally applicable to other platforms such as the 7750 SR-7/12. If other platforms, such as the 7750 SR-7/12 that support centralized CPU Protection, are used to explore Distributed CPU Protection then the centralized CPU Protection should be disabled (for the purposes of this example) so that it does not interfere with reproducing the same results as described below. In a normal production network CPU Protection and DCP are complimentary and can be used together. To disable centralized CPU Protection for the purposes of reproducing the results below please ensure that:

- **protocol-protection** is disabled.
- All rates in all polices (including any default polices) are configure to **max**.

Step 2. In order to activate DCP a policy is created and assigned to the interface.

The first policy that is used in this example is used to simply count protocol packets to see that they are indeed flowing from the tester to the router and being extracted and indentified.

The *dcp-policy-count* policy is configured as follows:

```
*A:PE-1# configure system security dist-cpu-protection
*A:PE-1>config>sys>security>dist-cpu-protection# info
----------------------------------------------
                policy "dcp-policy-count" create
                    description "Static policers with rate 0 for counting packets"
                    static-policer "sp-arp" create
                        rate packets 0 within 1
                    exit
                    static-policer "sp-icmp" create
                        rate packets 0 within 1
                    exit
                    static-policer "sp-igmp" create
                        rate packets 0 within 1
                    exit
                    protocol arp create
                        enforcement static "sp-arp"
```

```
        exit
        protocol icmp create
            enforcement static "sp-icmp"
        exit
        protocol igmp create
            enforcement static "sp-igmp"
        exit
    exit
```

For the *dcp-policy-count policy* configuration:

- The policy contains three static policers: s*p-arp*, *sp-icmp* and *sp-igmp*. These policers are then used by the three configured protocols that are part of the policy: *arp*, *icmp* and *igmp*.
- The list of protocols that are applicable to DCP are as follows: arp, dhcp, http-redirect, icmp, igmp, mld, ndis, pppoe-pppoa, all-unspecified, mpls-ttl, bfd-cpm, bgp, eth-cfm, isis, ldp, ospf, pim and rsvp. The all-unspecified protocol is a special “catch-all”. Please see the 7750 SR OS System Management Guide for more details.
- This policy instantiates three permanent (static) policers for every object (for example, interface) that the policy is associated with.
- The three protocols each reference their own static policer so each protocol will be independently rate limited. A single static policer can also be used to rate limit multiple protocols but that capability is not used in this example.
- The rate is set to 0 which means all packets will be considered as non-conformant to the policer. This configuration is used to provide counters of protocol packets. The DCP counters provide the count of packets exceeding the policing parameters since the given policer was previously declared as conformant or newly instantiated. A rate of zero ensures that the policer will never be declared as conformant and hence will never reset the counters.
- The exceed-action is not configured and takes the default value of *none.* The *log-events* parameter is not configured and is enabled by default. That means the policer will notify the operator when the first packet arrives but will not discard or mark any packets.

Step 3. Assign the *dcp-policy-count* to the interface:

```
*A:PE-1# configure router interface "int-pe1-to-tester"
*A:PE-1>config>router>if# dist-cpu-protection "dcp-policy-count"
```

Step 4. Examine some log and status on the router to get a baseline (no traffic is flowing from the tester to the router at this point). Notice that the cpu utilization is fairly low with an overall Idle of 96% and no task groups at more than 5% capacity usage. Future example output from this show routine will be snipped to only show relevant and interesting lines.

```
*A:PE-1# show system cpu

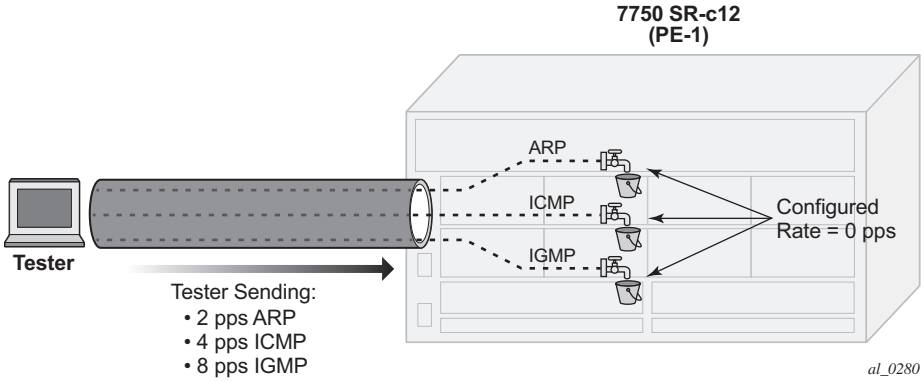
Step 5. Configure the tester to send ARP, ICMP and IGMP traffic to the router using the following rates:



- ARP: 2 packets per second (pps)
- ICMP: 4 pps
- IGMP: 8 pps

Here are some tips for how to configure the tester to send protocol packets that will be recognized by the router:

- ARP:
  - Set the MAC destination address to FF-FF-FF-FF-FF-FF
  - Use an ARP Request format
- ICMP:
  - Use an icmp type of 8 (echo request, such as **ping**).
  - Set the MAC destination address equal to the MAC address of the receiving port. The MAC address of port 1/1/4 can be seen in the output of show port 1/1/4 as the Configured Address.
  - Set the IP destination address to 192.168.10.1 and the IP source address to 192.168.10.2.
- IGMP:
  - Set the MAC destination address equal to the MAC address of the receiving port. The MAC address of port 1/1/4 can be seen in the output of show port 1/1/4 as the Configured Address.
  - Set the IP destination address to 224.0.0.2 and the IP source address to 0.0.0.0.
  - Set the IGMP version to 2, make the IGMP message type a Membership Query to Group 0.

Also ensure that the tester interleaves the three streams of protocol packets such that it schedules them independently in an interleaved fashion, not serially.

Figure 16 **Count Traffic with DCP Policy Count**

Step 6. Notice that DCP now reports some violations of the policy against the interface.

```
*A:PE-1# tools dump security dist-cpu-protection violators enforcement interface card
1
===============================================================================
Distributed Cpu Protection Current Interface Enforcer Policer Violators
===============================================================================

-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Violators on Slot-1 Fp-1
-------------------------------------------------------------------------------
int-pe1-to-tester               sp-arp                           [S] none
int-pe1-to-tester               sp-icmp                          [S] none
int-pe1-to-tester               sp-igmp                          [S] none
-------------------------------------------------------------------------------
[S]-Static [D]-Dynamic [M]-Monitor
-------------------------------------------------------------------------------
===============================================================================
```

After a few seconds the DCP exceed-count values can be seen incrementing.

Note the following details:

- Exceed-Count is non-zero. This will continue incrementing and will never reset since the rate configured in the DCP policy is zero.
- The Policer-State is Exceed. The policers have detected that the protocol is non-conformant to the configured rate.
- Detec. Time Remain stays at 29 seconds. This countdown timer is automatically reset to 30 seconds every time a policer is detected as non-conformant (which will be continually when the rate is set to 0 and packets of that protocol are being received).

```
*A:PE-1# show router interface "int-pe1-to-tester" dist-cpu-protection
===============================================================================
```

```
Interface "int-pe1-to-tester" (Router: Base)

Exceed-Count        : 290
Detec. Time Remain  : 29 seconds        Hold-Down Remain.   : none
-------------------------------------------------------------------------------
[snip]
```

Step 7. Keep the tester running.

Now a DCP policy that enforces protocol rates using static policers will be applied to the interface. First, the policy is created:

```
*A:PE-1# configure system security dist-cpu-protection
*A:PE-1>config>sys>security>dist-cpu-protection# policy "dcp-static-policy-1" create
                    description "Static policers for arp, icmp and igmp"
                    static-policer "sp-arp" create
                        rate packets 10 within 1
                        exceed-action discard
                    exit
                    static-policer "sp-icmp" create
                        rate packets 20 within 1
                        exceed-action discard
                    exit
                    static-policer "sp-igmp" create
                        rate packets 10 within 1
                        exceed-action discard
                    exit
                    protocol arp create
                        enforcement static "sp-arp"
                    exit
                    protocol icmp create
                        enforcement static "sp-icmp"
                    exit
                    protocol igmp create
                        enforcement static "sp-igmp"
```

```
            exit
        exit
```

For the dcp-static-policy-1 policy configuration, note that a few parameters are different than in the previously created dcp-policy-cou*nt* policy:

- The rates are set to low (but non-zero) values.
- The exceed-action is configured such that packets are dropped once the rate is exceeded.

Now assign the policy to the test interface:

```
*A:PE-1# configure router interface "int-pe1-to-tester"
*A:PE-1>config>router>if# dist-cpu-protection "dcp-static-policy-1"
*A:PE-1>config>router>if# exit all
*A:PE-1# show system security dist-cpu-protection policy "dcp-static-policy-1"
association
===============================================================================
Distributed CPU Protection Policy
===============================================================================
Policy Name : dcp-static-policy-1
Description : Static policers for arp, icmp and igmp

-------------------------------------------------------------------------------
Associations
-------------------------------------------------------------------------------

Managed SAP associations
-------------------------------------------------------------------------------
  None

Interface associations
-------------------------------------------------------------------------------
Router-Name : Base
  int-pe1-to-tester
-------------------------------------------------------------------------------
Number of interfaces : 1
===============================================================================
```

Step 8. Increase the rate of IGMP packets that the tester is sending to 1000pps (keep ARP and ICMP at 2pps and 4pps).

Figure 17 **Limit Traffic with dcp-static-policy-1**

Step 9. Notice that the system has identified a violation of the DCP rates for the igmp policer.

```
*A:PE-1# tools dump security dist-cpu-protection violators enforcement interface card
1
===============================================================================
Distributed Cpu Protection Current Interface Enforcer Policer Violators
===============================================================================
Interface                       Policer/Protocol                    Hld Rem
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Violators on Slot-1 Fp-1
-------------------------------------------------------------------------------
int-pe1-to-tester             sp-igmp                           [S] none
-------------------------------------------------------------------------------
[S]-Static [D]-Dynamic [M]-Monitor
-------------------------------------------------------------------------------
===============================================================================
```

After a few minutes the violation will be indicated as a log event. This delay is due to the design of DCP. In order to support large scale operation of DCP, and also to avoid overload conditions, a polling process is used to monitor state changes in the policers and to gather violations. This means there can be a delay between when an event occurs in the data plane and when the relevant state change or event notification occurs towards an operator, but in the meantime the policers are still operating and protecting the control plane.

```
*A:PE-1# show log log-id 15

Policer-Name        : sp-icmp
Card/FP             : 1/1               Policer-State       : Conform
Protocols Mapped    : icmp
Exceed-Count        : 0
Detec. Time Remain  : 0 seconds         Hold-Down Remain.   : none

Policer-Name        : sp-igmp
Card/FP             : 1/1               Policer-State       : Conform
Protocols Mapped    : igmp
Exceed-Count        : 0
Detec. Time Remain  : 0 seconds         Hold-Down Remain.   : none
-------------------------------------------------------------------------------
```

```
…[snip]…
```

An optional hold-down can be used in the configuration of the exceed-action of the policers in order to apply the exceed-action for a defined period (even if the policer goes conformant again during that period). The hold-down could be used, for example, to discard all packets associated with a policer for one hour after a violation is detected. An “indefinite” period is also supported which enforces discard or marking until the operator clears the policer with the **tools perform security dist-cpu-protection release-hold-down** command.

Step 14. The next scenario explored in this example is the use of DCP dynamic enforcement.

In order to use dynamic enforcement policers, a number of dynamic policers must be allocated to the DCP pool for the particular card being used.

```
*A:PE-1# configure card 1 fp dist-cpu-protection
*A:PE-1>config>card>fp>d-cpu-prot# info
----------------------------------------------
                dynamic-enforcement-policer-pool 1000
----------------------------------------------
```

The number allocated should be greater than the maximum number of dynamic policers expected to be in use on the card at one time. A conservative (large) number could be selected at first, and then the following show command can give data to help tune the pool to a smaller size over time:

```
*A:PE-1# show card 1 fp 1 dist-cpu-protection
===============================================================================
Card : 1 Forwarding Plane(FP) : 1
===============================================================================
Dynamic Enforcement Policer Pool : 1000
-------------------------------------------------------------------------------
-------------------------------------------------------------------------------
Statistics Information
-------------------------------------------------------------------------------
Dynamic-Policers Currently In Use      : 0
Hi-WaterMark Hit Count                 : 0
Hi-WaterMark Hit Time                  : 04/20/2013 08:16:24 UTC
Dynamic-Policers Allocation Fail Count : 0
-------------------------------------------------------------------------------
===============================================================================
```

If the dynamic-enforcement-policer-pool is too small then when a local-monitoring-policer detects violating traffic, the dynamic enforcement policers will not be able to be instantiated. A log event will warn the operator when the pool is nearly exhausted.

A sample dynamic enforcement policy is created as follows:

```
*A:PE-1# configure system security dist-cpu-protection
*A:PE-1>config>sys>security>dist-cpu-protection# policy "dcp-dynamic-policy-1" create
                    description "Dynamic policing policy"
                    local-monitoring-policer "local-mon" create
                        description "Monitor for arp, icmp, igmp
                                     and all-unspecified"
                        rate packets 100 within 10
                    exit
                    protocol arp create
                        enforcement dynamic "local-mon"
                        dynamic-parameters
                            rate packets 20 within 10
                            exceed-action discard
                        exit
                    exit
                    protocol icmp create
                        enforcement dynamic "local-mon"
                        dynamic-parameters
                            rate packets 20 within 10
                            exceed-action discard
                        exit
                    exit
                    protocol igmp create
                        enforcement dynamic "local-mon"
                        dynamic-parameters
                            rate packets 20 within 10
                            exceed-action discard
                        exit
                    exit
                    protocol all-unspecified create
                        enforcement dynamic "local-mon"
                        dynamic-parameters
                            rate packets 100 within 10
                            exceed-action discard
                        exit
                    exit
```

For the *dcp-dynamic-policy-1* policy configuration:

- The policy contains no static policers. Per-protocol enforcement policers will be instantiated dynamically but only if triggered by a violation of the local-monitoring-policer.
- A local-monitoring-policer is configured for the policy. The configured rate determines the rate of arriving protocol packets at which the policy will trigger the automatic instantiation of dynamic per-protocol policers for the interface.
- Four protocols are configured and they are all associated with the local-monitoring-policer. The all-unspecified protocol will include all other extracted control packets on the interface.

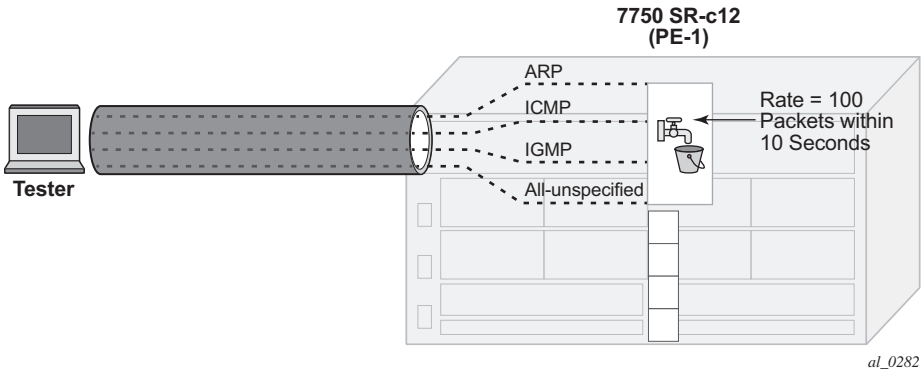
– Each protocol has its own configured dynamic rates that will be used by the dynamic enforcement policers if they are instantiated. Note these rates are lower than previous scenarios (the **within** parameter is 10 seconds instead of 1 second).

– When this DCP policy is associated with an interface, only a single policer (the local-monitoring-policer) will be instantiated (statically/ permanently). The per-protocol dynamic policers are only instantiated when there is a violation of the local-monitoring-policer.

The policy is then associated with the interface:

```
*A:PE-1# configure router interface "int-pe1-to-tester"
*A:PE-1>config>router>if# dist-cpu-protection "dcp-dynamic-policy-1"
```

Step 15. Configure the tester to send:



– 1pps of ARP

– 4pps of ICMP

– 1000pps of IGMP

Start the tester.

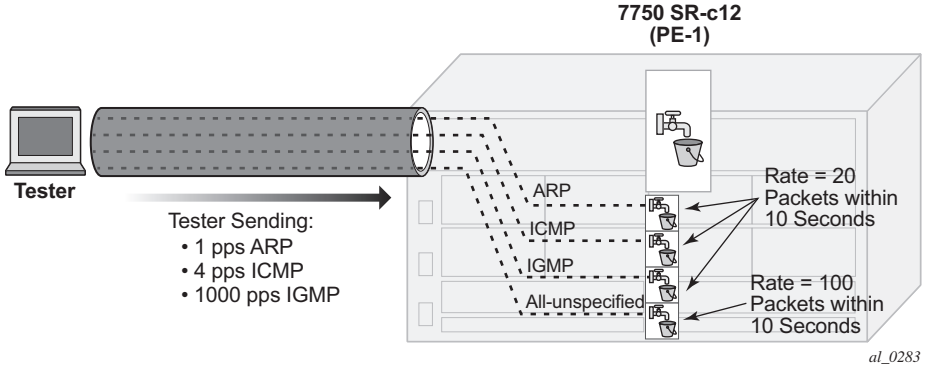


Figure 18 **Dynamic Policing – Local Monitor**

In Figure 18, the dynamic policers have not been instantiated yet.

Step 16. The local-monitoring-policer will become non-conforming since the aggregate arrival rate of arp+icmp+igmp+all-unspecified packets is greater than the configured local-monitoring-policer rate of 100 packets within 10 seconds. Dynamic enforcement policers will then be instantiated.

Figure 19 **Dynamic Policers Instantiated**

The ICMP and IGMP dynamic policers will see violations since their dynamic rates are being exceeded.

Conclusion

Distributed CPU Protection (DCP) offers a powerful rate limiting function for control protocol traffic that is extracted from the data path and sent to the CPM.

This example has demonstrated how to configure DCP on an interface and what indications SR OS provides to the operator during a potential attack or misconfiguration.

DCP can also be deployed in scenarios where per-SAP-per-protocol rate limiting is useful, such as for subscriber management in a subscriber per-vlan scenario. A DCP policy can be assigned to an MSAP policy on a Broadband Network Gateway, for example, to limit traffic related to certain protocols and to discard certain protocols. When deployed in a subscriber management scenario, DCP can help isolate SAPs (subscribers) from each other and even isolate protocols from each other within an individual SAP (subscriber). Many of the same concepts introduced in this example are applicable when DCP is deployed in a subscriber management application.

Event Handling System

This chapter provides information about Event Handling Systems (EHS).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

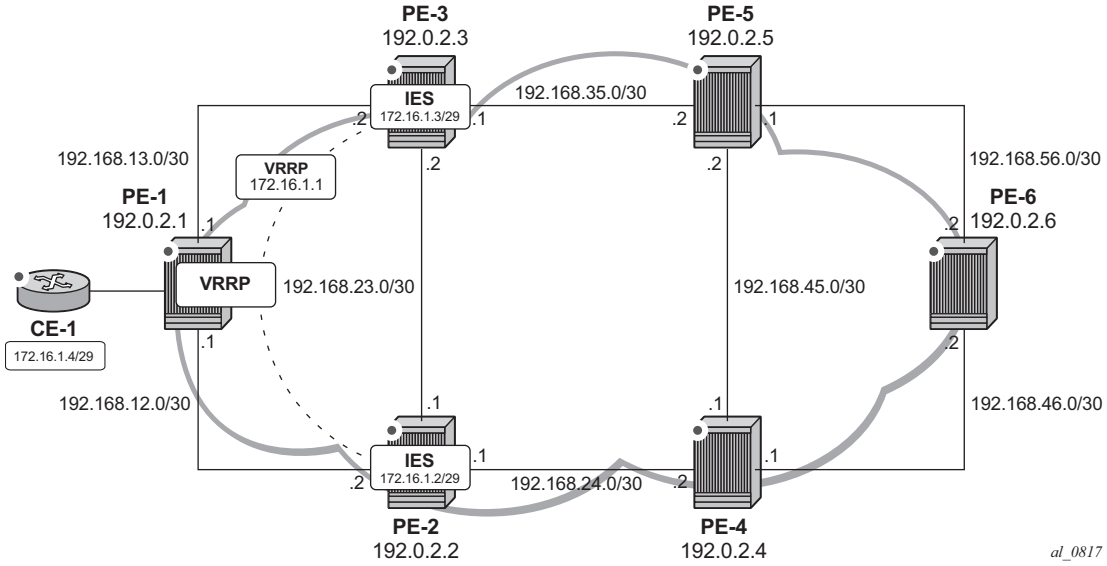
Applicability

This chapter was initially written for SR OS release 13.0.R3. The CLI in the current edition is based on SR OS release 14.0.R5.

SR OS release 13.0.R1 introduced Event Handling System (EHS).

SR OS release 14.0.R4 introduced EHS script enhanced capabilities, but the examples in this chapter do not include these enhancements, such as static variables, advanced syntax (shell scripting commands), and so on. A known issue in SR OS 14.0.R4 is that the results file is empty for a successful script run.

Overview



The Event Handling System (EHS) is a tool available in SR OS that allows operators to configure user-defined actions on the router in response to an event. The event is referred to as the trigger, and can be all or part of any event message generated by the event-control framework. The user-defined action is controlled by the script-control function. This script-control function references one or more scripts that are able to execute any command available in CLI when the trigger event occurs.

This feature allows for customized automated event management based on specific operator requirements.

Configuration

The topology shown in Figure 20 provides an example of an EHS configuration. All routers within the example topology participate in the same IS-IS Level-2 area and run LDP. All routers are BGP speakers and form part of Autonomous System 64496, exchanging routes for IPv4 address family only.

Figure 20 **Example Topology**

PE-1 has a connected CE router, CE-1, indexed into a VPLS service. The VPLS has spoke-SDPs to an IES instance on both PE-2 and PE-3, which provide a redundant default gateway to CE-1 using the Virtual Router Redundancy Protocol (VRRP). The subnet used for this redundant gateway connectivity between PE-2 and PE-3 is 172.16.1.0/29. The configuration at PE-3 is shown in the following output. The configuration at PE-2 is similar; the exception being IP addressing and VRRP priority, which is 254.

```
configure
    service
        ies 1 customer 1 create
            interface "redundant-interface" create
                address 172.16.1.3/29
                ip-mtu 1500
                vrrp 1
                    backup 172.16.1.1
                    priority 253
                    ping-reply
                exit
                spoke-sdp 31:1 create
                    no shutdown
                exit
```

```
            exit
            no shutdown
        exit
```

The objective of this configuration example is to ensure that both upstream and downstream traffic are always routed through the same PE router. That is, if PE-3 is VRRP Master, it will attract upstream traffic from CE-1 using the VRRP virtual IP/MAC, but PE-3 should also be the transit PE for downstream traffic destined toward CE-1. When both upstream and downstream traffic transit through the same PE router, it can simplify troubleshooting, QoS configuration, and reconciliation of ingress/egress statistics.

In normal operation, PE-2 is the VRRP master and advertises the BGP prefix 172.16.1.0/29 with a local preference of 100 (default value). Similarly, PE-3 is the VRRP backup and advertises the BGP prefix 172.16.1.0/29 with a local preference of 50, using a BGP export policy (route-policy). Therefore, upstream and downstream traffic normally transit through PE-2.

```
*A:PE-3# show router vrrp instance
===============================================================================
VRRP Instances
===============================================================================
Interface Name                   VR Id Own Adm  State       Base Pri   Msg Int
                                 IP        Opr  Pol Id      InUse Pri  Inh Int
-------------------------------------------------------------------------------
redundant-interface              1     No  Up   Backup       253       1
                                 IPv4      Up   n/a         253       No
  Backup Addr: 172.16.1.1
-------------------------------------------------------------------------------
Instances : 1
===============================================================================

*A:PE-3# show router bgp routes 172.16.1.0/29 hunt | match expression
"Network|Nexthop|To|Local Pref"
Network        : 172.16.1.0/29
Nexthop        : 192.0.2.3
To             : 192.0.2.6
Res. Nexthop   : n/a
Local Pref.    : 50                      Interface Name : NotAvailable
```

When PE-3 transitions from backup to master, it must modify its local preference attribute for prefix 172.16.1.0/29 to a value of 150 to attract downstream traffic destined toward CE-1. Similarly, when PE-3 reverts to backup, it must advertise the prefix with a local preference of 50.

Script Control

The first step in configuring event handling is to configure a script containing the CLI commands to be executed when the event is triggered. This script can be stored locally on the compact flash, or it can be stored off-node at a defined remote URL, where it can be accessed using FTP or TFTP. When the script is stored locally on the compact flash and the router is equipped with redundant CPMs, the script must be manually saved on the same compact flash on both CPMs, because it is not synchronized automatically.

The first requirement is to modify the local preference of the prefix 172.16.1.0/29 to 150 on transition to VRRP master. The script, which in this example is held locally on CF1:/, therefore contains the following commands (where the policy-statement, redundant-interface, is the name of the export policy used to advertise the 172.16.1.0/29 prefix):

```
*A:PE-3# file type cf1:/vrrp-master.txt
File: vrrp-master.txt
-------------------------------------------------------------------------------
exit all
config router policy-options
begin
policy-statement redundant-interface
entry 10
action accept
local-preference 150
exit
exit
exit
commit
exit all
```

The script file does not support variables or conditions. Output modifiers such as “| match” and “>” redirect are not supported. If these modifiers are present, the script will continue to run but the pipe/match or redirect will not work. Similarly, there is no syntax checking when the script file is created; instead, the script will fail with a command error. Also, transactional CLI (candidate edit) cannot be used in the script, and will fail with a command error.

Within the **system>script-control** context, the script is assigned a name and reference is made to its location. It is then put in the no shutdown state. When the script has been defined, a **script-policy** is configured that calls the previously configured script. The script-policy also specifies a location and filename for a results file that records the successful or unsuccessful conclusion of each script run and each command executed during that run. However, in release 14.0.R5, the result file is empty for a successful policy run (known issue in Release Notes - internal reference 234641-MI). Each time the script is run, the results are recorded in a file

with the name specified for results, followed by an underscore and the date and time that the script was run. A results file must be specified in order for the script to successfully run. The results file can be on the local compact flash, or a remote URL can be specified. As with the script, the script-policy must also be put in the no shutdown state.

```
configure
    system
        script-control
            script "vrrp-master-script"
                location "cf1:/vrrp-master.txt"
                no shutdown
            exit
            script-policy "vrrp-master-policy"
                results "cf1:/script-results.txt"
                script "vrrp-master-script"
                max-completed 4
                expire-time 3600
                lifetime forever
                no shutdown
            exit
        exit
```

The optional lifetime command specifies the maximum time that the script may run. The max-completed command specifies the maximum number of script run history status entries to be retained. An optional expire-time command specifies the maximum time that the system keeps the run history status (default is 1 h). The system maintains the script run history table, which has a maximum size of 255 entries. Entries are removed from this table when the max-completed or expire-time thresholds are crossed. If the table reaches the maximum value, subsequent script launch requests are not run until older run history entries expire (due to expire-time), or entries are manually cleared. To manually clear entries, the following command is used:

```
clear system script-control script-policy completed <script-policy-name>
```

The script run history status information can be viewed using the following command:

```
*A:PE-3# show system script-control script-policy "vrrp-master-policy"

===============================================================================
```

Event Handler

The second step in configuring event handling is to assign actions to be performed as a result of the event-trigger. These actions are typically one or more configured scripts defined as entries in an action-list. In the following output, the event-handler is assigned the name event-handler-1, and the action-list consists of a single entry. This entry calls the previously configured script-policy vrrp-master-policy (which in turn references the previously defined script vrrp-master-script). If multiple actions are required based on a single event-trigger, they can be configured in the action-list with subsequent entries, which are run in sequence (up to 1500 action-list entries are supported).

For this example, only a single entry is required; therefore, there is a one to one relationship between the event-handler and the action-list entry. Both the entry within the action-list and the handler should be put in the no shutdown state.

```
configure
    log
        event-handling
            handler "event-handler-1"
                action-list
                    entry 10
                        script-policy "vrrp-master-policy"
```

```
                    no shutdown
                exit
            exit
            no shutdown
        exit
    exit
```

Event Trigger

The final step in configuring event handling is to configure the event-trigger. The event-trigger defines the event that triggers the running of the script. The event-trigger is based on any event generated by the event-control framework, and can match against the application and event number (event_id). Log filters can also be used to match against specific events using the subject and/or message fields. Regular expressions can be used where required. EHS will not use any message that is suppressed through event-control configuration, or any event message that is throttled.

The general format for an event in an event log is as follows:

```
nnnn YYYY/MM/DD HH:MM:SS.SS Zone <severity>:<application> # <event_id> <router-name>
<subject> description
```

Where:

```
nnnnThe log entry sequence number
YYYY/MM/DDThe UTC date stamp for the log entry:
YYYY - Year
MM - Month
DD - Date
HH:MM:SS.SSThe UTC time stamp for the event
HH - Hours (24 hour format)
MM - Minutes
SS.SS - Seconds
ZoneTimezone
<severity>The severity level name of the event
<application>The application generating the log message
<event_id>The application’s event ID number for the event
<subject>The subject/affected object for the event
<message>A textual description of the event
```

In the example, the following event message is generated when PE-3 becomes VRRP Master:

```
2 2016/10/27 08:23:37.54 UTC MINOR: VRRP #2001 Base Becoming Master
"VRRP virtual router instance 1 on interface redundant-interface (primary address
172.16.1.3) changed state to master"
```

Therefore, the event-trigger configuration is based on an application of VRRP and an event number of 2001 (vrrptrapNewMaster). In the following output, vrrp 2001 is configured as the event. The trigger-entry is defined as 1, and in this example, there is only one trigger event. Up to 1500 trigger-entries can be included, each of which can act as a potential trigger event. The trigger-entry also references the previously configured event-handler-1. (Recall that the event-handler references the script-control, which in turn references the script that should be run.)

Finally, there is a reference to log-filter 1. Without more explicit filtering, event handling will be triggered on any event with the application of VRRP and event number 2001. There may be multiple VRRP instances running on this router, but the requirement is that event handling should only be triggered when the VRRP instance running on redundant-interface transitions to master at PE-3. Therefore, log-filter 1 is used to define a more explicit match using the message field, which contains an explicit reference to the interface. Both the trigger-entry and the event-handler should be put in the no shutdown state.

```
configure
    log
        filter 1
            default-action drop
            entry 10
                action forward
                match
                    message eq pattern "interface redundant-interface (primary
                                address 172.16.1.3) changed state to master"
                exit
            exit
        exit

configure
    log
        event-trigger
            event "vrrp" 2001
                trigger-entry 1
                    event-handler "event-handler-1"
                    log-filter 1
                    no shutdown
                exit
                no shutdown
            exit
        exit
    exit
```

The configuration of the example event handling for the failure event (PE-3 transitions to VRRP master) is now complete. By shutting down the spoke-SDP between PE-1 and PE-2, it is possible to simulate a failure event where the VRRP message path is broken. Therefore, four events are generated.

- The first indicates that PE-3 has become VRRP master for the interface named redundant-interface.

- The second indicates that EHS handler event-handler-1 was invoked by a CLI user.
- The third indicates that a script file has initiated an attempt to execute CLI commands contained in script file vrrp-master.txt.
- The fourth indicates that the attempt to execute those CLI commands was successful (in release 14.0.R5, result “none” is displayed for a successful script run; in release 13.0.R3, the result is “success”).

```
15 2016/10/27 09:13:59.03 UTC MINOR: VRRP #2001 Base Becoming Master
"VRRP virtual router instance 1 on interface redundant-interface (primary address
172.16.1.3) changed state to master"

16 2016/10/27 09:13:59.03 UTC MINOR: SYSTEM #2069 Base EHS script
"Ehs handler :"event-handler-1" with the description : "" was invoked by the cli-
user account "not-specified"."

17 2016/10/27 09:14:01.64 UTC MAJOR: SYSTEM #2052 Base CLI 'exec'
"A CLI user has initiated an 'exec' operation to process the commands in the SROS CLI
file cf1:\vrrp-master.txt"

18 2016/10/27 09:14:10.73 UTC MAJOR: SYSTEM #2053 Base CLI 'exec'
"The CLI user initiated 'exec' operation to process the commands in the SROS CLI
 file cf1:\vrrp-master.txt has completed with the result of none"
```

The results file is empty for a successful script run in release 14.0.R5 (known issue). However, in release 13.0.R3, the last message would indicate that the result is “success” and the result file would contain all the commands contained in the script. In release 13.0.R3, an example of the results file configured in the script-policy is as follows. A successful script run shows the commands contained in the script, followed by an indication that the commands were executed.

```
*A:PE-3# file type script-results.txt_20150608-160703.402470.out
File: script-results.txt_20150608-160703.402470.out
-------------------------------------------------------------------------------
*A:PE-3# exit all
*A:PE-3# config router policy-options
*A:PE-3# begin
*A:PE-3# policy-statement redundant-interface
*A:PE-3# entry 10
*A:PE-3# action accept
*A:PE-3# local-preference 150
*A:PE-3# exit
*A:PE-3# exit
*A:PE-3# exit
*A:PE-3# commit
*A:PE-3# exit all

```

The following outputs confirm that PE-3 is VRRP master, and that the local preference attribute for prefix 172.16.1.0/29 has changed to a value of 150. The result of this action is that PE-3 will now be the transit router for both upstream and downstream traffic.

```

The event-handler indicates that the referenced script was triggered and run using the command shown in the following output. The Action-List Entry Execution Statistics window provides statistics on the number of times an action (script) was queued to run, and the number of times an error was experienced, both during launch and due to a non-operational admin status. The remainder of the fields in the output are self-explanatory.

```

The example includes an event-trigger and script to meet the requirements of a fail-forward where PE-3 becomes VRRP master. Now, configuration is needed for when PE-3 reverts to VRRP backup. Without another event-trigger and script, PE-3 will continue to advertise the prefix 172.16.1.0/29 with a local preference of 150 and upstream/downstream traffic will be asymmetric through PE-1/PE-3 respectively.

As before, a script is required. Because PE-2 advertises the prefix with a local preference of 100 (default), PE-3 needs to advertise the same prefix with a lower value (50 in the following output), so that PE-2 is the preferred next hop.

```
*A:PE-3# file type cf1:/vrrp-backup.txt
File: vrrp-backup.txt
-------------------------------------------------------------------------------
exit all
config router policy-options
begin
policy-statement redundant-interface
entry 10
action accept
local-preference 50
exit
exit
exit
commit
exit all
```

The script must then be configured within the script-control context, and subsequently referenced in a script-policy as vrrp-backup-policy.

```
configure
    system
        script-control
            script "vrrp-backup-script"
                location "cf1:/vrrp-backup.txt"
                no shutdown
            exit
            script-policy "vrrp-backup-policy"
                results "cf1:/script-revert-results.txt"
                script "vrrp-backup-script"
                max-completed 4
                lifetime forever
                no shutdown
            exit
        exit
```

The event-handler acts as the interface between the configured script-policy and event-trigger. Therefore, a second event-handler is configured with an action-list consisting of a single entry referencing the newly configured vrrp-backup-policy.

```
configure
    log
        event-handling
            handler "event-handler-2"
                action-list
                    entry 10
                        script-policy "vrrp-backup-policy"
                        no shutdown
                    exit
                exit
                no shutdown
            exit
        exit
```

Finally, the event-trigger is configured. To revert to VRRP Backup, the application is VRRP and the event number is 2006 (tmnxVrrpBecameBackup). The configuration is filtered on the message field, as before, using log-filter 2, so that it is specific to the interface named redundant-interface.

```
configure
    log
        filter 2
            default-action drop
            entry 10
                action forward
                match
                    message eq pattern "interface redundant-interface changed
                                        state to backup"
                exit
            exit
        exit

configure
    log
        event-trigger
            event "vrrp" 2006
                trigger-entry 1
                    event-handler "event-handler-2"
                    log-filter 2
                    no shutdown
                exit
                no shutdown
            exit
        exit
    exit
```

The configuration of the example event handling for the revertive failure event (PE-3 transitions to VRRP backup) is now complete. By re-enabling the spoke-SDP between PE-1 and PE-2, the VRRP message path is restored, and PE-2 again becomes the VRRP master. The following events are generated. The first indicates that PE-3 has become VRRP backup for the interface named redundant-interface. The second indicates that EHS handler event-handler-2 was invoked by a CLI user. The third indicates that a script file has initiated an attempt to execute CLI commands contained in script file vrrp-backup.txt. The fourth indicates that the attempt to execute those CLI commands was successful (in release 14.0.R5, result “none” is displayed for a successful script run; in release 13.0.R3, the result is “success”).

```
7 2016/10/27 16:17:53.61 UTC MINOR: VRRP #2006 Base Becoming Backup
"VRRP virtual router instance 1 on interface redundant-interface changed state to
backup - current master is 172.16.1.2"

Conclusion

EHS allows operators to configure user-defined actions on the router when an event occurs. The event trigger can be anything that is generated by the event-control framework, and explicit filtering is possible using regular expressions. A user-defined action typically runs a script that allows any CLI commands to be executed. Multiple actions are permitted, running multiple scripts if required.

Interface Configuration

In This Section

This section provides interface configuration information for the following topics:

- Multi-Chassis APS and Pseudowire Redundancy Interworking
- Multi-Chassis LAG and Pseudowire Redundancy Interworking

Multi-Chassis APS and Pseudowire Redundancy Interworking

This chapter describes multi-chassis APS and pseudowire redundancy interworking.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS release 6.0.R2, but the CLI in the current edition is based on SR OS release 14.0.R5.The configuration in this chapter includes the use of the ATM ports. See the Release Notes for information about support of ATM (and other) MDAs on various platforms as well as MC-APS restrictions.

Overview

MC-APS

MC-APS is an extension to the APS feature to provide not only link redundancy but also node level redundancy. It can protect against nodal failure by configuring the working circuit of an APS group on one node while configuring the protect circuit of the same APS group on a different node.

The two nodes connect to each other with an IP link that is used to establish a signaling path between them. The relevant APS groups in both the working and protection routers must have the same group ID and working circuit, and the protect circuit must have compatible configurations (such as the same speed, framing, and port-type). Signaling is provided using the direct connection between the two service routers. A heartbeat protocol can be used to add robustness to the interaction between the two routers.

Signaling functionality includes support for:

- APS group matching between service routers.
- Verification that one side is configured as a working circuit and the other side is configured as the protect circuit. In case of a mismatch, a trap (incompatible-neighbor) is generated.
- Change in working circuit status is sent from the working router to keep the protection router in sync.
- Protection router, based on K1/K2 byte data, member circuit status, and external request, selects the active circuit and informs the working router to activate or de-activate the working circuit.

Pseudowire Redundancy

Pseudowire (PW) redundancy provides the ability to protect a pseudowire with a pre-provisioned pseudowire and to switch traffic over to the secondary standby pseudowire in case of a SAP and/or network failure condition. Normally, pseudowires are redundant by the virtue of the SDP redundancy mechanism. For instance, if the SDP is an RSVP LSP and is protected by a secondary standby path and/or by Fast-Reroute paths, the pseudowire is also protected.

However, there are a few applications in which SDP redundancy does not protect the end-to-end pseudowire path when there are two different destination 7x50 PE nodes for the same VLL service. The main use case is the provisioning of dual-homing of a CPE or access node to two 7x50 PE nodes located in different POPs. The other use case is the provisioning of a pair of active and standby BRAS nodes, or active and standby links to the same BRAS node, to provide service resiliency to broadband service subscribers.

Example Topology

The setup in this section contains two access nodes and 4 PE nodes. The access nodes can be any ATM switches that support 1+1 bi-directional APS. Figure 21 shows the physical topology of the setup. Figure 23 shows the use of both MC-APS in the access network and pseudowire redundancy in the core network to provide a resilient end-to-end VLL service.

Figure 21 **MC-APS Network Topology**

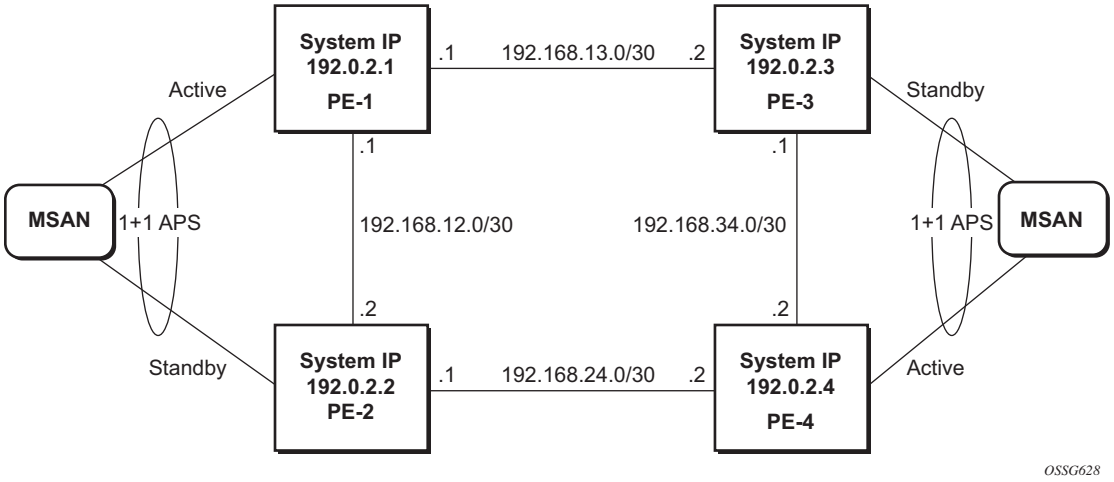

Figure 22 **Access Node and Network Resilience (Part 1)**

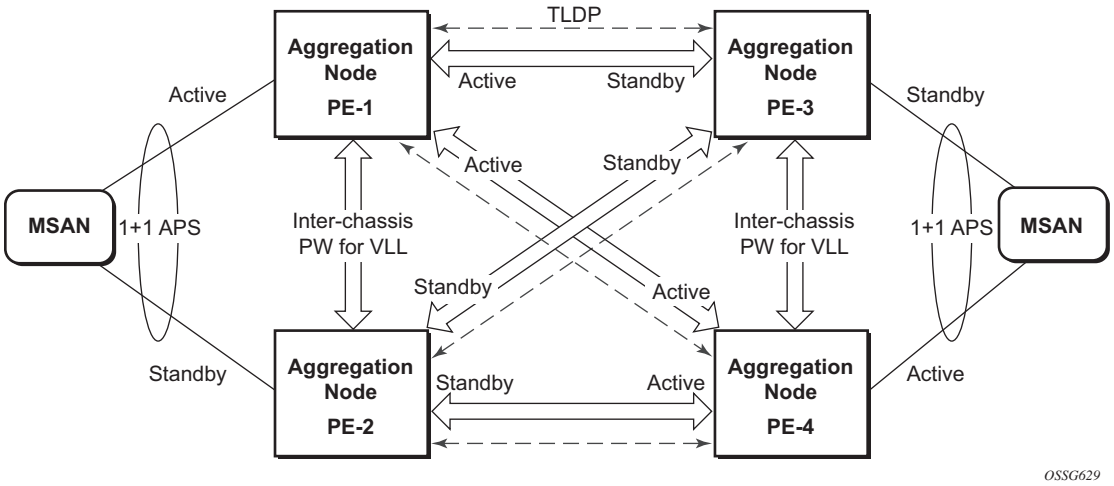

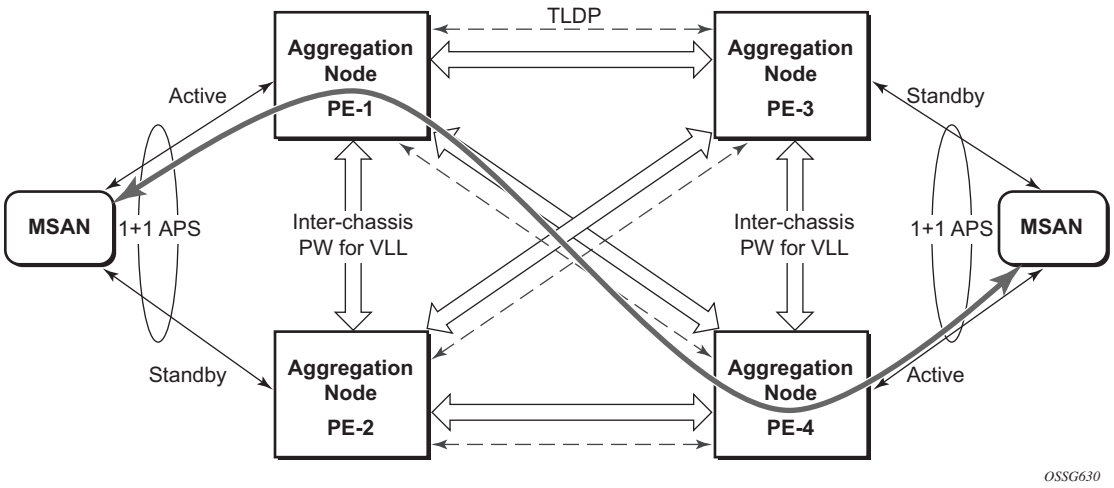

Figure 23 **Access Node and Network Resilience (Part 2)**

Configuration

The following configuration should be completed on the PEs before configuring MC-APS:

- Cards, MDAs and ports
- Interfaces
- IGP configured and converged
- MPLS
- SDPs configured between all PE routers

For the IGP, OSPF or IS-IS can be used. MPLS or GRE can be used for the transport tunnels. For MPLS, LDP or RSVP protocols can be used for signaling MPLS labels. In this example, OSPF and LDP are used. The following commands can be used to check if OSPF has converged and to make sure the SDPs are up (for example, on PE-1):

```
*A:PE-1# show router route-table

===============================================================================
*A:PE-1#
```

Step 1. APS configuration on MSANs

The access nodes can be any ATM switches that support 1+1 bi-directional APS. Here is an example on 7670RSP (Routing Switching Platform).

```
RSP> configure
RSP> port 1-6-1-1
RSP> options protection type 1+1
RSP> options protection switching bidirect
RSP> options protection
                                                                    (Standby)
#                  Type        Status           Name
1-6-1-1            STM1_IR8    OK
Protection Group Contains:
  Protection Port     : 1-6-1-1     (Standby)
  Working Port        : 1-5-1-1
Protection Type       : 1+1
Switching Type        : Non-Revertive
Switching Mode        : Bi-directional
```

```
Wait-To-Restore Timer :  5 minute(s)
```

Step 2. MC-APS configuration on PE-1 and PE-2

Assuming the link between MSAN and PE-1 is working circuit and the link between MSAN and PE-2 is protection circuit.

Configure APS on the PE-1 port. Specify the system IP address of neighbor node (PE-2) and working-circuit.

```
*A:PE-1# configure
    port 1/2/1
        sonet-sdh
        exit
        no shutdown

*A:PE-1# configure
    port aps-1
        aps
            neighbor 192.0.2.2
            working-circuit 1/2/1
        exit
        sonet-sdh
            path
                atm
                exit
                no shutdown
            exit
        exit
        no shutdown
```

Configure APS on the PE-2 port. Specify the system IP address of neighbor node (PE-1) and protect-circuit instead of working-circuit.

```
*A:PE-2# configure
    port 1/2/1
        sonet-sdh
        exit
        no shutdown

*A:PE-2# configure port aps-1
        aps
            neighbor 192.0.2.1
            protect-circuit 1/2/1
        exit
        sonet-sdh
            path
                atm
                exit
                no shutdown
            exit
        exit
        no shutdown
```

The following parameters can be configured under APS optionally.

- advertise-interval — This command specifies the time interval, in 100s of milliseconds, between 'I am operational' messages sent by both protect and working circuits to their neighbor for multi-chassis APS.
- hold-time — This command specifies how much time can pass, in 100s of milliseconds, without receiving an advertise packet from the neighbor before the multi-chassis signaling link is considered not operational.
- revert-time — This command configures the revert-time timer to determine how long to wait before switching back to the working circuit after that circuit has been restored into service.
- switching-mode — This command configures the switching mode for the APS port which can be bi-directional or uni-directional.

Step 3. Verify the APS status on PE-1.

```
*A:PE-1# show port aps-1

===============================================================================

===============================================================================
*A:PE-1#
```

Step 4. Verify the MC-APS status and parameters on PE-1 and PE-2

Detailed parameters of the APS configuration on PE-1 can be verified, as follows. The admin/oper status of APS group 1 shows up/up. K1/K2 byte shows N/A as APS 1+1 exchanges that information through the protection circuit.

The admin/oper status of the working circuit (the link between MSAN and PE-1) is up/up.

```
*A:PE-1# show aps detail

===============================================================================
APS Group: aps-1
===============================================================================

Tx L-AIS           : None
===============================================================================
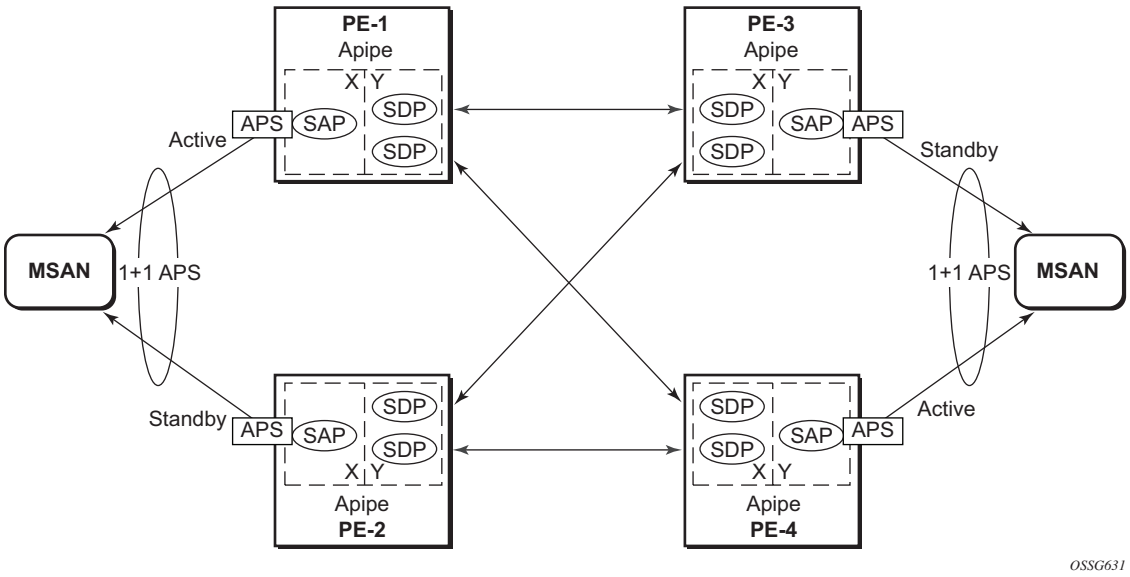
*A:PE-2#
```



Step 5. MC-APS configuration on PE-3 and PE-4

The MC-APS configuration on PE-3 and PE-4 is similar to the configuration on PE-1 and PE-2. Configure the working circuit on PE-4 and the protection circuit on PE-3.

Step 6. Pseudowire configuration

Configure an Apipe service on every PE and create endpoints X and Y. Associate the SAPs and spoke SDPs with the endpoints, as shown in Figure 24.

Figure 24 **Association of SAPs/SDPs and Endpoints**

```
*A:PE-1# configure
    service
        apipe 1 customer 1 create
            endpoint "X" create
            exit
            endpoint "Y" create
            exit
            sap aps-1:0/32 endpoint "X" create
            exit
            spoke-sdp 13:1 endpoint "Y" create
            exit
            spoke-sdp 14:1 endpoint "Y" create
            exit
            no shutdown
        exit
```

Syntax aps-1:0/32 specifies the APS group and VPI/VCI of the ATM circuit (aps-id:vpi/vci).

Likewise, an Apipe service, with endpoints, SAPs and spoke SDPs must be configured on the other PE routers.

Step 7. Pseudowire verification

The Apipe service is up in PE-1 (MC-APS working circuit), as follows:

```
*A:PE-1# show service service-using
===============================================================================
Services
===============================================================================
ServiceId    Type      Adm  Opr  CustomerId Service Name
-------------------------------------------------------------------------------
1            Apipe     Up   Up   1
2147483648   IES       Up   Down 1          _tmnx_InternalIesService
```

```
2147483649   intVpls   Up   Down 1          _tmnx_InternalVplsService
-------------------------------------------------------------------------------
Matching Services : 3
-------------------------------------------------------------------------------
===============================================================================
*A:PE-1#
```

The Apipe service is down in PE-2 (MC-APS protect circuit), as follows:

```
*A:PE-2# show service service-using
===============================================================================
Services
===============================================================================
ServiceId    Type      Adm  Opr  CustomerId Service Name
-------------------------------------------------------------------------------
1            Apipe     Up   Down 1
2147483648   IES       Up   Down 1          _tmnx_InternalIesService
2147483649   intVpls   Up   Down 1          _tmnx_InternalVplsService
-------------------------------------------------------------------------------
Matching Services : 3
-------------------------------------------------------------------------------
===============================================================================
*A:PE-2#
```

The Apipe service is down in PE-3 (MC-APS protect circuit), as follows:

```
*A:PE-3# show service service-using
===============================================================================
Services
===============================================================================
ServiceId    Type      Adm  Opr  CustomerId Service Name
-------------------------------------------------------------------------------
1            Apipe     Up   Down 1
2147483648   IES       Up   Down 1          _tmnx_InternalIesService
2147483649   intVpls   Up   Down 1          _tmnx_InternalVplsService
-------------------------------------------------------------------------------
Matching Services : 3
-------------------------------------------------------------------------------
===============================================================================
*A:PE-3#
```

The Apipe service is up in PE-4 (MC-APS working circuit), as follows:

```
*A:PE-4# show service service-using
===============================================================================
Services
===============================================================================
ServiceId    Type      Adm  Opr  CustomerId Service Name
-------------------------------------------------------------------------------
1            Apipe     Up   Up   1
2147483648   IES       Up   Down 1          _tmnx_InternalIesService
2147483649   intVpls   Up   Down 1          _tmnx_InternalVplsService
-------------------------------------------------------------------------------
Matching Services : 3
-------------------------------------------------------------------------------
===============================================================================
*A:PE-4#
```

Note: After configuring ICB spoke-SDPs, the Apipe will be up on all PEs.

Step 8. Verify SDP status

The status of SDP 23:1 on PE-2 can be verified as follows.

Peer Pw Bits shows the status of the pseudowire on the peer node. In this example, both the local node (PE-2) as the remote node (PE-3) are sending the **lacIngressFault lacEgressFault** and **pwFwdingStandby** flags. This is because the Apipe service on these nodes is down because the MC-APS is in protection status.

```
*A:PE-2# show service id 1 sdp 23:1 detail

===============================================================================
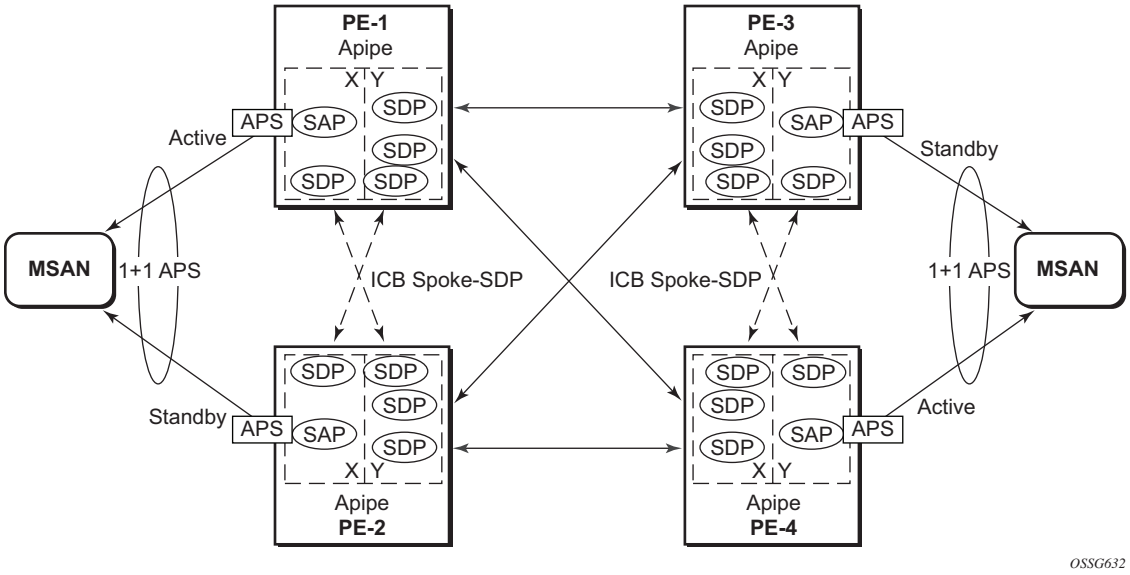
*A:PE-2#
```

In case of failure, the access link can be protected by MC-APS. An MPLS network failure can be protected by pseudowire redundancy. Node failure can be protected by the combination of MC-APS and pseudowire redundancy.



Step 9. Inter-Chassis Backup (ICB) pseudowire configuration.

Configuring Inter-Chassis Backup (ICB) is optional. It can reduce traffic impact by forwarding traffic on ICB spoke SDPs during MC-APS switchover. The ICB spoke SDP cannot be added to the endpoint if the SAP is not part of an MC-APS (or MC-LAG) instance. Conversely, a SAP which is not part of a MC-APS (or MC-LAG) instance cannot be added to an endpoint which already has an ICB spoke SDP. Forwarding between ICBs is blocked on the same node. The user has to explicitly indicate the spoke SDP is actually an ICB at creation time. Figure 5 shows some setup examples where ICBs are required.

After configuring ICB spoke SDPs, the Apipe will be in admin/oper up/up status on all PE routers.

ICB SDPs are configured and associated to endpoints, as shown in Figure 25.

Figure 25 **ICB Spoke SDPs and Association with the Endpoints**

Two ICB spoke SDPs must be configured in the Apipe service on each PE router, one in each endpoint. The same SDP IDs can be used for the ICBs since the far-end will be the same. However, the vc-id must be different. The ICB spoke SDPs must cross, meaning one end should be associated with endpoint X and the other end (on the other PE) should be associated with endpoint Y.

An ICB is always the last forwarding resort. Only one spoke SDP will be forwarding. If there is an ICB and an MC-APS SAP in an endpoint, the ICB will only forward if the SAP goes down. If an ICB resides in an endpoint together with other spoke SDPs the ICB will only forward if there is no other active spoke SDP.

The following shows the additional configuration for ICB on each PE:

```
*A:PE-1# configure
    service
        apipe 1
            spoke-sdp 12:1 endpoint "X" icb create
            exit
            spoke-sdp 12:2 endpoint "Y" icb create
            exit

*A:PE-2# configure
    service
        apipe 1
            spoke-sdp 21:1 endpoint "Y" icb create
            exit
            spoke-sdp 21:2 endpoint "X" icb create
            exit

*A:PE-3# configure
    service
        apipe 1
            spoke-sdp 34:1 endpoint "X" icb create
            exit
            spoke-sdp 34:2 endpoint "Y" icb create
            exit

*A:PE-4# configure
    service
        apipe 1
            spoke-sdp 43:1 endpoint "Y" icb create
            exit
            spoke-sdp 43:2 endpoint "X" icb create
            exit
```

Step 10. Verification of active objects for each endpoint

The following command shows which objects are configured for each endpoint and which is the active object at this moment:

```
*A:PE-1# show service id 1 endpoint

===============================================================================
Service 1 endpoints
===============================================================================
Endpoint name               : X
Description                 : (Not Specified)

Spoke-sdp: 13:1 Prec:4                          Oper Status: Up
Spoke-sdp: 14:1 Prec:4                          Oper Status: Up
===============================================================================
===============================================================================
*A:PE-1#
```

On PE-1, both the SAP and the spoke SDP 14:1 are active. The other objects do not forward traffic.

Step 11. Other types of setups

The following figures show other setups that combine MC-APS and pseudowire redundancy.

Figure 26 **Additional Setup Example 1 (Part 1)**

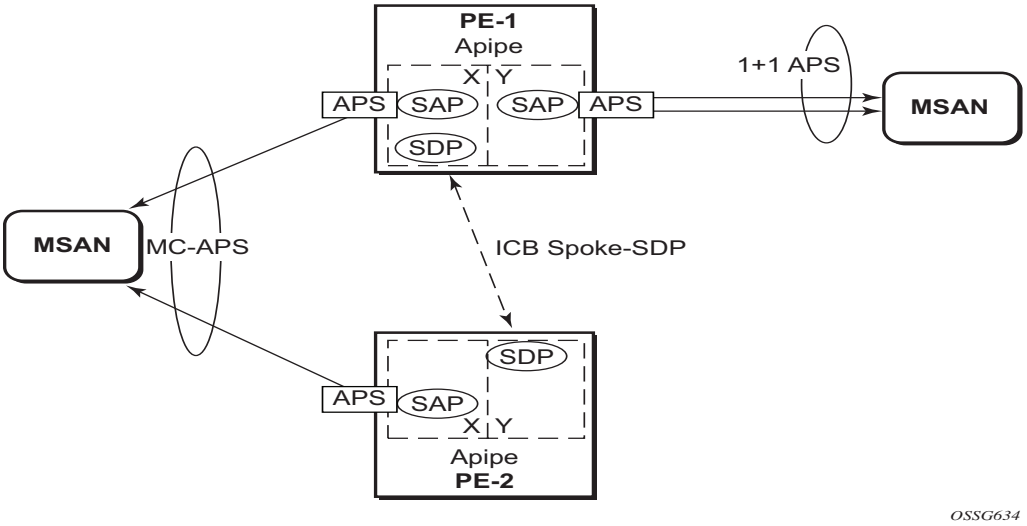

Figure 27 **Additional Setup Example 1 (Part 2)**

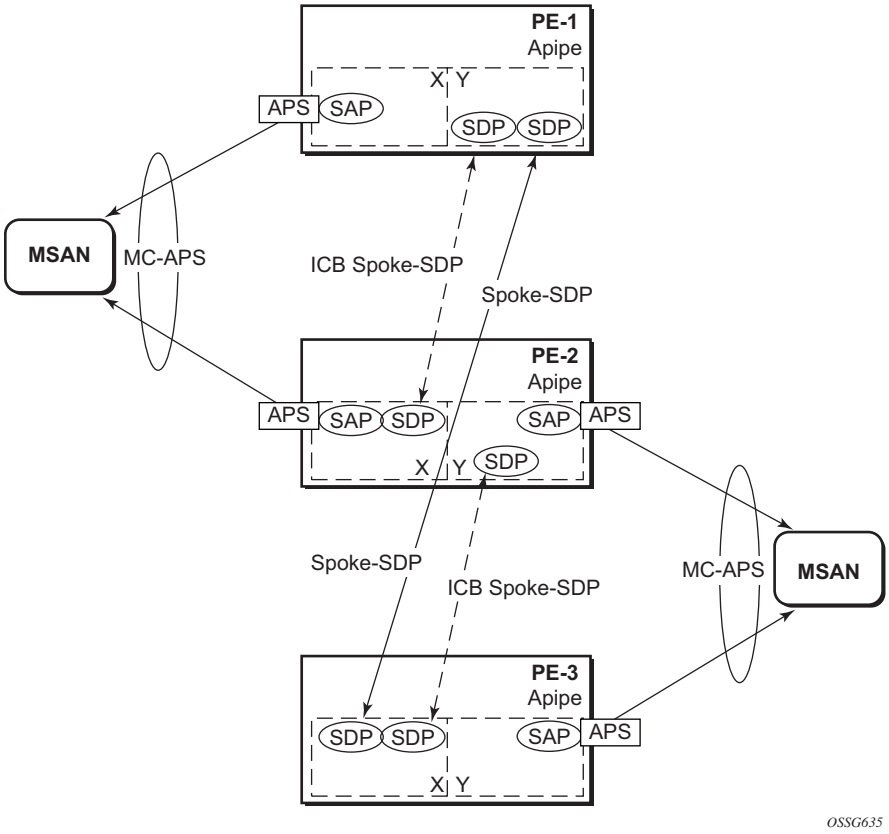

Figure 28 **Additional Setup Example 2 (Part 1a)**

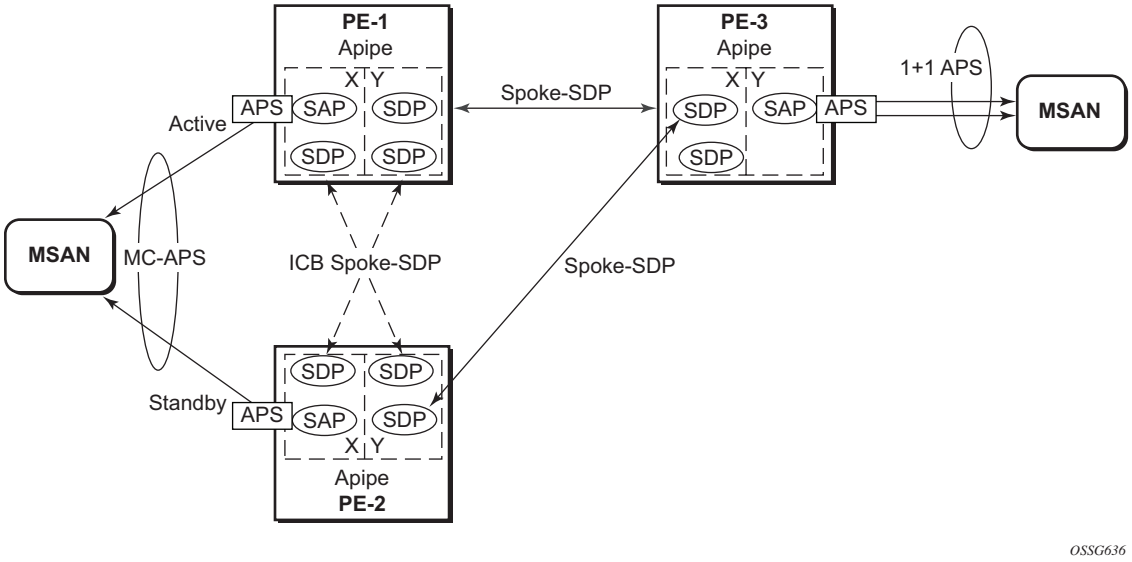

Figure 29 **Additional Setup Example 2 (Part 1b)**

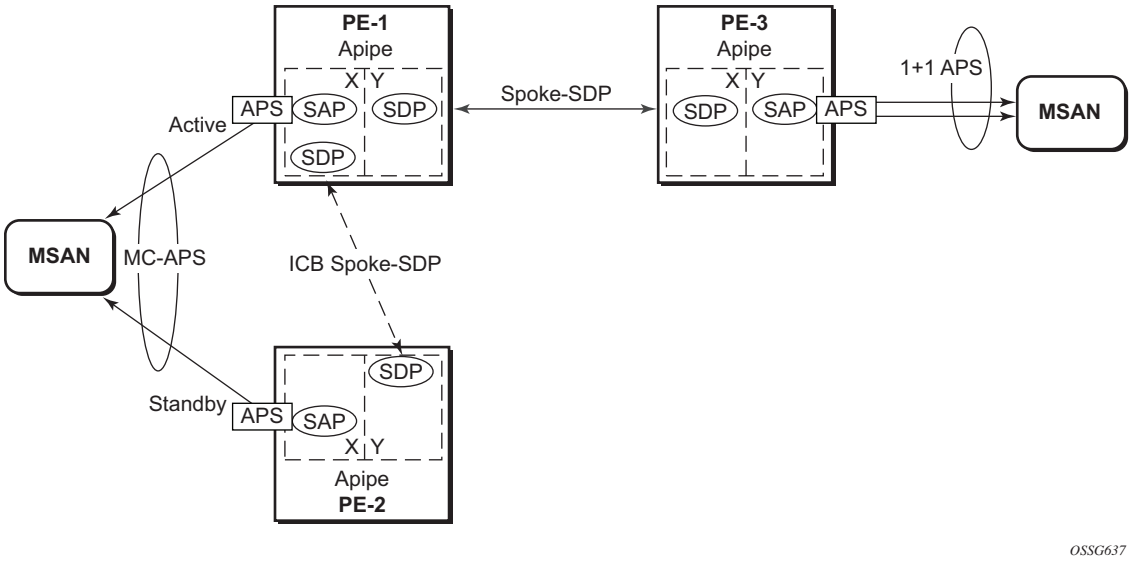

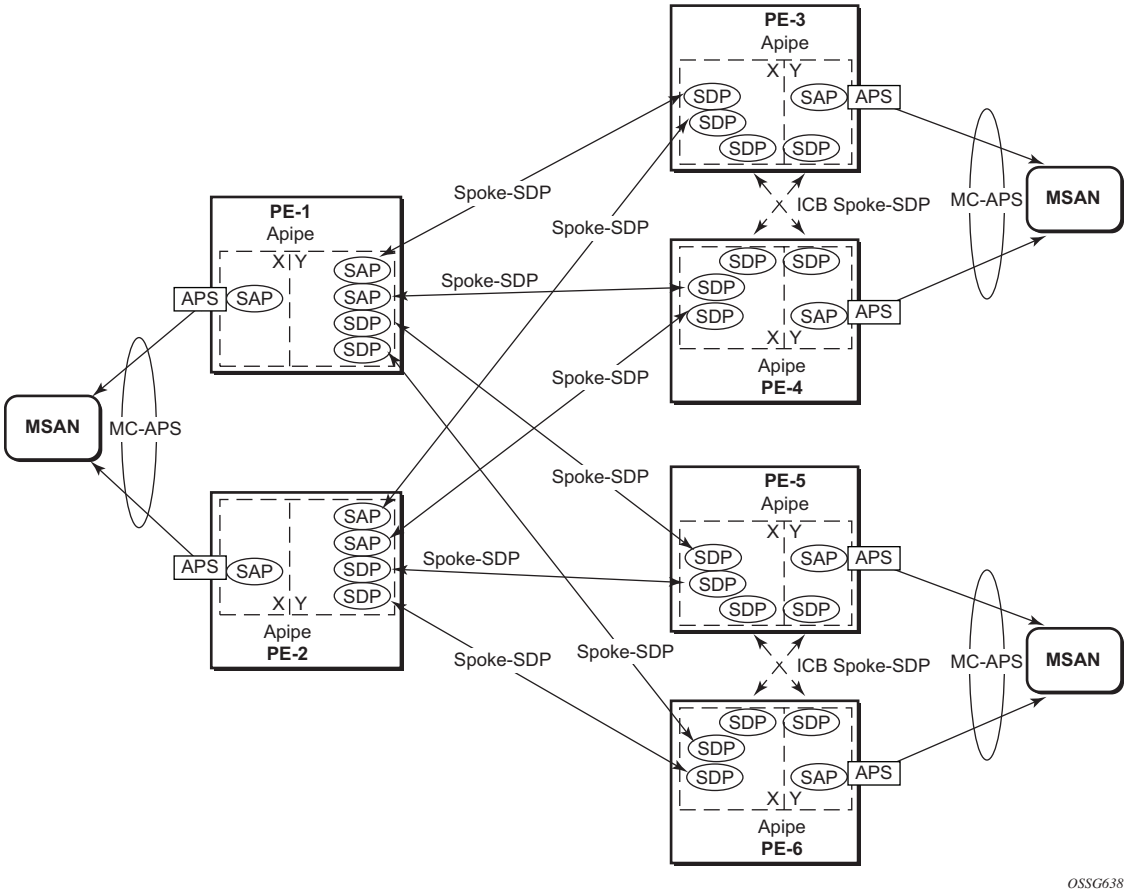

Figure 30 **Additional Setup Example 2 (Part 2)**

Forced Switchover

MC-APS convergence can be forced with the **tools perform aps** command:

```
*A:PE-1# tools perform aps force
  - force <aps-id> {protect|working} [number <number>]

 <aps-id>             : aps-<group-id>
                          aps            - keyword
                          group-id       - [1..128]
 <protect|working>    : keyword
 <number>             : [1-2]
```

After the forced switchover, it is important to clear the forced switchover:

```
*A:PE-1# tools perform aps clear
  - clear <aps-id> {protect|working} [number <number>]
```

```
<aps-id>              : aps-<group-id>
                          aps            - keyword
                          group-id       - [1..128]
<protect|working>     : protect|working
<number>              : [1-2]
```

Conclusion

In addition to Multi-Chassis LAG, Multi-Chassis APS provides a solution for both network redundancy and access node redundancy. It supports ATM VLL and Ethernet VLL with ATM SAP. Access links and PE nodes are protected by APS and the MPLS network is protected by pseudowire redundancy/FRR. With this feature, Nokia can provide resilient end-to-end solutions.

Multi-Chassis LAG and Pseudowire Redundancy Interworking

This chapter provides information about Multi-Chassis Link Aggregation (MC-LAG) and pseudowire redundancy interworking.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

MC-LAG is supported only on Ethernet MDAs, and this only for access ports, because the LAG group must be in access mode.

This chapter was initially written for SR OS release 7.0.R5. However, the CLI in the current edition is based on SR OS release 14.0.R5.

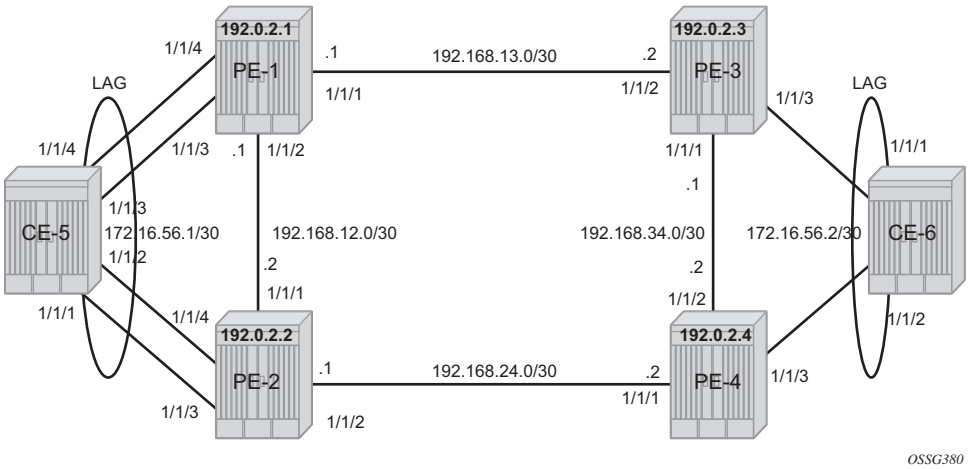
Overview

MC-LAG

MC-LAG is an extension to the LAG feature to provide not only link redundancy but also node-level redundancy. This feature provides a Nokia added value solution which is not defined in any IEEE standard.

A proprietary messaging system between redundant-pair nodes supports coordinating the LAG switchover.

Multi-chassis LAG supports LAG switchover coordination: one node connected to two redundant-pair peer nodes with the LAG. During the LACP negotiation, the redundant-pair peer nodes act like a single node using active/stand-by signaling to ensure that only links of one peer node are used at a time.



Pseudowire Redundancy

Pseudowire (PW) redundancy provides the ability to protect a pseudowire with a pre-provisioned pseudowire and to switch traffic over to the secondary standby pseudowire in case of a SAP and/or network failure condition. Normally, pseudowires are redundant by the virtue of the SDP redundancy mechanism. For instance, if the SDP is an RSVP LSP and is protected by a secondary standby path and/or by Fast-Reroute paths, the pseudowire is also protected.

However, there are a few applications in which SDP redundancy does not protect the end-to-end pseudowire path when there are two different destination 7x50 PE nodes for the same VLL service. The main use case is the provision of dual-homing of a CPE or access node to two 7x50 PE nodes located in different POPs. The other use case is the provisioning of a pair of active and standby BRAS nodes, or active and standby links to the same BRAS node, to provide service resiliency to broadband service subscribers.

Example Topology

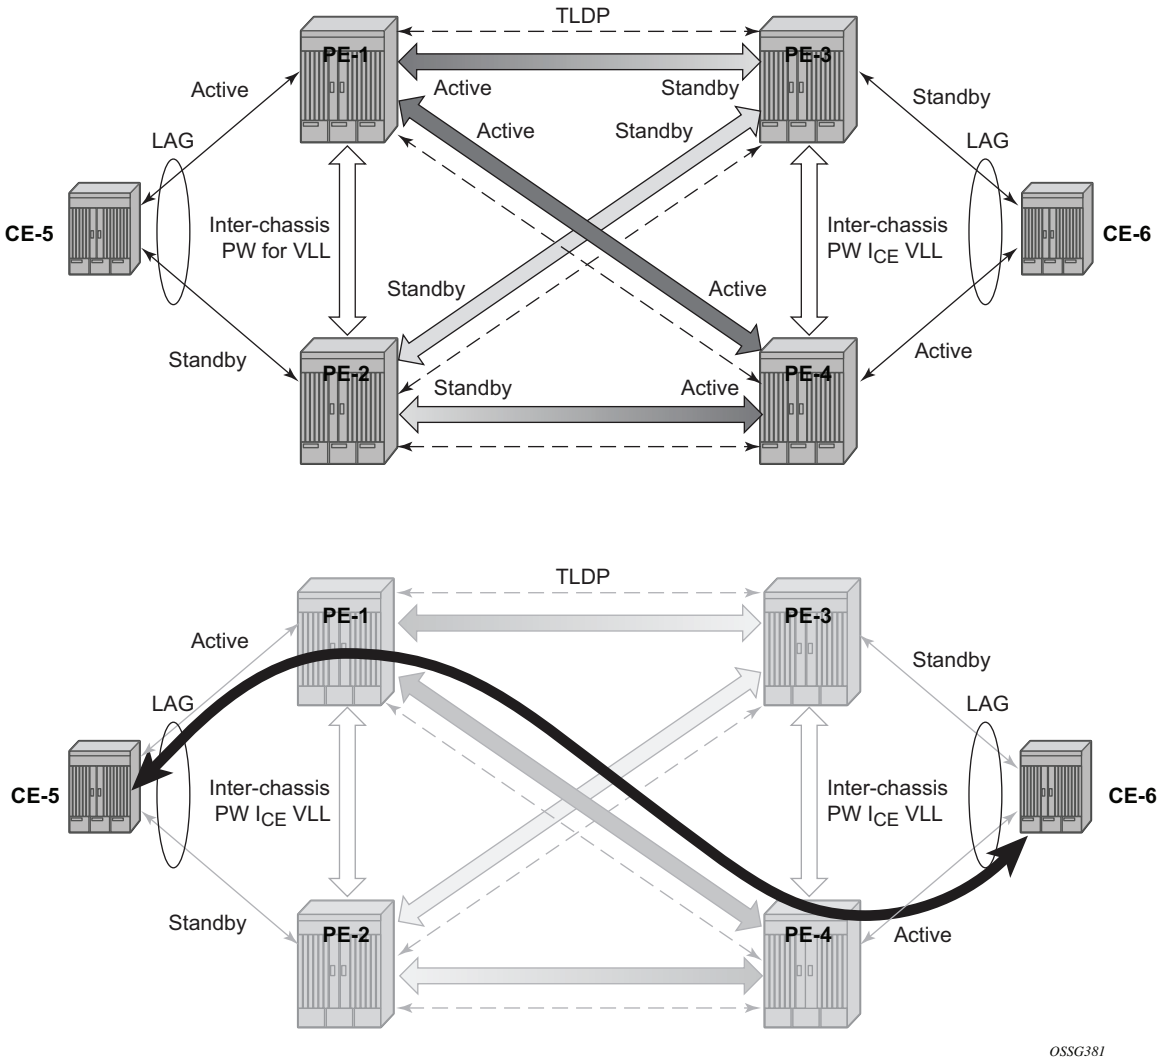


Figure 31 **MC-LAG Example Topology**

This section describes a setup which contains 2 CE and 4 PE nodes. The CE nodes can be any routing/switching device that support the OUT_OF_SYNC signaling as described in IEEE Standard 802.3-2005 section 3 section 43.6.1. Figure 31 shows the physical topology of the setup.

Figure 32 shows the use of both MC-LAG in the access network and pseudowire redundancy in the core network to provide a resilient end-to-end VLL service between CE-5 and CE-6.

Figure 32 **Network Resiliency**

When an SDP is in standby, it sends the pseudowire status bit pwFwdingStandby to its peer.

Configuration

It is assumed that the following base configuration has been implemented on the PEs:

- Cards, MDAs and ports

- Interfaces
- IGP configured and converged
- MPLS
- SDPs configured between all PE routers

Either OSPF or IS-IS can be used as the IGP. Both LDP or RSVP can be used for signaling the transport MPLS labels. Alternatively, GRE can be used for the transport tunnels.

It does not matter if the SDPs are using LDP, RSVP, or GRE. In this example, OSPF and LDP are used.

The following command is used to check if OSPF has converged (for example, on PE-1):

```
*A:PE-1# show router route-table

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref

===============================================================================
*A:PE-1#
```

Step 1. MC-LAG configuration on CEs.

The LAG configuration on CEs is only included for completeness of the example; any CE device could be used.

Auto-negotiation must be switched off or set to limited on all ports that will be included into the LAG in order to guarantee a specific port speed.

Note: Disabling autonegotiation on Gigabit ports is not allowed because the IEEE 802.3 specification for Gigabit Ethernet requires autonegotiation to be enabled for far end fault detection.

Configure LACP on the LAG with at least one side of the LAG in **active** mode.

```
*A:CE-5# configure port 1/1/[1..4] ethernet autonegotiate limited
*A:CE-5# configure port 1/1/[1..4] no shutdown
*A:CE-5# configure lag 1
        port 1/1/1 1/1/2 1/1/3 1/1/4
        lacp active
        no shutdown
```

Step 2. LAG configuration on PEs.

The PE ports connected to the CEs must be configured as access ports because they will be used in the redundant pseudowire service. The LAG must also be configured in access mode.

The LAG encapsulation type (null | dot1q | qinq) must match the port encapsulation type of the LAG members.

Auto-negotiation must be switched off or configured to limited.

Configure LACP on the LAG. At least 1 side of the LAG (PE or CE) must be configured in **active** mode.

```
*A:PE-1# configure port 1/1/[3..4] ethernet mode access
*A:PE-1# configure port 1/1/[3..4] ethernet autonegotiate limited
*A:PE-1# configure port 1/1/[3..4] no shutdown
```

```
*A:PE-1# configure lag 1
        mode access
        port 1/1/3 1/1/4
        lacp active
        no shutdown
```

Step 3. MC-LAG configuration on PE-1 and PE-2

The redundant PEs must act as one virtual node toward the CE. They have to be able to communicate the same LACP parameters to the CE side.

The following parameters uniquely identify a LAG instance:

- lacp-key
- system-id
- system-priority

These three parameters must be configured with the same value on both redundant PEs.

Multi-chassis redundancy with a peering session (which operates by an IP connection using UDP destination port 1025) is configured toward the redundant PE system address and MC-LAG redundancy is enabled, as follows. The peering session can be configured with MD5 authentication.

```
*A:PE-1# configure
    redundancy
        multi-chassis
            peer 192.0.2.2 create
                authentication-key "441dO/0RgDhHgzYwpOCTK9zbKjv4GZ/z" hash2
                mc-lag
                    lag 1 lacp-key 1 system-id 00:00:00:00:00:01 system-priority 100
                    no shutdown
                exit
                no shutdown
            exit
        exit

*A:PE-2# configure
    redundancy
        multi-chassis
            peer 192.0.2.1 create
                authentication-key "441dO/0RgDg2CA0JlyzVNQBoRc327b1j" hash2
                mc-lag
                    lag 1 lacp-key 1 system-id 00:00:00:00:00:01 system-priority 100
                    no shutdown
                exit
                no shutdown
            exit
        exit
```

Step 4. MC-LAG verification.

Verify MC peers showing that the authentication and admin state are enabled.

```
*A:PE-1# show redundancy multi-chassis sync
```

```
===============================================================================
Multi-chassis Peer Table
===============================================================================
Peer
-------------------------------------------------------------------------------
Peer IP Address         : 192.0.2.2
Description             : (Not Specified)
Authentication          : Enabled
Source IP Address       : 192.0.2.1
Admin State             : Enabled
Warm standby            : No
Remote warm standby     : No
-------------------------------------------------------------------------------
Sync: Not-configured
-------------------------------------------------------------------------------
===============================================================================
===============================================================================
*A:PE-1#
```

Step 5. Verify MC-LAG peer status and LAG parameters.

```
*A:PE-1# show redundancy multi-chassis mc-lag peer 192.0.2.2
===============================================================================
Multi-Chassis MC-Lag Peer 192.0.2.2
===============================================================================
Last State chg  : 10/25/2016 07:40:53
Admin State     : Up                 Oper State           : Up
KeepAlive       : 10 deci-seconds    Hold On Ngbr Failure : 3
-------------------------------------------------------------------------------
Lag Id Lacp   Remote Source Oper   System Id          Sys   Last State Changed
       Key    Lag Id MacLSB MacLSB                    Prio
-------------------------------------------------------------------------------
1      1      1      Def    n/a    00:00:00:00:00:01  100   10/25/2016 07:40:54
-------------------------------------------------------------------------------
Number of LAGs : 1
===============================================================================
*A:PE-1#
```

There is a fixed keepalive timer of 1 second. The **hold-on-neighbor-failure multiplier** command indicates the interval that the standby node will wait for packets from the active node before assuming a redundant-neighbor failure. The **hold-on-neighbor-failure multiplier** command is configurable in the **config>redundancy>multi-chassis>peer>mc-lag** context. The standby node will also assume a redundant-neighbor failure when there is no route available to the redundant-neighbor.

```
*A:PE-1# configure
    redundancy
        multi-chassis
            peer 192.0.2.2
                mc-lag
                    hold-on-neighbor-failure 10
```

In this example, the *lag-id* is 1 on both redundant PEs. This is not mandatory. If the *lag-id* on PE-2 is, for example 2, the following should be configured on PE-1:

```
*A:PE-1# configure
    redundancy
        multi-chassis
            peer 192.0.2.2
                mc-lag
                    lag 1 remote-lag 2 lacp-key 1 system-id 00:00:00:00:00:01
                                                  system-priority 100
```

Step 6. Verify MC-LAG

```
*A:PE-1# show lag 1
===============================================================================
Lag Data
===============================================================================
Lag-id         Adm     Opr     Weighted Threshold Up-Count MC Act/Stdby
-------------------------------------------------------------------------------
1              up      up      No       0         2        active
===============================================================================
*A:PE-1#

*A:PE-2# show lag 1
===============================================================================
Lag Data
===============================================================================
Lag-id         Adm     Opr     Weighted Threshold Up-Count MC Act/Stdby
-------------------------------------------------------------------------------
1              up      down    No       0         0        standby
===============================================================================
*A:PE-2#
```

In this case, the LAG on PE-1 is active (operationally up) whereas the LAG on PE-2 is standby (operationally down).

The selection criteria by default is highest number of links and priority. In this example, the number of links and the priority of the links is the same on both redundant PEs. Whichever PE's LAG gets the operational status **up** first, will be the active.

LAG ports of one PE could be preferred over the other PE by configuring port priority. For example, the following command lowers the priority of the LAG ports on PE-1, thus giving this LAG higher preference. The default priority is 32768, but it is modified to a value of 10, as follows:

```
*A:PE-1# configure lag 1 port 1/1/3 1/1/4 priority 10
```

The selection criteria can be configured as highest-count, highest-weight or best-port (the default is highest count).

```
*A:PE-1# configure lag 1 selection-criteria
  - selection-criteria [best-port|highest-count|highest-weight] [slave-to-partner]
[subgroup-hold-time <hold-time>]
```

```
  - no selection-criteria

 <best-port|highest*> : keywords
 <slave-to-partner>   : keyword
 <hold-time>          : [0..2000] tenths of a second | infinite
```

If highest-weight is configured, the sum of the weights of the LAG members is considered. The weight of an individual LAG member is calculated as priority 65535 (the default is 32768).

Step 7. Verify detailed MC-LAG status on PE-1

```
*A:PE-1# show lag 1 detail
===============================================================================
LAG Details

===============================================================================
```

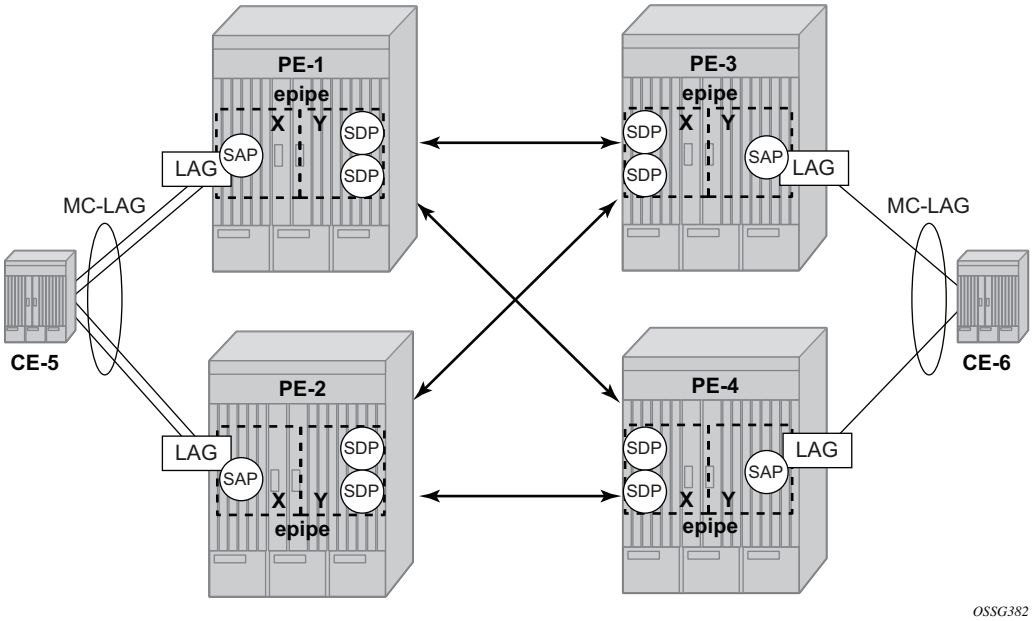
After changing the LAG port priorities from default (32768) to 10, the LAG on PE-1 is in up/up state and the ports are in up/active/up status. This show command also displays actor and partner bits set in the LACP messages.

Step 8. MC-LAG configuration on PE-3 and PE-4.



The MC-LAG configuration on PE-3 and PE-4 is similar to the configuration on PE-1 and PE-2. In this case, the priority of the LAG port on PE-4 is lowered to obtain the behavior in Figure 32 where the LAGs on PE-1 and PE-4 are active.

Step 9. Pseudowire configuration.

Configure an Epipe service on every PE and create endpoints **x** and **y** (the endpoint names can be any text string). Traffic can only be forwarded between two endpoints, for example, it is not possible for objects associated with the same endpoint to forward traffic to each other.

Associate the SAPs and spoke SDPs with the endpoints as shown in Figure 33.

Figure 33 **Association of SAPs/SDPs and Endpoints**

```
*A:PE-1# configure
    service
        epipe 1 customer 1 create
            endpoint "X" create
            exit
            endpoint "Y" create
            exit
            sap lag-1 endpoint "X" create
            exit
            spoke-sdp 13:1 endpoint "Y" create
            exit
            spoke-sdp 14:1 endpoint "Y" create
            exit
            no shutdown
        exit
```

Likewise, an Epipe service, endpoints, SAPs and spoke SDPs must be configured on the other PE routers.

Step 10. Pseudowire verification.

```

===============================================================================
*A:PE-4#
```

The Epipe service on PE-2 and PE-3 is down and up on PE-1 and PE-4. This reflects the standby behavior shown in Figure 32. However, after configuring ICB spoke SDPs (described later in this document), the Epipe will be in up/up status on all PE routers.

Step 11. Verify SDP status

Local pseudowire bits indicate the status of the pseudowire on the PE node. These pseudowire bits will be sent to the peer. Peer pseudowire bits indicate the status of the pseudowire on the peer, as sent by the peer. The following example is taken on PE-2:

```
*A:PE-2# show service id 1 sdp 23:1 detail

-------------------------------------------------------------------------------
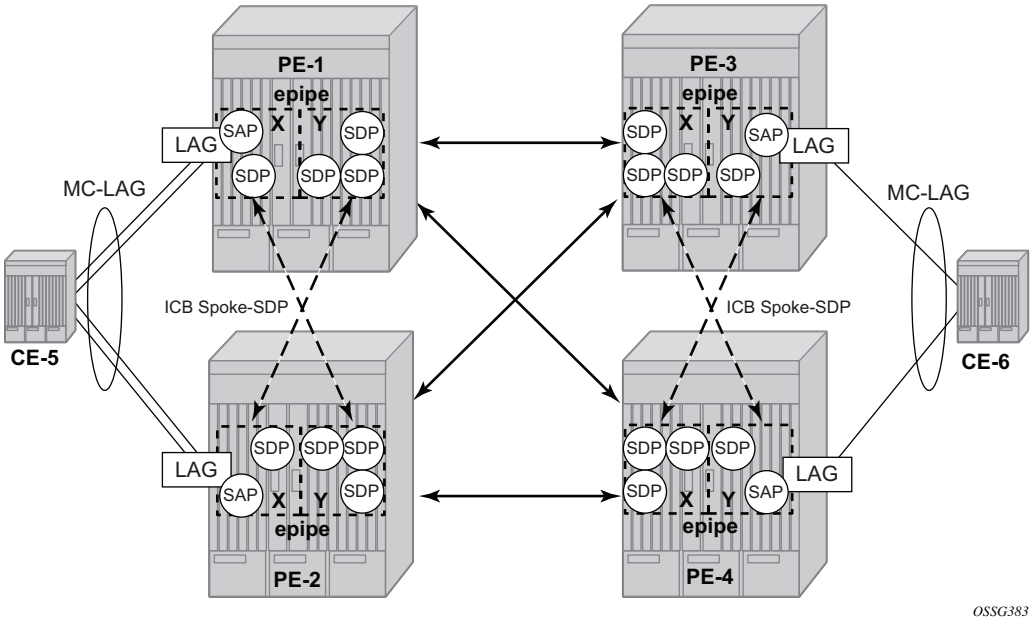
Number of SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
*A:PE-2#
```

In this example, the remote side of the SDP is sending lacIngressFault lacEgressFault pwFwdingStandby flags. This is because the Epipe service on PE-3 is down because the MC-LAG is in standby/down status.

Link and node protection can be tested. The access links are protected by the MC-LAG, the PE routers are protected by the combination of MC-LAG/ pseudowire redundancy. The SDPs can be protected by FRR in the case of RSVP-TE or LDP.

Revertive behavior is expected when different MC-LAG port priorities are configured or if the number of MC-LAG ports is different on the MC-LAG peers: convergence takes place when the active PE fails and convergence takes place again when that PE is online again.

In case of revertive behavior, MC-LAG convergence might take less time than the setup of the spoke SDPs, thus creating a temporary black-hole. To avoid this situation, it is best to configure **hold-time up** on the LAG ports. In that case, the ports are kept in a down state for a configured period of time after the node has rebooted. This is done to ensure that the SDPs are operationally up when the MC-LAG convergence takes place. The **hold-time up** is expressed in seconds.



```
*A:PE-1# configure port 1/1/3 ethernet hold-time up 50
*A:PE-1# configure port 1/1/4 ethernet hold-time up 50
```

Step 12. Inter-Chassis Backup (ICB) pseudowire configuration.

In this setup, the configuration of ICBs is optional. It can be used to speed up convergence by forwarding in-flight packets during MC-LAG transition. Figure 35 shows some setup examples where ICBs are required. ICBs cannot be configured at endpoints where the other object is a standard SAP, only MC-LAG SAPs and pseudowires are allowed with ICBs.

ICB SDPs and associated to endpoints as shown in Figure 34.

Figure 34 **ICB Spoke SDPs and Their Association with the Endpoints**

Two ICB spoke SDPs must be configured in the Epipe service on each PE router, one in each endpoint. Different SDP IDs can be used for the ICBs (as opposed to the regular pseudowires), but this is not necessary, because the far-end will be the same. The *vc-id* must be different however.

The ICB spoke SDPs must cross, one end should be associated with endpoint **x** and the other end (on the other PE) should be associated with endpoint **y**. After configuring the ICB spoke SDPs, the Epipe service will be up/up on all four PE routers.

Only one spoke SDP will be forwarding. If there is an ICB and a MC-LAG SAP in an endpoint, the ICB will only forward if the SAP goes down. If an ICB resides in an endpoint together with other spoke SDPs, the ICB will only forward if there is no other active spoke SDP.

The following output shows the additional Epipe service configuration on each PE:

```
*A:PE-1# configure
    service
        epipe 1
            spoke-sdp 12:1 endpoint "X" icb create
            exit
            spoke-sdp 12:2 endpoint "Y" icb create
            exit

*A:PE-2# configure
    service
```

```
        epipe 1
            spoke-sdp 21:1 endpoint "Y" icb create
            exit
            spoke-sdp 21:2 endpoint "X" icb create
            exit

*A:PE-3# configure service
        epipe 1
            spoke-sdp 34:1 endpoint "X" icb create
            exit
            spoke-sdp 34:2 endpoint "Y" icb create
            exit

*A:PE-4# configure service
        epipe 1
            spoke-sdp 43:1 endpoint "Y" icb create
            exit
            spoke-sdp 43:2 endpoint "X" icb create
            exit
```

Step 13. Verification of active objects for each endpoint.

The following command shows which objects are configured for each endpoint and which is the active object at this moment:

```
*A:PE-1# show service id 1 endpoint

===============================================================================

===============================================================================
===============================================================================
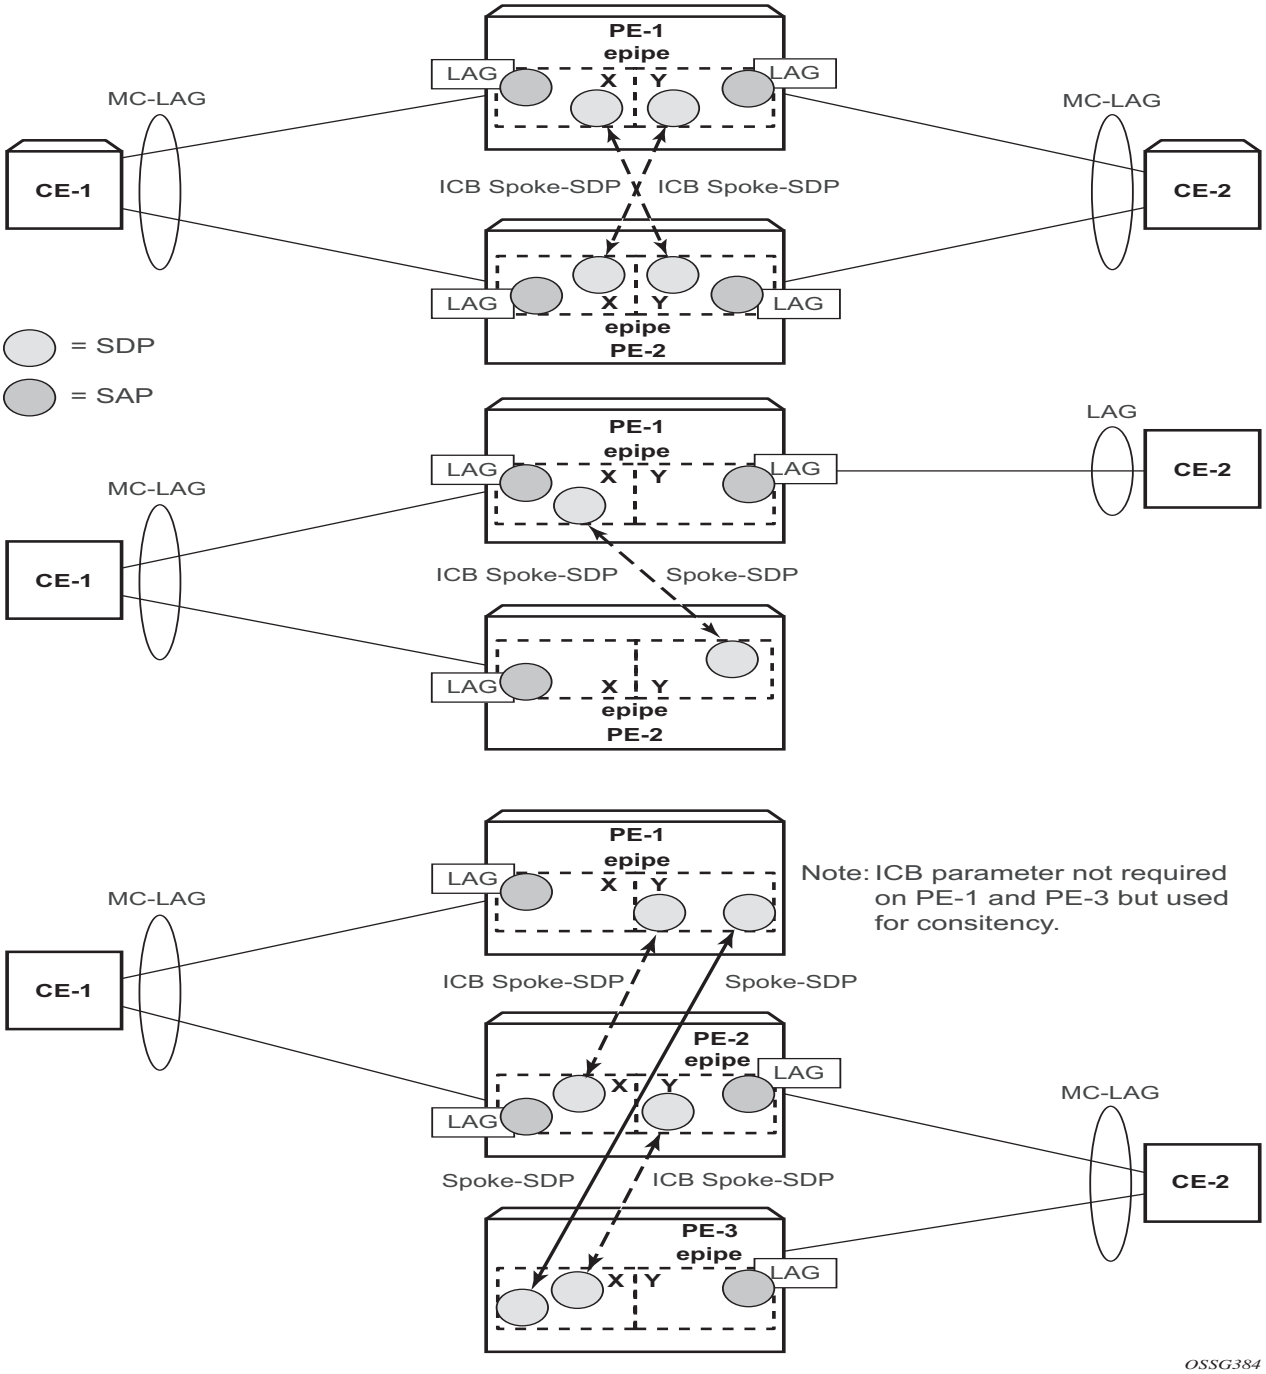
*A:PE-1#
```

On PE-1, the SAP and the spoke SDP 14:1 are active. The other objects do not forward traffic.

Step 14. Other types of setups.

Figure 35 and Figure 36 show other setups that combine MC-LAG and pseudowire redundancy.

Figure 35 **Additional Setup Example 1**



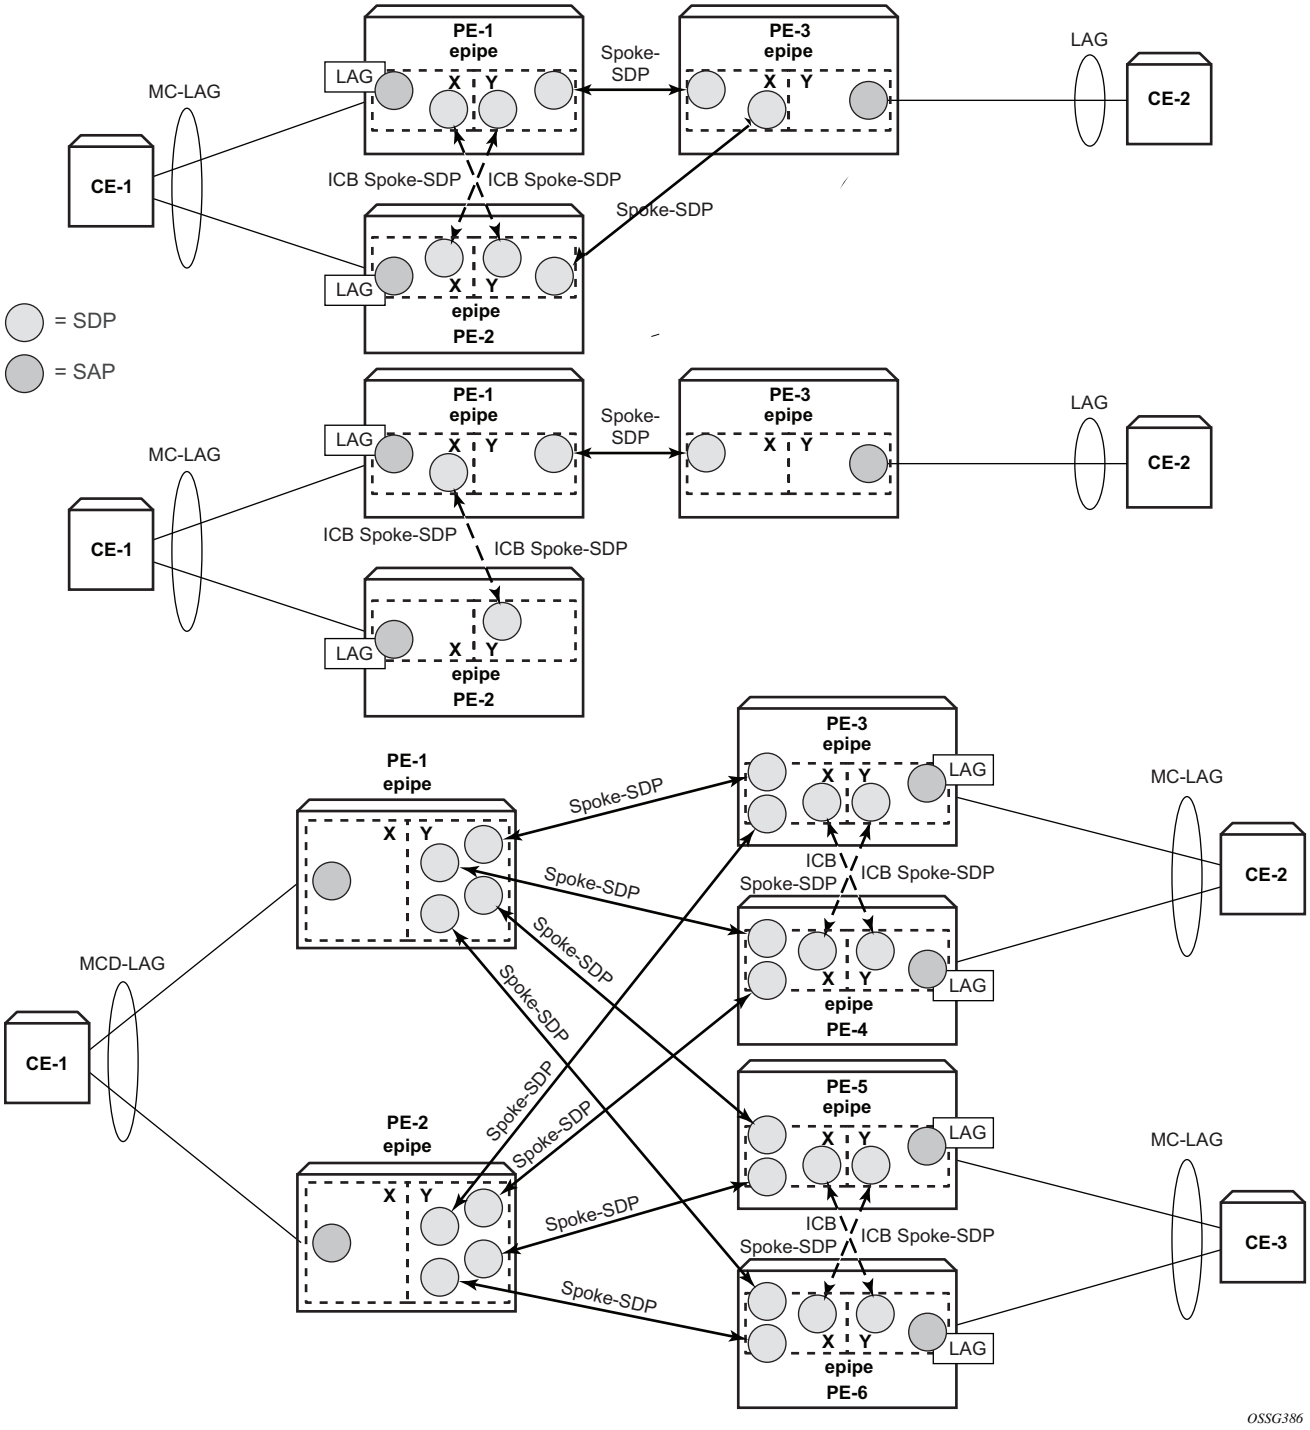


Figure 36 **Additional Setup Example 2**

MC-LAG in VPLS Services

MC-LAG can also be configured in VPLS services. When the MC-LAG converges, the PE that transitions to standby state for the MC-LAG will send out an LDP address withdrawal message to all peers configured in the VPLS service. Both types of SDPs (spoke and mesh) support this feature. The PE peers will then flush all the MAC addresses learned through the PE that sent the LDP MAC address withdrawal message.

Because a VPLS service is a multipoint service, pseudowire redundancy is not required. The MC-LAG redundancy configuration is identical.

Forced Switchover

MC-LAG convergence can be forced with **tools perform lag** command:

```
*A:PE-1# tools perform lag force
  - force all-mc {active|standby}
  - force lag-id <lag-id> [sub-group <sub-group-id>] {active|standby}
  - force peer-mc <ip-address> {active|standby}

 <lag-id>             : [1..800]
 <sub-group-id>       : [1..16]
 <all-mc>             : keyword
 <ip-address>         : ipv4-address   - a.b.c.d
                        ipv6-address   - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
 <active|standby>     : keywords

*A:PE-1# tools perform lag force lag-id 1 standby

*A:PE-1# show lag 1
===============================================================================
Lag Data
===============================================================================
Lag-id         Adm     Opr     Weighted Threshold Up-Count MC Act/Stdby
-------------------------------------------------------------------------------
1              up      down    No       0         0        standby
===============================================================================
*A:PE-1#
```

After the forced switchover, it is important to clear the forced switchover:

```
*A:PE-1# tools perform lag clear-force
  - clear-force all-mc
  - clear-force lag-id <lag-id> [sub-group <sub-group-id>]
  - clear-force peer-mc <ip-address>
```

```
 <lag-id>             : [1..800]
 <sub-group-id>       : [1..16]
 <all-mc>             : keyword
 <ip-address>         : ipv4-address   - a.b.c.d
                        ipv6-address   - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D

*A:PE-1# tools perform lag clear-force lag-id 1
```

Conclusion

MC-LAG is a Nokia added value redundancy feature that offers fast access link convergence in Epipe and VPLS services for CE devices that support standard LACP. PE node convergence for VPLS services is enhanced by using LDP address withdrawal messages to flush the FDB on the PE peers. PE node convergence for Epipes is guaranteed by using pseudowire redundancy.

Router Configuration

In This Section

This section provides configuration information for the following topics:

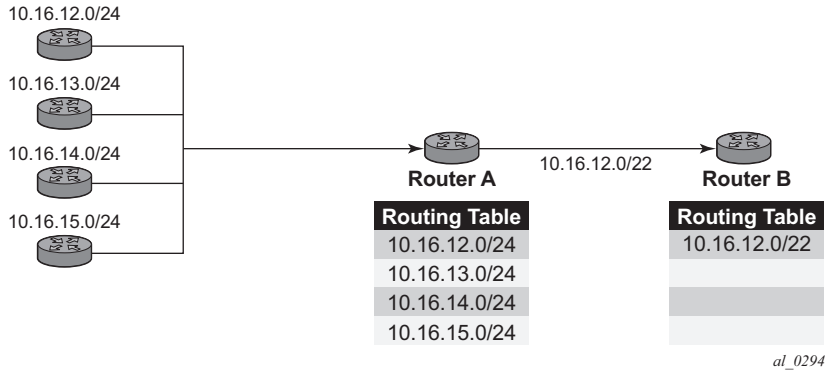
- Aggregate Route Indirect Next-Hop Option
- Bi-Directional Forwarding Detection
- LFA Policies Using OSPF as IGP

Aggregate Route Indirect Next-Hop Option

This chapter provides information about aggregate route indirect next-hop option configurations.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion



Applicability

This chapter was initially written for SR OS release 11.0.R1. The CLI in this edition corresponds to release 14.0.R2.

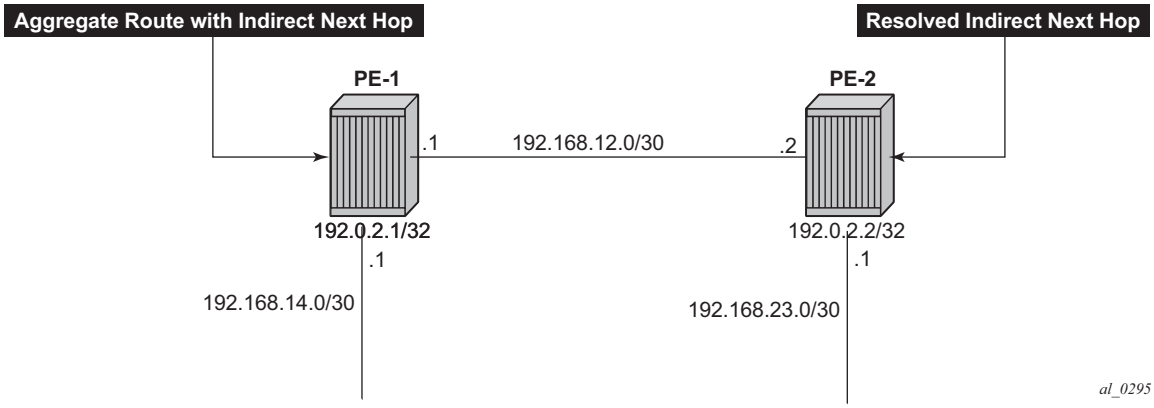
Overview

The 7x50s have for many releases supported the ability to configure IPv4 and IPv6 aggregate routes. A configured aggregate route that has the best preference for the prefix is added to the routing table (activated) when it has at least one contributing route and removed when there are no longer any more contributing routes. A contributing route is any route installed in the forwarding table that is a more-specific match of the aggregate. (10.16.12.0/24 is a contributing route to the aggregate route 10.16.12.0/22, but for this same aggregate 10.16.0.0/16 and 10.0.0.0/8 are not contributing routes).

Figure 37 **Aggregate Routes**

In Figure 37, Router A could choose to advertise all the four routes or one aggregate route. By aggregating the four routes, fewer updates are sent on the link between routers A and B, router B needs to maintain a smaller routing table resulting in better convergence and router B saves on computational resources by evaluating fewer entries in its routing table.

Release 11.0.R1 added the ability to configure an indirect hop for aggregate routes. The indirect next hop specifies where packets will be forwarded if they match the aggregate route, but not a more specific route in the IP forwarding table.



Different network operators have different requirements on how to forward a packet that matches an aggregate route but not any of the more-specific routes in the forwarding table that activated the aggregate. In general, there are three different options:

a. The packet can be forwarded according to the next-most specific route, ignoring the aggregate route. This can lead to routing loops in some topologies.
b. The packet can be discarded.
c. The packet can be forwarded toward an indirect next-hop address that is configured by the operator. The indirect next-hop could be the address of a threat management server that analyzes the packets it receives for security threats. This option requires the aggregate route to be installed in the forwarding table with a resolved next-hop interface determined from a route lookup of the indirect next-hop address.

Configuration

The example topology is shown in Figure 38.

Figure 38 **Example topology**

Initial Configuration

The nodes have the following basic configuration:

- Cards, MDAs
- Ports
- Router interfaces

The router interfaces on PE-1 are configured as follows:

```
*A:PE-1# configure router
      interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-4"
            address 192.168.14.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
```

The configuration on the other nodes is similar. The IP addresses are shown in Figure 38. In this example, static routes will be configured. There is no need for an IGP, but could be configured.

Aggregate Route with Indirect Next Hop Option

This feature adds a keyword **indirect** and an associated IP address parameter to the aggregate command in these configuration contexts:

- **config>router**
- **config>service>vprn**

The aggregate route configuration commands are as follows:

```
configure [router | vprn <vprn-id> ] aggregate
  - no aggregate <ip-prefix/ip-prefix-length>
  - aggregate <ip-prefix/ip-prefix-length> [summary-only] [as-set]
    [aggregator <as-number:ip-address>] [black-hole [generate-icmp]]
    [community <comm-id>][description <description>]
  - aggregate <ip-prefix/ip-prefix-length> [summary-only] [as-set]
    [aggregator <as-number:ip-address>] [community <comm-id>]
    [indirect <ip-address>][description <description>]

 <ip-prefix/ip-pref*> : ipv4-prefix    - a.b.c.d (host bits must be 0)
                        ipv4-prefix-le - [0..32]
                        ipv6-prefix    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
                        ipv6-prefix-le - [0..128]
 <summary-only>       : keyword
 <as-set>             : keyword
 <as-number:ip-addr*> : as-number      - [1..4294967295]
                        ip-address     - a.b.c.d
 <black-hole>         : keyword
 <comm-id>            : [72 chars max]
                        <2 byte-asnumber:comm-val>|<well-known-comm>
                        2 byte-asnumber - [0..65535]
                        comm-val        - [0..65535]
                        well-known-comm - no-export|no-export-subconfed|
                                          no-advertise
 <ip-address>         : [64 chars max]
 <generate-icmp>      : keyword
 <description-string> : [80 chars max]
```

Parameters:

- **indirect** — This indicates that the aggregate route has an indirect address. The indirect option is mutually exclusive with the black-hole option. To change the next-hop type of an aggregate route (for example from black-hole to indirect) the route must be deleted and then re-added with the new next-hop type (however other configuration attributes can generally be changed dynamically).

- <ip-address> — Installing an aggregate route with an indirect next-hop is supported for both IPv4 and IPv6 prefixes. However if the aggregate prefix is IPv6 the indirect next-hop must be an IPv6 address and if the aggregate prefix is IPv4 the indirect next-hop must be an IPv4 address.

An indirect next-hop address of an aggregate route may be resolved by any of the following route types:

- Direct/local route
- Static route with regular next-hop, black-hole next-hop or an indirect next-hop
- OSPFv2 or RIP IPv4 route (applicable only to IPv4 aggregate routes)
- LDP shortcut route (applicable only to IPv4 aggregate routes])
- OSPFv2 or IS-IS shortcut route (IPv4 route with an LDP/RSVP or RSVP tunnel next-hop) (applicable only to IPv4 aggregate routes)
- OSPFv3 or IS-IS route
- BGP route resolved by an IGP route
- BGP route resolved by a BGP route
- BGP labeled-IPv4 route resolved by an LDP or RSVP tunnel (applicable only to IPv4 aggregate routes
- 6PE route resolved by an LDP tunnel or static route with black-hole next-hop (applicable only to IPv6 aggregate routes)
- BGP-VPN route resolved by a BGP labeled-IPv4 route, LDP tunnel, or RSVP tunnel (applicable only to aggregate routes configured in a VPRN context)

If an indirect next-hop is not resolved, the aggregate route will show up as black-hole.

The actual configuration of the aggregate route 10.16.12.0/22 is as follows:

```
*A:PE-1# configure router aggregate 10.16.12.0/22 community 64496:64498 indirect
192.168.11.11
```

This creates an aggregate route, but there are no contributing routes that are more specific defined yet. Therefore the aggregate route remains inactive.

```
*A:PE-1# show router aggregate

-------------------------------------------------------------------------------
192.0.2.1/32                                    Local   Local     00h01m57s   0
       system                                                          0
192.168.12.0/30                                 Local   Local     00h01m52s   0
       int-PE-1-PE-2                                                   0
192.168.14.0/30                                 Local   Local     00h01m52s   0
       int-PE-1-PE-4                                                   0
-------------------------------------------------------------------------------
No. of Routes: 3
```

Configure Contributing Routes

The aggregate route remains inactive as long as there is no contributing route which is more specific than the aggregate route. The following contributing routes are statically configured on PE-1:

```
*A:PE-1# configure router
        static-route-entry 10.16.12.0/24
            next-hop 192.168.14.2
                no shutdown
            exit
        exit
        static-route-entry 10.16.13.0/24
            next-hop 192.168.14.2
                no shutdown
            exit
        exit
        static-route-entry 10.16.14.0/24
            next-hop 192.168.14.2
                no shutdown
            exit
        exit
        static-route-entry 10.16.15.0/24
            next-hop 192.168.14.2
                no shutdown
            exit
        exit
```

As a result, the aggregate route becomes active:

```
*A:PE-1# show router aggregate
===============================================================================
Legend: G - generate-icmp enabled
===============================================================================
Aggregates (Router: Base)
===============================================================================
Prefix                                        Aggr IP-Address   Aggr AS
   Summary                                       AS Set          State
     NextHop                                       Community     NextHopType
-------------------------------------------------------------------------------
10.16.12.0/22                                 0.0.0.0           0
   False                                         False           Active
    192.168.11.11                                 64496:64498       Indirect
-------------------------------------------------------------------------------
No. of Aggregates: 1
===============================================================================
*A:PE-1#
```

The active aggregate route is added to the route table, as well as the contributing routes:

```
*A:PE-1# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref

10.16.12.0/24                                 Remote  Static    00h00m00s  5
       192.168.14.2                                               1
10.16.13.0/24                                 Remote  Static    00h00m00s  5
       192.168.14.2                                               1
10.16.14.0/24                                 Remote  Static    00h00m00s  5
       192.168.14.2                                               1
10.16.15.0/24                                 Remote  Static    00h00m00s  5
       192.168.14.2                                               1
192.0.2.1/32                                  Local   Local     00h04m10s  0
       system                                                     0
192.168.12.0/30                               Local   Local     00h04m05s  0
       int-PE-1-PE-2                                              0
192.168.14.0/30                               Local   Local     00h04m05s  0
       int-PE-1-PE-4                                              0
-------------------------------------------------------------------------------
No. of Routes: 8
```

The aggregate route is black-holed since the next hop is not resolved. There is no route to 192.168.11.0/24.

Configure Route to Indirect Next Hop

A static route is configured on PE-1to the indirect next hop, as follows:

```
*A:PE-1# configure router
        static-route-entry 192.168.11.0/24
            next-hop 192.168.12.2
                no shutdown
            exit
        exit
```

In the route table, the aggregate route is no longer black-holed. The next hop for the indirect next hop is 192.168.12.2 (PE-2).

```
*A:PE-1# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref

-------------------------------------------------------------------------------
10.16.12.0/22                                   Remote  Aggr      00h02m05s  130
       192.168.12.2                                                    0
10.16.12.0/24                                   Remote  Static    00h02m05s  5
       192.168.14.2                                                    1
10.16.13.0/24                                   Remote  Static    00h02m05s  5
       192.168.14.2                                                    1
10.16.14.0/24                                   Remote  Static    00h02m05s  5
       192.168.14.2                                                    1
10.16.15.0/24                                   Remote  Static    00h02m05s  5
       192.168.14.2                                                    1
192.0.2.1/32                                    Local   Local     00h06m15s  0
       system                                                          0
192.168.11.0/24                                 Remote  Static    00h02m05s  5
       192.168.12.2                                                    1
192.168.12.0/30                                 Local   Local     00h06m10s  0
       int-PE-1-PE-2                                                   0
192.168.14.0/30                                 Local   Local     00h06m10s  0
       int-PE-1-PE-4                                                   0
-------------------------------------------------------------------------------
No. of Routes: 9
```

In this example, PE-2 is the resolved indirected next hop and it has a route for prefix 10.16.12.0/22:

```
*A:PE-2# configure router
        static-route-entry 10.16.12.0/22
            next-hop 192.168.23.2
                no shutdown
            exit
        exit
```

The route table on PE-2 looks as follows:

```
*A:PE-2# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
```

```
-------------------------------------------------------------------------------
10.16.12.0/22                                 Remote  Static    00h00m00s  5
       192.168.23.2                                                    1
192.0.2.2/32                                  Local   Local     00h13m44s  0
       system                                                          0
192.168.12.0/30                               Local   Local     00h13m44s  0
       int-PE-2-PE-1                                                   0

       int-PE-2-PE-3                                                   0
-------------------------------------------------------------------------------
No. of Routes: 4
```

Conclusion

Aggregate routes offer several advantages, the key being reduction in the routing table size and overcoming routing loops, among other things. Aggregate routes with indirect next hop option helps in faster network convergence by decreasing the number of route table changes. This example shows how to configure aggregate routes with indirect next hop option.

Bi-Directional Forwarding Detection

This chapter provides information about bi-directional forwarding (BFD) detection.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to the 7x50 series. BFD timing differences among platforms will be indicated. Note that the centralized cpm-np type is only supported by 7750/7450s equipped with SF/CPM 2 or higher.

This chapter was originally written for and tested on release 8.0.R4. The CLI now corresponds to release 13.0.R6.

Overview

Bi-Directional Forwarding Detection (BFD) is a light-weight protocol which provides rapid path failure detection between two systems. It has been published as a series of RFCs (RFC 5880, *Bidirectional Forwarding Detection (BFD)*, to RFC 5884, *Bidirectional Forwarding Detection (BFD) for MPLS Label Switched Paths (LSPs)*.

If a system running BFD stops receiving BFD messages on an interface, it will determine that there has been a failure in the path and notifies other protocols associated with the interface. BFD is useful in situations where two nodes are interconnected through either an optical Dense Wavelength Division Multiplexing (DWDM) or Ethernet network. In both cases, the physical network has numerous extra devices which are not part of the Layer 3 network and therefore, the Layer 3 nodes are incapable of detecting failures which occur in the physical network on spans to which the Layer 3 devices are not directly connected.

BFD protocol provides rapid link continuity checking between network devices, and the state of BFD can be propagated to IP routing protocols to drastically reduce convergence time in cases where a physical network error occurs in a transport network.

RFC 5880 defines two modes of operation for BFD:

- Asynchronous mode (supported) — Uses periodic BFD control messages to test the path between systems
- Demand mode (not supported)

In addition to the two operational modes, an echo function is defined (SR OS routers only supports response sending, this is looping back received BFD messages to the original sender).

BFD is running between two peers and supported for the following scenarios:

- BFD for ISIS
- BFD for OSPF
- BFD for PIM
- BFD for Static route
- BFD for RSVP

  BFD for I-LDP
- BFD for T-LDP

  BFD for MPLS-TP
- BFD for OSPF CE-PE adjacencies
- BFD for IPSec
- BFD for VRRP

  BFD for SRRP

The scenarios shown in Figure 39 are described in this chapter.

Figure 39 **BFD Multi-Scenarios**

Configuration

BFD packets are processed both locally (processed on the IOM CPU) and centrally (processed on the CPM).

Starting with release 8, the CPM is able to centrally generate the BFD packets at a sub second interval as low as 10 msec. However it should be noted that the BFD state machine is still implemented in software. It is the BFD packet generation that can be now selectively delegated to CPM hardware as needed. This is applicable when sub second operations or exceeding the IOM scaling limits is required.

Centralized sessions are processed:

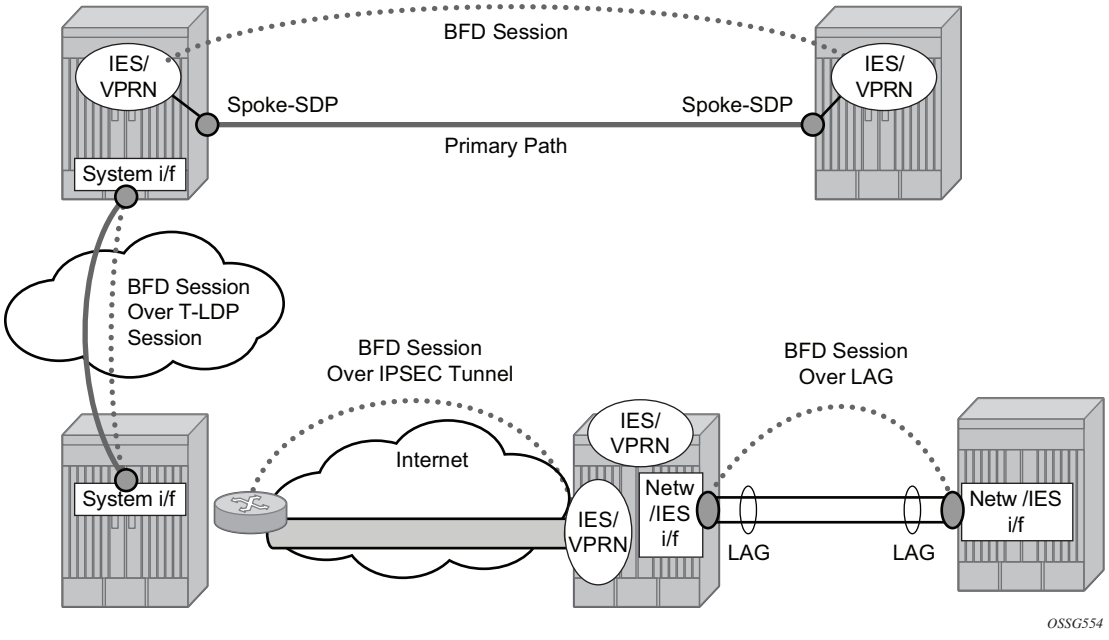
- in software by 7x50 SR-1 and ESS-1, and 7x50 equipped with SF/CPM 1.
- in hardware by 7x50 equipped with SF/CPM 2 or higher.

Minimum transmitting and receiving intervals are as follows:

- Centralized sessions:

- Minimum 300 ms in 7x50 SR-1 and ESS-1
- Minimum 100 ms in 7x50 equipped with SF/CPM 1 and in every 7x50 up to Release 7.0
- Minimum 10 ms in 7x50 equipped with SF/CPM 2 or higher

• Local sessions:



- Minimum 100 ms

The following applications require BFD to run centrally on the SF/CPM and a centralized session will be created independently of the type explicitly declared by the user:

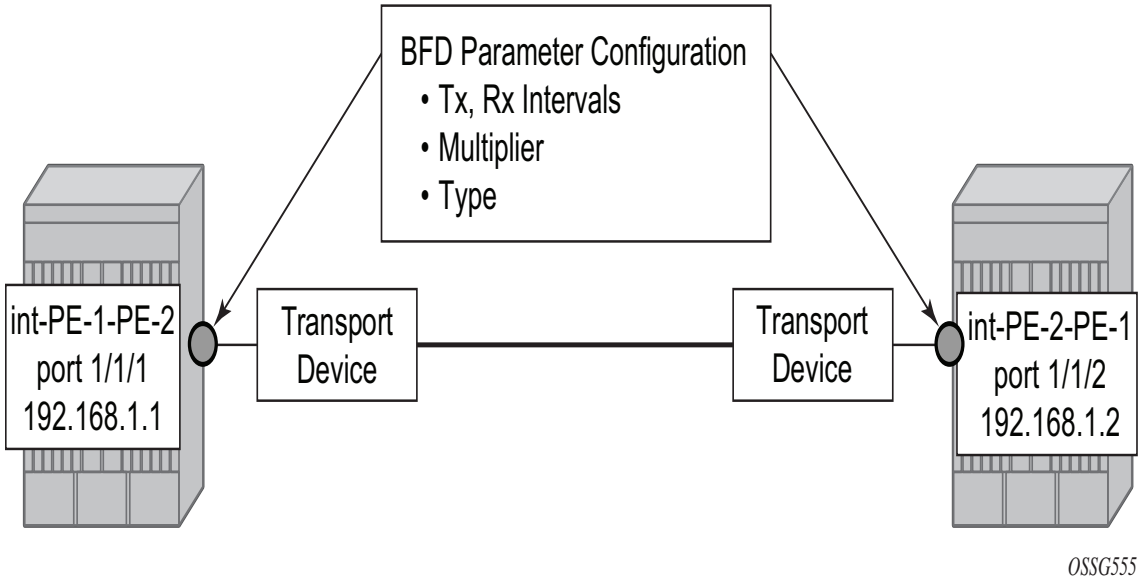
- BFD for IES/VPRN over Spoke SDP
- BFD for LAG and VSM Interfaces
- Protocol associations using loopback and system interfaces (e.g. BFD for T-LDP)
- BFD for IPSec sessions
- BFD sessions associated with multi-hop peering (BGP)

Figure 40 shows the most relevant scenarios where centralized BFDsessions are used.

Figure 40 **BFD Centralized Sessions**

On the other end, when the two peers are directly connected, the BFD session is local by default, but in a 7x50 equipped with SF/CPM 2 or higher, the user can choose what session type (local or centralized) to implement.

As general rule, the following steps are required to configure and enable a BFD session when peers are directly connected:



1. Configure BFD parameters on the peering interfaces.
2. Check that the Layer 3 protocol, that is to be bound to BFD, is up and running.
3. Enable BFD under the Layer 3 protocol interface.

Since most of the following procedures share the same first step, it is described only once in the next paragraph and then referred to in the following paragraphs.

BFD Base Parameter Configuration and Troubleshooting

The reference topology for the generic configuration of BFD over two local peers is shown in Figure 41.

Figure 41 **BFD Interface Configuration**

To configure BFD between two peers, the user should firstly enable base level BFD on interfaces between PE-1 and PE-2.

On PE1:

```
configure
    router
        interface "int-PE-1-PE-2"
            address 192.168.1.1/30
            port 1/1/1
            bfd 100 receive 100 multiplier 3
            no shutdown
        exit
    exit
exit
```

On PE2:

```
configure
    router
        interface "int-PE-2-PE-1"
            address 192.168.1.2/30
            port 1/1/2
            bfd 100 receive 100 multiplier 3
            no shutdown
        exit
    exit
exit
```

The following **show** commands are used to verify the BFD configuration on the router interfaces on PE1 and PE2.

On PE1:

```
*A:PE-1# show router bfd interface
===============================================================================
BFD Interface
===============================================================================
Interface name                      Tx Interval    Rx Interval    Multiplier
-------------------------------------------------------------------------------
int-PE-1-PE-2                       100            100            3
-------------------------------------------------------------------------------
No. of BFD Interfaces: 1
===============================================================================
*A:PE-1#
```

On PE2:

```
*A:PE-2# show router bfd interface
===============================================================================
BFD Interface
===============================================================================
Interface name                      Tx Interval    Rx Interval    Multiplier
-------------------------------------------------------------------------------
int-PE-2-PE-1                       100            100            3
-------------------------------------------------------------------------------
No. of BFD Interfaces: 1
===============================================================================
```

```
*A:PE-2#
```

Note that, BFD being an asynchronous protocol, it is possible to configure different tx and rx intervals on the two peers. This is because BFD rx/tx interval values are signaled in the BFD packets while establishing the BFD session.

In 7x50s equipped with SF/CPM 2 or higher, configurable BFD parameters are as follows:

```
bfd <transmit-interval> [receive <receive-interval>] [multiplier <multiplier>]
                                  [echo-receive <echo-interval>] [type <cpm-np>]
no bfd

 <transmit-interval>  : [10..100000] in milliseconds
 <receive-interval>   : [10..100000] in milliseconds
 <multiplier>         : [3..20]
 <echo-interval>      : [100..100000] in milliseconds
 <cpm-np>             : keyword - use CPM network processor
```

Note that it is possible to force the BFD session to be centrally managed by the CPM hardware.

As regards the echo function, it is possible to set the minimum echo receive interval, in milliseconds, for the BFD session. The default value is 100 ms.

If a BFD session is running, it is possible to modify its parameters, but to change its type, the session must be previously shut down manually. Note that this causes the upper layer protocols bound to it to be brought down as well.

```
configure
    router
        interface "int-PE-1-PE-2"
            bfd 100 receive 100 multiplier 3
        exit
    exit
exit
```

Forcing a centralized session in the case of directly connected peers can be useful when:

- Lower Tx and Rx intervals are desired (up to 10 ms instead of 100 ms supported by local sessions)
- There are no more available local (IOM) sessions
- Max limit of 500 packet per second per IOM has been reached

The instructions illustrated in following paragraphs are required to complete the configuration and enable BFD.

The BFD session should come up. To verify it, execute a **show router bfd session** command (bound to OSPF in the following example).

```
*A:PE-1# show router bfd session
===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
===============================================================================
If/Lsp Name/Svc-Id/RSVP-sess  State                 Tx Intvl  Rx Intvl  Multipl
  Rem Addr/Info/SdpId:VcId    Protocols             Tx Pkts   Rx Pkts   Type
   LAG port                      LAG ID
-------------------------------------------------------------------------------
int-PE-1-PE-2                 Up                    100       100       3
   192.168.1.2                ospf2                 114       96        iom
-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
*A:PE-1#
```

If the command gives a negative output, troubleshoot it by firstly checking that the protocol that is bound to it is up: for instance, check the OSPF neighbor adjacency as shown in following example.

```
*A:PE-1# show router ospf neighbor
===============================================================================
Rtr Base OSPFv2 Instance 0 Neighbors
===============================================================================
Interface-Name                   Rtr Id          State      Pri  RetxQ   TTL
   Area-Id
-------------------------------------------------------------------------------
int-PE-1-PE-2                    192.0.2.2       Full       1    0       34
   0.0.0.0
-------------------------------------------------------------------------------
No. of Neighbors: 1
===============================================================================
*A:PE-1#
```

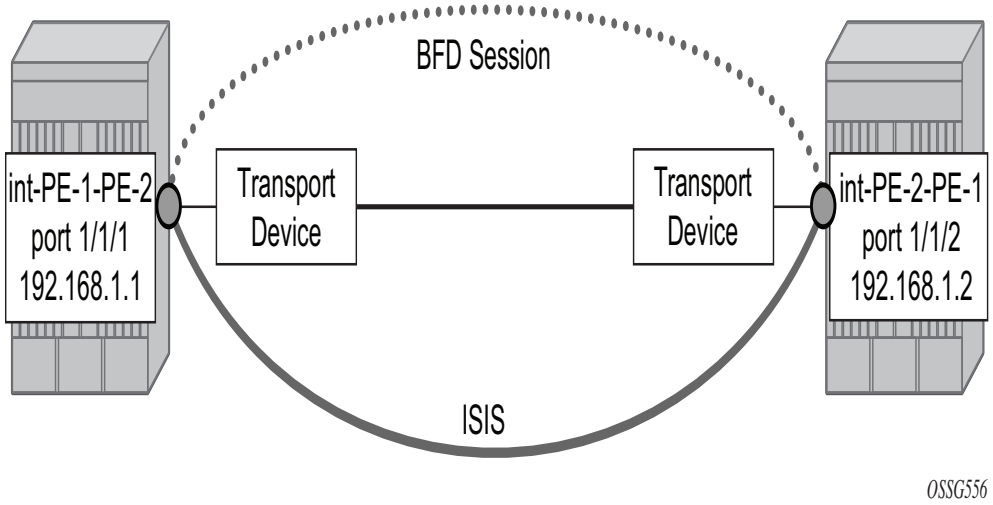
Then check whether a BFD resource limit has been reached (maximum number of local/centralized sessions or maximum number of packet per second per IOM).

If the overloaded limit is the maximum supported number of sessions, the cause is shown in log-id 99 (maxSessionsPerSlot).

In this case, when one of the running sessions is manually removed or goes down, then the additional configured session will come up. If the IOM limit is reached, it is possible to bring up the session by changing the session type to centralized.

To check if IOM CPU is able to start more local BFD sessions, execute a **show router bfd session summary** command.

If the **show router bfd session** command reports that the BFD session is down, then check the BFD peer's configuration and state.



The **show router bfd session src <*ip-address*> detail** command can help debugging the BFD session. The sent and received counters are not supported for cpm-np type sessions.

```
*A:PE-1# show router bfd session src 192.168.1.1 detail

BFD for IS-IS

The goal of this section is to configure BFD on a network interlink between two 7750 nodes that are IS-IS peers. The topology used is shown in Figure 42.

Figure 42 **BFD for ISIS**

For the base BFD configuration, please refer to BFD Base Parameter Configuration and Troubleshooting.

Apply BFD to the ISIS Interfaces.

On PE1:

```
configure
    router
        isis
            interface "int-PE-1-PE-2"
                bfd-enable ipv4
            exit
        exit
    exit
exit
```

On PE2:

```
configure
    router
        isis
            interface "int-PE-2-PE-1"
                bfd-enable ipv4
            exit
        exit
    exit
exit
```

Finally, verify that the BFD session is operational between PE1 and PE2.

On PE1:

```
*A:PE-1# show router bfd session

*A:PE-2#
```

BFD for OSPF

The goal of this section is to configure BFD on a network interlink between two 7750 nodes that are OSPF peers.

For this scenario, the topology is shown in Figure 43.

Figure 43 **BFD for OSPF**

For the base BFD configuration, refer to BFD Base Parameter Configuration and Troubleshooting.

Apply BFD on the OSPF Interfaces.

On PE1:

```
configure
    router
        ospf
            area 0
                interface "int-PE-1-PE-2"
                    bfd-enable
                exit
            exit
        exit
    exit
exit
```

On PE2:

```
configure
    router
        ospf
            area 0
                interface "int-PE-2-PE-1"
                    bfd-enable
                exit
            exit
        exit
    exit
exit
```

Verify that the BFD session is operational between PE1 and PE2.

On PE1:

```
*A:PE-1# show router bfd session
===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
```

```

No. of BFD sessions: 1
===============================================================================
*A:PE-2#
```

BFD for PIM

Since the implementation of PIM uses an Interior Gateway Protocol (IGP) in order to determine its Reverse Path Forwarding (RPF) tree, BFD configuration to support PIM will require BFD configuration of both the IGP protocol and the PIM protocol. Let's assume that IGP protocol is OSPF and that the starting configuration is as described in the previous section.

In this paragraph, configure and enable BFD for PIM on the same interfaces that were previously configured with BFD for OSPF, in reference to the topology shown in Figure 44.

Figure 44 **BFD for OSPF and PIM**

Since BFD has been already configured on the router interfaces, let's start by applying BFD on the PIM Interface.

On PE1:

```
configure
    router
        pim
            interface "int-PE-1-PE-2"
                bfd-enable ipv4
            exit
        exit
    exit
exit
```

On PE2:

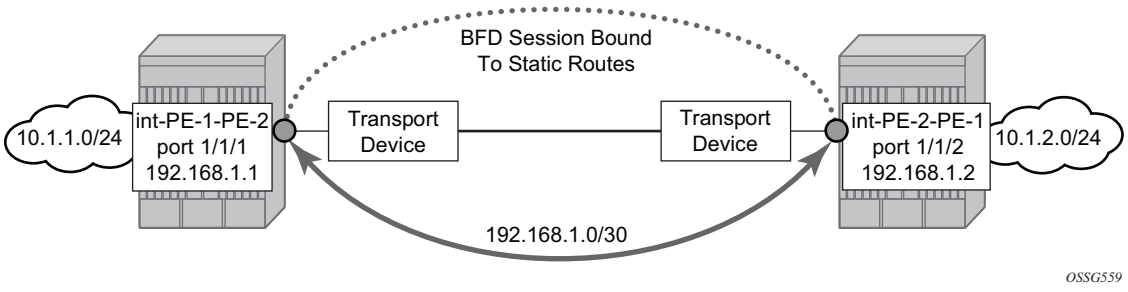
```
configure
    router
        pim
            interface "int-PE-2-PE-1"
                bfd-enable ipv4
            exit
        exit
    exit
exit
```

The final step is to verify whether the BFD Session is operational between PE1 and PE2 for PIM.

On PE1:

```
*A:PE-1# show router bfd session
===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
===============================================================================
If/Lsp Name/Svc-Id/RSVP-sess  State                 Tx Intvl  Rx Intvl  Multipl
  Rem Addr/Info/SdpId:VcId    Protocols             Tx Pkts   Rx Pkts   Type
   LAG port                      LAG ID
```

```
-------------------------------------------------------------------------------
int-PE-1-PE-2                 Up                    100       100       3
   192.168.1.2                ospf2 pim             614       615       iom
-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
*A:PE-1#
```



On PE2:

```

===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
===============================================================================
If/Lsp Name/Svc-Id/RSVP-sess  State                 Tx Intvl  Rx Intvl  Multipl
  Rem Addr/Info/SdpId:VcId    Protocols             Tx Pkts   Rx Pkts   Type
   LAG port                      LAG ID
-------------------------------------------------------------------------------
int-PE-2-PE-1                 Up                    100       100       3
   192.168.1.1                ospf2 pim             617       617       iom
-------------------------------------------------------------------------------
No. of BFD sessions: 1
===============================================================================
*A:PE-2#
```

BFD for Static Routes

The following procedures will go through the necessary steps to configure the base level BFD configuration and then apply BFD to the static routes between PE1 and PE2, using the topology shown in Figure 45.

Figure 45 **BFD for Static Routes**

First, create the static routes for the remote networks both in PE-1 and PE-2.

On PE1:

```
configure
```

```
    router
        static-route 10.1.2.0/24 next-hop 192.168.1.2
    exit
exit
```

On PE2:

```
configure
    router
        static-route 10.1.1.0/24 next-hop 192.168.1.1
    exit
exit
```

Next, verify that static routes are populated in the routing table.

On PE1:

```
*A:PE-1# show router route-table protocol static
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.1.2.0/24                                   Remote  Static    00h00m15s  5
       192.168.1.2                                                1
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-1#
```

On PE2:

```
*A:PE-2# show router route-table protocol static
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
10.1.1.0/24                                   Remote  Static    00h00m14s  5
       192.168.1.1                                                1
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-2#
```

The next step is to configure the base level BFD on PE1 and PE2.

Refer to paragraph BFD Base Parameter Configuration and Troubleshooting.

Then apply BFD to the static routing entries using the BFD interfaces as next-hop.

On PE1:

```
configure
    router
        static-route 10.1.2.0/24 next-hop 192.168.1.2 bfd-enable
    exit
exit
```

On PE2:

```
configure
    router
        static-route 10.1.1.0/24 next-hop 192.168.1.1 bfd-enable
    exit
exit
```

Note that BFD cannot be enabled if the next hop is indirect or the **blackhole** keyword is specified.

Finally, show the BFD session status.

On PE1:

```
*A:PE-1# show router bfd session

```

BFD for IES

The goal of this section is to configure BFD for one IES service over a spoke SDP.

The IES service is configured in both 7750 nodes, PE1 and PE2, and their interfaces are connected by spoke SDP's. The topology is shown in Figure 46.

Figure 46 **BFD for IES over Spoke SDP**

Note that in this scenario BFD is run between the IES interfaces independent of the SDP/LSP paths.

The first step is to configure the IES service on both nodes.

On PE-1:

```
configure
    service
        ies 2 customer 1 create
            interface int-IES-PE-1-PE-2 create
                address 192.168.3.1/30
                spoke-sdp 1020:1 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

On PE-2:

```
configure
    service
        ies 2 customer 1 create
            interface int-IES-PE-2-PE-1 create
                address 192.168.3.2/30
                spoke-sdp 2010:1 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

The next step is to add the IES interfaces to the OSPF area domain.

On PE-1:

```
configure
    router
        ospf
            area 0
                interface "int-IES-PE-1-PE-2"
                exit
            exit
        exit
    exit
exit
```

On PE-2:

```
configure
    router
        ospf
            area 0
                interface "int-IES-PE-2-PE-1"
                exit
            exit
        exit
    exit
exit
```

Then verify that OSPF and the services are up using show commands on both routers.

On PE-1:

```
*A:PE-1# show service id 2 base
===============================================================================

   0.0.0.0
-------------------------------------------------------------------------------
No. of Neighbors: 2
===============================================================================
*A:PE-2#
```

Then configure BFD on the IES interfaces.

On PE-1:

```
configure
    service
        ies 2
            interface "int-IES-PE-1-PE-2"
                bfd 100 receive 100 multiplier 3
            exit
        exit
    exit
exit
```

On PE-2:

```
configure
    service
        ies 2
            interface "int-IES-PE-2-PE-1"
                bfd 100 receive 100 multiplier 3
            exit
        exit
    exit
exit
```

Finally, enable BFD on the interfaces under OSPF area 0.

On PE-1:

```
*A:PE-1# configure router ospf area 0.0.0.0 interface int-IES-PE-1-PE-2 bfd-enable
```

On PE-2:

```
*A:PE-2# configure router ospf area 0.0.0.0 interface int-IES-PE-2-PE-1 bfd-enable
```

Note that in case of BFD over spoke SDP, a centralized BFD session is created even if a physical link exists between the two nodes. In fact, the next output shows that BFD session type is cpm-np. This is because the spoke SDP is terminated at the CPM. This is also true for BFD running over LAG bundles.

The cpm-np type only exists in 7x50 SR/ESS systems equipped with SF/CPM 2 or higher. When other network elements run centralized BFD sessions like this one, the BFD type is shown as **central**.

```

===============================================================================
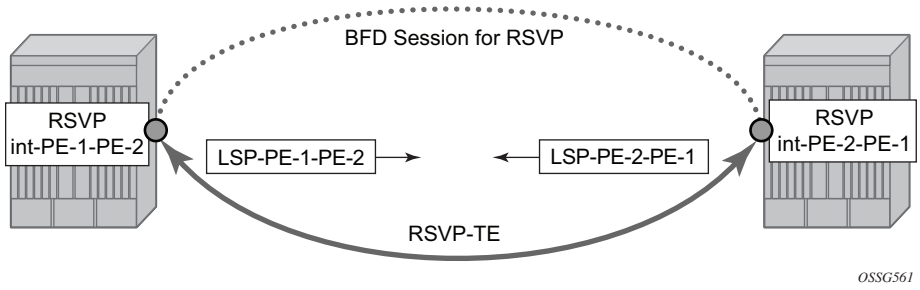
*A:PE-2#
```



Note that in the case of centralized BFD sessions, transmitted and received packet counters are not shown.

BFD for RSVP

The goal of this section is to configure BFD between two RSVP interfaces configured in two 7750 nodes.

For this scenario, the topology is shown in Figure 47.

Figure 47 **BFD for RSVP**

To enable the BFD session between the two RSVP peers, the user should follow these steps:

First, configure BFD on interfaces between PE-1 and PE-2 as described in BFD Base Parameter Configuration and Troubleshooting.

Next, configure MPLS, creating the path, the LSP and the interfaces within MPLS (and RSVP).

On PE-1:

```
configure
    router
        mpls
            interface "system"
                no shutdown
            exit
            interface "int-PE-1-PE-2"
                no shutdown
            exit
        exit
        rsvp
            interface "system"
                no shutdown
            exit
            interface "int-PE-1-PE-2"
                no shutdown
            exit
            no shutdown
        exit
        mpls
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                cspf
                primary "dyn"
                exit
                no shutdown
            exit
            no shutdown
        exit
```

```
    exit
exit
```

On PE-2:

```
configure
    router
        mpls
            interface "system"
                no shutdown
            exit
            interface "int-PE-2-PE-1"
                no shutdown
            exit
        exit
        rsvp
            interface "system"
                no shutdown
            exit
            interface "int-PE-2-PE-1"
                no shutdown
            exit
            no shutdown
        exit
        mpls
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-2-PE-1"
                to 192.0.2.1
                cspf
                primary "dyn"
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

Next, verify that the RSVP session is up.

```
*A:PE-1# show router rsvp session
===============================================================================
RSVP Sessions
===============================================================================
From            To              Tunnel LSP   Name                          State
                                ID     ID
-------------------------------------------------------------------------------
192.0.2.1       192.0.2.2       1      50176 LSP-PE-1-PE-2::dyn            Up
192.0.2.2       192.0.2.1       1      45568 LSP-PE-2-PE-1::dyn            Up
-------------------------------------------------------------------------------
Sessions : 2
===============================================================================
*A:PE-1#
```

Then, apply BFD on the RSVP Interfaces.

On PE1:

```
configure
    router
        rsvp
            interface "int-PE-1-PE-2"
                bfd-enable
            exit
        exit
    exit
exit
```

On PE2:

```
configure
    router
        rsvp
            interface "int-PE-2-PE-1"
                bfd-enable
            exit
        exit
    exit
exit
```

Finally, verify that the BFD session is operational between PE1 and PE2.

On PE1:

```
*A:PE-1# show router bfd session

===============================================================================
*A:PE-2#
```

BFD for T-LDP

BFD tracking of an LDP session associated with a T-LDP adjacency allows for faster detection of the liveliness of the session by registering the transport address of an LDP session with a BFD session.

The goal of this paragraph is to configure BFD for T-LDP, referring to the scheme shown in Figure 48.

Figure 48 **BFD for T-LDP**

The parameters used for the BFD session are configured under the loopback interface corresponding to the LSR-ID (by default, the LSR-ID matches the system interface address).

```
configure
    router
        interface "system"
            bfd 300 receive 3000 multiplier 3
        exit
    exit
exit
```

By enabling BFD for a selected targeted session, the state of that session is tied to the state of the underlying BFD session between the two nodes.

When using BFD over other links with the ability to reroute, such as spoke-SDPs, the interval and multiplier values configuring BFD should be set to allow sufficient time for the underlying network to re-converge before the associated BFD session expires. A general rule of thumb should be that the expiration time (interval * multiplier) is three times the convergence time for the IGP network between the two endpoints of the BFD session.

Before enabling BFD, ensure that the T-LDP session is up.

On PE-1:

```
*A:PE-1# show router ldp session
===============================================================================

-------------------------------------------------------------------------------
No Matching Entries Found
===============================================================================
*A:PE-2#
```

Then, enable the BFD session.

```
configure
    router
        ldp
            targeted-session
                peer 192.0.2.2
                    bfd-enable
                exit
            exit
        exit
    exit
exit
```

Note that the loopback interface can be used to source BFD sessions to many peers in the network.

Finally, check that the BFD session is up.

On PE-1:

```
*A:PE-1# show router bfd session
===============================================================================
Legend:  wp = Working path   pp = Protecting path

```

When the T-LDP session comes up, a centralized BFD session is always created (cpm-np) even if the local interface has a direct link to the peer.

BFD for OSPF PE-CE Adjacencies

This feature extends BFD support to OSPF within a VPRN context when OSPF is used as the PE-CE protocol. In this section, the topology used is shown in Figure 49.

Figure 49 **BFD for OSPF PE-CE I/F**

First, configure the VPRN service interface int-PE-1-CE-1 on PE-1 with BFD parameters.

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 1:1
            vrf-target target:1:1
            interface "int-PE-1-CE-1" create
                address 172.16.0.1/24
                bfd 100 receive 100 multiplier 3
                sap 1/1/2:1 create
                exit
            exit
            ospf
                area 0.0.0.0
                    interface "int-PE-1-CE-1"
                        no shutdown
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
    exit
exit
```

Next, configure the router interface on CE-1 and add it to the OSPF area 0 domain.

```
configure
    router
        interface "int-CE-1-PE-1"
            address 172.16.0.2/24
            port 1/1/1:1
            bfd 100 receive 100 multiplier 3
            no shutdown
        exit
        ospf
            area 0
                interface int-CE-1-PE-1
                exit
            exit
        exit
    exit
exit
```

Then, ensure that OSPF adjacency is up.

On PE-1:

```
*A:PE-1# show router 1 ospf neighbor
===============================================================================
Rtr vprn1 OSPFv2 Instance 0 Neighbors
===============================================================================
Interface-Name                   Rtr Id          State      Pri  RetxQ   TTL
   Area-Id
-------------------------------------------------------------------------------
int-PE-1-CE-1                    192.0.2.5       Full       1    0       37
   0.0.0.0
-------------------------------------------------------------------------------
No. of Neighbors: 1
===============================================================================
*A:PE-1#
```

On CE-1:

```
*A:CE-1# show router ospf neighbor
===============================================================================
Rtr Base OSPFv2 Instance 0 Neighbors
===============================================================================
Interface-Name                   Rtr Id          State      Pri  RetxQ   TTL
   Area-Id
-------------------------------------------------------------------------------
int-CE-1-PE-1                    192.0.2.1       Full       1    0       36
   0.0.0.0
-------------------------------------------------------------------------------
No. of Neighbors: 1
===============================================================================
*A:CE-1#
```

Then, enable BFD on the PE-1-CE-1 interface on PE-1.

```
configure service vprn 1 ospf area 0 interface int-PE-1-CE-1 bfd-enable
```

Enable BFD on the CE-1-PE-1 interface on CE-1.

```
configure router ospf area 0 interface int-CE-1-PE-1 bfd-enable
```

Finally, check that the BFD sessions are up in both PE-1 and CE-1.

```
*A:PE-1# show router 1 bfd session

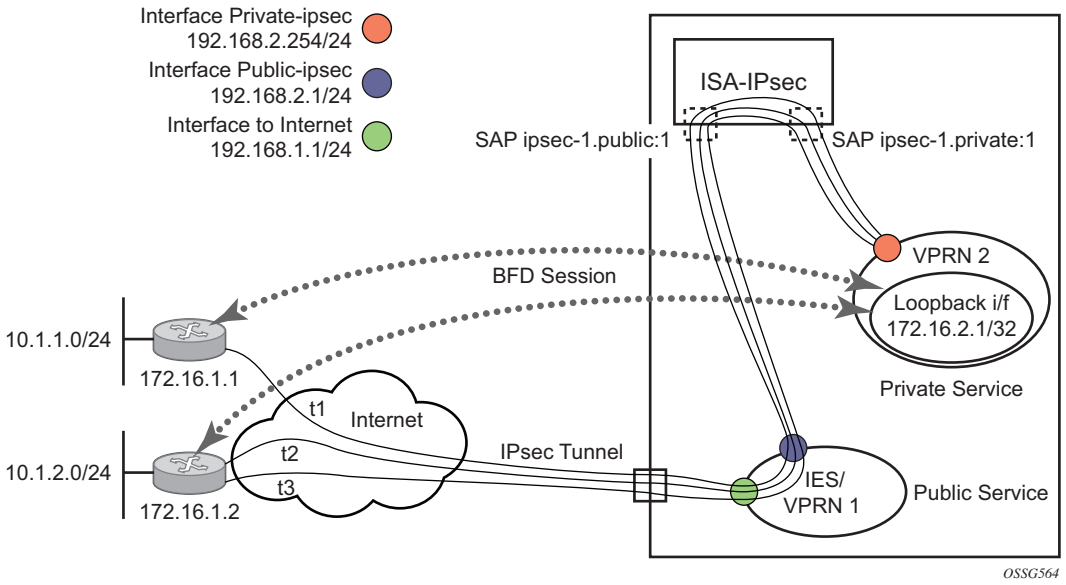
```



BFD within IPSec Tunnels

The ability to assign a BFD session to a given static LAN-to-LAN IPSec tunnel that provides heart-beat mechanism for fast failure detection has been introduced in Release.8.0.

IPSec needs a Multi-service Integrated Service Adapter (MS-ISA) installed, so this scenario is only applicable to 7750 SR-7/12 equipped with IOM-2 or 3.

The topology used is shown in Figure 50.

Figure 50 **BFD Sessions within IPSec Tunnels**

The first step is to configure MS-ISA card as **type isa-tunnel**.

```
configure
    card 1
        card-type iom3-xp
        mda 1
            mda-type m4-10gb-xp-xfp
        exit
        mda 2
            mda-type isa-tunnel
        exit
        no shutdown
    exit
exit
```

Next, instantiate the tunnels t1, t2 and t3 from the private service (in this example, VPRN 2) to the peers passing through the public service (in this example VPRN 1, but it could be instead an IES).

Since the configuration of IPSec tunnels is out of the scope of this section, only relevant command lines are reported to configure the interfaces shown in Figure 50.

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 1:1
            interface "toInternet" create
                address 192.168.1.1/24
                sap 1/1/2 create
                exit
            exit
```

```
            interface "public-ipsec" create
                address 192.168.2.1/24
                sap tunnel-1.public:1 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

```
configure
    service
        vprn 2 customer 1 create
            ipsec
                security-policy 1 create
                    entry 10 create
                        local-ip 192.168.3.1/32
                        remote-ip any
                    exit
                exit
            exit
            route-distinguisher 1:2
            interface "private-ipsec" tunnel create
                sap tunnel-1.private:1 create
                    ipsec-tunnel "t1" create
                        security-policy 1
                        local-gateway-address 192.168.2.254 peer 172.16.1.1
                                                            delivery-service 1
                        dynamic-keying
                            pre-shared-key "vpn1secret"
                        exit
                    exit
                    ipsec-tunnel "t2" create
                        security-policy 1
                        local-gateway-address 192.168.2.254 peer 172.16.1.2
                                                            delivery-service 1
                        dynamic-keying
                            pre-shared-key "vpn1secret"
                        exit
                    exit
                    ipsec-tunnel "t3" create
                        security-policy 1
                        local-gateway-address 192.168.2.254 peer 172.16.1.2
                                                            delivery-service 1
                        dynamic-keying
                            pre-shared-key "vpn1secret"
                        exit
                    exit
                exit
            exit
            interface "loop" create
                address 172.16.2.1/32
                loopback
            exit
            static-route 10.1.1.0/24 ipsec-tunnel "t1"
```

```
            static-route 10.1.2.0/24 ipsec-tunnel "t2" metric 1
            static-route 10.1.2.0/24 ipsec-tunnel "t3" metric 5
            no shutdown
        exit
    exit
exit
```

Then configure the BFD parameters within loopback interface loop (refer to BFD Base Parameter Configuration and Troubleshooting).

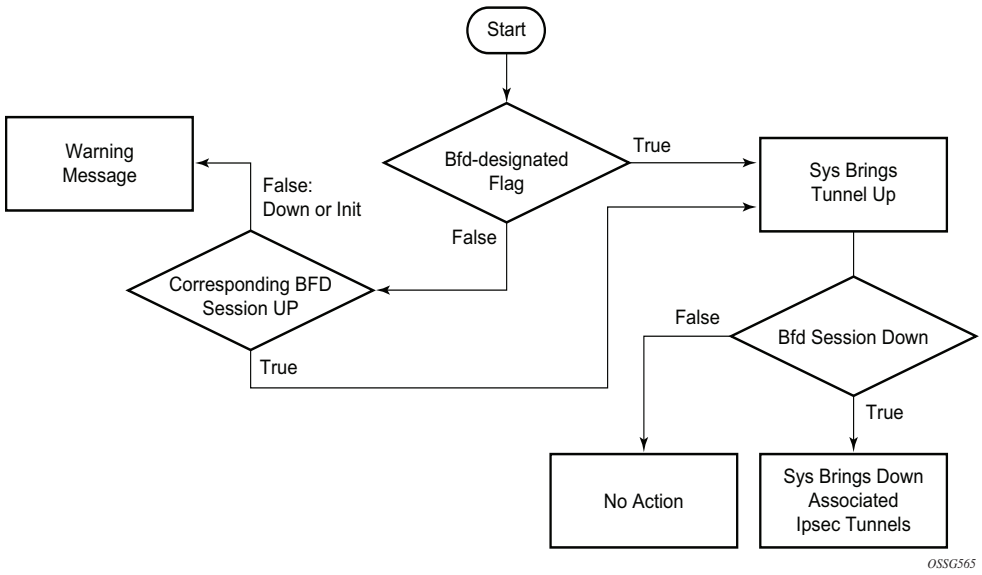
```
configure
    service
        vprn 2
            interface "loop"
                bfd 100 receive 100 multiplier 3
            exit
        exit
    exit
exit
```

And finally enable BFD within the tunnels.

```
configure
    service
        vprn 2
            interface "private-ipsec" tunnel create
                sap tunnel-1.private:1 create
                    ipsec-tunnel "t1" create
                        bfd-enable service 2 interface "loop" dst-ip 172.16.1.1
                    exit
                    ipsec-tunnel "t2" create
                        bfd-designate
                        bfd-enable service 2 interface "loop" dst-ip 172.16.1.2
                    exit
                    ipsec-tunnel "t3" create
                        bfd-enable service 2 interface "loop" dst-ip 172.16.1.2
                    exit
                exit
            exit
        exit
    exit
exit
```

The BFD-enable parameters are as follows:

- **service** <*service-id*> — Specifies the service-id where the BFD session resides.
- **interface** <*interface-name*> — Specifies the name of the interface used by the BFD session.
- **dst-ip** <*ip-address*> — Specifies the destination address to be used for the BFD session.



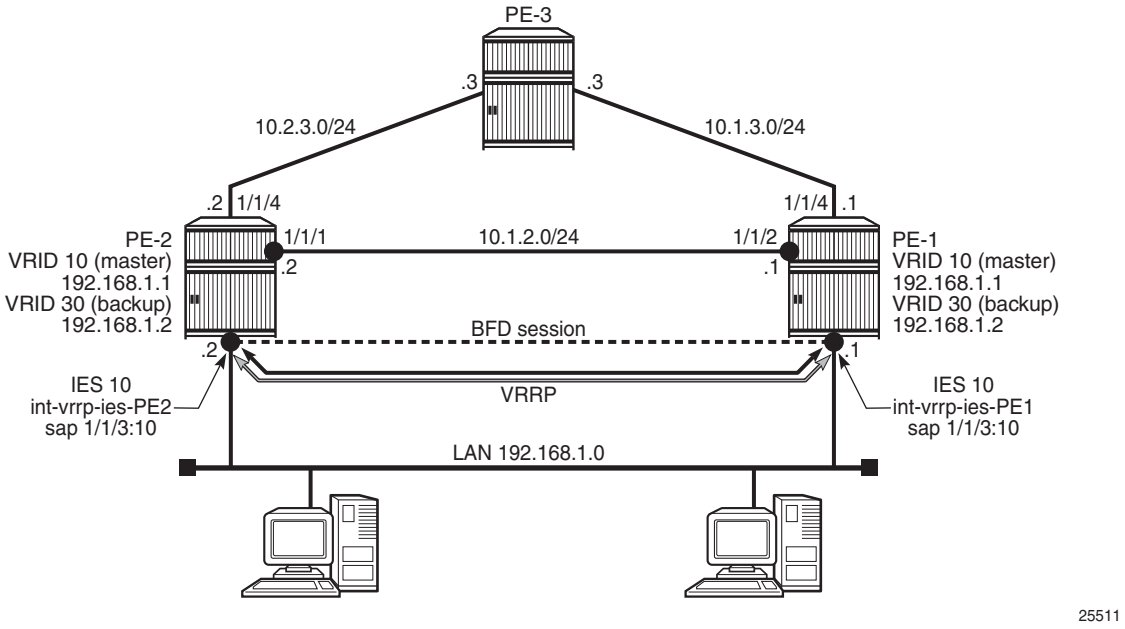
The following statements are to be taken into consideration to correctly configure BFD in this environment:

- BFD over IPSec sessions are centralized, managed by the hardware on the CPM.
- Only BFD over static lan-to-lan tunnel is supported in Release 8.0 (not dynamic).
- Only one BFD session is allowed between a given source/destination address pair.
- Each tunnel can be associated to only one BFD session but multiple tunnels can be associated to the same BFD session.
- In case multiple tunnels share the same BFD session, one IPSec tunnel carries BFD traffic: the BFD-DESIGNATED tunnel.

Referring to Figure 50 and to the above configuration, the tunnels t2 and t3 share the same BFD-session. Tunnel t2 is the bfd-designated tunnel, the BFD session runs within it and the other tunnel t3 shares its BFD session. If the BFD session goes down, the system will bring down both the designated tunnel t2 and the associated tunnel t3.

The state machine in Figure 51 shows the decision process in case of shared BFD sessions.

Figure 51 **Logic for Shared BFD Sessions**



BFD for VRRP

This feature assigns a BFD session to provide a heart-beat mechanism for the given VRRP instance. It should be noted that there can be only one BFD session assigned to any given VRRP instance, but there can be multiple VRRP sessions using the same BFD session.

In this section, the topology is shown in Figure 52.

Figure 52 **BFD for VRRP**

First, create the LAN subnet. Two PE routers are connected by IES or VPRN services (in following examples IES 10 is created in both routers).

On PE-1:

```
configure
    service
        ies 10 customer 1 create
            interface "int-vrrp-ies-PE-1" create
                address 192.168.1.1/24
                sap 1/1/3:10 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

On PE-2:

```
configure
    service
        ies 10 customer 1 create
            interface "int-vrrp-ies-PE-2" create
                address 192.168.1.2/24
                sap 1/1/3:10 create
                exit
            exit
            no shutdown
        exit
    exit
exit
```

Verify that the IES services are operational (**show service service-using**) and verify that you can ping the remote interface IP address.

Next, configure the VRRP parameters for both PE-1 and PE-2, enable VRRP on the IES interface that connects to the 192.168.1.0/24 subnet.

In this section, the configurations are shown for the VRRP owner mode for master but any other scenario for VRRP can be configured (non owner mode for master).

In the following examples two VRRP instances are created on the 192.168.1.0/24 subnet:

```
     VRID = 10  Master (owner)  = PE-1
                Backup          = PE-2
                VRRP IP =  192.168.1.1
     VRID = 30  Master (owner)  = PE-2
                Backup          = PE-1
                VRRP IP =  192.168.1.2
```

Host 1 is configured with default gateway = 192.168.1.1, and host 2 is configured with default gateway = 192.168.1.2.

On PE-1:

```
configure service ies 10 customer 1 create
            interface "int-vrrp-ies-PE-1" create
                vrrp 10 owner
                    backup 192.168.1.1
                exit
                vrrp 30
                    backup 192.168.1.2
                    ping-reply
                    telnet-reply
                    ssh-reply
                exit
            exit
```

```
            no shutdown
        exit
    exit
exit
```

On PE-2:

```
configure service ies 10 customer 1 create
            interface "int-vrrp-ies-PE-2" create
                vrrp 10
                    backup 192.168.1.1
                    ping-reply
                    telnet-reply
                    ssh-reply
                exit
                vrrp 30 owner
                    backup 192.168.1.2
                exit
            exit
            no shutdown
        exit
    exit
exit
```

To bind the VRRP instances with a BFD session, add the following command under any VRRP instance: **bfd-enable** *service-id* **interface** *interface-name* **dst-ip** *ip-address*.

Note that the IES service-id must be declared where the interface is configured.

On PE-1:

```
configure service ies 10 customer 1 create
            interface "int-vrrp-ies-PE-1" create
                vrrp 10 owner
                    bfd-enable 10 interface "int-vrrp-ies-PE-1" dst-ip 192.168.1.2
                exit
                vrrp 30
                    bfd-enable 10 interface "int-vrrp-ies-PE-1" dst-ip 192.168.1.2
                exit
            exit
            no shutdown
        exit
    exit
exit
```

On PE-2:

```
configure service ies 10 customer 1 create
            interface "int-vrrp-ies-PE-2" create
                vrrp 10
                    bfd-enable 10 interface "int-vrrp-ies-PE-2" dst-ip 192.168.1.1
                exit
                vrrp 30 owner
                    bfd-enable 10 interface "int-vrrp-ies-PE-2" dst-ip 192.168.1.1
```

```
            exit
          exit
          no shutdown
        exit
    exit
exit
```

The parameters used for the BFD are set by the BFD command under the IP interface.

Note that unlike the previous scenarios, the user can enter the commands above, enabling the BFD session, even if the specified interface (vrrp_ies_PE1) has not been configured with BFD parameters.

If it has not been configured yet, the BFD session will be initiated only after the following configuration.

On PE-1:

```
configure service ies 10 interface "int-vrrp-ies-PE-1" bfd 1000
                                          receive 1000 multiplier 10
```

On PE-2:

```
configure service ies 10 interface "int-vrrp-ies-PE-2" bfd 1000
                                          receive 1000 multiplier 10
```

Finally, verify that the BFD session is up (for instance on PE-1):

```
*A:PE-1# show router bfd session src 192.168.1.1 detail

===============================================================================
*A:PE-1#
```

Finally, for troubleshooting: it could be that the BFD session between the two IP interfaces is up but (in one or both peers) the command **show router vrrp instance interface** *interface-name* gives the following output regarding BFD for one or more VRID's.

```
*A:PE-1# show router vrrp instance interface "int-vrrp-ies-PE-1"
---snipped ---
-------------------------------------------------------------------------------
BFD Interface
-------------------------------------------------------------------------------
Service ID          : None
Interface Name      : int-vrrp-ies-PE-1
Src IP              :
Dst IP              : 192.168.1.2
Session Oper State  : notConfigured

---snipped ---
*A:PE-1#
```

To fix this, check that BFD has been correctly configured for the VRRP istances.

For instance, in the following example, the cause of the misconfiguration is that the IES service-id is not declared in the bfd-enable command:

```
configure service ies 10
            interface int-vrrp-ies-PE-1
                vrrp 10
                    bfd-enable 10 interface int-vrrp-ies-PE-1 dst-ip 192.168.1.2
                exit
            exit
        exit
    exit
exit
```

Conclusion

BFD is a light-weight protocol which provides rapid path failure detection between two systems and it is useful in situations where the physical network has numerous intervening devices which are not part of the Layer 3 network.

BFD is linked to a protocol state. For BFD session to be established, the prerequisite condition is that the protocol to which the BFD is linked must be operationally active. Once the BFD session is established, the state of the protocol to which BFD is tied to is then determined based on the BFD session's state. This means that if the BFD session goes down, the corresponding protocol will be brought down.

In this section several scenarios where BFD could be implemented have been described, including the configuration, show output and troubleshooting hints.

LFA Policies Using OSPF as IGP

This chapter provides information about LFA policies using OSPF as IGP.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS release 12.0.R4, but the CLI in this edition corresponds to release 14.0.R2.

Overview

Loop Free Alternate (LFA) is a local control plane feature. When multiple LFAs exist, RFC 5286, *Basic Specification for IP Fast Reroute: Loop-Free Alternates*, chooses the LFA providing the best coverage of the failure cases. In general, this means that node LFA has preference above link LFA. In some deployments, however, this can lead to suboptimal LFA. For example, an aggregation router (typically using lower bandwidth links) protecting a core node/link (typically using high bandwidth links) is potentially undesirable.

For this reason, the operator wants to have more control in the LFA next-hop selection algorithm. This is achieved by the introduction of LFA Shortest Path First (SPF) policies.

LFA policies can work in combination with IP fast reroute (FRR) and/or LDP FRR.

Implementation

The SROS LFA policy implementation is built around the concept of route-next-hop (NH) templates which are applied to IP interfaces. A route-next-hop template specifies criteria which influence the selection of an LFA backup NH for either:

- a set of prefixes in a prefix-list or
- a set of prefixes which resolve to a specific primary NH

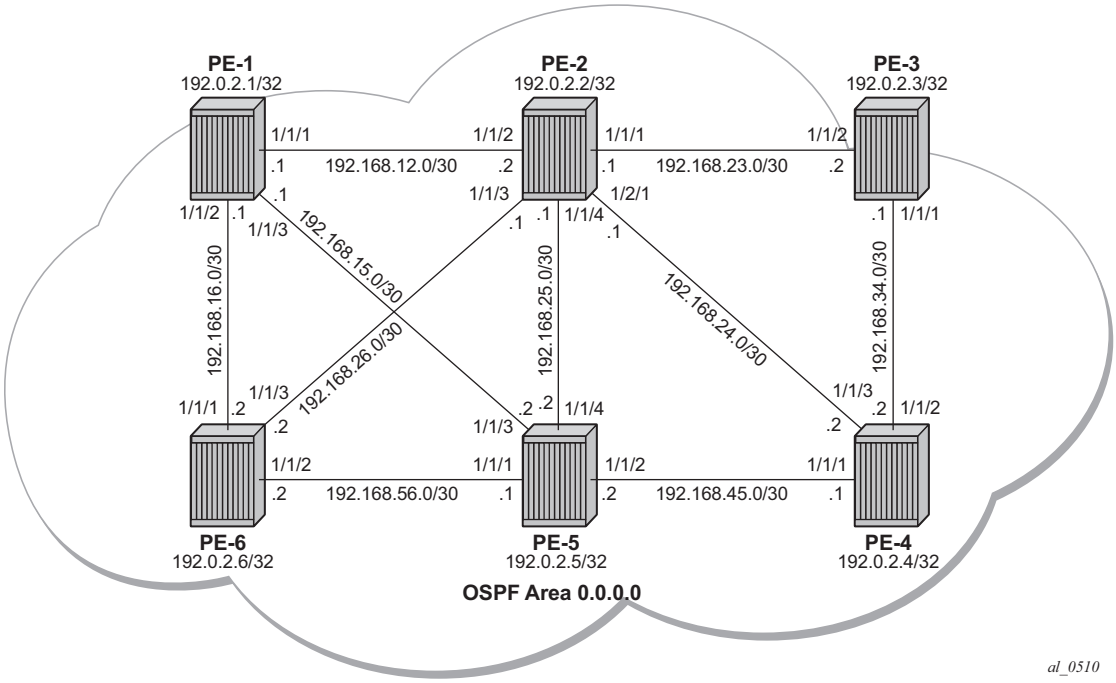
See http://tools.ietf.org/html/draft-litkowski-rtgwg-lfa-manageability for further information. Two powerful methods which can be used as criteria inside a route-next-hop template are IP admin groups and IP shared risk link groups (SRLGs). IP SRLG and IP admin group criteria are applied before running the LFA NH algorithm. IP admin groups and IP SRLGs work in a similar way as the well-known MPLS admin groups and MPLS SRLGs.

For example, when one or more IP admin groups/SRLGs are applied to an IP interface, the same MPLS admin group/SRLG rules apply:

- IP interfaces which do not include one or more of the admin groups defined in the **include** statements are pruned before computing the LFA next-hop.
- IP interfaces which belong to admin groups which have been explicitly excluded using the **exclude** statement are pruned before computing the LFA next-hop.
- IP interfaces which belong to the SRLGs used by the primary NH of a prefix are pruned before computing the LFA next-hop.

For more information about MPLS admin groups, see chapter RSVP Point-to-Point LSPs; for SRLGs, see chapter Shared Risk Link Groups for RSVP-Based LSP.

For compatibility reasons with the existing MPLS, admin groups and SRLGs, a single set of admin groups and SRLGs are defined within the **configure router if-attribute** context .



Once one or more admin groups or SRLGs have been defined, theyare applied to an MPLS interface and/or an IP interface.

In the SR OS implementation, IP admin groups and SRLGs are locally significant, meaning they are not advertised by the IGP.

The well-known MPLS admin groups and SRLGs are advertised in TE link TLVs and sub-TLVs when the traffic-engineering option is enabled in the IGP protocol.

Other selection criteria which can be configured inside a route-next-hop template are protection type preference and NH type preference. More details on these parameters are provided later in this chapter.

Figure 53 **Example Topology**

Configuration

Step 1. Configuring an IP/MPLS network with LDP FRR enabled on PE-7.

Since the focus is not on how to set up an IP/MPLS network, only summary bullets are provided.

- The system and IP interface addresses are configured according to Figure 53.
- OSPF area 0 is selected as the interior gateway protocol (IGP) to distribute routing information between all PEs. All OSPF interfaces are set up as **type point-to-point** to avoid running the designated router/ backup designated router (DR/BDR) election process. All links have the default metric, which is 10 in this example, except for interface “int-PE-2-PE-5” on PE-2, which is configured with a metric of 20.
- Enable link LDP on all interfaces. This establishes a full mesh of LDP LSPs between all PE system interfaces. As an example, the tunnel-table on PE-2 looks as follows:

```
*A:PE-2# show router tunnel-table

===============================================================================
IPv4 Tunnel Table (Router: Base)
```

```
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.1/32      ldp       MPLS  65537     9        192.168.12.1   10
192.0.2.3/32      ldp       MPLS  65538     9        192.168.23.2   10
192.0.2.4/32      ldp       MPLS  65539     9        192.168.24.2   10
192.0.2.5/32      ldp       MPLS  65540     9        192.168.12.1   20
192.0.2.6/32      ldp       MPLS  65541     9        192.168.26.2   10
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-2#
```

The LDP LSP metric follows the IGP cost.

– Enable LDP FRR on PE-2. This is a two-fold configuration command: first the IGP needs to be triggered to do LFA NH computation, and secondly, FRR needs to be enabled within the LDP context. This is configured as follows:

```
*A:PE-2# configure router ospf loopfree-alternate
*A:PE-2# show router ospf status | match LFA
LFA                          : Enabled
Remote-LFA                   : Disabled
```

Remote LFA can be enabled for segment routing, but this is beyond the scope of this chapter.

```
*A:PE-2# configure router ldp fast-reroute
*A:PE-2# show router ldp status | match FRR
FRR                : Enabled             Mcast Upstream FRR   : Disabled
```

Multicast upstream FRR is for multicast LDP and is beyond the scope of this chapter.

After issuing these two CLI commands, the software pre-computes both a primary and a backup Next-hop Label Forwarding Entry (NHLFE) for each LDP FEC in the network and downloads them into the IOM/IMM. The primary NHLFE corresponds to the label of the FEC received from the primary NH as per standard LDP resolution of the FEC prefix in the Routing Table Manager (RTM). The backup NHLFE corresponds to the label received for the same FEC from an LFA NH. The **show router route-table alternative** command adds an LFA flag to the associated alternative NH for a specific destination prefix. Other useful IGP related show commands are **show router ospf lfa-coverage** and **show router ospf routes alternative detail**.

```
*A:PE-2# show router route-table alternative

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref

No. of IPv4 Prefix Active Bindings: 21
===============================================================================
*A:PE-2#
```

Finally, a synchronization timer is enabled between the IGP and LDP protocol when LDP FRR is enabled. From the moment that the interface for the previous primary NH is restored, the IGP may re-converge back to that interface before LDP has completed the FEC exchange with its neighbor over that interface. This may cause LDP to de-program the LFA NH from the FEC and blackhole the traffic. In this example a timer of 10 seconds is used. This is configured as follows:

```
*A:PE-x# configure router interface <itf-name> ldp-sync-timer 10
```

When this timer is set, on restoring a failed interface, the IGP advertises this link into the network with an infinite metric for the duration of this timer. When the failed link is restored, the **ldp-sync-timer** is started, and LDP adjacencies are brought up over the restored link and a label exchange is completed between the peers. After the **ldp-sync-timer expires**, the normal metric is advertised into the network again.

At this point, everything is in place to start creating LFA policies to influence the calculated LFA NHs.

Step 2. Create a route-next-hop policy template.

This is a mandatory step in the context of LFA policies. The route-next-hop template name is 32 characters at maximum. Creating a route-next-hop policy is done in the following way:

```
*A:PE-x# configure router route-next-hop-policy template <template name>
```

Commands within a **route-next-hop** policy template follow the **begin-abort-commit** model. After a **commit**, the IGP re-evaluates the template and schedules a new LFA SPF to re-compute the LFA NH for the prefixes associated with this template.

Step 3. Configure admin group constraints in route-next-hop policy.

This is an optional step in the context of LFA policies. Firstly, configure a group-name and a group-value for each admin group locally on the router. This is configured as follows:

```
*A:PE-x# configure router if-attribute admin-group <group-name> value <group-value>
```

Second, configure the admin group membership of the IP interface(s) (network, IES or VPRN). Up to five admin groups can be applied to an IP interface in one command but the command can be applied multiple times. The configured IP admin group membership applies to all levels/areas the interface is participating in, as follows:

```
*A:PE-x# configure router interface <itf-name> if-attribute admin-group <group-name>
[ <group-name> ... (upto 5 max)]
*A:PE-x# configure service vprn <svc-id> interface <itf-name> if-attribute admin-group
<group-name> [ <group-name> ... (upto 5 max)]
*A:PE-x# configure service ies <svc-id> interface <itf-name> if-attribute admin-group
<group-name> [ <group-name> ... (upto 5 max)]
```

Third, add the IP admin group constraints to the route-next-hop policy template one by one. The **include-group** statement instructs the LFA SPF selection algorithm to select a subset of LFA NHs among the links which belong to one or more of the specified admin groups. A link which does not belong to at least one of the admin groups is excluded. The **pref** option is used to provide a relative preference for the admin group selection. A lower preference value means that LFA SPF will first attempt to select an LFA backup NH which is a member of the corresponding admin group. If none is found, then the admin group with the next higher preference value is evaluated. If no preference is configured, then it is the least preferred (default preference value is 255).

When evaluating multiple **include-group** statements having the same preference, any link which belongs to one or more of the included admin groups can be selected as an LFA next-hop. There is no relative preference based on how many of those included admin groups the link is a member.

The **exclude-group** command simply prunes all links belonging to the specified admin group before making the LFA backup NH selection for a prefix. If the same group name is part of both **include** and **exclude** statements, the exclude statement will takes precedence. In other words, the **exclude** statement can be viewed as having an implicit preference value of 0.

This is configured as follows:

```
*A:PE-x# configure router route-next-hop-policy template <template-name> exclude-
group <group-name>
*A:PE-x# configure router route-next-hop-policy template <template-name> include-
group <group-name> [pref <preference>]
```

Step 4. Configure SRLG constraints in route-next-hop policy.

This is an optional step in the context of LFA policies. Firstly, configure a group-name and group-value, of each SRLG group locally on the router. This is configured as follows:

```
*A:PE-x# configure router if-attribute srlg-group <group-name> value <group-value>
[penalty-weight <penalty-weight>]
```

Second, configure the SRLG group membership of the IP interfaces (network, IES or VPRN). Up to five SRLG groups can be applied to an IP interface in one command but the command can be applied multiple times. The configured IP SRLG group membership is applied in all levels/areas the interface is participating in. This is configured as follows:

```
*A:PE-x# configure router interface <itf-name> if-attribute srlg-group <group-name> [
<group-name> ... (upto 5 max)]
*A:PE-x# configure service vprn <svc-id> interface <itf-name> if-attribute srlg-group
<group-name> [ <group-name> ... (upto 5 max)]
*A:PE-x# configure service ies <svc-id> interface <itf-name> if-attribute srlg-group
<group-name> [ <group-name> ... (upto 5 max)]
```

Third, add IP SRLG group constraints to the route-next-hop policy template. When this command is applied to a prefix, the LFA SPF attempts to select an LFA NH which uses an outgoing interface that does not participate in any of the SRLGs of the outgoing interface used by the primary NH. This is configured as follows:

```
*A:PE-x# configure router route-next-hop-policy template <template-name> srlg-enable
```

Step 5. Configure the protection type in route-next-hop policy.

This is an optional step in the context of LFA policies. With the use of LFA policies, the user can also select if link protection or node protection is preferred for IP prefixes and LDP FEC prefixes protected by a backup LFA NH. By default, node protection is chosen. The implementation falls back to link protection if no LFA NH is found for node protection. This is configured as follows:

```
*A:PE-x# configure router route-next-hop-policy template <template-name> protection-
type {link|node}
```

Step 6. Configure the NH preference type in route-next-hop policy.

This is an optional step in the context of LFA policies. With the use of LFA policies, the user can also select if tunnel backup NH or IP backup NH is preferred for IP prefixes and LDP FEC prefixes protected by a backup LFA NH. By default, IP backup NH is chosen. The implementation falls back to the other type (tunnel) if no LFA NH of the preferred type is found. This is configured as follows:

```
*A:PE-x# configure router route-next-hop-policy template <template-name> nh-type
{ip|tunnel}
```

Step 7. Apply the route-next-hop policy template to an IP interface.

When the route-next-hop policy is applied to an IP interface, all prefixes using this interface as primary NH take the selection criteria specified in Step 3, Step 4, Step 5 and Step 6 into account. This is configured as follows:

```
*A:PE-x# configure router ospf area interface lfa-policy-map route-nh-template
<template-name>
*A:PE-x# configure router ospf3 area interface lfa-policy-map route-nh-template
<template-name>
*A:PE-x# configure service vprn ospf area interface lfa-policy-map route-nh-template
<template-name>
*A:PE-x# configure service vprn ospf3 area interface lfa-policy-map route-nh-template
<template-name>
```

LFA Policy Examples

All of the examples focus on providing another LFA NH for LDP FEC prefix 192.0.2.1/32 and 192.0.2.6/32 (the system IP addresses of PE-1 and PE-6), with PE-2 being the Point of Local Repair (PLR).

See Example Topology for the example topology.

The default LFA NH (without policy) for LDP FEC prefix192.0.2.1/32 is as follows:

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.1/32

192.168.12.1                              1/1/2

-------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 4
===============================================================================
*A:PE-2#
```

This default LFA NH can be changed by adding specific selection criteria inside a route-next-hop policy template.

Example 1: LFA Policy with Admin Group Constraint

The objective is to force the LFA NH for both LDP FEC prefixes to use the path between PE-2 and PE-5.

Define admin group ‘red’ with value ‘1’ and apply it to the IP interfaces PE-2 to PE-1 and PE-2 to PE-6.

```
*A:PE-2# configure router if-attribute admin-group "red" value 1
*A:PE-2# configure router interface "int-PE-2-PE-1" if-attribute admin-group "red"
*A:PE-2# configure router interface "int-PE-2-PE-6" if-attribute admin-group "red"
```

Define a route-next-hop policy template ‘LFA_NH_exclRed’, which excludes IP admin group ‘red’.

```
*A:PE-2# configure
    router
        route-next-hop-policy
            begin
            template "LFA_NH_exclRed"
                exclude-group "red"
            exit
            commit
```

The policy is applied ot the OSPF interfaces toward PE-1 and PE-6, as follows:

```
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-1" lfa-policy-map route-
nh-template "LFA_NH_exclRed"
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-6" lfa-policy-map route-
nh-template "LFA_NH_exclRed"
```

From the moment that the route-next-hop policy template ‘LFA_NH_exclRed’ is applied to the OSPF interfaces toward PE-1 and PE-6, the LFA NHs for both LDP FEC prefixes change. They now both point to the IP interface from PE-2 to PE-5 as LFA backup NH:

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.1/32

192.168.25.2                            1/1/4

-------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 4
===============================================================================
```

```
*A:PE-2#
```

Example 2: LFA Policy with SRLG Constraint

The objective is to force the LFA NH for both LDP FEC prefixes to use the path from PE-2 to PE-5.

Define SRLG group ‘blue’ with value ‘2’ and apply it to the IP interfaces PE-2 to PE-5 and PE-2 to PE-6.

```
*A:PE-2# configure router if-attribute srlg-group "blue" value 2

*A:PE-2# configure router interface "int-PE-2-PE-1" if-attribute srlg-group "blue"
*A:PE-2# configure router interface "int-PE-2-PE-6" if-attribute srlg-group "blue"
```

Define a route-next-hop policy template ‘LFA_NH_SRLG’, where SRLG is enabled, as follows:

```
*A:PE-2# configure
    router
        route-next-hop-policy
            begin
            template "LFA_NH_SRLG"
                srlg-enable
            exit
            commit
```

The policy is applied to the OSPF interface toward PE-1 and PE-6, as follows:

```
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-1" lfa-policy-map route-
nh-template "LFA_NH_SRLG"
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-6" lfa-policy-map route-
nh-template "LFA_NH_SRLG"
```

Only one LFA policy mapping is allowed on an OSPF interface at a time. The new LFA policy mapping replaces the previous one.

The LFA NHs for both LDP FEC prefixes will both point now to the interface from PE-2 to PE-5 as LFA backup NH, as follows:

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.1/32

===============================================================================
*A:PE-2#
```

The LFA policy mapping is removed from the OSPF interfaces as follows:

```
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-1" no lfa-policy-map
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-6" no lfa-policy-map
```

Example 3: LFA Policy with NH-type Constraint

The objective is to force the LFA NH for IP prefix 192.0.2.6/32 to use an RSVP tunnel.

Enable IP FRR as follows:

```
*A:PE-2# configure router ip-fast-reroute
```

Set up an RSVP LSP tunnel toward 192.0.2.6 with a strict MPLS path going over PE-2 to PE-4 to PE-5 to PE-6.

Note: Since an RSVP LSP is set up between PE-2 and PE-6, MPLS/RSVP protocols also need to be enabled on all the corresponding IP interfaces along the MPLS path.

```
*A:PE-2# configure
    router
        mpls
            interface "int-PE-2-PE-4"
            exit
            path "path-PE-2-PE-4-PE-5-PE-6"
                hop 10 192.168.24.2 strict
                hop 20 192.168.45.2 strict
                hop 30 192.168.56.2 strict
                no shutdown
            exit
            lsp "LSP-PE-2-PE-6-strict"
                to 192.0.2.6
                primary "path-PE-2-PE-4-PE-5-PE-6"
                exit
                no shutdown
            exit
            no shutdown
```

Enable RSVP shortcut within the IGP on PE-2 and indicate that the newly created RSVP LSP is a possible shortcut candidate for LFA backup NH only.

```
*A:PE-2# configure router ospf rsvp-shortcut
*A:PE-2# configure router mpls lsp "LSP-PE-2-PE-6-strict" igp-shortcut lfa-only
```

Displaying the tunnel-table on PE-2 shows that an LDP LSP and an RSVP LSP is available toward PE-6:

```
*A:PE-2# show router tunnel-table 192.0.2.6

===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.6/32      rsvp      MPLS  1         7        192.168.24.2   16777215
192.0.2.6/32      ldp       MPLS  65541     9        192.168.26.2   10
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-2#
```

The RSVP tunnel with tunnel ID 1 corresponds to the RSVP LSP “LSP-PE-2-PE-6-strict”, as can be seen as follows:

```
*A:PE-2# show router mpls lsp

===============================================================================
MPLS LSPs (Originating)
===============================================================================
LSP Name                            To               Tun     Fastfail  Adm  Opr
                                                     Id      Config
-------------------------------------------------------------------------------
LSP-PE-2-PE-6-strict                192.0.2.6        1       No        Up   Up
-------------------------------------------------------------------------------
LSPs : 1
===============================================================================
*A:PE-2#
```

By default, the preferred NH type is IP, not tunnel. Therefore, the RSVP tunnel will not be used for the LFA backup, as can be seen in the following output:

```
*A:PE-2# show router route-table alternative 192.0.2.6/32

===============================================================================

===============================================================================
*A:PE-2#
```

Define a route-next-hop policy template **"LFA_NH_Tunnel"**, where nh-type is set to **tunnel**.

```
*A:PE-2# configure
    router
        route-next-hop-policy
            begin
            template "LFA_NH_Tunnel"
                nh-type tunnel
            exit
            commit
```

Apply the policy template to the interface toward PE-6, as follows:

```
*A:PE-2# configure router ospf area 0 interface "int-PE-2-PE-6" lfa-policy-map route-
nh-template "LFA_NH_Tunnel"
```

The LFA NH uses the RSVP tunnel. The reference to the RSVP tunnel-ID (1) in the following show output corresponds with the tunnel-ID shown in the preceding **show router tunnel-table 192.0.2.6** output:

```
*A:PE-2# show router route-table alternative 192.0.2.6/32

```

Example 4: Exclude Prefix from LFA Policy

The objective is to force no LFA NH for LDP FEC prefix 192.0.2.1/32 where PE-2 is the PLR.

The IP/LDP FRR implementation in SR OS allows to exclude an IGP interface, IGP area (OSPF), or IGP level (IS-IS) from the LFA SPF computation. The user also has the ability to exclude specific prefixes from the LFA SPF by using well-known prefix-lists and policy statements.

This is configured as follows:

```
*A:PE-2# configure
    router
        policy-options
            begin
            prefix-list "lo0-PE-1"
                prefix 192.0.2.1/32 exact
            exit
            policy-statement "LFA_Exclude_PE-1"
                entry 10
                    from
                        prefix-list "lo0-PE-1"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The configured policy statement is applied to the IGP protocol, as follows:

```
*A:PE-2# configure router ospf loopfree-alternate-exclude prefix-policy
"LFA_Exclude_PE-1"
```

From the moment that it is applied, the existing LFA NH entries for LDP FEC prefix 192.0.2.5/32 disappear instantly (compare with the preceding Example 1):

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.1/32

```

Conclusion

In production MPLS networks where IP FRR and/or LDP FRR are deployed, it is possible that the existing calculated LFA NHs are not always taking the most optimal or desirable paths.

With LFA policies, operators have better control on the way in which LFA backup NHs are computed.

Different selection criteria can be part of the route-next-hop policy: IP admin groups, IP SRLG groups, protection type preference and NH type preference.

Unicast Routing Protocols

In This Section

This section provides configuration information for the following topics:

- Associating Communities with Static and Aggregate Routes
- BGP FlowSpec for IPv4 and IPv6
- BGP Multipath
- BGP Route Leaking
- IS-IS Link Bundling
- Policy Chaining and Logical Expressions
- Separate BGP RIBs for Labeled Routes

Associating Communities with Static and Aggregate Routes

This chapter provides information about associating communities with static and aggregate routes configurations.

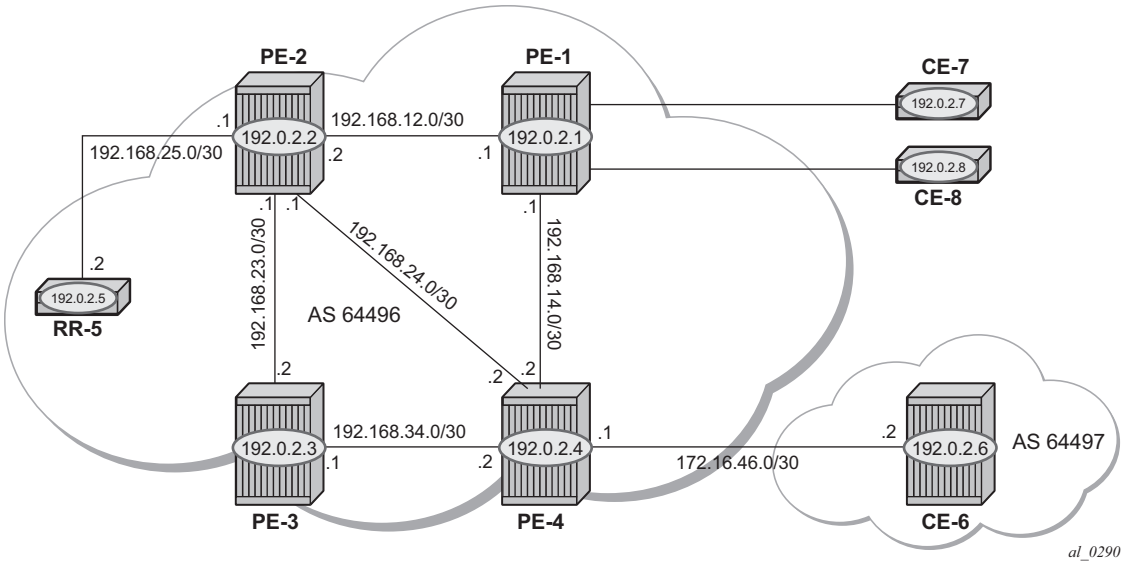
Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter was initially written for SR OS release 11.0.R3, but the CLI in this edition corresponds to release 14.0.R2. There are no prerequisites for this configuration.

Introduction



Border gateway protocol (BGP) communities are optional, transitive attributes attached to BGP route prefixes to carry additional information about that route prefix. A number of route prefixes can have the same community attached such that it can be matched by a route policy. As a result, the presence of a community value can be used to influence and control route policy.

A BGP community is a 32-bit value that is written as two separate 16 bit numbers separated by a colon. The first number usually represents the autonomous system (AS) number that defines or originates the community whilst the second is set by the network administrator.

Knowledge of RFC 4271 (BGP-4) and RFC 1997 (BGP Communities Attribute) is assumed throughout this document, as well as knowledge of multi-protocol BGP (MP-BGP) and RFC 4364 (BGP/MPLS IP VPNs).

Overview

Figure 54 **Example Topology**

The example topology is displayed in Figure 54. The setup uses 7750 Service Router (SR) nodes. PE-1 to PE-4 and the Route Reflector (RR-5) are located in the same Autonomous System (AS); AS64496. CE-6 is in a separate AS 64497 and peers using eBGP with its directly connected neighbor, PE-4.

The objectives are:

- To configure static-routes in a VPRN in PE-1 with various community values – including well-known communities – export them to other PEs within the same AS, and then via eBGP to CE-6. During this process, the community values for each route will be examined to ensure that the transitive nature of the attribute is maintained.
- To associate a community with an aggregate route that represents a larger number of composite prefixes. The aggregate will be advertised in place of the composite prefixes.

The following configuration tasks should be completed as a pre-requisite:

- Full mesh IS-IS or OSPF between all of the PE routers and the route reflector.
- iBGP between the RR and all PEs.
- eBGP between PE-4 and CE-6.
- Link-layer LDP between each PE.

Associating Communities with Static and Aggregate Routes

It is possible to add a single community value to a static and aggregate route without using a route policy.

The community value can be in the 4-byte format comprising of a 2-byte AS value, followed by a 2 byte decimal value, separated by a colon. It can also be the name of a well-known standard community; no-export, no-advertise, no-export-subconfed.

Any community added can be matched using a route policy.

The purpose of this example is to provision static and aggregate IPv4 route prefixes and associate a community with each route. These routes are then redistributed into the BGP protocol and advertised to other BGP speakers.

This is shown for IPv4 routes within a VPRN. Well-known, standard communities will also be configured to show that the correct behavior is observed.

Configuration

The first step is to configure an iBGP session between each of the PEs and the Route Reflector (RR). The address family negotiated between peers is vpn-ipv4.

The configuration for all PEs is as follows:

```
configure
    router
        autonomous-system 64496
        bgp
            group "internal"
                family vpn-ipv4
                peer-as 64496
                neighbor 192.0.2.5
                exit
            exit
```

The IP addresses can be derived from Figure 54.

The configuration for RR-5 is:

```
configure
    router
        autonomous-system 64496
        bgp
            cluster 0.0.0.1
```

```
            group "RR-clients"
                family vpn-ipv4
                peer-as 64496
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.4
                exit
            exit
```

On RR-5, show that BGP sessions with each PE are established, and have correctly negotiated the VPN IPv4 address family capability.

```

VPRN: IPv4

Figure 55 **CE Connections for Next-Hops**

The VPRN configuration for PE-1 is as follows:

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-1-CE-7" create
                address 172.16.17.1/30
                sap 1/2/1:1.0 create
                exit
            exit
            interface "loop1" create
```

```
                address 192.0.2.100/32
                loopback
            exit
            interface "int-PE-1-CE-8" create
                unnumbered "loop1"
                sap 1/2/2:1.0 create
            exit
        exit
        no shutdown
```

For unnumbered interfaces, an IP address is borrowed from a loopback interface, for example from the system interface, see MPLS chapter Unnumbered Interfaces in RSVP-TE and LDP.

LDP is used as the label-switching protocol for next-hop resolution.

PE-4 is configured with an interface toward CE-6 that supports eBGP. The following export policy is configured:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-VPN-accept"
                entry 10
                    from
                        protocol bgp-vpn
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

The configuration of the VPRN service is as follows:

```
configure
    service
        vprn 1 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-4-CE-6" create
                address 172.16.46.1/30
                sap 1/2/1:1 create
                exit
            exit
            bgp
                group "VPRN1-external"
```

```
                export "BGP-VPN-accept"
                peer-as 64497
                neighbor 172.16.46.2
                exit
            exit
        exit
        no shutdown
```

Static Routes with Communities

A static route has a number of next-hop options: direct connected IP address, black-hole, indirect IP address, and interface-name.

Figure 55 shows a pair of Customer Edge (CE) routers connected to PE1. The link to CE-7 is a numbered link. The link to CE-8 is an unnumbered link. The loopback interface address is used as a reference address for the unnumbered Ethernet interface.

Beyond CE-7 are a number of /24 subnets. Static routes to these individual subnets are created on PE-1 using a static route with a next-hop type of “interface address” or an “indirect address”. The indirect address is learned using a static route.

Beyond CE-8 is a single /24 subnet. A static route to this subnet is created with an interface-name as the next-hop.

There are a number of well-known, standard communities:

- no-export: the route is not advertised to any external peer. This route should be present in the route tables of all BGP speakers in the originating AS, but not in those in neighboring ASs.
- no-advertise: the route is not advertised to any peer. This route should not be present in any router as BGP-learned route.

The requirement for each subnet is:

- 10.100.100.0/24 must not be advertised outside of the AS. This must be associated with the standard, well-known community no-export. The community value is encoded as 65535:65281 (0xFFFFFF01), but the CLI requires the keyword **no-export**.

```
configure service vprn 1
            static-route-entry 10.100.100.0/24
                next-hop 172.16.17.2
                    community no-export
                    no shutdown
                exit
```

- 10.100.101.0/24 must be advertised with a community of 64496:101

```
configure service vprn 1
            static-route-entry 10.100.101.0/24
                next-hop 172.16.17.2
                    community 64496:101
                    no shutdown
                exit
```

- 10.100.102.0/24 must not be advertised to any BGP peer. This must be associated with the standard, well-known community **no-advertise**. The community value is encoded as 65535:65282 (0xFFFFFF02), but the CLI requires the keyword **no-advertise**.

```
configure service vprn 1
            static-route-entry 10.100.102.0/24
                next-hop 172.16.17.2
                    community no-advertise
                    no shutdown
                exit
```

- 10.100.103.0/24 must be advertised with a community of 64496:103 and a route tag of 10.

```
configure service vprn 1
            static-route-entry 10.100.103.0/24
                next-hop 172.16.17.2
                    community 64496:103
                    tag 10
                    no shutdown
                exit
            exit
```

- 10.100.104.0/24 must be advertised with a community of 64496:104. It is reachable via 192.0.2.7 which, in turn, is reachable via 172.16.17.2. For more information about this configuration, see chapter Associating Communities with Static and Aggregate Routes. This is using a static route which does not need to be advertised – hence it is associated with the **no-advertise** community.

```
configure service vprn 1
            static-route-entry 10.100.104.0/24
                indirect 192.0.2.7
                    community 64496:104
                    no shutdown
                exit
            exit
            static-route-entry 192.0.2.7/32

                    no shutdown
                exit
            exit
```

- 10.100.105.0/24 must be advertised with a community of 64496:105. It is reachable via the unnumbered interface to CE-8.

```
configure service vprn 1
            static-route-entry 10.100.105.0/24
                next-hop "int-PE-1-CE-8"
                    community 64496:105
                    no shutdown
                exit
            exit
```

On PE-1, configure static routes that match the static routes from Figure 55, and the preceding conditions.

The default behavior of a VPRN is to export all static and connected routes into a BGP labeled route with the appropriate route-target extended community configured in the vrf-target statement. A single community string can be added using the static-route community commands shown above. If multiple communities are required, then a VRF-export policy should be used. This is outside the scope of this chapter.

Examine the BGP table of PE-1 to establish that routes have been exported correctly in VPN IPv4 toward RR-5.

```

-------------------------------------------------------------------------------
Routes : 7
===============================================================================
*A:PE-1#
```

There are only seven exported routes. The route prefixes associated with the **no-advertise** community are not present, as expected.

Examining the BGP table of PE-4 shows the presence of the expected routes, with the correct community values.

The prefix 10.100.100.0/24 is a member of community **no-export**. This is not advertised to PE-4.

In release 14.0.R1, the **show router bgp routes** command has been restructured to support more consistent parameter ordering. In most cases, a family filter must be specified before all other filtering parameters, except for the prefix.

```

Aggregate Routes with Communities

An aggregate route can be configured to represent a larger number of prefixes. For example, a set of prefixes 10.101.0.0/24 to 10.101.7.0/24 can be represented as a single aggregate prefix of 10.101.0.0/21.

This is due to the fact that the third octet in the range 0 to 7 can be represented by the 8 bits 00000000 to 00000111. The first 5 bits of this octet are common, along with the previous 2 octets, giving a prefix where the first 21 bits are common. Therefore, the aggregate can be written as 10.101.0.0/21.

In order to illustrate the configuration of an aggregate, consider following.

Figure 56 **CE-7 Connectivity**

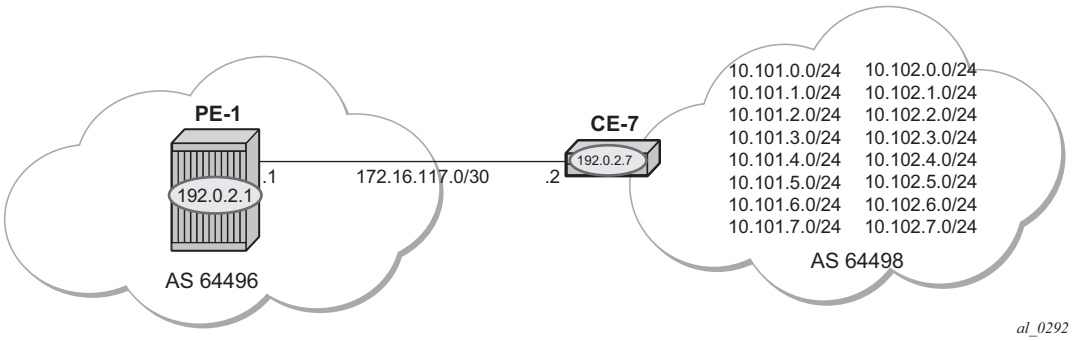

Figure 56 shows a CE router (CE-7), in AS 64498, that advertises a series of contiguous prefixes via BGP.

- 10.101.0.0/24 to 10.101.7.0/24
- 10.102.0.0/24 to 10.102.7.0/24

Instead of advertising all of these prefixes out of the VPRN towards an external CE individually, an aggregate route can be configured that summarizes each set of eight prefixes and a community can be directly associated with each aggregate route.

The configuration for a VPRN on PE-1, including the external BGP configuration is as follows:

```
*A:PE-1# configure
    service
        vprn 2 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:2
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:2
            interface "int-PE-1-CE-7_2nd" create
                address 172.16.117.1/30
                sap 1/2/1:2.0 create
                exit
            exit
            bgp
                group "external"
                    peer-as 64498
                    neighbor 172.16.117.2
                    exit
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The neighbor relationship shows:

```
*A:PE-1# show router 2 bgp neighbor

-------------------------------------------------------------------------------
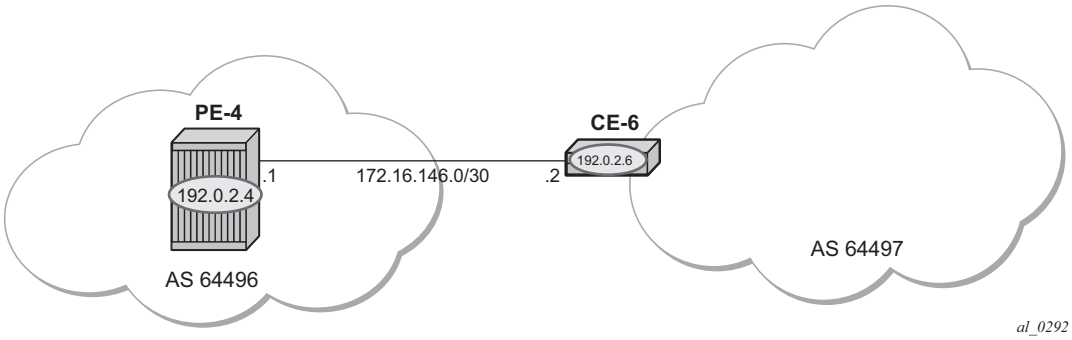
Routes : 16
===============================================================================
*A:PE-1#
```



PE-4 also has a VPRN 2 instance configured, so that it will receive the imported BGP routes. The configuration for PE-4 is:

```
*A:PE-4# configure
    service
        vprn 2 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:2
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:2
            interface "int-PE-4-CE-6_2nd" create
                address 172.16.146.1/30
                sap 1/2/1:2 create
                exit
            exit
            bgp
                group "VPRN2-external"
                    peer-as 64497
```

```
                neighbor 172.16.146.2
                exit
            exit
            no shutdown
        exit
        no shutdown
    exit
```

Figure 57 shows the connectivity between PE-4 and CE-6. PE-4 will only forward a summarizing aggregate route toward CE-6.

Figure 57 **CE-6 Connectivity**

PE-4 receives labeled BGP route prefixes from PE-1 via the route reflector and installs them in the FIB for router instance 2:

```
*A:PE-4# show router 2 route-table

===============================================================================
Route Table (Service: 2)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age         Pref
      Next Hop[Interface Name]                                     Metric

*A:PE-4#
```

The CE-6 configuration for an interface toward PE-4 is as follows:

```
*A:CE-6# configure
    service
        ies 2 customer 1 create
            interface "int-CE-6-PE-4_2nd" create
                address 172.16.146.2/30
                sap 1/1/1:2 create
                exit
            exit
            no shutdown
```

The BGP configuration of CE-6:

```
*A:CE-6# configure
    router
        bgp
            group "external-toVPRN2onPE-4"
                peer-as 64496
                neighbor 172.16.146.1
                exit
            exit
            no shutdown
```

The BGP neighbor state for PE-4:

```
*A:PE-4# show router 2 bgp neighbor 172.16.146.2

===============================================================================
* indicates that the corresponding row element may have been truncated.
*A:PE-4#
```

In order to advertise a summarizing aggregate route with an associated community string, an aggregate route is required. In this case, the 10.101.x.0/24 group of prefixes will be associated with community 64496:101. The 10.102.x.0/24 group of prefixes will be associated with the standard community n**o-export**, so that it will not be advertised to any external peer.

The configuration required on PE-4 is as follows:

```
configure
    service
        vprn 2
            aggregate 10.101.0.0/21 community 64496:101
            aggregate 10.102.0.0/21 community no-export
        exit
```

An export policy is required on PE-4 to allow the advertising of the aggregate route. No community is applied using this policy.

```
configure
    router
        policy-options
            begin
```

```
            policy-statement "PE-4-VPN-Agg"
                entry 10
                    from
                        protocol aggregate
                    exit
                    action accept
                    exit
                exit
            commit
            exit
```

This is applied as an export policy within the group context of the BGP configuration of the VPRN.

```
configure
    service
        vprn 2
            bgp
                group "VPRN2-external"
                    export "PE-4-VPN-Agg"
                exit
```

The aggregate route 10.101.0.0/21 is received at CE-6 via BGP. The community that was associated with this prefix is seen: 64496:101. The route is seen as an aggregate, with PE-4 as the aggregating router (192.0.2.4). The “Atomic Aggregate” attribute is present, meaning that PE-4 has not advertised any details of the AS Paths of the composite routes.

Conclusion

Community strings can be added to static and aggregate routes. This example shows the configuration of communities with both static and aggregate routes, together with the associated show outputs which can be used to verify and troubleshoot them.

BGP FlowSpec for IPv4 and IPv6

This chapter provides information about BGP FlowSpec for IPv4 and IPv6.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to 7750 SR-7/12, 7750 SRc4/c12, 7750 SR-12E, 7750 SR-a, 7750 SR-e, XRS-20/40/16c, and 7450 ESS-7/12 in mixed-mode. Only interfaces supported on IOM3-XP, IOM4-e, XMA/C-XMA, IOM-a, and IMM cards can be configured for FlowSpec filtering. Also, all network interfaces must be on IOM3-XP, IOM4-e, XMA/C-XMA, IOM-a, or IMM cards in order to enable FlowSpec on any spoke-SDP interface.

Overview

The base BGP Flow Specification (FlowSpec) is defined in RFC 5575 (Flow Specification) and describes a method of encoding IPv4 flow specification information into Network Layer Reachability Information (NLRI). Draft-ietf-idr-flow-spec-v6 followed, and was considered an extension of RFC 5575 to include the IPv6 address family. The flow specification is an n-tuple consisting of one or more matching criteria, which can be applied to IP traffic. The FlowSpec NLRI is encoded into Multiprotocol BGP using MP_REACH_NLRI and MP_UNREACH_NLRI attributes.

As well as the flow specification defining match criteria, extended community attributes are defined to provide traffic filtering actions for the specified flow specification. Therefore, a FlowSpec route (MP_REACH_NLRI) contains a description of the traffic to be matched (using FlowSpec NLRI), and the filtering action to be taken with that traffic (using traffic filtering action extended communities). RFC 7674 provided an update to the original RFC 5575 specification to clarify the formatting of some of these traffic actions, notably redirect to VRF.

Initially, the primary use for FlowSpec was to dynamically distribute traffic filtering rules for mitigating distributed denial of service (DDoS) attacks. A router receiving a FlowSpec update can dynamically create IP filters to prevent both intra-AS and inter-AS DDoS attacks. Prevention is typically implemented by dropping traffic at the ingress point of the network (or nearest possible point toward the source of the DDoS attack) or by redirecting traffic to a separate routing context for forwarding (off-ramping) to a traffic-cleansing device. The ability to redirect traffic led to FlowSpec being considered for software defined networking (SDN)-driven applications or network re-optimization tools. In those cases, a subset of traffic needs to be forced (redirected) into a specific routing context or tunnel/label switched path (LSP) for network capacity optimization or to meet a service level agreement (SLA).

BGP FlowSpec uses AFI 1 (IPv4) or AFI 2 (IPv6) with SAFI 133 (IPv4 dissemination of flow specification rules) or SAFI 134 (VPNv4 dissemination of flow specification rules). Currently, only IPv4 and IPv6 are supported in SR OS.

The FlowSpec NLRI may consist of several components that form the flow specification. A packet only matches the flow specification when it matches all of the components in the NLRI. Table 1 lists the component types that are currently defined, their type values, and their support in SR OS. Flow specification components must follow strict ordering. If present in the specification, a component must precede any other component of higher type value.

Table 2 **FlowSpec Component Types**

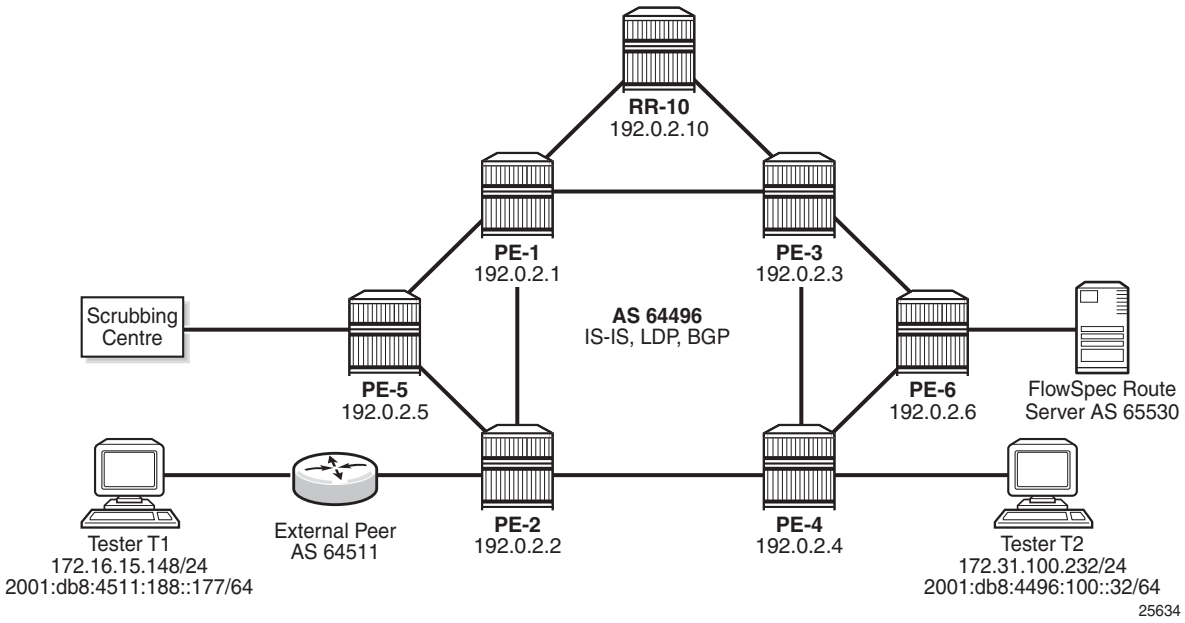
Type Value	Component Type	SR OS Support
1	Destination Prefix	Yes
2	Source Prefix	Yes
3	IP Protocol	Partial (TCP/UDP only)
4	Port	Yes (specific number or single contiguous range)
5	Destination Port	Yes
6	Source Port	Yes
7	ICMP Type	Yes
8	ICMP Code	Yes
9	TCP Flags	SYN/ACK only
10	Packet Length	No
11	DiffServ Code Point	Yes

Table 2 **FlowSpec Component Types**

Type Value	Component Type	SR OS Support
12	Fragment	Yes (non-first only, first-only, fragment true, fragment false. Last fragment matching is not supported).

The traffic filtering action for a flow specification uses a number of extended community attributes. The attributes standardized in RFC 5575 are listed in Table 2, with their types and support in SR OS. The traffic rate extended community specifies the rate in bytes per second, where a rate of zero specifies a drop action. The traffic action extended community consists of six bytes; only the two least significant bits of the last byte are currently defined. The terminal action (T-bit), when set to 1, indicates that subsequent filtering rules should be applied (like a next-entry action). When this bit is set to zero, and this action is applied, the evaluation of the traffic filter stops. The sample bit (S-bit), when set to 1, enables traffic sampling and logging for this flow specification. The redirect to VRF and mark traffic class extended communities are self-explanatory, with a route-target value being used to define the target redirect VRF.

Table 3 **FlowSpec Extended Community Attributes**



Type	Extended Community	SR OS Support
0x8006	Traffic Rate	0 (= drop)
0x8007	Traffic Action S-bit	Yes (uses default filter log 101)
0x8007	Traffic Action T-bit	No
0x8008	Redirect to VRF	Yes
0x8009	Mark Traffic Class	No

Example Topology

The example topology used throughout this chapter is shown in Figure 1. PE-1 through PE-6 and RR-10 participate in IS-IS Level-2 and LDP. All devices form part of network AS 64496, with all PE routers peering in IBGP with the Route-Reflector RR-10 for address families IPv4, IPv6, VPN-IPv4, VPN-IPv6, Flow-IPv4, and Flow-IPv6.

To allow for tunneling of IPv4 traffic in MPLS, all PE routers are configured for BGP next-hop-resolution using LDP shortcut-tunnels. To allow for tunneling of IPv6 traffic in MPLS, all PE routers are configured to run 6PE, with peering sessions configured to advertise labels for the IPv6 address family. Therefore, all IPv4 and IPv6 traffic is tunneled in MPLS.

Figure 58 **Example Topology**

To demonstrate FlowSpec, the following items are connected to AS 64496:

- PE-2 is connected to an external peer in AS 64511, which advertises the IPv4 prefix 172.16.0.0/20 and the IPv6 prefix 2001:db8:4511::/48 in EBGP. Both prefixes are advertised within AS 64496 by PE-2.
- PE-4 advertises IPv4 prefix 172.31.100.0/24 and IPv6 prefix 2001:db8:4496::/48 into IBGP, which PE-2 subsequently advertises in EBGP to AS 64511.
- Tester T1 is connected to the external peer in AS 64511 and sources and sinks traffic from IPv4 address 172.16.15.148 and IPv6 address 2001:db8:4511:188::177. Tester T2 is connected to PE-4 and sources and sinks traffic from IPv4 address 172.31.100.232 and IPv6 address 2001:db8:4496:100:32.
- PE-6 externally peers with a FlowSpec route server belonging to AS 65530.
- PE-5 connects to a DDoS scrubbing center with two interfaces:

– A "dirty" interface for forwarding of mitigated traffic toward the scrubbing center for cleansing. This interface is connected to an off-ramp VPRN configured on PE-5 and PE-2. PE-5 has static IPv4/IPv6 default routes toward the scrubbing center, which are subsequently advertised into the off-ramp VPRN. This provides sufficient routing information to attract redirected traffic from PE-2 toward the scrubbing center for cleansing.
– A "clean" interface for traffic received from the scrubbing center after it has been cleansed. This interface is connected to an IES service and is therefore routed toward its destination using the Global Routing Table (GRT).

Configuration

As an example of FlowSpec configuration, the following output shows the BGP configuration at PE-5. Similar configurations are applied on all other PE routers. All PE routers within AS 64496 peer as clients with RR-10 for the address families IPv4, IPv6, VPN-IPv4, VPN-IPv6, Flow-IPv4, and Flow-IPv6. The latter two are required for propagating the FlowSpec routes, and represent the only part of the BGP configuration required by FlowSpec.

The next-hop-resolution context allows for IPv4 traffic advertised by unlabeled BGP routes to use shortcut tunnels using the best tunnel type, based on tunnel-table preference. Because AS 64496 is only configured for LDP, LDP-based LSPs will be used for these shortcut tunnels. Similarly, to permit tunneling of IPv6 traffic in MPLS, the neighbor context contains the advertise-label ipv6 command to enable 6PE functionality.

```
bgp
    next-hop-resolution
        shortcut-tunnel
            family ipv4
                resolution any
            exit
        exit
    exit
    group "IBGP"
        family ipv4 ipv6 vpn-ipv4 vpn-ipv6 flow-ipv4 flow-ipv6
        peer-as 64496
        neighbor 192.0.2.10
            authentication-key <password> hash2
            advertise-label ipv6
        exit
    exit
    no shutdown
exit
```

PE-2 uses an IES to externally peer with AS 64511. The peering is for the IPv4 and IPv6 address families, and a separate IPv4/IPv6 BGP session is maintained for each address family. This external peering point is the point where ingress FlowSpec filters are instantiated. In the following output, the flowspec and flowspec-ipv6 parameters are configured within the SAP ingress context, to enable FlowSpec for IPv4 and IPv6, respectively. As well as SAPs, FlowSpec can also be enabled on spoke-SDPs within routed interfaces, and is supported within the base and VPRN routing instances.

```
ies 1 customer 1 create
    interface "to-AS64511" create
        address 192.168.2.1/30
        ipv6
            address 2001:db8:1b0c:2121::2/127
        exit
        sap 1/1/4:10.* create
            ingress
                flowspec
                flowspec-ipv6
            exit
        exit
    exit
    service-name "FlowSpec-test"
    no shutdown
exit
```

FlowSpec Operation

With FlowSpec enabled, FlowSpec routes can be advertised to dynamically trigger the instantiation of ingress filters. When valid FlowSpec routes are received, the system creates these filters on all interfaces where FlowSpec is enabled.

This section demonstrates the use of FlowSpec for traffic black-holing and traffic redirection for both IPv4 and IPv6.

IPv4 FlowSpec

To validate the instantiation of ingress filters based on IPv4 FlowSpec routes, a bidirectional traffic stream is commenced between Tester T1 (172.16.15.148) in AS 64511 and Tester T2 (172.31.100.232) in AS 64496. In the Tester T1 to Tester T2 direction, the destination port is TCP port 4191.

An IPv4 FlowSpec route is subsequently established to black-hole/drop traffic with a source address of 172.16.15.148 (Tester T1) and a destination address of 172.31.100.232 (Tester T2), for any destination ports in the range 4190-4199. The following output shows the route as received at PE-2.

```
1 2016/02/01 17:08:51.80 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.10
"Peer 1: 192.0.2.10: UPDATE

"
```

The route is shown as an MP_REACH_NLRI for address family Flow-IPv4 (AFI 1 SAFI 133). The NLRI uses the source and destination prefixes, the IP protocol, and the destination-port components to describe the flow and create the filter match criteria. The traffic rate extended community is then used to define a rate of 0, which is the filter drop action.

SR OS does not support a non-zero traffic rate. Although the route will be accepted, no filters will be instantiated.

Unlike other address families, there is no strict requirement for the Next-Hop attribute to be present in the MP_REACH_NLRI. The Length of Next-Hop in the Address field can optionally be set to zero and should be ignored on receipt.

The received FlowSpec route can also be verified in the RIB, which provides a concise output of the flow attributes and traffic filtering function, as follows.

```
A:PE-2# show router bgp routes flow-ipv4

```

The dynamically created FlowSpec IPv4 ingress filter is shown in the following output, using the filter identifier "fSpec-0", created for the base routing instance. The entry within the filter is 32767 and indicates that it has been inserted by BGP FlowSpec. If a static ingress IP filter is also in use, FlowSpec generated filter entries are processed after all static filter entries (also referred to as user-defined filter entries), but prior to the default static filter action. The output shows a count of ingress matches, which are dropped. This is verified with the loss of traffic from Tester T1 to Tester T2, but not vice versa.

```

```

When the route is withdrawn and PE-2 receives an MP_UNREACH_NLRI for the same FlowSpec NLRI, the dynamically created filter entries are removed and all associated hardware resources (TCAM entries) are released.

Instead of dropping traffic at the ingress point to the network, an alternative option is to redirect the mitigated traffic to a traffic-cleansing device, if this infrastructure exists. FlowSpec has the Redirect to VRF extended community for this purpose, with the process of forwarding traffic toward a scrubbing center frequently referred to as off-ramping. At PE-2, a VPRN is configured to off-ramp traffic toward the scrubbing center connected to PE-5, as shown in the following output.

In the case of FlowSpec, traffic redirection is half-duplex. That is, traffic is forwarded from PE-2 toward PE-5, but not from PE-5 toward PE-2. This is because when the traffic has been cleansed, it re-enters the network at PE-5 within an IES, and is therefore routed toward its destination using the GRT. This process is frequently referred to as on-ramping. As a result of this half-duplex traffic flow, only a vrf-target import statement is created. There is no requirement to export any routes from PE-2.

```
vprn 2 customer 1 create
    route-distinguisher 64496:2
    auto-bind-tunnel
        resolution any
    exit
    vrf-target import target:64496:2
    service-name "FlowSpec-OffRamp-VRF"
    no shutdown
exit
```

The VPRN used for the purpose of off-ramping is also configured at PE-5 and has a single SAP toward the scrubbing center, as shown in the following output. Static IPv4 and IPv4 default routes are configured with next hops of the scrubbing center and these are advertised into VPN-IPv4/VPN-IPv6 using route-policy. There is no requirement for PE-5 to import any BGP-VPN routes.

```
vprn 2 customer 1 create
    vrf-export "vrf2-export"
    route-distinguisher 64496:2
    interface "OffRamp-to-Scrubbing-Center" create
        address 192.168.2.5/30
        ipv6
            address 2001:db8:1b0c:2121::4/127
        exit
        sap 1/1/3:12 create
        exit
    exit
    static-route 0.0.0.0/0 next-hop 192.168.2.6
    static-route ::/0 next-hop 2001:db8:1b0c:2121::5
```

```
            service-name "FlowSpec-OffRamp-VRF"
            no shutdown
        exit
```

The following output shows the on-ramp IES at PE-5. This is the point where cleansed traffic re-enters the network and is forwarded toward its destination using the GRT.

```
 ies 3 customer 1 create
            interface "OnRamp-from-Scrubbing-Center" create
                address 192.168.2.9/30
                ipv6
                    address 2001:db8:1b0c:2121::6/127
                exit
                sap 1/1/3:13 create
                exit
            exit
            service-name "FlowSpec-OnRamp-IES"
            no shutdown
        exit
```

To validate the instantiation of the redirection filter, the same bidirectional traffic stream is started between Tester T1 (172.16.15.148) in AS 64511 and Tester T2 (172.31.100.232) in AS 64496. In the Tester T1 to Tester T2 direction, the destination port is TCP port 4191. When the IPv4 FlowSpec route is received at PE-2, the NLRI shows the same traffic match criteria previously used for the black-hole/drop scenario. However, the extended community has changed to redirect-to-vrf with a route-target value of 64496:2, as shown in the following output.

```
1 2016/02/02 10:48:07.81 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.10

"
```

The FlowSpec ingress filter in the following output uses the filter identifier "fSpec-0" and the entry 32767 inserted by BGP FlowSpec. The output shows that there are ingress packet/byte matches against the defined match criteria received in the FlowSpec NLRI. The match action field indicates an action of forward, and the forwarding router/service ID ("Fwd Rtr/SvcId") is service ID 2 (the off-ramp VPRN).

Traffic is correctly received in the Tester T1 to Tester T2 direction, and also in the opposite Tester T2 to Tester T1 direction. However, traffic in the Tester T1 to Tester T2 direction is redirected by PE-2 toward the scrubbing center attached to PE-5, before being forwarded to its destination at PE-4.

```

IPv6 FlowSpec

To validate the instantiation of ingress filters based on IPv6 FlowSpec routes, a bidirectional traffic stream is commenced between Tester T1 (2001:db8:4511:188::177) in AS 64511 and Tester T2 (2001:db8:4496:100::32) in AS 64496. In the Tester T1 to Tester T2 direction, the destination port is TCP port 4191.

An IPv6 FlowSpec route is then established to black-hole/drop traffic with a source address of 2001:db8:4511:188::177 (Tester T1) and a destination address of 2001:db8:4496:100::32 (Tester T2), for any destination ports in the range 4190-4199. The following output shows the route as received at PE-2.

```
1 2016/02/04 14:08:37.80 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.10
"Peer 1: 192.0.2.10: UPDATE
Peer 1: 192.0.2.10 - Received BGP UPDATE:

    Flag: 0xc0 Type: 16 Len: 8 Extended Community:
        rate-limit: 0:0
"
```

The route is shown as an MP_REACH_NLRI for address family Flow-IPv6 (AFI 2 SAFI 133). As with the FlowSpec IPv4 example, the NLRI uses the source and destination prefixes, the IP protocol, and the destination-port components to describe the flow and create the filter match criteria. The traffic rate extended community is then used to define a rate of 0, which is equivalent to a filter drop action.

The dynamically created FlowSpec IPv6 ingress filter is shown in the following output. Although this is an IPv6 filter, the filter identifier "fSpec-0" is still used for the base routing instance. The filter entry is 32767 and indicates that it has been inserted by BGP FlowSpec. The output shows a count of ingress matches, which are dropped in accordance with the Match action field. This is verified with the loss of traffic from Tester T1 to Tester T2, but not vice versa.

```
A:PE-2# show filter ipv6 "fSpec-0"

Egr. Matches : 0 pkts
```

The FlowSpec IPv6 route with the drop action is subsequently withdrawn, restoring the traffic flow between Tester T1 and Tester T2.

To off-ramp IPv6 traffic toward the scrubbing center, the same redirect infrastructure is used as in the IPv4 example:

- PE-2 and PE-5 use the same off-ramp VPRN (VPRN 2), which transports both VPN-IPv4 and VPN-IPv6 traffic.
- PE-5 uses the same on-ramp (IES). When traffic is returned from the scrubbing center, PE-5 routes packets toward their destination using the GRT.

An IPv6 FlowSpec route with a redirect-to-VRF extended community is then sourced by the FlowSpec route generator. When the route is received at PE-2, the NLRI shows the same traffic match criteria previously used for the IPv6 black-hole/drop scenario. However, the extended community has changed to *redirect-to-vrf* with a route-target value of 64496:2, as shown in the following output.

```
1 2016/02/04 17:00:28.74 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.10

FlowSpec Validation

FlowSpec routes are typically originated and contained within the administrative domain of an operator; particularly when used for DDoS mitigation purposes. This approach means applying ingress filters at the point where traffic enters the autonomous system (AS), such as an external peering point.

For these filters to be optimal, they should be instantiated as close as possible to the source of the attack traffic, even if that means applying filters within another operator's domain. This means that FlowSpec routes must be exchanged between autonomous systems, which requires that:

- A trust relationship exists between those autonomous systems.
- A method of validating FlowSpec routes advertised between autonomous systems exists. This is referred to as FlowSpec validation.

When FlowSpec validation is enabled, it introduces an additional step in the BGP path selection process. That is, a FlowSpec NLRI is only considered feasible if the originator of the FlowSpec route matches the originator of the best-match unicast route for the destination prefix embedded in the FlowSpec NLRI. The originator is defined as being either the BGP originator path attribute, if Route Reflection is being used, or the transport address of the BGP peer, if this attribute is not present.

FlowSpec validation is enabled at the BGP, group, or neighbor level, using the flowspec-validate command, as shown in the following output, and can be supported within the base and VPRN routing contexts. Within the test topology, it is enabled on all IBGP sessions within AS 64496, and also at PE-2's EBGP peering session to AS 64511.

```
router Base
        group "EBGP"
            neighbor 192.168.2.2
                family ipv4 flow-ipv4
```

```
                peer-as 64511
                flowspec-validate
                split-horizon
            exit
        exit
```

To verify the use of FlowSpec validation, the external peer in AS 64511 will attempt to instantiate an IPv4 FlowSpec filter at PE-4. The FlowSpec NLRI uses Tester T2's IP address (172.31.100.232) as the source prefix and Tester T1's IP address (172.16.15.148) as the destination prefix.

Initially, the external peer in AS 64511 originates only the IPv4 FlowSpec route, but does not advertise the IPv4 prefix 172.16.0.0/20, which would be the destination prefix contained in the FlowSpec NLRI. Therefore, PE-2 cannot match the originator of the FlowSpec IPv4 route with the originator of the best-match unicast route for the destination prefix in the FlowSpec NLRI, and the route is not validated. That is, because AS 64511 does not advertise the prefix 172.16.0.0/20, there is no unicast route for the destination prefix in the FlowSpec NLRI. This is shown in the following output, where the FlowSpec route from AS 64511 is held in RIB-In, but is not flagged as used, valid, or best. Therefore, the route remains inactive and is not propagated any further by PE-2.

```
*A:PE-2# show router bgp routes flow-ipv4
===============================================================================

      Src Pref  : 172.31.100.232/32
-------------------------------------------------------------------------------
Routes : 1
===============================================================================
```

The external peer in AS 64511 now advertises the prefix 172.16.0.0/20, together with the same IPv4 FlowSpec route with NLRI, containing a source prefix of 172.16.15.148/32 and destination prefix of 172.31.100.232/32. When the route is received at PE-2, the route can be validated because the best-match unicast route for the destination prefix in the FlowSpec NLRI, and the actual FlowSpec route, have a common originator. Therefore, the route is installed as valid, used, and best, and is advertised internally by PE-2 to AS 64496, as shown in the following output.

The originator in this case is the BGP transport address because no Route-Reflection exists on the external peering between AS 64511 and AS 64496.

```

The FlowSpec route is reflected by RR-10 and received at PE-4, where FlowSpec validation again takes place. Because Route-Reflection exists within AS 64496, both the IPv4 prefix 172.16.0.0/20 and the FlowSpec IPv4 route have a common originator ID (inserted by RR-10) of 192.0.2.2 (PE-2). Therefore, the route is validated, and again installed as valid, used, and best, as shown in the following output.

```
*A:PE-4# show router bgp routes flow-ipv4

Resource Consumption

Similar to static filters consuming hardware resources, also dynamically instantiated FlowSpec filters consume hardware resources (TCAM entries) on the associated linecards. Therefore, resources must be checked and monitored to ensure that the system operates within its scaling boundaries.

Before the activation of any FlowSpec routes, there are two ingress ACL/QoS entries consumed for IPv4 and another two entries for IPv6, as shown in the following output.

```
*A:PE-2# tools dump system-
resources | match expression "Hardware Resource|Ingress ACL/QoS Entries" post-
lines 1
Hardware Resource Usage for Slot #1, CardType iom-xp-b, Cmplx #0:
                                |   Total   | Allocated |    Free
         Ingress ACL/QoS Entries |      32768|          2|      32766
        Ingress IPv6 ACL Entries |      14336|          2|      14334
```

A FlowSpec IPv4 route matches on a source/destination IP address only. When the filter is dynamically instantiated, a single ingress ACL/QoS entry is consumed, as shown in the following output.

```
*A:PE-2# tools dump system-
resources | match expression "Hardware Resource|Ingress ACL/QoS Entries" post-
lines 1
Hardware Resource Usage for Slot #1, CardType iom-xp-b, Cmplx #0:
                                |   Total   | Allocated |    Free
         Ingress ACL/QoS Entries |      32768|          3|      32765
        Ingress IPv6 ACL Entries |      14336|          2|      14334
```

Similarly, a single entry is consumed if the source/destination IP address is used with a source/destination port. However, if ranges are used for port definition, a number of entries are consumed. A FlowSpec IPv4 route matching the source/destination IP address and a destination port range of 4190 to 4199 consumes four entries, as shown in the following output.

```
*A:PE-2# tools dump system-
resources | match expression "Hardware Resource|Ingress ACL/QoS Entries" post-
lines 1
Hardware Resource Usage for Slot #1, CardType iom-xp-b, Cmplx #0:
                                |   Total   | Allocated |    Free
         Ingress ACL/QoS Entries |      32768|          6|      32762
        Ingress IPv6 ACL Entries |      14336|          2|      14334
```

TCAM entries are not consumed on a per-interface basis. When TCAM entries are consumed on a linecard for a FlowSpec NLRI match criteria, the same criteria can be used for filtering across multiple IP interfaces on the same linecard without consuming additional TCAM entries.

Conclusion

FlowSpec IPv4 and IPv6 provide a dynamic way to activate (and tear down) ingress filters to mitigate against DDoS attacks. SR OS supports a wide range of match criteria (FlowSpec NLRI) coupled with the ability to either drop or redirect mitigated traffic. This offers flexibility not only in what traffic is matched, but also in traffic treatment, depending on the availability of a traffic-cleansing infrastructure.

The ability of FlowSpec to dynamically create and remove filters has some immediate benefits:

- Reduces the likelihood of configuration errors on one or more devices
- Allows for temporary use of hardware resources, which are released when the threat has passed
- Allows for a push configuration from a single point to a potentially large number of network devices, without having to visit each one to configure filters manually.

BGP Multipath

This chapter provides information about BGP Multipath.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R4.

In release 14.0.R1, BGP multipath has been improved by offering more control over the selection of the eligible multipaths. This chapter provides information about these enhancements.

Overview

When BGP multipath is enabled, traffic can be forwarded to an IP prefix destination over multiple BGP paths that are considered equal by the BGP decision process. BGP multipath is supported in base router and VPRNs. The **multipath** command specifies the maximum number of BGP paths that each BGP RIB can submit to the route table for an IP prefix. The equal cost multipath (ECMP) limit defines how many paths are selected for installation in the forwarding information base (FIB). Traffic in the data path that matches the IP prefix is load-balanced across the ECMP next hops on a per-packet hash calculation.

Note: As described in chapter Separate BGP RIBs for Labeled Routes, labeled routes and unlabeled routes do not mix.

The BGP multipath enhancements in SR OS release 14.0.R1 are the following:

1. The **multipath** command in the base router and VPRN BGP contexts contains the following options:

   multipath *max-paths* [**ebgp** *ebgp-max-paths*] [**ibgp** *ibgp-max-paths*] [**restrict** {**same-neighbor-as** | **exact-as-path**}]

   - **max-paths** is the default maximum number of paths. It is overruled by **ebgp-max-paths** and **ibgp-max-paths**. However, if there is no maximum set for the number of eBGP paths or iBGP paths, then the maximum number of paths is set by **max-paths**.
   - **ebgp-max-paths** specifies the maximum number of paths that can be used when the best path is eBGP.
   - **ibgp-max-paths** specifies the maximum number of paths that can be used when the best path is iBGP.
   - **restrict same-neighbor-as** forces multipaths to have the same AS path length (unless **as-path-ignore** is configured) and the same neighbor AS.
   - **restrict exact-as-path** forces multipaths to have the exact same AS paths.

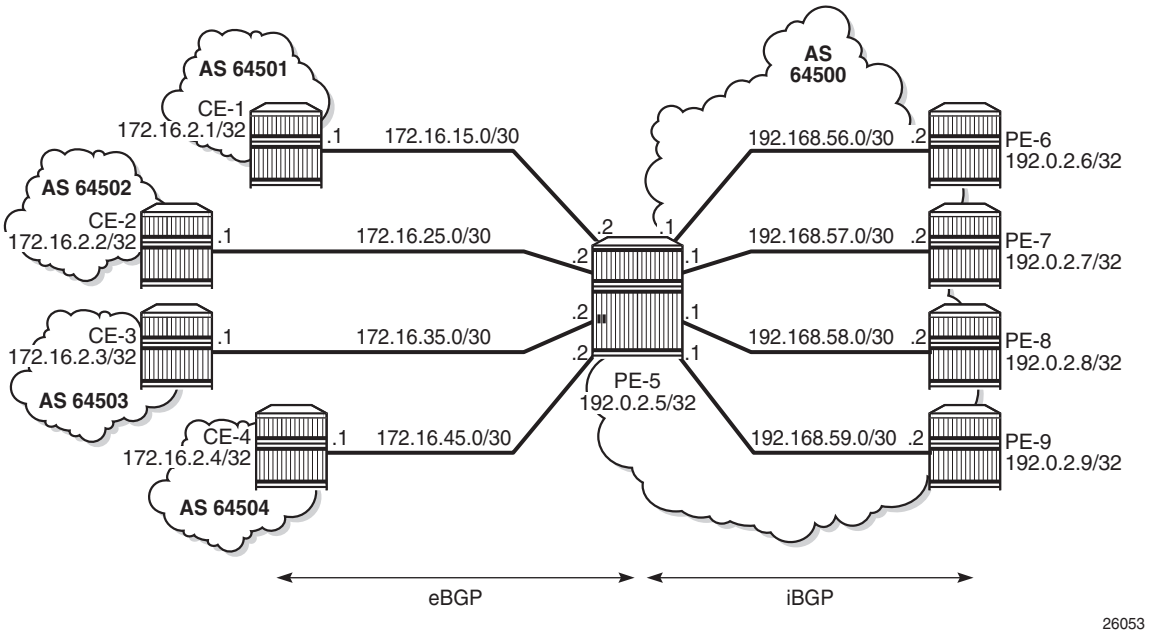
```
*A:PE-5# configure router bgp multipath
  - multipath <max-paths> [ebgp <ebgp-max-paths>] [ibgp <ibgp-max-paths>] [restrict
    {same-neighbor-as|exact-as-path}]
  - no multipath

 <max-paths>          : [1..16]
 <ebgp-max-paths>     : [1..16]
 <ibgp-max-paths>     : [1..16]
```

2. The **ebgp-ibgp-equal** command is added to the **best-path-selection** contexts in base router and VPRN BGP contexts. When this command is configured, as follows, the BGP decision process skips the step that prefers eBGP over iBGP. This enables load-balancing between eBGP and iBGP paths. The earlier **eibgp-loadbalance** command, from previous releases, can still be used, but it is only applicable in a VPRN, not in the base router.

```
*A:PE-5# configure router bgp best-path-selection
  - best-path-selection

 [no] always-compare* - Determine how the Multi-Exit Discriminator (MED) path
                        attribute is used in the BGP route selection process
 [no] as-path-ignore  - Determine whether the AS Path is used in determining the
                        best BGP route
 [no] compare-origin* - Enable/Disable compare validation state
 [no] deterministic-* - Enable/Disable deterministic Multi-Exit Discriminator
 [no] ebgp-ibgp-equal - Determine whether EBGP and IBGP learned paths are
                        considered equal
 [no] ignore-nh-metr* - Enable/Disable ignore next-hop metric
 [no] ignore-router-* - Enable/Disable ignore router-id
 [no] origin-invalid* - Enable/Disable origin invalid unusable routes.
```



The **eibgp-loadbalance** command in a VPRN is used to provide ECMP over BGP-VPN (imported routes) and BGP routes. It is called eibgp-loadbalance because, in such scenarios, BGP-VPN is typically used between iBGP peers and BGP is used between eBGP peers. However, this is not always the case, so the name can be misleading.

Configuration

The examples in this section show the BGP configuration in the base router. For BGP multipath in a VPRN, the configuration is similar.

Figure 59 shows the example configuration with the used IP addresses. PE-5 has eBGP sessions with CEs in different autonomous systems (ASs) and iBGP sessions with PE-6, PE-7, PE-8, and PE-9.

Figure 59 **Example Topology**

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS in AS 64500
- LDP in AS 64500

- BGP on all nodes (eBGP between CEs and PE-5; iBGP between PEs)
- Export policy "export-bgp" accepting routes from protocol direct on all nodes

The BGP configuration on CE-1 is as follows:

```
configure
    router
        autonomous-system 64501
        bgp
            min-route-advertisement 1
            group "eBGP"
                export "export-bgp"
                peer-as 64500
                neighbor 172.16.15.2
                exit
            exit
        exit
    exit
exit
```

The BGP configuration on the other nodes that advertise routes to PE-5 is similar.

The BGP configuration on PE-5 is as follows:

```
configure
    router
        autonomous-system 64500
        bgp
            min-route-advertisement 1
            group "eBGP"
                neighbor 172.16.15.1
                    peer-as 64501
                exit
                neighbor 172.16.25.1
                    peer-as 64502
                exit
                neighbor 172.16.35.1
                    peer-as 64503
                exit
                neighbor 172.16.45.1
                    peer-as 64504
                exit
            exit
            group "iBGP"
                peer-as 64500
                neighbor 192.0.2.6
                exit
                neighbor 192.0.2.7
                exit
                neighbor 192.0.2.8
                exit
                neighbor 192.0.2.9
                exit
            exit
        exit
    exit
```

```
exit
```

The following will be configured and verified:

- BGP multipath with different limits for eBGP and iBGP paths
- BGP multipath with equal treatment for eBGP and iBGP paths
- BGP multipath restricted to the same neighbor AS
- BGP multipath restricted to the exact AS path
- EIBGP load-balancing in a VPRN

BGP Multipath with Different eBGP and iBGP Limits

On PE-5, BGP multipath is configured as follows:

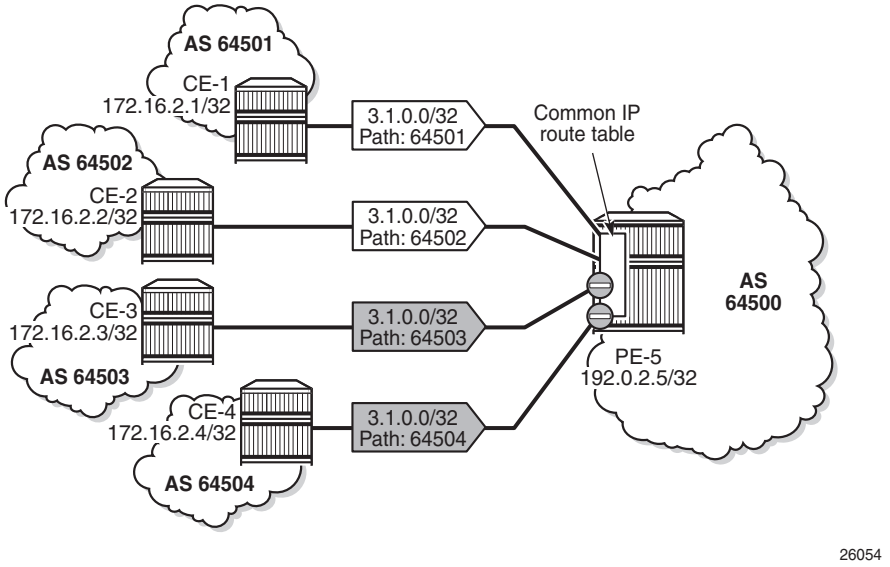
```
*A:PE-5# configure router bgp multipath 8 ebgp 2 ibgp 3
```

It is mandatory to specify a maximum for BGP multipaths, as follows, but that is overruled by the individual limits for eBGP and iBGP. It is optional to configure limits for eBGP and iBGP.

```
*A:PE-5# configure router bgp multipath ebgp 2 ibgp 3
                                        ^
Error: Missing parameter
```

It is allowed to specify a lower value for multipath than for either eBGP or iBGP, as follows:

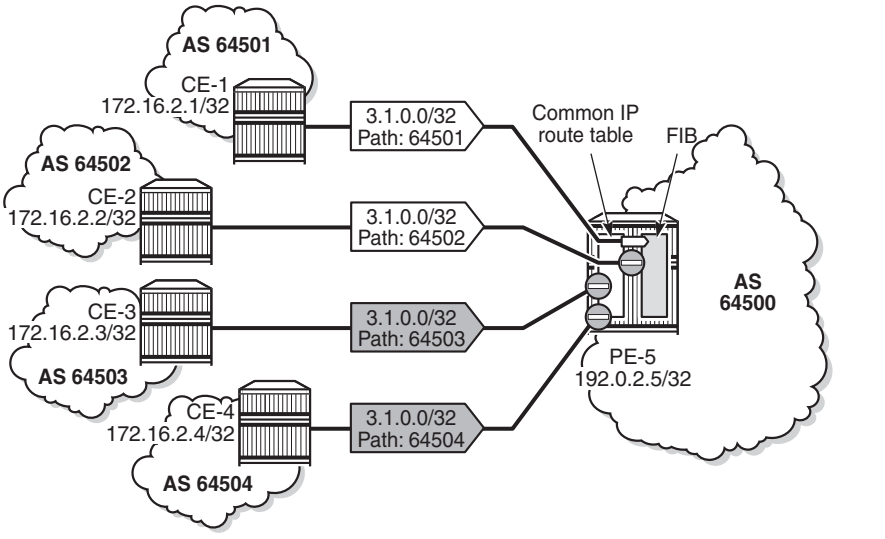
```
*A:PE-5# configure router bgp multipath 1 ebgp 2 ibgp 3
```



With this configuration, regardless of the value of multipath, there can be two eBGP routes for the same prefix and three iBGP routes for the same prefix. If the best route is eBGP, the multipath value is 2; if the best route is iBGP, the multipath value is 3. The value for multipath (1) is never used when limits for both eBGP and iBGP are configured.

```
*A:PE-5# configure router bgp multipath 3 ebgp 2
```

If the best route is eBGP, the multipath value is 2, and if the best route is iBGP, the multipath value is 3.



In this example, all four eBGP neighbors advertise prefix 3.1.0.0/32 to PE-5 and all four iBGP neighbors advertise prefix 3.2.0.0/32 to PE-5. PE-5 receives four eBGP routes for prefix 3.1.0.0/32, but only two will be added to the common IP route table, as shown in Figure 60.

Figure 60 **BGP Multipath with eBGP Limit 2**

These routes can only be added to the FIB if ECMP is configured to a value at least equal to the number of routes allowed in BGP multipath. By default, ECMP is disabled and only one route is added to the FIB, as shown in Figure 61.

Figure 61 **eBGP Multipath with Limit 2 and ECMP Disabled**

With ECMP disabled, only one of the four paths is active for prefix 3.1.0.0/32, as follows:

```
*A:PE-5# show router bgp routes 3.1.0.0/32

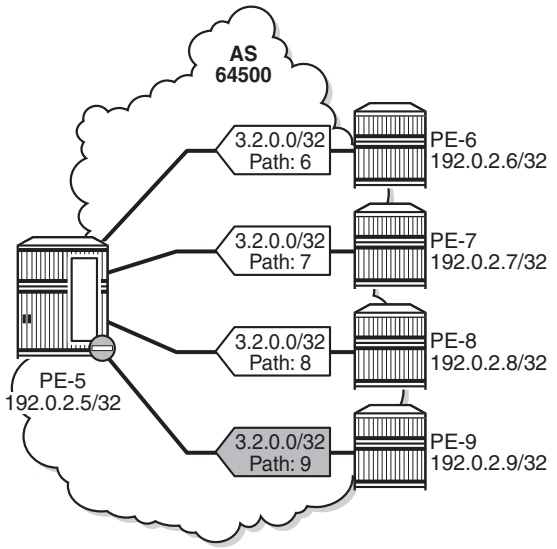
      172.16.45.1                                          None        -
      64504
-------------------------------------------------------------------------------
Routes : 4
```

In the remainder of the chapter, ECMP will be configured with a value of eight, implying that the routes added to the common IP route table will be added to the FIB as well. ECMP is configured on PE-5 as follows:

```
*A:PE-5# configure router ecmp 8
```

With ECMP configured with a limit of eight, two eBGP paths are active for prefix 3.1.0.0/32.

The first two of the following BGP routes for prefix 3.1.0.0/32 are used on PE-5:



```
*A:PE-5# show router bgp routes 3.1.0.0/32
===============================================================================
 BGP Router ID:192.0.2.5        AS:64500       Local AS:64500
===============================================================================

      64504
-------------------------------------------------------------------------------
Routes : 4
```

The four iBGP neighbors of PE-5 advertise prefix 3.2.0.0/32 to PE-5. BGP multipath has a limit of three for iBGP routes. Consequently, three BGP routes will be added to the common IP route table and to the FIB, as shown in Figure 62.

Figure 62 **BGP Multipath with iBGP Limit 3 and ECMP Limit 8**

Three iBGP paths are active for prefix 3.2.0.0/32, as follows:

```
*A:PE-5# show router bgp routes 3.2.0.0/32
===============================================================================
 BGP Router ID:192.0.2.5        AS:64500       Local AS:64500
```

```

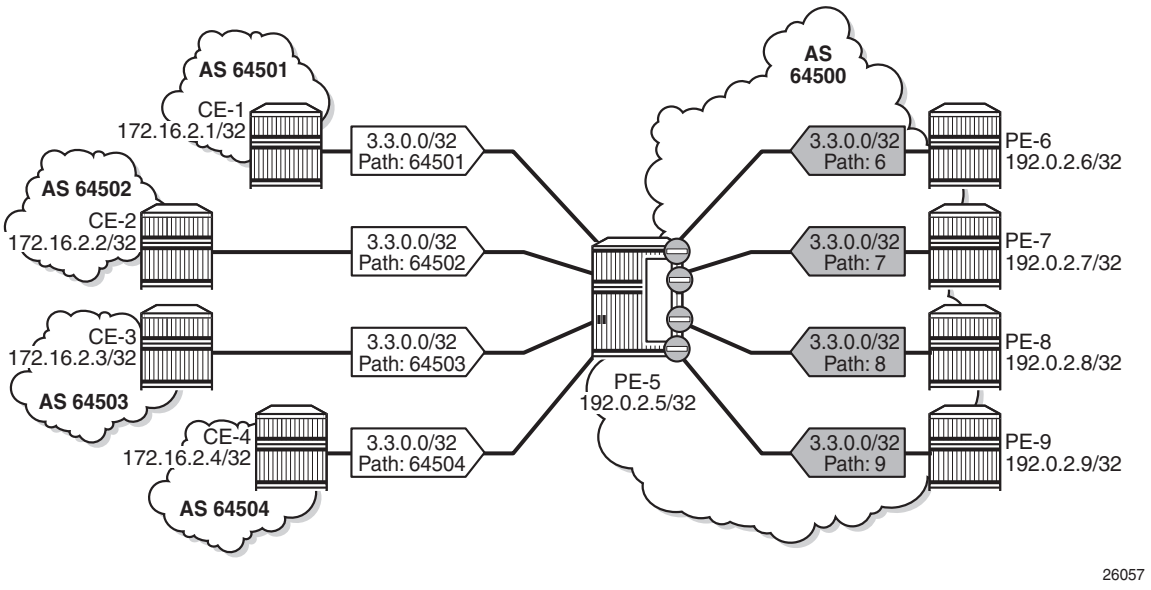
```



BGP Multipath with eBGP Equal to iBGP

It is optional to specify limits for eBGP and iBGP; an overall multipath limitation is sufficient, such as:

```
*A:PE-5# configure router bgp multipath 6
```

With this configuration, there can be six routes for the same prefix. These routes can be eBGP or iBGP routes. By default, eBGP routes are preferred and, therefore, only the four eBGP routes will be imported in the common IP route table, as shown in Figure 63.

Figure 63 **BGP Multipath with Limit 6 and eBGP Preferred**

Only the four eBGP paths are active, as follows:

```
*A:PE-5# show router bgp routes 3.3.0.0/32
===============================================================================

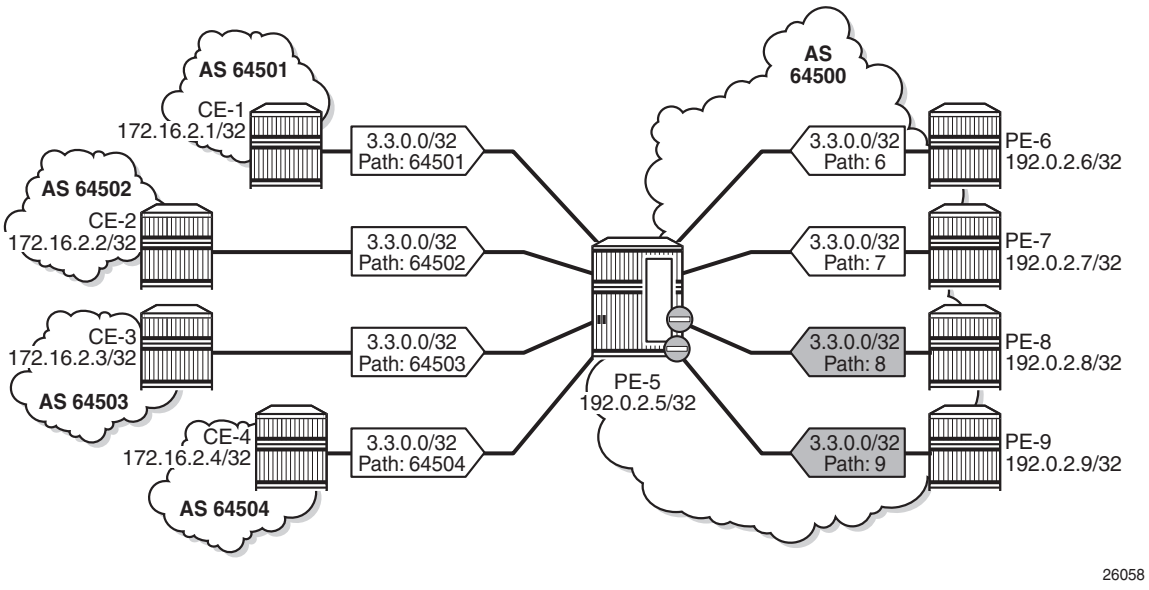
      9
-------------------------------------------------------------------------------
Routes : 8
```

The BGP decision process prefers eBGP over iBGP, but this step can be skipped by configuring the following:

```
*A:PE-5# configure router bgp best-path-selection ebgp-ibgp-equal ipv4
```



This configuration only skips one step in the BGP decision process. If the best route is still eBGP, the eBGP multipath limit applies; if the best route is iBGP, the iBGP multipath limit applies.

Optionally, other best path selection criteria can also be configured, such as ignore-nh-metric, as follows:

```
*A:PE-5# configure router bgp best-path-selection ignore-nh-metric
```

However, when all other path options are identical (such as local preference, MED, IGP cost, and other criteria from the BGP decision process), or when the best-path-selection is configured to ignore specific path options, and the only differentiator is an originator ID, the remaining steps in the BGP decision process do not exclude any routes. In that case, six of the eight eligible BGP paths will be included in the BGP multipath, as shown in Figure 64.

Figure 64 **BGP Multipath with Limit 6, eBGP Equal to iBGP, and Other Path Options Identical**

From the eight advertised BGP routes for prefix 3.3.0.0/32, six paths will be active, as follows:

```
*A:PE-5# show router bgp routes 3.3.0.0/32

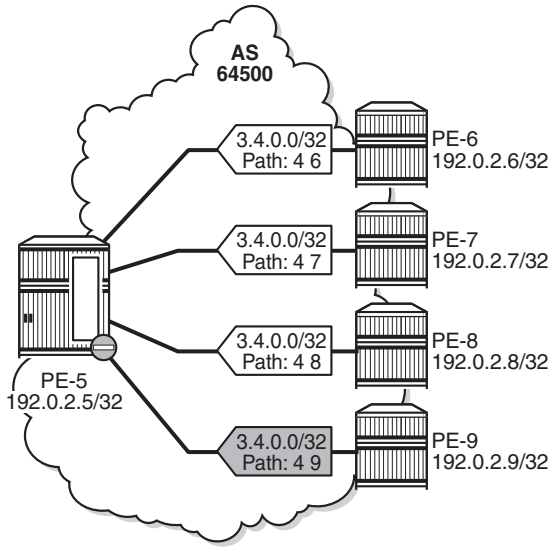
BGP Multipath Restricted to the Same Neighbor AS

BGP multipath can be configured with the restriction that the neighbor AS must be the same for all the active paths. When all routes have a different neighbor AS, only one path will be active. This can be shown for prefix 3.2.0.0/32 that is advertised by the iBGP neighbors. The BGP multipath configuration on PE-5 is as follows:

```
*A:PE-5# configure router bgp multipath 8 ebgp 2 ibgp 3 restrict same-neighbor-as
```

Figure 65 shows that with the restriction to the same neighbor AS, only one path is active because all BGP routes have a different neighbor AS.

Figure 65 **BGP Multipath Configured with Restriction to the Same Neighbor AS**



Only one BGP path will be active, because all the other routes have a different neighbor AS, as follows:

```
*A:PE-5# show router bgp routes 3.2.0.0/32
===============================================================================
 BGP Router ID:192.0.2.5        AS:64500       Local AS:64500

Routes : 4
```

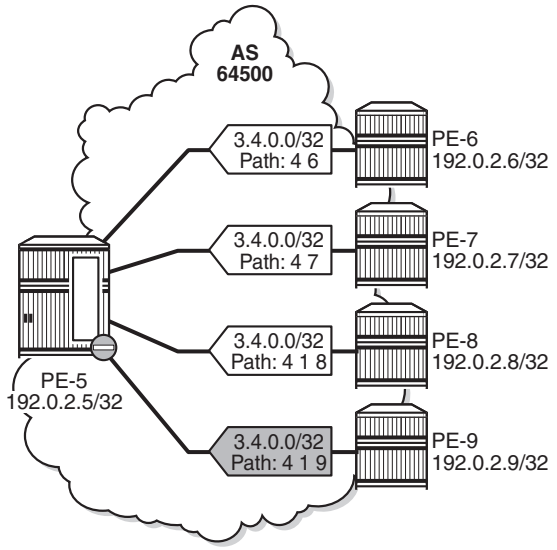
The restriction that the neighbor AS must be the same does not overrule the BGP selection criterion that the shorter AS path is preferred. When the AS path is longer for the routes advertised by neighbors 192.0.2.8 and 192.0.2.9, only the BGP paths with the shorter AS path will be active, as shown in Figure 67.

Figure 67 **BGP Multipath Restricted to the Same Neighbor AS: AS Paths of Different Lengths**

All BGP routes advertised by the iBGP neighbors have the same neighbor AS, but the AS path is longer for neighbors 192.0.2.8 and 192.0.2.9. The routes advertised by these neighbors will not be selected as best path and will not be added to the route table. Only the two BGP routes with the shorter AS path will be active, as follows:



```
*A:PE-5# show router bgp routes 3.4.0.0/32

-------------------------------------------------------------------------------
Routes : 4
```

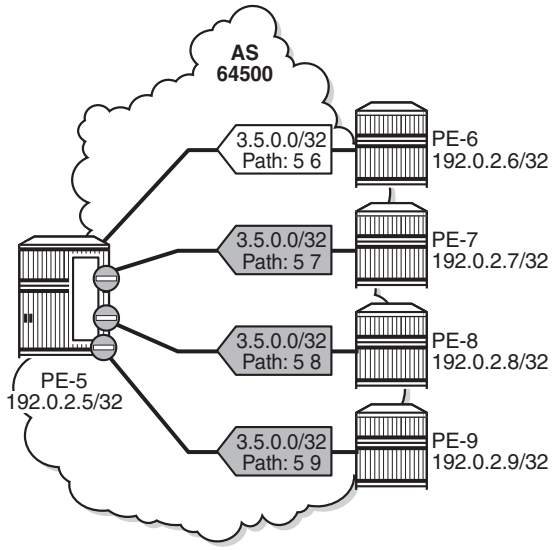
The best selection path settings are restored as follows:

```
*A:PE-5# configure router bgp best-path-selection no as-path-ignore
```

BGP Multipath Restricted to the Exact AS Path



The BGP multipath configuration on PE-5 restricts BGP to only use identical AS paths, as follows:

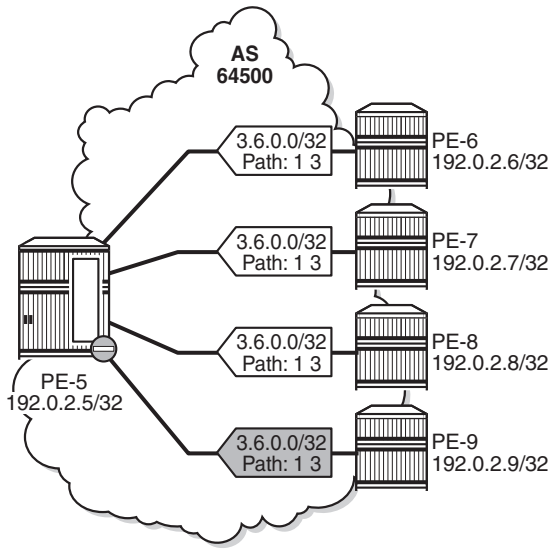
```
*A:PE-5# configure router bgp multipath 8 ebgp 2 ibgp 3 restrict exact-as-path
```

The four iBGP neighbors advertise prefixes 3.5.0.0/32 and 3.6.0.0/32 to PE-5, see Figure 11 and Figure 12. The AS paths for prefix 3.5.0.0/32 are not identical, but the neighbor AS is the same, and the AS path is of equal length. The AS paths for prefix 3.6.0.0/32 are identical.

The BGP multipath configuration specifies that the AS paths must be identical, which is not the case for the received BGP routes for prefix 3.5.0.0/32. Only one BGP route will be imported in the route table, as shown in Figure 69.

Figure 69 **BGP Multipath Restricted to Exact Same AS. All AS Paths are Different.**

All the BGP routes for prefix 3.5.0.0/32 have a different AS path. Only the BGP route advertised by neighbor 192.0.2.6 will be active, as follows:



```
*A:PE-5# show router bgp routes 3.5.0.0/32
===============================================================================
 BGP Router ID:192.0.2.5        AS:64500       Local AS:64500
===============================================================================

```

EIBGP Load-Balancing in a VPRN

The **eibgp-loadbalance** command is used to perform ECMP over BGP-VPN (imported routes) and BGP routes, not to make eBGP routes equal to iBGP routes. Typically, BGP-VPN routes are used between iBGP peers and BGP routes are used between eBGP peers. This explains the naming of the command, but it can be misleading. Not all BGP-VPN routes are iBGP routes and not all BGP routes are eBGP routes. Four different types of routes are received by PE-5 in the following example:

- two BGP routes learned from eBGP peers CE-1 and CE-2
- two BGP-VPN routes learned from eBGP peers CE-3 and CE-4
- two BGP routes learned from iBGP peers PE-6 and PE-7
- two BGP-VPN routes learned from iBGP peers PE-8 and PE-9

VPRN 1 is configured on all nodes. On PE-5, ECMP must be configured in this VPRN to a value of 8, as follows:

```
*A:PE-5# configure service vprn 1 ecmp 8
```

In this example, the best path selection criteria will be such that iBGP routes are treated as equal to eBGP routes, as explained in section BGP Multipath with eBGP Equal to iBGP. This is configured for BGP routes and for VPN-BGP routes, as follows:

```
*A:PE-5# configure router bgp best-path-selection ebgp-ibgp-equal vpn-ipv4
*A:PE-5# configure service vprn 1 bgp best-path-selection ebgp-ibgp-equal ipv4
```

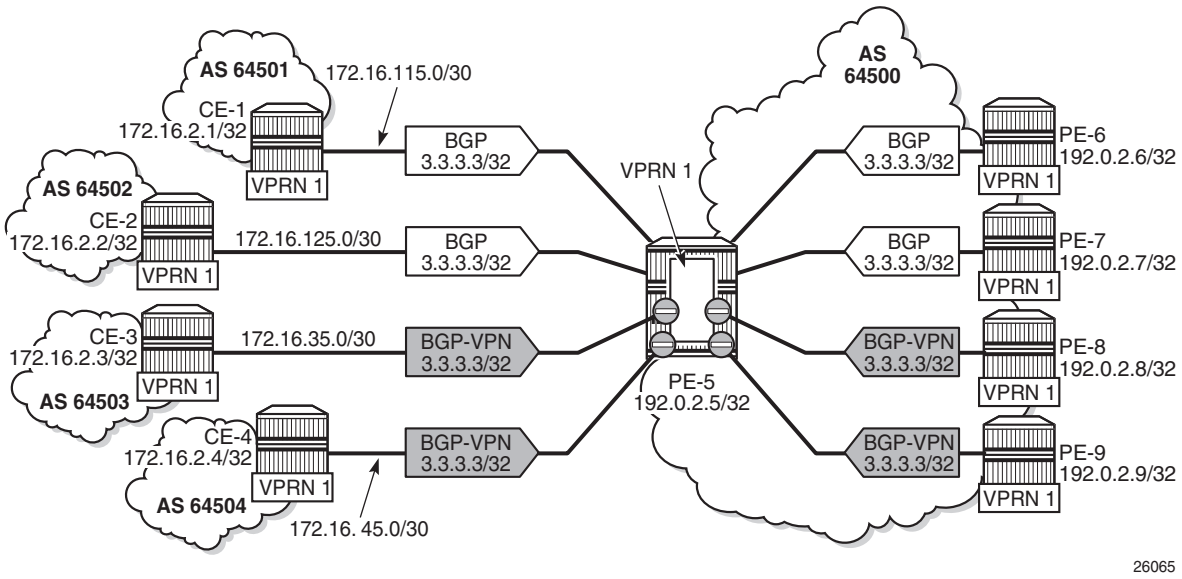
Optionally, other best path selection criteria can also be configured, such as ignore-nh-metric and as-path-ignore, as follows:

```
*A:PE-5# configure router bgp best-path-selection as-path-ignore vpn-ipv4
*A:PE-5# configure service vprn 1 bgp best-path-selection as-path-ignore ipv4

*A:PE-5# configure router bgp best-path-selection ignore-nh-metric
*A:PE-5# configure service vprn 1 bgp best-path-selection ignore-nh-metric
```

BGP multipath is configured with an eBGP multipath limit of 4 and an iBGP multipath limit of 4, as follows:

```
*A:PE-5# configure service vprn 1 bgp multipath 4 ebgp 4 ibgp 4
```



The **eibgp-loadbalance** command is not configured yet. By default, the BGP decision process prefers BGP routes over BGP-VPN routes, and therefore, the routing table only contains BGP routes and no BGP-VPN routes, as follows:

```
*A:PE-5# show router 1 route-table 3.3.3.3/32
===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
3.3.3.3/32                                      Remote  BGP       00h01m11s  170
       172.16.115.1                                               0
3.3.3.3/32                                      Remote  BGP       00h01m11s  170
       172.16.125.1                                               0
3.3.3.3/32                                      Remote  BGP       00h01m11s  170
       192.168.156.2                                              0
3.3.3.3/32                                      Remote  BGP       00h01m11s  170
       192.168.157.2                                              0
-------------------------------------------------------------------------------
No. of Routes: 4
```

The first two routes in this routing table are eBGP routes learned from CE-1 and CE-2. The latter two routes are iBGP routes learned from PE-6 and PE-7. EBGP routes and iBGP routes are treated as equal, but BGP routes are still preferred to BGP-VPN routes.

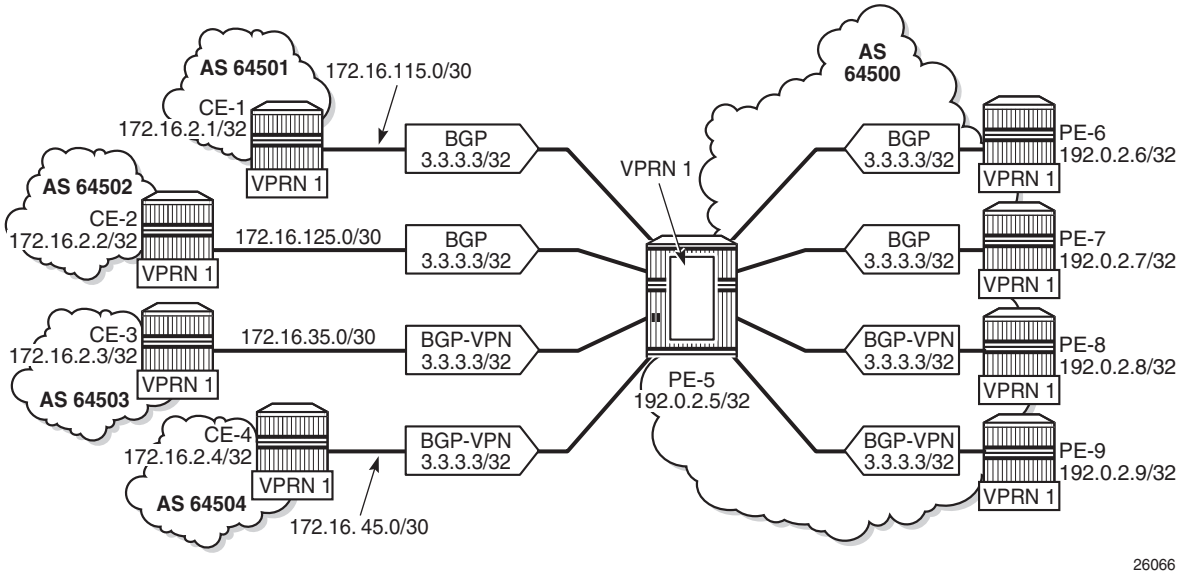
Figure 71 shows that the BGP routes are preferred. Even though it is allowed to have a maximum of four eBGP routes and four iBGP routes, only two eBGP routes are included and only two iBGP routes are included. No BGP-VPN routes are used, as follows.

Figure 71 **EBGP Equal to IBGP: No EIBGP Load-Balancing**

BGP-VPN routes will be treated equally to BGP routes after configuring the following command:

```
*A:PE-5# configure service vprn 1 bgp eibgp-loadbalance
```

When BGP-VPN routes are treated equal to BGP routes, the routing table for prefix 3.3.3.3/32 contains eight entries, as follows:



```
*A:PE-5# show router 1 route-table 3.3.3.3/32
===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age         Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
3.3.3.3/32                                      Remote  BGP VPN   00h00m04s  170
       172.16.35.1 (tunneled)                                          0
3.3.3.3/32                                      Remote  BGP VPN   00h00m04s  170
       172.16.45.1 (tunneled)                                          0
3.3.3.3/32                                      Remote  BGP       00h00m04s  170
       172.16.115.1                                                    0
3.3.3.3/32                                      Remote  BGP       00h00m04s  170
       172.16.125.1                                                    0
3.3.3.3/32                                      Remote  BGP VPN   00h00m04s  170
       192.0.2.8 (tunneled)                                            0
3.3.3.3/32                                      Remote  BGP VPN   00h00m04s  170
       192.0.2.9 (tunneled)                                            0
3.3.3.3/32                                      Remote  BGP       00h00m04s  170
       192.168.156.2                                                   0
3.3.3.3/32                                      Remote  BGP       00h00m04s  170
       192.168.157.2                                                   0
```

```
-------------------------------------------------------------------------------
No. of Routes: 8
```

The first two BGP-VPN entries are eBGP routes learned from CE-3 and CE-4 and the other two BGP-VPN entries are iBGP routes learned from PE-8 and PE-9.

Figure 72 shows that when EIBGP load-balancing is configured, the BGP-VPN routes are equal to the BGP routes. All other selection criteria are also equal in this example and all eight routes are used in the routing table, as follows.

Figure 72 **EBGP Equal to IBGP: EIBGP Load-Balancing Enabled**

This example shows that the **eibgp-loadbalance** command can be used in combination with **best-path-selection ebgp-ibgp-equal**, because their scope is different.

Conclusion

BGP multipath allows the IP routing table to have multiple BGP paths to the same destination. Different path limits can be applied for eBGP and iBGP paths. It is possible to treat eBGP and iBGP routes as equal. Restrictions can be imposed related to AS path.

BGP Route Leaking

This chapter provides information about BGP route leaking.

Topics in this chapter include:

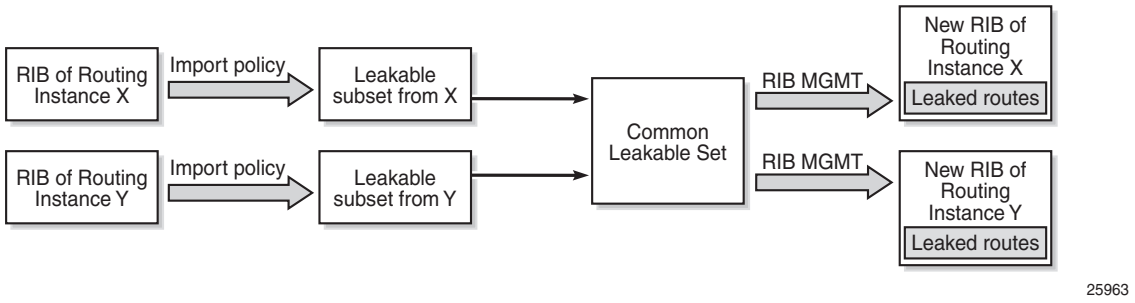
- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R4.

Overview

Route leaking refers to the process of copying a route from one router context to another.



Network administrators may need to leak routes between routing instances in the same SR OS router. BGP route leaking is an alternative to using import/export policies based on communities to exchange routes between virtual router and forwarders (VRFs).

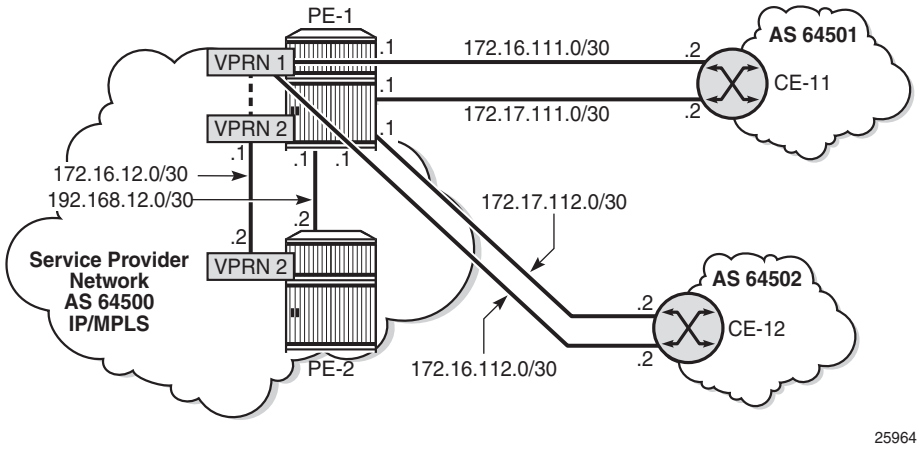
It is possible to leak a copy of a BGP route (including all its path attributes) from one routing instance to another in the same SR OS router. This BGP route leaking capability applies to IPv4, IPv6, and label-IPv4 routes. Leaking is supported from the GRT to a VPRN, from one VPRN to another VPRN, and from a VPRN to the GRT. Any valid BGP route for an IPv4 or IPv6 prefix can be leaked. A BGP route does not have to be the best path or used for forwarding in the source instance in order to be leaked, but it does have to be valid (that is, the next-hop must be resolved; the AS PATH must not exhibit a loop, for example).

An IPv4 or IPv6 BGP route becomes a candidate for leaking to another instance when it is specially marked by a BGP import policy. This special marking is achieved by accepting the route with a **bgp-leak** action in the route policy. Routes that are candidates for leaking to other instances show a **leakable** flag in the output of various show router bgp commands.

To copy a leakable BGP route from a source instance into the BGP RIB of a target instance, the target instance must be configured with a leak-import policy that matches and accepts the leakable route. There are separate leak-import policies for IPv4 and IPv6 routes. Up to 15 leak-import policies can be chained together for more complex examples. In the target instance, the **show router bgp routes** command displays leaked BGP RIB-IN routes in addition to direct RIB-IN routes learned from neighbors of the routing instance. A **leaked** flag is added to the leaked RIB-IN entries. Figure 73shows the process of BGP route leaking.

Figure 73 **BGP Route Leaking Process**

Leaked BGP routes can be advertised to BGP neighbors (peers) of the target routing instance. The BGP next hop of a leaked route is automatically reset to self whenever it is advertised to a peer of the target instance. Normal route advertisement rules apply: by default, the leaked route is advertised if it is the overall best path that is used as the active route to the destination and it is not blocked by the IBGP-to-IBGP split-horizon rule.



A BGP route leaked into a VPRN can be exported from the VPRN as a VPN-IPv4/v6 route if it matches the VRF export policy. Normal VPN export rules apply: by default, the leaked route is exported if it is the overall best path and it is used as the active route to the destination.

This chapter describes BGP route leaking only. For other routes, such as IS-IS, OSPF, RIP, and static routes, VPRN route leaking mechanisms apply that are protocol independent, see chapter Traffic Leaking from VPRN to GRT.

Configuration

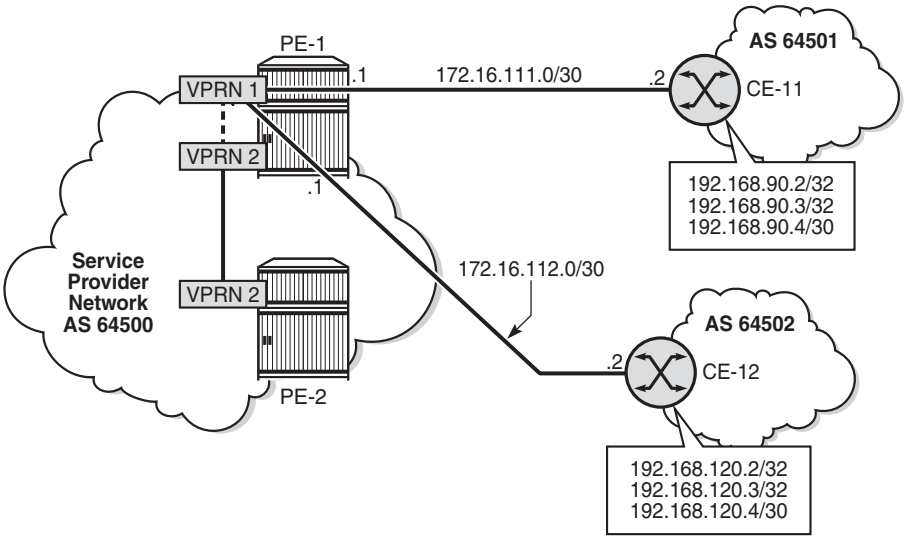
Figure 74 shows the example topology used in this chapter, including the IPv4 addresses. For each of the examples, a dedicated figure will show the specific topology, which is a subset of the topology in Figure 2. The interfaces also have IPv6 addresses, which will be shown in Figure 6 and Figure 7. VPRN 2 also has CEs attached, but for simplicity, these are not shown on the figures and no CLI will be shown for any CE.

Figure 74 **Example Topology**

The following examples will be explained:

- Example 1 - BGP IPv4 Route Leaking between VPRNs. Global BGP Policy
- Example 2 - BGP IPv4 Route Leaking between VPRNs per Neighbor
- Example 3 - BGP IPv4 Route Leaking from VPRN to GRT per BGP Group
- Example 4 - BGP IPv4 Route Leaking from GRT to VPRN per Neighbor
- Example 5 - BGP IPv6 Route Leaking between VPRNs. Global VPRN BGP Configuration
- Example 6 - BGP IPv6 Route Leaking from GRT to VPRN and from VPRN to VPRN

Initial Configuration



The nodes in the example topology have the following initial configuration:

- Cards, MDAs, ports
- Router interfaces
- IGP (IS-IS or OSPF) between the PEs
- LDP between the PEs
- VPRN 1 on PE-1; VPRN 2 on PE-1 and PE-2
- BGP (IBGP between the PEs; EBGP between PE-1 and the CEs)
  - On the PEs, BGP is configured in the base router and in the VPRNs.
- Loopback addresses and black-hole static routes in the CEs. Different routes are exported to GRT and VPRN 1 on PE-1

Example 1 - BGP IPv4 Route Leaking between VPRNs. Global BGP Policy

Figure 75 shows the topology for this example. CE-11 exports routes such as 192.168.90.2/32 to VPRN 1 on PE-1, and CE-12 exports routes such as 192.168.120.2/32 to VPRN 1 on PE-1.

Figure 75 **BGP IPv4 Route Leaking Between VPRNs**

BGP leaking is disabled by default. The routing table for VPRN 1 on PE-1 includes routes that are learned from CE-11 and CE-12, as shown:

```
*A:PE-1# show router 1 route-table
```

```
===============================================================================

       system                                                        0
172.16.12.0/30                                Local   Local     00h47m19s  0
       int-PE-1-PE-2_VPN2                                            0
-------------------------------------------------------------------------------
No. of Routes: 2
```

To configure BGP route leaking, an import policy is required in VPRN 1. The BGP route leaking policy is configured on PE-1, as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-Leak-Policy"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

By adding the action accept **bgp-leak**, BGP routes are imported and marked as BGP leakable, meaning they are available to be copied - with their complete set of BGP path attributes - to the BGP RIB-IN of another routing instance.

The BGP route leaking policy can be applied in VPRN 1 in the general BGP configuration (as is the case here), in the group context, or per neighbor:

```
configure
    service
        vprn 1
            bgp
                import "BGP-Leak-Policy"
            exit
        exit
    exit
exit
```

With the preceding configuration, SR OS is marking all the BGP routes imported into the VPRN as leakable. The BGP routes originate from CE-11 or CE-12 in this example.

The following command shows which BGP routes in VPRN 1 are marked as leakable:

```
*A:PE-1# show router 1 bgp routes ipv4 leakable
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
```

```

Res. Nexthop   : 172.16.111.2
---snip---
```

```
Flags          : Used  Valid  Best  IGP  Leakable
Route Source   : External
---snip---
```

BGP leakable routes can be imported into another VPRN. Prefix lists can be used to filter specific routes for BGP leaking, but that is not configured in this example. The following import policy is configured on PE-1 to import BGP leakable routes:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

In each of the examples, the same import policy will be used. The import policy to import BGP leakable routes is applied in the VPRN 2 on PE-1 as follows:

```
configure
    service
        vprn 2
            bgp
                rib-management
                    ipv4
                        leak-import "Import-Leakable-Routes"
                    exit
                exit
            exit
        exit
    exit
exit
```

The following command shows that VPRN 2 imported leaked BGP routes from VPRN 1. The status code "l" indicates that the route is leaked.

```
*A:PE-1# show router 2 bgp routes ipv4 leaked

       S = Sticky ECMP requested
===============================================================================
*A:PE-2#
```

Example 2 - BGP IPv4 Route Leaking between VPRNs per Neighbor

The topology used for this example is the same as for Example 1; see Figure 75. Both CEs export the same routes as in the preceding example, and the BGP route leaking policy is identical:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-Leak-Policy"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

In the preceding example, the BGP route leaking policy was applied in the global BGP context in VPRN 1 and consequently, it applied to routes from all neighbors. In this example, the BGP route leaking policy is applied in VPRN 1 for neighbor CE-11 only, as follows:

```
configure
    service
        vprn 1
            bgp
                group "EBGP_64500to64501_IPv4"
                    neighbor 172.16.111.2
                        import "BGP-Leak-Policy"
                    exit
                exit
            exit
        exit
    exit
exit
```

This import policy implies that only routes learned from CE-11 will be leakable. The following command shows all the BGP routes learned in VPRN 1 on PE-1. Not all of these are leakable.

```
*A:PE-1# show router 1 bgp routes

 Origin codes  : i - IGP, e - EGP, ? - incomplete
===============================================================================
BGP IPv4 Routes
===============================================================================
Flag  Network                                           LocalPref   MED
      Nexthop (Router)                                  Path-Id     Label
      As-Path
-------------------------------------------------------------------------------
u*>i  192.168.90.2/32                                   None        None
      172.16.111.2                                      None        -
      64501
u*>i  192.168.90.3/32                                   None        None
      172.16.111.2                                      None        -
      64501
u*>?  192.168.90.4/30                                   None        None
```

```
      172.16.111.2                                          None        -
      64501
-------------------------------------------------------------------------------
Routes : 3
===============================================================================
*A:PE-1#
```

The BGP leakable routes can be imported into another VPRN instance. The import policy is the same as for Example 1:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This import policy is applied in VPRN 2 in the same way as in Example 1:

```
configure
    service
        vprn 2
            bgp
                rib-management
                    ipv4
                        leak-import "Import-Leakable-Routes"
                    exit
                exit
            exit
        exit
    exit
exit
```

The following command shows the leaked routes in VPRN 2. Each of these routes is leaked from VPRN 1, as indicated between brackets in the following output. Only routes learned from CE-11 in VPRN 1 are leaked to VPRN 2.

```
*A:PE-1# show router 2 bgp routes ipv4 leaked
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete
===============================================================================
BGP IPv4 Routes
===============================================================================
```

```
Flag  Network                                                 LocalPref   MED
      Nexthop (Router)                                        Path-Id     Label
      As-Path
-------------------------------------------------------------------------------
u*>li 192.168.90.2/32                                       100         None
      172.16.111.2 (VPRN 1)                                 None        -
      64501

Example 3 - BGP IPv4 Route Leaking from VPRN to GRT per BGP Group

Figure 76 shows the topology for this example. CE-11 and CE-12 export the same routes to VPRN 1. These routes will be marked as leakable and leaked to the GRT.

Figure 76 **BGP IPv4 Route Leaking from VPRN to GRT**

The routing table for VPRN 1 in PE-1 contains the BGP routes exported by CE-11 and CE-12, as follows:

```
*A:PE-1# show router 1 route-table
===============================================================================
Route Table (Service: 1)
===============================================================================
Dest Prefix[Flags]                                Type    Proto     Age        Pref
      Next Hop[Interface Name]                                        Metric
-------------------------------------------------------------------------------
172.16.1.1/32                                     Local   Local     01h03m55s  0
       system                                                          0
172.16.111.0/30                                   Local   Local     01h03m55s  0
       int-PE-1-CE-11                                                  0
172.16.112.0/30                                   Local   Local     01h03m55s  0
       int-PE-1-CE-12                                                  0
192.168.90.2/32                                   Remote  BGP       00h00m34s  170
       172.16.111.2                                                    0
192.168.90.3/32                                   Remote  BGP       00h00m34s  170
       172.16.111.2                                                    0
192.168.90.4/30                                   Remote  BGP       00h00m34s  170
       172.16.111.2                                                    0
192.168.120.2/32                                  Remote  BGP       00h32m53s  170
       172.16.112.2                                                    0
192.168.120.3/32                                  Remote  BGP       00h32m53s  170
       172.16.112.2                                                    0
192.168.120.4/32                                  Remote  BGP       00h32m53s  170
       172.16.112.2                                                    0
-------------------------------------------------------------------------------
No. of Routes: 9
```

The routing table of the base router does not include any of the BGP routes exported by the CEs, as follows:

```
*A:PE-1# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
172.17.111.0/30                                 Local   Local     01h16m32s  0
       int-PE-1-CE-11                                               0
172.17.112.0/30                                 Local   Local     01h16m32s  0
       int-PE-1-CE-12                                               0
192.0.2.1/32                                    Local   Local     01h16m32s  0
       system                                                       0
192.0.2.2/32                                    Remote  ISIS      01h16m14s  15
       192.168.12.2                                                 10
192.168.12.0/30                                 Local   Local     01h16m32s  0
       int-PE-1-PE-2                                                0
-------------------------------------------------------------------------------
No. of Routes: 5
```

The BGP routes are marked as leakable after applying the following configuration:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-Leak-Policy"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

This BGP route leaking policy can be applied in the general BGP configuration of VPRN 1, or per BGP group (as is the case here), or per BGP neighbor:

```
configure
    service
        vprn 1
            bgp
                group "EBGP_64500to64501_IPv4"
                    import "BGP-Leak-Policy"
                exit
            exit
        exit
    exit
exit
```

The following command shows the leakable BGP routes in VPRN 1:

```
*A:PE-1# show router 1 bgp routes ipv4 leakable
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500

      64501
-------------------------------------------------------------------------------
Routes : 3
===============================================================================
*A:PE-1#
```

The leakable BGP routes in VPRN 1 can be imported into the GRT. The import policy is identical to the import policy in the preceding examples, as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This import policy is applied in the base router, as follows:

```
configure
    router
        bgp
            rib-management
                ipv4
                    leak-import "Import-Leakable-Routes"
```

```
            exit
          exit
        exit
    exit
exit
```

As a result, the leakable BGP routes in VPRN 1 are leaked to the GRT, as follows:

```
*A:PE-1# show router bgp routes ipv4 leaked
===============================================================================

-------------------------------------------------------------------------------
No. of Routes: 6
```

Example 4 - BGP IPv4 Route Leaking from GRT to VPRN per Neighbor

Figure 77 shows the topology for this example, and the corresponding IP addresses. CE-11 exports routes such as 192.168.100.2/32 to the base router and CE-12 exports routes such as 192.168.121.2/32 to the base router. The routes will be leaked from the base router to VPRN 2.

Figure 77 **BGP IPv4 Route Leaking from GRT to VPRN**

The GRT in PE-1 includes BGP routes learned from CE-11 and CE-12, as follows:

```
*A:PE-1# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                                Type    Proto     Age        Pref
      Next Hop[Interface Name]                                       Metric
-------------------------------------------------------------------------------

       192.168.12.2                                                   10
192.168.12.0/30                                   Local   Local     01h14m10s  0
       int-PE-1-PE-2                                                  0
192.168.100.102/32                                Remote  BGP       00h02m37s  170
```

```
       172.17.111.2                                                    0
192.168.100.103/32                          Remote  BGP       00h02m37s  170
       172.17.111.2                                                    0
192.168.100.104/30                          Remote  BGP       00h02m37s  170
       172.17.111.2                                                    0
192.168.121.2/32                            Remote  BGP       00h12m52s  170
       172.17.112.2                                                    0
192.168.121.3/32                            Remote  BGP       00h12m52s  170
       172.17.112.2                                                    0
192.168.121.4/30                            Remote  BGP       00h12m52s  170
       172.17.112.2                                                    0
-------------------------------------------------------------------------------
No. of Routes: 11
```

The BGP leaking policy is the same as in the preceding examples:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-Leak-Policy"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

The BGP route leaking policy is applied on the base router for neighbor CE-11 only, as follows:

```
configure
    router
        bgp
            group "EBGP_64500to64501_IPv4"
                neighbor 172.17.111.2
                    import "BGP-Leak-Policy"
                exit
            exit
        exit
    exit
exit
```

The following command shows that only the routes imported from neighbor CE-11 are marked as leakable in the GRT:

```
*A:PE-1# show router bgp routes ipv4 leakable
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500

      64501
-------------------------------------------------------------------------------
Routes : 3
===============================================================================
*A:PE-1#
```

The leakable BGP routes in the GRT can be imported into VPRN 2. The import policy is identical to the import policy in the preceding examples, as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This import policy is applied in VPRN 2, as follows:

```
configure
    service
        vprn 2
            bgp
                rib-management
                    ipv4
                        leak-import "Import-Leakable-Routes"
                    exit
                exit
            exit
        exit
    exit
exit
```

The following command shows the imported leaked BGP routes in VPRN 2. The source of these leaked routes is the base router, not a VPRN.

```
*A:PE-1# show router 2 bgp routes ipv4 leaked
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================

Example 5 - BGP IPv6 Route Leaking between VPRNs. Global VPRN BGP Configuration

Figure 6 shows the topology and the IP addresses used for this example. CE-11 exports routes such as 2001:db8:90::2/128 to VPRN 1 on PE-1, and CE-12 exports routes such as 2001:db8:120::2/128 to VPRN 1 on PE-1.

Figure 78 **BGP IPv6 Route Leaking between VPRNs**

```
*A:PE-1# show router 1 route-table ipv6

       int-PE-1-CE-11                                                0
2001:db8:112::/127                              Local   Local     01h41m55s  0
       int-PE-1-CE-12                                                0
2001:db8:120::2/128                             Remote  BGP       00h02m05s  170
       2001:db8:112::1                                               0
2001:db8:120::3/128                             Remote  BGP       00h02m05s  170
```

```
       2001:db8:112::1                                                  0
2001:db8:120::4/126                          Remote  BGP       00h02m05s  170
       2001:db8:112::1                                                  0
-------------------------------------------------------------------------------
No. of Routes: 9
```

The BGP route leaking policy is the same as for IPv4 routes:

```
configure
    router
        policy-options
            begin
            policy-statement "BGP-Leak-Policy"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

This import policy is applied in the BGP context of VPRN 1, as follows:

```
configure
    service
        vprn 1
            bgp
                import "BGP-Leak-Policy"
            exit
        exit
    exit
exit
```

With the preceding configuration, all the routes imported into the VPRN using BGP are marked as leakable.

The following command shows which BGP IPv6 routes are marked as leakable in VPRN 1:

```
*A:PE-1# show router 1 bgp routes ipv6 leakable
===============================================================================

      64502
u*>?  2001:db8:120::4/126                                 None        None
      2001:db8:112::1                                     None        -
      64502
-------------------------------------------------------------------------------
Routes : 6
===============================================================================
*A:PE-1#
```

The BGP leakable routes can be imported into VPRN 2 when the following import policy is configured and applied in VPRN 2:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The only difference from IPv4 routes is that the policy is applied to the IPv6 context of the RIB management:

```
configure
    service
        vprn 2
            bgp
                rib-management
                    ipv6
                        leak-import "Import-Leakable-Routes"
                    exit
                exit
            exit
        exit
```

```
    exit
exit
```

The following command shows that the VPRN is importing the leaked BGP IPv6 routes from another VPRN instance:

```
*A:PE-1# show router 2 bgp routes ipv6 leaked
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================

Example 6 - BGP IPv6 Route Leaking from GRT to VPRN and from VPRN to VPRN

Figure 7 shows the topology and the IPv6 addresses used in this example. CE-11 exports IPv6 routes such as 2001:db8:90::2/128 to VPRN 1 and IPv6 routes such as 2001:db8:100::2/128 to the GRT. CE-12 exports IPv6 routes such as 2001:db8:120::2/128 to VPRN 1 and IPv6 routes such as 2001:db8:121::2/128 to the GRT.

Figure 79 **BGP IPv6 Route Leaking from GRT and VPRN to VPRN**

The IPv6 routing table in the GRT contains routes exported by CE-11 and CE-12, as follows:

```
*A:PE-1# show router route-table ipv6
===============================================================================
```

```
IPv6 Route Table (Router: Base)
===============================================================================

       int-PE-1-CE-11                                                0
2001:db8:112::/127                              Local   Local     00h12m14s  0
       int-PE-1-CE-12                                                0
2001:db8:120::2/128                             Remote  BGP       00h11m12s  170
       2001:db8:112::1                                               0
2001:db8:120::3/128                             Remote  BGP       00h11m12s  170
       2001:db8:112::1                                               0
2001:db8:120::4/126                             Remote  BGP       00h11m12s  170
       2001:db8:112::1                                               0
```

```
-------------------------------------------------------------------------------
No. of Routes: 9
```

The policy to mark imported BGP routes as leakable can be identical to the policy used in the preceding examples. However, in this case, prefix-lists are added as a filter. The base router may accept routes such as 2001:db8:100::2/128 and 2001:db8:121::2/128.

```
configure
    router
        policy-options
            begin
            prefix-list "2001:db8:90::"
                prefix 2001:db8:90::/100 longer
            exit
            prefix-list "2001:db8:120::"
                prefix 2001:db8:120::/100 longer
            exit
            policy-statement "BGP-Leak-Policy_90_120"
                entry 10
                    from
                        protocol bgp
                        prefix-list "2001:db8:90::"
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
                entry 20
                    from
                        protocol bgp
                        prefix-list "2001:db8:120::"
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

This import policy is applied in the general BGP settings for VPRN 1, as follows:

```
configure
    service
        vprn 1
            bgp
                import "BGP-Leak-Policy_90_120"
            exit
        exit
    exit
exit
```

In a similar way, the base router may accept routes such as 2001:8db:100::2/128 and 2001:8db:121::2/128:

```
configure
    router
        policy-options
            begin
            prefix-list "2001:db8:100::"
                prefix 2001:db8:100::/100 longer
            exit
            prefix-list "2001:db8:121::"
                prefix 2001:db8:121::/100 longer
            exit
            policy-statement "BGP-Leak-Policy_100_121"
                entry 10
                    from
                        protocol bgp
                        prefix-list "2001:db8:100::"
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
                entry 20
                    from
                        protocol bgp
                        prefix-list "2001:db8:121::"
                    exit
                    action accept
                        bgp-leak
                    exit
                exit
            exit
            commit
```

This BGP leaking policy is applied for neighbor CE-11 in the base router, as follows. The routes exported by CE-12 will not be marked as leakable.

```
configure
    router
        bgp
            group "EBGP_64500to64501_IPv6"
                neighbor 2001:db8:17:111::1
                    import "BGP-Leak-Policy_100_121"
                exit
            exit
        exit
    exit
exit
```

The following command shows which routes are marked as leakable in the GRT:

```
*A:PE-1# show router bgp routes ipv6 leakable
===============================================================================

-------------------------------------------------------------------------------
Routes : 6===============================================================================
```

```
=====
*A:PE-1#
```

On PE-1, a policy is created to import the BGP leakable routes (the same as in the preceding examples), as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "Import-Leakable-Routes"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This import policy is configured for IPv6 routes in VPRN2, as follows:

```
configure
    service
        vprn 2
            bgp
                rib-management
                    ipv6
                        leak-import "Import-Leakable-Routes"
                    exit
                exit
            exit
        exit
    exit
exit
```

The following command shows the leaked IPv6 routes in VPRN 2:

```
*A:PE-1# show router 2 bgp routes ipv6 leaked
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500

Conclusion

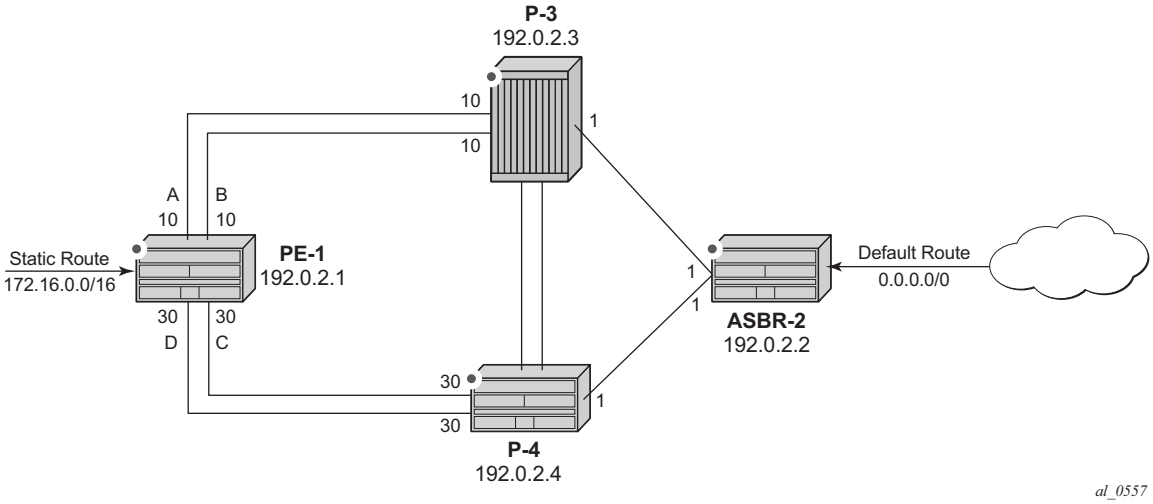
BGP provides many ways to manipulate routes. In this example, IPv4/IPv6 routes learned from BGP neighbors could be marked as "leakable" and imported into other routing instances (VPRN to VPRN, VPRN to GRT, GRT to VPRN) without the use of communities in the network policy.

IS-IS Link Bundling

This chapter provides information about IS-IS link bundling.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion



Applicability

The chapter was initially written for SR OS release 11.0.R6. However, the CLI in the current edition is based on release 14.0.R5.

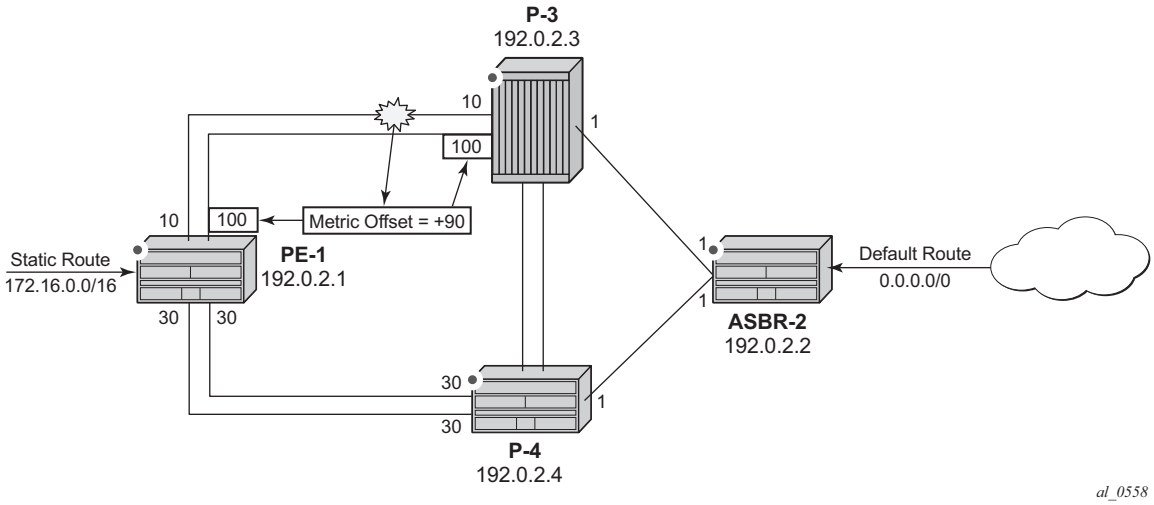
Overview

Intermediate System to Intermediate System (IS-IS) Link Bundling allows for the grouping of a number of IS-IS interfaces into a single virtual link, called an IS-IS link group. It is used in conjunction with Equal Cost Multipath (ECMP) to dynamically change the metric of parallel IS-IS links if one or more links fail or suffer some sort of performance degradation.

Figure 80 **Link Bundle Schematic**

Consider the network in Figure 80, where a Provider Edge router PE-1 connects to a core network comprised of two Provider (P) routers and a single Autonomous System Border Router (ASBR). The links between PE-1 and P-3, and PE-1 and P-4 are 10 Gigabit Ethernet links. The links between ASBR-2 and P-3 and P-4 are both 100 Gigabit links. The link metrics are as shown in Figure 80.

In order to maximize the use of link bandwidth, ECMP is enabled on all routers and set to a value of 2, so that IP traffic flowing between PE1 and P-3, and PE-1 and P-4, is load balanced across the two links.



A default route is injected into the ASBR-2 router and re-distributed via a policy statement into IS-IS, so that traffic flowing from PE-1 to the ASBR is resolved by this route. Traffic flows between PE-1 and ASBR-2, using the path with the lowest IS-IS metric, via P-3 with a metric of 11. The second path PE-1 to ASBR-2 via P-4 has the same bandwidth, but a higher IS-IS metric of 31.

Traffic in the reverse direction flows toward a user subnet described by a static route configured on PE-1, which is redistributed into IS-IS using a policy statement. Once again, the shortest path between ASBR-2 and PE-1 is via P-3, so the bi-directional traffic flow is symmetric.

If one of the links between PE-1 and P-3 fails, traffic still flows via P-3, because the IS-IS metric is unchanged, but this now has less bandwidth than the second path via P-4. It is desirable to make use of the additional bandwidth of the second path, but this requires a change in metric. This can be achieved using IS-IS link bundling.

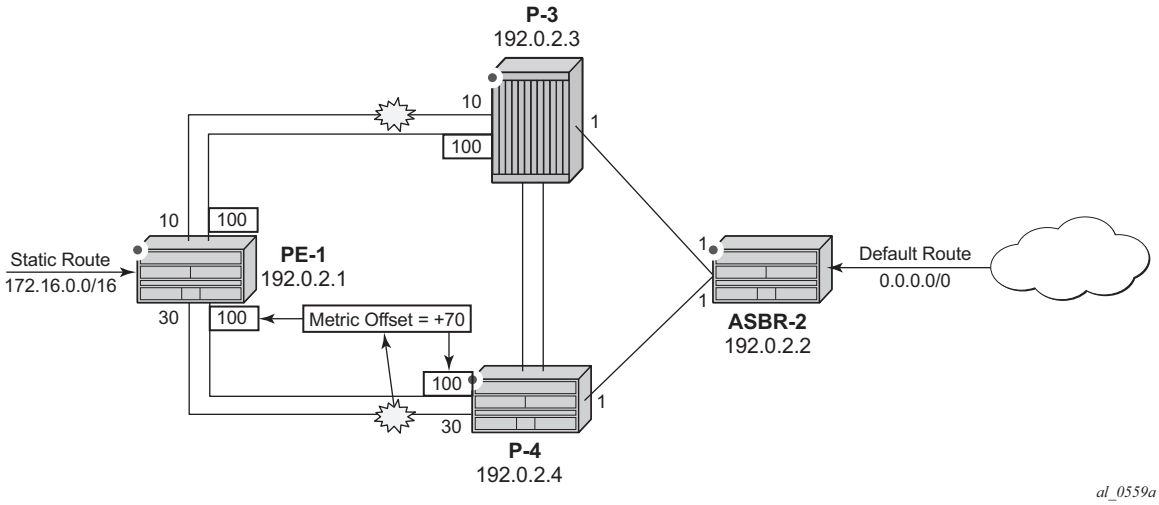
IS-IS link bundling allows for the creation of a group of IS-IS links, where the failure of a member link allows the metric of the remaining members of the link group to be increased by an offset value.

Figure 81 **Effect of Single Link Failure on Bundle Group**

Using Figure 81 as an example, the links between PE-1 and P-3 are included in a bundle group. To illustrate the change in metrics, a default static route is configured on ASBR-2 and re-distributed into IS-IS, and the path to this route is monitored at PE-1. Similarly, a static route to subnet 172.16.0.0/16 is configured on PE-1 and redistributed into IS-IS and viewed on ASBR-2.

Should one of the links between PE-1 and P-3 fail, the metric of the remaining members can be increased by an offset, for example 90, so that the metric of the remaining link becomes 10+90 = 100. The IS-IS metric between PE-1 and ASBR-2 via P-3 is now 101. The metric offset is applied to each remaining IS-IS interface individually and is advertised within the IS-IS database as the default cost in the TE-IS neighbors Type Length Variable (TLV).

The path between PE-1 and ASBR-2 via P-4 now has the lowest IS-IS metric, and any affected routers within the IS-IS area will try and re-route the traffic based on the new metric.



The fundamentals of this feature are:

- The treatment of all member links in a link group bundle as a single virtual interface.
- The increase in metric by a specific offset value of each remaining individual link within the group when a failure of one or more links occurs.

– The application of the offset occurs when the number of active links drops below a configured threshold.
– The offset is removed when the number of active links within the link group bundle reaches the configured reversion threshold.
– A link bundle is required on a router for the thresholds and offsets to apply.

Consider a second and subsequent failure where a link between PE-1 and P-4 also fails, so that there is only one active IS-IS interface between PE-1 and each of its neighboring P routers. This is shown in Figure 82.

Figure 82 **Double Link Failure**

In this case, the metric for the remaining link between PE-1 and P-4 can be increased by an offset value of +70 so that the IS-IS metric PE-1 to P-4 becomes 100, the same as that between PE-1 and P-3 when a link has failed.

PE-1 now sees two equal cost paths to the default route – one via P-3 and one via P-4, so there are still two 10Gigabit Ethernet links across which the traffic can be load shared.

This can be summarized using the following table, where ABCD are the 4 links as per Figure 80 and link status is Up (U) or Down (D).

Table 4 **Status of the links A, B, C, and D**

ABCD Status	A (metric,status)	B (metric,status)	C (metric,status)	D (metric,status)
UUUU	10 Transmit	10 Transmit	30 Idle	30 Idle
UDUU	100 Idle	Down	30 Transmit	30 Transmit

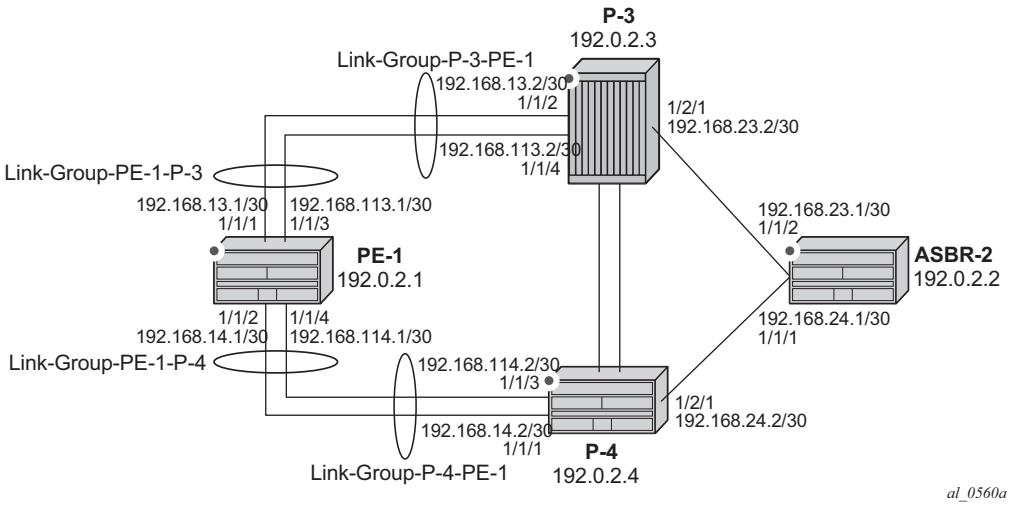


Table 4 **Status of the links A, B, C, and D**

ABCD Status	A (metric,status)	B (metric,status)	C (metric,status)	D (metric,status)
UDUD	100 Transmit	Down	100 Transmit	Down
UUUD	10 Transmit	10 Transmit	100 Idle	Down

Configuration

The example topology is shown in Figure 83.

Figure 83 **Example Topology**

The PE-1 router configuration commands are as follows.

```
*A:PE-1# configure
    router
        interface "int-PE-1-P-3-1"
            address 192.168.13.1/30
            port 1/1/1
        exit
        interface "int-PE-1-P-3-2"
            address 192.168.113.1/30
            port 1/1/3
        exit
        interface "int-PE-1-P-4-1"
            address 192.168.14.1/30
            port 1/1/2
        exit
```

```
        interface "int-PE-1-P-4-2"
            address 192.168.114.1/30
            port 1/1/4
        exit
        interface "system"
            address 192.0.2.1/32
        exit
        ecmp 2
```

The IP router configuration for the remaining routers can be derived from Figure 83.

The IS-IS network is a level 1 network.

The IS-IS configuration for PE-1, including the interface metrics is as follows:

```
*A:PE-1# configure
    router
        isis
            level-capability level-1
            area-id 49.0001
            advertise-passive-only
            level 1
                wide-metrics-only
            exit
            interface "system"
                passive
            exit
            interface "int-PE-1-P-3-1"
                interface-type point-to-point
                level 1
                    metric 10
                exit
            exit
            interface "int-PE-1-P-3-2"
                interface-type point-to-point
                level 1
                    metric 10
                exit
            exit
            interface "int-PE-1-P-4-1"
                interface-type point-to-point
                level 1
                    metric 30
                exit
            exit
            interface "int-PE-1-P-4-2"
                interface-type point-to-point
                level 1
                    metric 30
                exit
            exit
```

The IS-IS configuration for the remaining routers can be derived from Figure 83.

The following configuration is for the static route and export policy on ASBR-2. The configuration of the static route on PE-1 is similar.

```
*A:ASBR-2# configure router static-route-entry 0.0.0.0/0 black-hole no shutdown

*A:ASBR-2# configure router
        policy-options
            begin
            policy-statement "STATIC-ISIS"
                entry 10
                    from
                        protocol static
                    exit
                    to
                        level 1
                    exit
                    action accept
                        metric set igp
                    exit
                exit
            exit
            commit
        exit

*A:ASBR-2# configure router isis export "STATIC-ISIS"
```

Link Group Configuration

PE-1 contains 2 link groups. The first link group contains the IS-IS interfaces toward P-3. The second contains the interfaces toward P-4.

Each link-group is configured using a unique name, which is unique per router, and the IS-IS interface names are configured within the group as group members.

The metric offset value is the amount by which the IS-IS metric of active member links are increased when the number of links drops below a configured threshold.

The IS-IS link group configuration for PE-1 for the interfaces toward P-3 is as follows:

```
*A:PE-1# configure
    router
        isis
            link-group "Link-Group-PE-1-P-3"
                level 1
                    ipv4-unicast-metric-offset 90
                    member "int-PE-1-P-3-1"
                    member "int-PE-1-P-3-2"
                    revert-members 2
                    oper-members 2
                exit
            exit
        exit
```

Similarly, the IS-IS link group for PE-1 for the interfaces toward P-4 is:

```
*A:PE-1# configure
    router
        isis
            link-group "Link-Group-PE-1-P-4"
                level 1
                    ipv4-unicast-metric-offset 70
                    member "int-PE-1-P-4-1"
                    member "int-PE-1-P-4-2"
                    revert-members 2
                    oper-members 2
                exit
            exit
        exit
```

Within the link-group, two thresholds are configured:

- oper-members threshold
- revert-members threshold

If the number of operational links in the link-group drops below the oper-members value, then all interfaces associated with that IS-IS link group have their interface metric increased by the configured offset value. As a result, IS-IS then tries to reroute traffic over lower cost paths.

If the number of operational links in the link-group equals the revert-members threshold value, then all interfaces associated with that IS-IS link group have their interface metric decreased by the configured offset value.

In this configuration, there is a requirement to increase the metric of each interface within a link-group when a single interface fails. This means that the oper-members value is set to 2. In normal working circumstances, when both interfaces are active, the metric used is the configured interface metric. This means that the revert-members value must also be set to 2.

It is not possible to set the oper-members threshold to a value higher than that of the revert-members.

For completeness, the IS-IS configuration of each P-router is as follows.

P-3

```
*A:P-3# configure
    router
        isis
            level-capability level-1
            area-id 49.0001
            advertise-passive-only
            level 1
                wide-metrics-only
            exit
            interface "system"
                passive
```

```
            exit
            interface "int-P-3-PE-1-1"
                interface-type point-to-point
                level 1
                    metric 10
                exit
            exit
            interface "int-P-3-PE-1-2"
                interface-type point-to-point
                level 1
                    metric 10
                exit
            exit
            interface "int-P-3-ASBR-2"
                interface-type point-to-point
                level 1
                    metric 1
                exit
            exit
            link-group "Link-Group-P-3-PE-1"
                level 1
                    ipv4-unicast-metric-offset 90
                    member "int-P-3-PE-1-1"
                    member "int-P-3-PE-1-2"
                    revert-members 2
                    oper-members 2
                exit
            exit
        exit
```

P-4

```
*A:P-4# configure
    router
        isis
            level-capability level-1
            area-id 49.0001
            advertise-passive-only
            level 1
                wide-metrics-only
            exit
            interface "system"
                passive
            exit
            interface "int-P-4-PE-1-1"
                interface-type point-to-point
                level 1
                    metric 30
                exit
            exit
            interface "int-P-4-PE-1-2"
                interface-type point-to-point
                level 1
                    metric 30
                exit
            exit
            interface "int-P-4-ASBR-2"
                interface-type point-to-point
```

```
            level 1
                metric 1
            exit
        exit
        link-group "Link-Group-P-4-PE-1"
            level 1
                ipv4-unicast-metric-offset 70
                member "int-P-4-PE-1-1"
                member "int-P-4-PE-1-2"
                revert-members 2
                oper-members 2
            exit
        exit
    exit
```

An overview of all of the link groups can be shown using the following commands, in this case on node PE-1.

The link group status is as follows:

```
*A:PE-1# show router isis link-group-status
===============================================================================
Router Base ISIS Instance 0 Link-Group Status
===============================================================================
Link-group              Mbrs   Oper   Revert Active Level   State
                               Mbr     Mbr    Mbr
-------------------------------------------------------------------------------
Link-Group-PE-1-P-3     2      2      2      2      L1      normal
Link-Group-PE-1-P-4     2      2      2      2      L1      normal
===============================================================================
*A:PE-1#
```

The output for the individual link group members is as follows:

For "Link-Group-PE-1-P-3" at PE-1:

```
*A:PE-1# show router isis link-group-member-status level 1 "Link-Group-PE-1-P-3"
===============================================================================
Router Base ISIS Instance 0 Link-Group Member
===============================================================================
Link-group            I/F name               Level      State
-------------------------------------------------------------------------------
Link-Group-PE-1-P-3   int-PE-1-P-3-1         L1         Up
Link-Group-PE-1-P-3   int-PE-1-P-3-2         L1         Up
-------------------------------------------------------------------------------
Legend: BER = bitErrorRate
===============================================================================
*A:PE-1#
```

For "Link-Group-PE-1-P-4" at PE-1:

```
*A:PE-1# show router isis link-group-member-status level 1 "Link-Group-PE-1-P-4"
===============================================================================
Router Base ISIS Instance 0 Link-Group Member
===============================================================================
```

```
Link-group            I/F name                Level      State
-------------------------------------------------------------------------------
Link-Group-PE-1-P-4   int-PE-1-P-4-1          L1         Up
Link-Group-PE-1-P-4   int-PE-1-P-4-2          L1         Up
-------------------------------------------------------------------------------
Legend: BER = bitErrorRate
===============================================================================
*A:PE-1#
```

For P-3, the link group status is as follows:

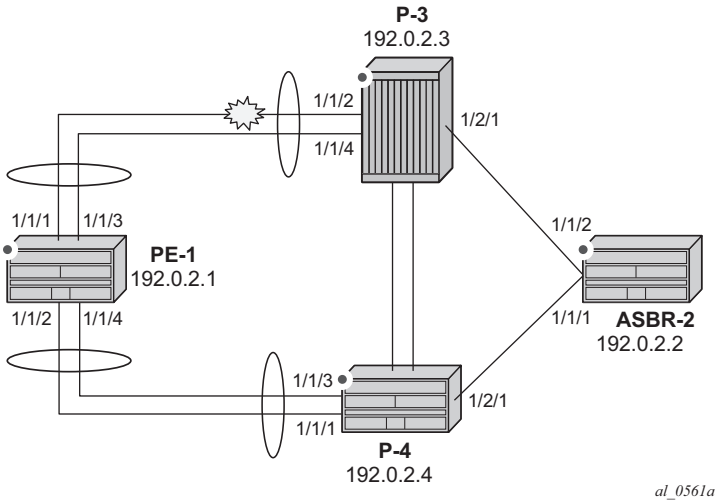
```
*A:P-3# show router isis link-group-status
===============================================================================
Router Base ISIS Instance 0 Link-Group Status
===============================================================================
Link-group              Mbrs   Oper   Revert Active Level   State
                               Mbr     Mbr    Mbr
-------------------------------------------------------------------------------
Link-Group-P-3-PE-1     2      2      2      2      L1      normal
===============================================================================
*A:P-3#
```

For P-3, the link group member status is as follows:

```
*A:P-3# show router isis link-group-member-status level 1 "Link-Group-P-3-PE-1"
===============================================================================
Router Base ISIS Instance 0 Link-Group Member
===============================================================================
Link-group            I/F name                Level      State
-------------------------------------------------------------------------------
Link-Group-P-3-PE-1   int-P-3-PE-1-1          L1         Up
Link-Group-P-3-PE-1   int-P-3-PE-1-2          L1         Up
-------------------------------------------------------------------------------
Legend: BER = bitErrorRate
===============================================================================
*A:P-3#
```

Routing Table PE-1

In a normal working state, the routing table for PE-1 contains the default route for forwarding traffic toward ASBR-2. Because ECMP is set to a value of 2, two entries are available with next-hops pointing toward P-3, as follows. The metric for each path is 11.



```
*A:PE-1# show router route-table 0.0.0.0/0

===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
0.0.0.0/0                                       Remote  ISIS      00h02m27s  15
       192.168.13.2                                                    11

Failure of link member PE-1 to P-3

Figure 84 **Link Failure**

One of the links between PE-1 and P-3 is put into a failed state by shutting down port 1/1/2 on P-3, as per Figure 84.

```
*A:P-3# configure port 1/1/2 shutdown
```

The route-table on PE-1 shows that the metric for the default route prefix, 0.0.0.0/0, has increased from 11 to 31, and the next-hops are now interface addresses on P-4, as follows:

```
A:PE-1# show router route-table 0.0.0.0/0
===============================================================================

Conclusion

IS-IS link bundling allows service providers to configure multiple IS-IS interfaces as a single link group for ECMP purposes and allow link metric increases if an interface within the bundle group fails. This example provides the configuration for IS-IS link bundling, together with the associated commands and outputs which can be used for verifying and troubleshooting.

Policy Chaining and Logical Expressions

This chapter provides information about policy statement chaining and logical expressions.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R4. In SR OS releases earlier than 14.0.R1, only policy chaining was supported. SR OS release 14.0.R1 introduced support for route policy logical expressions using the logical operators AND, OR, and NOT. The **action drop** replaces the **action reject** in SR OS release 14.0.R4, and later.

Overview

Multiple policies can be chained together for sequential evaluation. For more complex evaluation logic, logical expressions (with operators AND, OR, and NOT) can be used. A logical expression can be included in a larger policy chain. Route policy logical expressions are supported in the following contexts:

- BGP export
- BGP import
- BGP leak-import (RIB leaking)
- VRF import
- VRF export
- GRT export (GRT leaking)

Table 5 shows a comparison between examples of policy chaining and policy logical expressions.

Table 5 **Policy Chaining Versus Policy Logical Expressions**

Policy chaining example	Policy logical expressions example
configure router bgp import "A" "B" "C"	configure router bgp import "[A] OR [B]"
For each route, policy A is evaluated first. • If policy A matches the route with **action next-policy**, then apply any route modifications and continue to evaluate policy B, and so on. • When the route is matched in a policy with **action accept** or **drop/reject**, the evaluation is completed.	Several logical operators can be used. This example shows an OR relationship between policy A and policy B. For each route, policy A is evaluated first. A true/false result is determined for policy A: • If true, the logical expression with operator OR is true already, and the evaluation is completed. • If false, then policy B is evaluated to determine the final true/false result. The final result is mapped back to a policy action (**accept**, **next-policy**, and so on).

Note: In SR OS release 14.0.R4, and later, the **action drop** replaces the **action reject**. The difference is that with **action drop**, it is possible to modify attributes in the same way as for **action accept**. This behavior is useful when a NOT operation makes a false expression true and the attributes are required. In a similar way, it is possible that an OR operation is true, even though the first policies that were evaluated were false. Routes are accepted when the final result is true and all policies that were evaluated will modify the route attributes. Examples of this behavior are included in the Configuration section.

To configure policy chaining - which may or may not include a policy logical expression - the syntax is the following:

```
*A:PE-1# configure router bgp export
  - export <plcy-or-long-expr> [<plcy-or-expr> [<plcy-or-expr>...(upto 14 max)]]
  - no export
```

```
<plcy-or-long-expr>  : <policy-name> | <long-expr>
                       <policy-name>  - [64 chars max]
                       <long-expr>    - [255 chars max]
<plcy-or-expr>       : <policy-name> | <expr>
                       <policy-name>  - [64 chars max]
                       <expr>         - [64 chars max]
```

A policy chain is 15 policies at maximum, one of which can be a logical expression. A logical expression in the policy chain can contain a maximum of 16 policies and can be anywhere in the command: the first operand can contain up to 255 characters, while the remaining operands can contain a maximum of 64 characters.

Policies in a logical expression need to be enclosed in square brackets. Like single policies, the logical expression can be enclosed in double quotes or not, as follows:

```
*A:PE-1# configure router bgp import [C]AND[A] "B"
*A:PE-1# configure router bgp import "[C]AND[A]" "B"
```

The logical expression can be anywhere in the policy chain, as follows:

```
*A:PE-1# configure router bgp import "B" [C]AND[A]
```

When quotes are used, spaces are allowed in the logical expression, as follows:

```
*A:PE-1# configure router bgp import "[A] AND [B]"
```

Without quotes, the logical operators are interpreted as policy names, as follows:

```
*A:PE-1# configure router bgp import [A] AND [B]
WARNING: CLI Policy "AND" does not exist.
```

The following message is raised when more than one logical expression is included in the policy chain:

```
*A:PE-1# configure router bgp import [C]AND[A] [C]AND[B]
INFO: BGP #1001 Configuration failed because of inconsistent values -
 BGP [VR 1] Policy stmts nbr logical expressions exceeded
```

The following message is raised when the logical expression is duplicated in the policy chain:

```
*A:PE-2# configure router bgp import [C]AND[A] "B" [C]AND[A]
INFO: BGP #1001 Configuration failed because of inconsistent values -
 BGP [VR 1] Policy stmts should be unique and set in order!
```

The following message is raised when the logical operators are not in uppercase:

```
*A:PE-1# configure router bgp import [A]and[B]
INFO: BGP #1001 Configuration failed because of inconsistent values -
 BGP [VR 1] Policy stmts expression format error
```

The following message is raised when more than 16 policies are in a policy expression:

```
*A:PE-1# configure router bgp export
[1]AND[2]AND[3]AND[4]AND[5]AND[6]AND[7]AND[8]AND[9]AND[10]AND[11]AND[12]AND[13]AND[1
4]AND[15]AND[16]

*A:PE-1# configure router bgp export [1]AND[2]AND[3]AND[4]AND[5]AND[6]AND[7]AND[8]
AND[9]AND[10]AND[11]AND[12]AND[13]AND[14]AND[15]AND[16]AND[17]
INFO: BGP #1001 Configuration failed because of inconsistent values -
 BGP [VR 1] Policy stmts expression format error
```

Route Policy Logical Expressions

Logical expressions are evaluated to be true or false. Table 6 shows the mapping of policy actions to Boolean values.

Table 6 **Boolean Values for the Policy Actions**

Policy action	Boolean value
Accept	True
Next-entry	True
Next-policy	True
Reject	False
Drop	False

Note: : The policy **action drop** replaces **action reject** in release 14.0.R4, and later. The **action drop** supports route attribute modifications while **action reject** does not. SR OS automatically converts reject actions to drop actions.

Table 7 shows the evaluation actions for the logical operators NOT, OR, and AND.

Table 7 **Actions for the Logical Operators**

Logical Operator	Action
NOT <expr>	Swaps the true/false result of the expression.

Table 7 **Actions for the Logical Operators (Continued)**

Logical Operator	Action
<expr1> OR <expr2>	If expr1 is true, the result is true and expr2 need not be evaluated. If expr1 is false, expr2 must be evaluated. The final result is true if either expression is true; otherwise, it is false.
<expr1> AND <expr2>	If expr1 is false, the result is false and expr2 need not be evaluated. If expr1 is true, expr2 must be evaluated. The final result is true only if both expressions are true.

Table 8 shows the mapping of the final result of an expression to a policy action. Routes will be dropped when the entire expression is false.

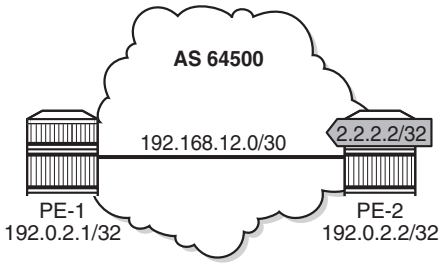

Table 8 **Mapping Final Result of an Expression to a Policy Action**

Final result	Action
True	**accept**, **next-entry**, or **next-policy** (depending on the last entry evaluated)
False	**drop/reject**

Configuration

Figure 1 shows the example topology including the advertised route.

Figure 86 **Example Topology**

The initial configuration of the routers includes the following:

- Cards, MDAs, ports
- Router interfaces
- IS-IS
- LDP
- BGP
- Export policy "export-bgp" accepting routes for prefix 2.2.2.2/32 on PE-2.

It is possible to configure VPRNs and assign policies to BGP in the VPRN, but in this chapter, all examples are for BGP in the base router.

Policy Chaining and Policy Logical Expressions

In this section, three route policies are configured that will add a community and set the local preference (LP): only policy C does not set LP. Policy C has **action next-policy**, and policies A and B have **action accept**. The configuration is as follows:

```
configure
    router
        policy-options
            begin
            community "A" members "1:1"
            community "B" members "2:2"
            community "C" members "3:3"
            policy-statement "A"
                entry 10
                    action accept
                        community add "A"
                        local-preference 110
                    exit
                exit
            exit
            policy-statement "B"
                entry 10
                    action accept
                        community add "B"
                        local-preference 200
                    exit
                exit
            exit
            policy-statement "C"
                entry 10
                    action next-policy
                        community add "C"
                    exit
                exit
            exit
            commit
```

Initially, policy chaining will be configured without a logical expression. Subsequently, policy chaining will be configured with only one policy logical expression and no other policies in the chain, as described in the following sections.

Policy Chaining without Logical Expression

Policy chaining may include one logical expression, but in this example, there is no policy logical expression in the chain.

Policy chaining is configured as follows on PE-1:

```
*A:PE-1# configure router bgp import "C" "A" "B"
```

PE-1 receives route 2.2.2.2/32 from PE-2. For each route, PE-1 evaluates policy C first. This policy adds community C (3:3) and has **action next-policy**, which implies that the next policy also needs to be evaluated. Policy A adds community A (1:1) and sets the LP to a value of 110 (by default, the local preference equals 100). Policy A has **action accept** and, therefore, the evaluation is completed. The local preference and the community are shown in the following output:

```
*A:PE-1# show router bgp routes hunt brief

```

Policy Logical Expressions with Two Policies

In the following examples, the policy chain contains only a policy logical expression. When both policy A and policy B need to be executed, the logical operator to be used is AND. The sequence is important in this case, because both policies A and B set the LP and the last executed policy will set the final value for the LP. The following import policy expression is configured on PE-1:

```
*A:PE-1# configure router bgp import "[A]AND[B]"
```

Policy A is evaluated first and it adds community A (1:1) and sets LP 110. Then, policy B is evaluated, which adds community B (2:2) and sets LP 200.

```
*A:PE-1# show router bgp routes hunt brief | match "Local Pref."
Local Pref.    : 200                    Interface Name : int-PE-1-PE-2

*A:PE-1# show router bgp routes hunt brief | match "Community"
Community      : 2:2 1:1
```

When the policy expression is [B]AND[A], the order is reversed. First, policy B sets LP 200, then policy A sets LP 110, as follows:

```
*A:PE-1# show router bgp routes hunt brief | match "Local Pref."
Local Pref.    : 110                    Interface Name : int-PE-1-PE-2

*A:PE-1# show router bgp routes hunt brief | match "Community"
Community      : 1:1 2:2
```

When the policy expression contains operator OR instead of AND, the first true expression results in a completed evaluation. Because both policy A and policy B result in a true expression, whichever policy is evaluated first is executed and the second one is skipped. When policy A is evaluated first and the result is true, policy B will be skipped. Therefore, the community will be A (1:1) and the LP 110, as follows:

```
*A:PE-1# configure router bgp import "[A]OR[B]"

*A:PE-1# show router bgp routes hunt brief | match "Local Pref."
Local Pref.    : 110                    Interface Name : int-PE-1-PE-2

*A:PE-1# show router bgp routes hunt brief | match "Community"
Community      : 1:1
```

Likewise, when policy B is evaluated first and the result is true, policy A will be skipped. The added community will be B (2:2) and the LP 200, as follows:

```
*A:PE-1# configure router bgp import "[B]OR[A]"
```

```
*A:PE-1# show router bgp routes hunt brief | match "Local Pref."
Local Pref.    : 200                    Interface Name : int-PE-1-PE-2

*A:PE-1# show router bgp routes hunt brief | match "Community"
Community      : 2:2
```

The logical operator NOT swaps the result from true to false, and vice versa. When policy A is evaluated as true, NOT[A] is false. A false expression in an AND relationship leads to a false result. The next policy in the logical expression need not be evaluated. No communities will be added and no LP will be set (the default value for LP is 100). The route will be rejected as invalid, as follows:

```
*A:PE-1# configure router bgp import "NOT[A]AND[B]"

*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2

---snip---
Community      : No Community Members
---snip---
Flags          : Invalid  IGP  Rejected
---snip---
```

However, a false NOT[A] expression in an OR relation may still lead to the expression being evaluated to true, as follows:

```
*A:PE-1# configure router bgp import "NOT[A]OR[B]"

*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------

---snip---
Community      : 2:2 1:1
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

Policy B is evaluated as true for the route and, therefore, the entire logical expression "NOT[A]OR[B]" is true, and the route is accepted. Every policy in the expression that was evaluated, before the entire logical expression was recognized to be true, is executed, including policy A. This implies that policy A adds community A (1:1) to the route and sets LP to a value of 110. Then, policy B adds community B (2:2) to the route and overwrites the LP to a value of 200.

The import policy "[B] OR NOT[A]" is true after the first policy is evaluated as true. Only policy B is executed and the assigned community is B (2:2) and the LP is 200, as follows:

```
*A:PE-1# configure router bgp import "[B] OR NOT[A]"

*A:PE-1# show router bgp routes hunt brief
---snip---

---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

Table 9 summarizes the results for these different scenarios.

Table 9 **Assigned LP and Communities for the Import Logical Expressions**

Import Logical Expression	Assigned LP	Assigned Community
import "[A] AND [B]"	200	2:2 1:1
import "[B] AND [A]"	110	1:1 2:2
import "[A] OR [B]"	110	1:1
import "[B] OR [A]"	200	2:2
import "NOT[A] AND [B]"	None	None (Route rejected)
import "NOT[A] OR [B]"	200	2:2 1:1
Import "[B] OR NOT[A]"	200	2:2

Policy Logical Expressions with Three Policies

In policy chaining, the next policy in the chain will be evaluated when the action is **next-policy**. In policy logical expressions, the next policy will be evaluated depending on the logical operator and the Boolean value for the previous policies in the expression.

Policy C has **action next-policy** instead of **accept** and adds community C (3:3), but does not set the LP.

Several logical expressions can be made with policies A, B, and C. The following import policy has all three policies in an AND relationship. The expression is evaluated as true and all policies are executed: three communities are added and the LP is set.

```
*A:PE-1# configure router bgp import "[C]AND[A]AND[B]"
```

The first policy adds community C (3:3), the second policy adds community A (1:1) and sets LP 110, and the third policy adds community B (2:2) and sets LP 200, as follows:

```
*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 200                    Interface Name : int-PE-1-PE-2
---snip---
Community      : 2:2 1:1 3:3
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

The import policy "[C]AND[A]OR[B]" results in the first two being executed. Policy C is evaluated as true, and the logical operation is AND. Therefore, the next policy needs to be evaluated too. Policy A is also evaluated as true and the next operation is OR. The final result is evaluated as true without evaluating policy B. The communities added are C and A (3:3 and later 1:1) and the LP is 110.

```
*A:PE-1# configure router bgp import "[C]AND[A]OR[B]"

*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
```

```
---snip---
Local Pref.    : 110                    Interface Name : int-PE-1-PE-2
---snip---
Community      : 1:1 3:3
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

The import policy "[C]OR[A]OR[B]" is evaluated as true after the first policy is evaluated as true. Even though the action in policy C is **next-policy**, the next policy in this expression does not need to be evaluated, because the expression is true. Only policy C is executed and it adds the community C (3:3), but does not configure the LP, as follows:

```
*A:PE-1# configure router bgp import "[C]OR[A]OR[B]"

*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 100                    Interface Name : int-PE-1-PE-2
---snip---
Community      : 3:3
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

However, if the policy chain contains not only a logical expression, but also single policies, the action next-policy ensures that a following policy in the chain is executed; for example, policy D in the following policy chain:

```
*A:PE-1# configure router bgp import "[C]OR[A]OR[B]" "D"
```

The expression "[C]OR[A]OR[B]" is true after policy C has been evaluated, but policy C has as **action next-hop** and policy D is the next policy to be evaluated.

The import policy "[C]OR[A]AND[B]" evaluates policy C as true. Policy C has an OR relation with policy A in the logical expression {[C]OR[A]}, and therefore, policy A need not be evaluated. There is an AND relation with policy B and policy B is evaluated as true. Therefore, the entire logical expression "[C]OR[A]AND[B]" is true and the route will be accepted. Both policy C and B are executed. First, policy C adds community C (3:3), then policy B adds community B (2:2) and sets LP 200, as follows:

```
*A:PE-1# configure router bgp import "[C]OR[A]AND[B]"

*A:PE-1# show router bgp routes hunt brief
```

```

import "[C] AND [A] OR [B]"	110	1:1 3:3
import "[C] OR [A] OR [B]"	None	3:3
import "[C] OR [A] AND [B]"	200	2:2 3:3

Combinations of Policy Logical Operations Using Brackets

For this section, the following communities and policies are configured on PE-1. All these policies have a **from** condition that matches a community (D, E, F, G). Besides these policies, there are also export policies on PE-2 that add one or more communities (D, E, F, G) to the advertised routes. On PE-1, incoming route 2.2.2.2/32 will have one or more communities that may or may not match the **from** condition in the following route policies.

```
configure
    router
        policy-options
            begin
```

```
community "D" members "4:4"
community "E" members "5:5"
community "F" members "6:6"
community "G" members "7:7"
policy-statement "D"
    entry 10
        from
            community "D"
        exit
        action accept
            local-preference 4
        exit
    exit
    default-action drop
    exit
exit
policy-statement "E"
    entry 10
        from
            community "E"
        exit
        action accept
            local-preference 5
        exit
    exit

exit
policy-statement "G"
    entry 10
        from
            community "G"
        exit
        action accept
            local-preference 7
        exit
    exit
    default-action drop
    exit
exit
commit
```

The received routes have community E (5:5) present. The following import policy is configured on PE-1:

```
*A:PE-1# configure router bgp import "([D]AND[E])OR([F]AND[G])"
```

The first policy that is evaluated requires community D (4:4) to be present. This is not the case and the expression between brackets, ([D]AND[E]), is false. Policy E need not be evaluated. The next policy to be evaluated is F and it requires community F (6:6), which is not present. The second expression between brackets, ([F]AND[G]), is therefore also false and policy G need not be evaluated. The entire policy logical expression is false and the route will be rejected.

The following commands show what policy evaluation caused the route to be rejected. For the entire logical expression "([D]AND[E])OR([F]AND[G])", the last policy that was evaluated, and that caused the route to be rejected, was policy F, as follows:

```
*A:PE-1# show router bgp policy-test "([D]AND[E])OR([F]AND[G])" family ipv4
prefix 0.0.0.0/0 longer display-rejects brief

---snip---
Flags          : Invalid  IGP  Rejected
---snip---
```

In the second example, the incoming route contains communities D (4:4) and E (5:5). The same policy logical expression "([D]AND[E])OR([F]AND[G])" is evaluated as true because both policy D and policy E are true. There is an OR relationship with the rest of the expression and, therefore, the entire logical expression is true. Policy E is the last policy to be evaluated, as follows:

```
*A:PE-1# show router bgp policy-test "([D]AND[E])OR([F]AND[G])" family ipv4
prefix 0.0.0.0/0 longer display-rejects brief

      Network
-------------------------------------------------------------------------------
Accepted by Logical expression last policy E Entry 10
      2.2.2.2/32
-------------------------------------------------------------------------------
Routes : 1
```

The route is accepted as valid and gets LP 5. The communities D (4:4) and E (5:5) were already present for the incoming route. The first policy that was executed, was policy D and it set the LP to a value of 4. Policy E was the second and last policy that was executed and it set the LP to a value of 5, as follows:

```
*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 5                      Interface Name : int-PE-1-PE-2
---snip---
Community      : 5:5 4:4
Cluster        : No Cluster Members
Originator Id  : None                   Peer Router Id : 192.0.2.2
Fwd Class      : None                   Priority       : None
Flags          : Used  Valid  Best  IGP
---snip---
```

For the third example, the incoming route contains communities D (4:4) and E (5:5). The logical expression "([D]OR[E])AND([F]OR[G])" will be evaluated as false and the route will be rejected, follows:

```
*A:PE-1# configure router bgp import "([D]OR[E])AND([F]OR[G])"
```

First, policy D is evaluated as true because community D (4:4) is present. Policy D has an OR relationship with policy E, which will be true without the need to evaluate policy E. The next policy to be evaluated is F. Policy F requires the community F (6:6) to be present, which is not the case. The logical expression [F]OR[G] can only be true if policy G is true. Policy G requires community G (7:7) to be present, which is false. The last policy that was evaluated before the route was rejected was policy G, as follows:

```
*A:PE-1# show router bgp policy-test "([D]OR[E])AND([F]OR[G])" family ipv4
prefix 0.0.0.0/0 longer display-rejects brief
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
```

```
===============================================================================
 Legend -

                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete

===============================================================================
BGP IPv4 Routes
===============================================================================
      Network
-------------------------------------------------------------------------------
Rejected by Logical expression last policy G Default action
      2.2.2.2/32
-------------------------------------------------------------------------------
 Total Routes : 1 Routes rejected : 1
```

The route was rejected and, therefore, no policy was executed. The LP kept its default value of 100, as follows:

```
*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 100                    Interface Name : int-PE-1-PE-2
---snip---
Community      : 5:5 4:4
---snip---
Flags          : Invalid  IGP  Rejected
---snip---
```

For the fourth example, the incoming route has communities E (5:5) and G (7:7). The logical expression "([D]OR[E])AND([F]OR[G])" will be evaluated as true and the route will be accepted. First, policy D is evaluated as false. Policy D has an OR relationship with policy E, which will be evaluated as true. Consequently, the expression [D]OR[E] is true. This expression has an AND relationship with the expression [F]OR[G].

The next policy to be evaluated is F. Policy F requires the community F (6:6) to be present, which is false. The logical expression [F]OR[G] can only be true if policy G is true. Policy G requires community G (7:7) to be present, which is true. This makes [F]OR[G] true and also the entire expression "([D]OR[E])AND([F]OR[G])".

The last policy that was evaluated before the route was accepted was policy G, as follows:

```
*A:PE-1# show router bgp policy-test "([D]OR[E])AND([F]OR[G])" family ipv4
prefix 0.0.0.0/0 longer display-rejects brief
===============================================================================

Routes : 1
```

The route was accepted and has the changes of all policies that were evaluated: initially, policy D set the LP to 4. This value was overwritten by policy E to 5, by policy F to 6, and finally by policy G to a value of 7, as follows:

```
*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
RIB In Entries
-------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 7                      Interface Name : int-PE-1-PE-2
---snip---
Community      : 5:5 7:7
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

Table 11 summarizes the results for these different scenarios.

Table 11 **Assigned LP for the Import Logical Expressions**

Ingress Community	Import Logical Expression	Assigned LP
5:5	import "([D]AND[E])OR([F]AND[G])"	Prefix rejected
5:5 4:4	import "([D]AND[E])OR([F]AND[G])"	5
5:5 4:4	import "([D]OR[E])AND([F]OR[G])"	Prefix rejected
5:5 7:7	import "([D]OR[E])AND([F]OR[G])"	7

Modification of Attributes While Processing

During the policy evaluation process, some prefix attributes can be modified while processing, and these modified attributes can be used as criteria for other policies in the logical expression.

In the following example, two route policies are configured:

- Policy X adds a new community Y (11:11) to the incoming route update.
- Policy Y uses community Y (11:11) as the only match criterion and removes communities X and Y. Policy Y also sets the LP to a value of 9, which is used here as an indication that policy Y was executed.

An export policy on PE-2 adds community X (10:10) to prefix 2.2.2.2/32 (not shown here).

Route policies X and Y are configured as follows on PE-1:

```
configure
    router
        policy-options
            begin
            community "X" members "10:10"
            community "Y" members "11:11"
            policy-statement "X"
                entry 10
                    from
                        community "X"
                    exit
                    action accept
                        community add "Y"
                    exit
                exit
            exit
            policy-statement "Y"
                entry 10
                    from
                        community "Y"
                    exit
                    action accept
                        community remove "X" "Y"
                        local-preference 9
                    exit
                exit
            exit
            commit
```

When no import policy is applied on PE-1, the received route 2.2.2.2/32 has community 10:10 and the default LP, as follows:

```
*A:PE-1# show router bgp routes hunt brief
---snip---
-------------------------------------------------------------------------------
```

```
RIB In Entries
------------------------------------------------------------------------------
Network        : 2.2.2.2/32
Nexthop        : 192.0.2.2
---snip---
Local Pref.    : 100                    Interface Name : int-PE-1-PE-2
---snip---
Community      : 10:10
---snip---
Flags          : Used  Valid  Best  IGP
---snip---
```

The import policy "[X]AND[Y]" is configured on PE-1, as follows:

```
*A:PE-1# configure router bgp import "[X]AND[Y]"
```

The route update contains community X (10:10) and policy X is evaluated as true. Policy X adds community Y (11:11) to the route. Policy Y requires this community and is evaluated as true. Therefore, the entire logical expression "[X]AND[Y]" is true and the route is accepted. Policy Y removes communities X (10:10) and Y (11:11), and sets the LP to a value of 9, as follows:

```
*A:PE-1# show router bgp routes hunt brief
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500

```

Conclusion

Route policy chaining and logical expressions allow complex route processing logic to be broken into smaller components. These policy components are reusable and facilitate the process of updating route control logic. Logical expressions offer more flexible combinations of policy statements.

Separate BGP RIBs for Labeled Routes

This chapter provides information about separate border gateway protocol (BGP) route information bases (RIBs) for labeled-unicast routes.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R4.

Release 14.0.R4 introduced separate BGP RIBs for labeled-unicast routes.

Overview

In SR OS releases earlier than 14.0.R4, BGP maintained one RIB for both unlabeled IPv4 and labeled-unicast IPv4 routes and another RIB for both unlabeled IPv6 and labeled-unicast IPv6 routes. In SR OS release 14.0.R4, and later, the labeled-unicast and unlabeled routes are held in separate RIBs: IPv4, label-IPv4, IPv6, and label-IPv6.

Table 12 compares the previous BGP RIB architecture to the current one.

Table 12 **Comparison of the BGP RIB Architectures**

	SR OS earlier than 14.0.R4	SR OS 14.0.R4 and later
BGP peer with both labeled-unicast (SAFI 4) and unlabeled IP (SAFI 1) routes	SAFI 1 and SAFI 4 are mutually exclusive. Received routes with the non-negotiated SAFI are treated as route withdrawals.	Both labeled and unlabeled routes can be advertised to the same neighbor.

Table 12 **Comparison of the BGP RIB Architectures (Continued)**

	SR OS earlier than 14.0.R4	SR OS 14.0.R4 and later
RR default behavior	BGP RR re-advertises all types of routes to all its clients, including labeled routes to unlabeled peers and vice versa.	BGP RR only re-advertises labeled-unicast routes to labeled-unicast peers and unlabeled routes to unlabeled IP peers, unless route-table-import policies are used to allow route leaking.
Route-table import policies	No route-table import policies supported. All active routes are automatically imported to BGP RIB.	Route-table import policies can save BGP memory by blocking the import of unnecessary IP routes. All unlabeled and all labeled BGP-owned routes are by default imported into both BGP RIBs.

BGP Common IPv4 RIB Implementation

In SR OS releases earlier than 14.0.R4, unlabeled IP routes and labeled IP routes for the same prefix were considered different paths to the same destination. SR OS could not advertise both labeled and unlabeled routes to the same neighbor. If the advertise-label ipv4 command was configured on a session, labeled routes were advertised, and unlabeled routes were not expected and not sent. For labeled routes, scarce MPLS datapath resources were consumed. In many networks, advertising a labeled route was only required for certain prefixes and not the entire IPv4 or IPv6 routing table.

Another issue with the common IPv4 RIB architecture is shown in Figure 87.

Figure 87 **RR-1 with Common IPv4 RIB**

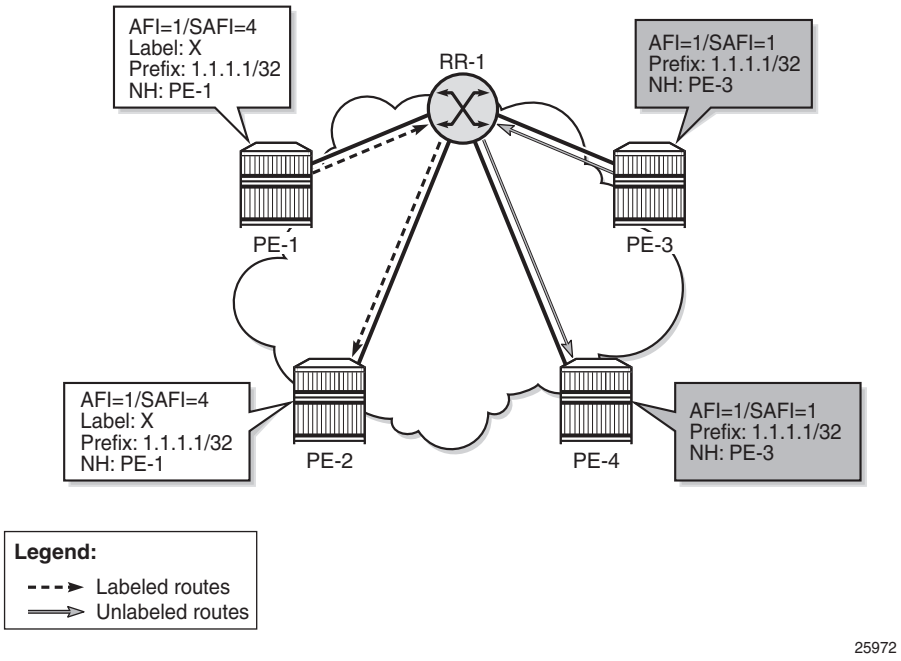
Route reflector RR-1 has two clients sending labeled-IPv4 routes (PE-1, PE-2) and two other clients sending unlabeled IPv4 routes (PE-3, PE-4). The RR is intended to be a control plane RR and not configured to perform next-hop-self toward any of the clients. When both PE-1 (labeled) and PE-3 (unlabeled) send a route for IPv4 prefix 1.1.1.1/32, the RR uses the BGP decision process to select the best path for 1.1.1.1/32. Assume that PE-3 sends the best path. This path will be advertised to clients PE-2 (labeled) and PE-4 (unlabeled).

The route received from PE-3 is unlabeled, and can be advertised as an unlabeled route to peer PE-4. However, toward PE-2, the route must get a label Y, according to the configured label in the **advertise-label ipv4** command, but the next hop cannot remain PE-3, because PE-3 does not expect any labels. Therefore, RR-1 must set next-hop-self and data traffic between PE-2 and PE-3 will flow via RR-1 where label Y will be pushed or popped. This is not a desirable situation.

BGP Separate Labeled-IPv4 RIB Implementation

In SR OS release 14.0.R4, and later, a separate RIB is used for labeled-IPv4 routes. With this implementation, client PE-2 learns the best labeled-IPv4 route and client PE-4 learns the best unlabeled IPv4 route. RR-1 does not need to set next-hop-self and traffic can be sent directly from PE-2 to PE-1 and from PE-4 to PE-3. The RR is used only for control traffic, as intended. Figure 88 shows how RR-1 sends a labeled-IPv4 route to PE-2 with label X and next hop PE-1.

Figure 88 **RR-1 with Separate Labeled-IPv4 RIB Implementation**



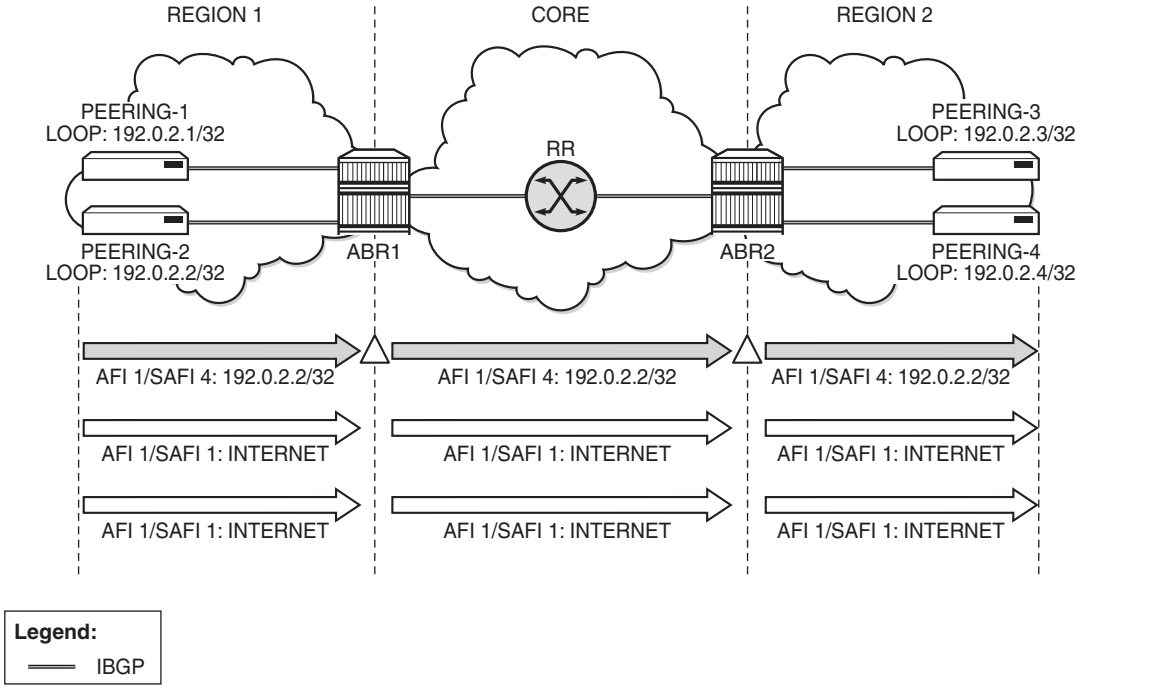


Figure 89 shows a seamless MPLS use case, which is a good example of the coexistence of labeled (AFI 1/SAFI 4) and unlabeled (AFI 1/SAFI 1) BGP sessions.

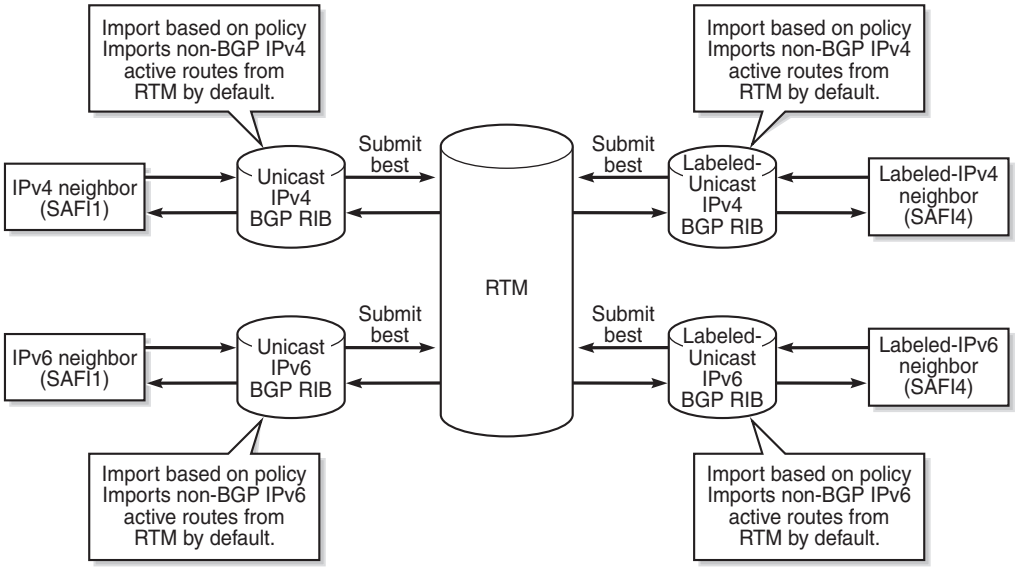

Figure 89 **Seamless MPLS - Separate Labeled-IPv4 Implementation**

RIB Architecture

Figure 90 shows the system architecture with four separate RIBs for IPv4 and IPv6 routes.

Figure 90 **System Architecture with Separate RIBs for Labeled-Unicast and Unlabeled Routes**

Labeled-unicast routes from peers are stored in a labeled RIB and unlabeled routes from the same or different peers are stored in a non-labeled RIB. Both labeled and unlabeled routes can be sent and received to and from the same peer. Different sets of routes can be advertised to labeled/unlabeled peers. Labeled and unlabeled BGP sessions are using the common equal cost multipath (ECMP) and multipath limit.

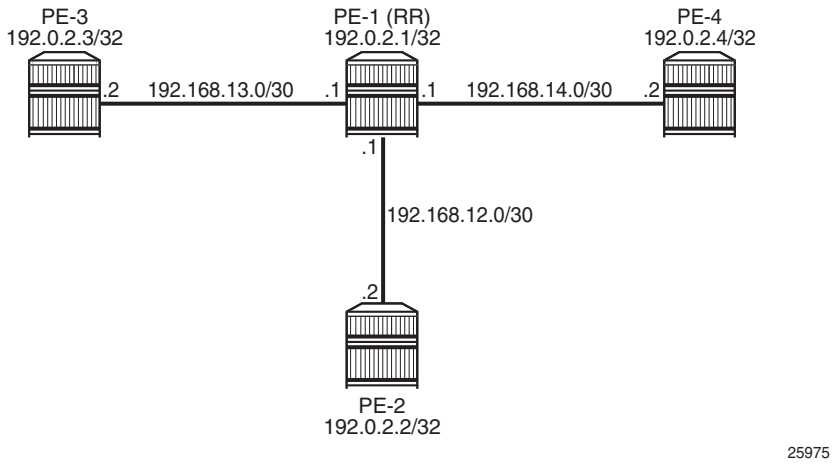
More user control is provided over the RTM route import process. By default, a RIB imports all non-BGP active routes from RTM, but a user-defined route policy can be applied. Route policies can be used to reduce BGP memory usage.

The configuration for labeled IP routes has changed in SR OS release 14.0.R4:

- The **advertise-label** command is deprecated.
- Address families mapped to the RIBs are: **ipv4, label-ipv4, ipv6, label-ipv6**.
- In route policies, protocol types **bgp** and **bgp-label** can be used.
- The default RTM preference for labeled IP routes is configurable (**label-preference**) in the BGP context of the base router or a VPRN. The default preference is 170.

The consequences of having four separate RIBs instead of two are the following:

- Increased BGP memory usage is possible because the same route may be present in two RIBs. This can be avoided by a good route-table-import policy.



- By default, BGP unlabeled routes are no longer advertised to BGP label peers and vice versa. However, non-default route-table-import policies can accept BGP routes of the other type.
- The paths that are advertised to a peer for a prefix may be different, even if full routes are leaked between labeled and unlabeled RIBs. Leaking is done through the RTM and each RIB submits its best path. However, by default, the same route will be sent to both the labeled and unlabeled peer if the route-table-import policy allows the import to the BGP/BGP-Label owned routes.
- Care must be taken during upgrade.

Configuration

All the examples are based on labeled and unlabeled IPv4 addresses. For IPv6, the configuration is similar.

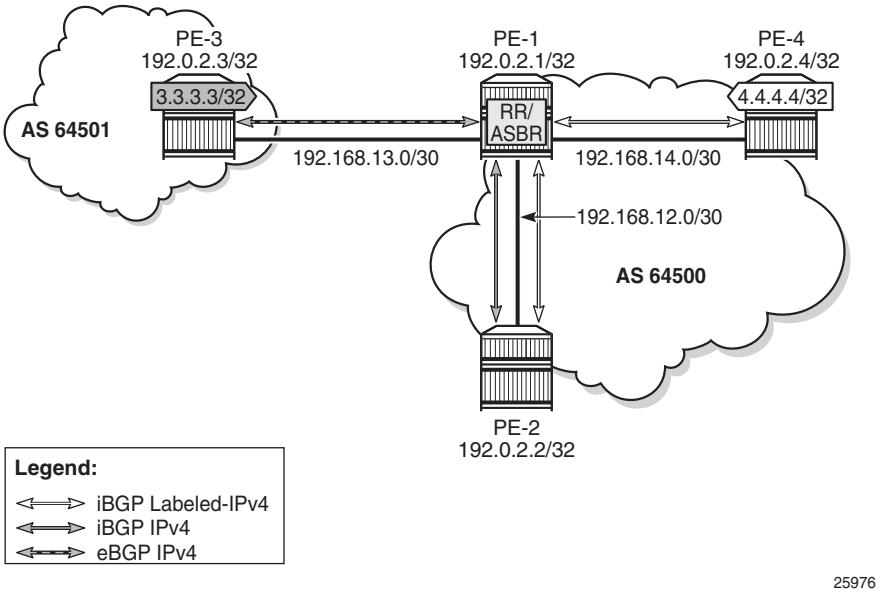
Figure 91 shows the example topology using IPv4 addresses.

Figure 91 **Example IPv4 Topology**

The initial configuration includes:

- Cards, MDAs, ports
- Router interfaces
- IS-IS in AS 64500 (PE-1, PE-2, PE-4)
- LDP in AS 64500
- Loopback addresses 3.3.3.3/32 in PE-3 and 4.4.4.4/32 in PE-4

- Export policy "export-bgp" accepting routes from protocol direct on all nodes



The following will be configured and verified:

1. Coexistence of labeled and unlabeled address families for BGP
2. Applying next-hop-self
3. Export Policy to Advertise Route as Labeled/Unlabeled
4. Behavior of RR with a mix of labeled and unlabeled iBGP sessions

Coexistence of Labeled and Unlabeled Address Families for BGP

Figure 92 shows the eBGP and iBGP sessions that are established between the nodes and the routes advertised for the loopback addresses.

Figure 92 **BGP Sessions**

PE-1 acts as RR for PE-2 and PE-4, and it is an autonomous system border router (ASBR) toward PE-3. PE-1 has two single-family connections: unlabeled IPv4 to PE-3 and labeled IPv4 to PE-4. PE-1 also has one dual-family connection to PE-2. The BGP configuration on PE-1 is as follows:

```
configure
```

```
    router
        autonomous-system 64500
        bgp
            min-route-advertisement 1
            split-horizon
            group "eBGP"
                peer-as 64501
                neighbor 192.168.13.2
                    family ipv4
                exit
            exit
            group "iBGP"
                cluster 192.0.2.1
                export "export-bgp"
                peer-as 64500
                neighbor 192.0.2.2
                    family ipv4 label-ipv4
                exit
                neighbor 192.0.2.4
                    family label-ipv4
                exit
            exit
        exit
    exit
exit
```

The BGP configuration on PE-2 is as follows:

```
configure
    router
        autonomous-system 64500
        bgp
            min-route-advertisement 1
            split-horizon
            group "iBGP"
                export "export-bgp"
                peer-as 64500
                neighbor 192.0.2.1
                    family ipv4 label-ipv4
                exit
            exit
        exit
    exit
exit
```

The BGP configuration on PE-3 in AS 64501 is as follows:

```
configure
    router
        autonomous-system 64501
        bgp
            min-route-advertisement 1
            split-horizon
            group "eBGP"
                export "export-bgp"
                peer-as 64500
                neighbor 192.168.13.1
```

```
                family ipv4
            exit
        exit
    exit
exit
```

The BGP configuration on PE-4 is as follows:

```
configure
    router
        autonomous-system 64500
        bgp
            min-route-advertisement 1
            split-horizon
            group "iBGP"
                export "export-bgp"
                peer-as 64500
                neighbor 192.0.2.1
                    family label-ipv4
                exit
            exit
        exit
    exit
exit
```

The BGP summary on PE-1 shows that there is a dual-family connection with PE-2: IPv4 and Lbl-IPv4. PE-1 has an Lbl-IPv4 connection with PE-4 and an IPv4 connection with PE-3.

```

*A:PE-2#
```

As expected, the prefixes from address family label-ipv4 are advertised independently from the prefixes from address family ipv4.

Applying Next-Hop-Self

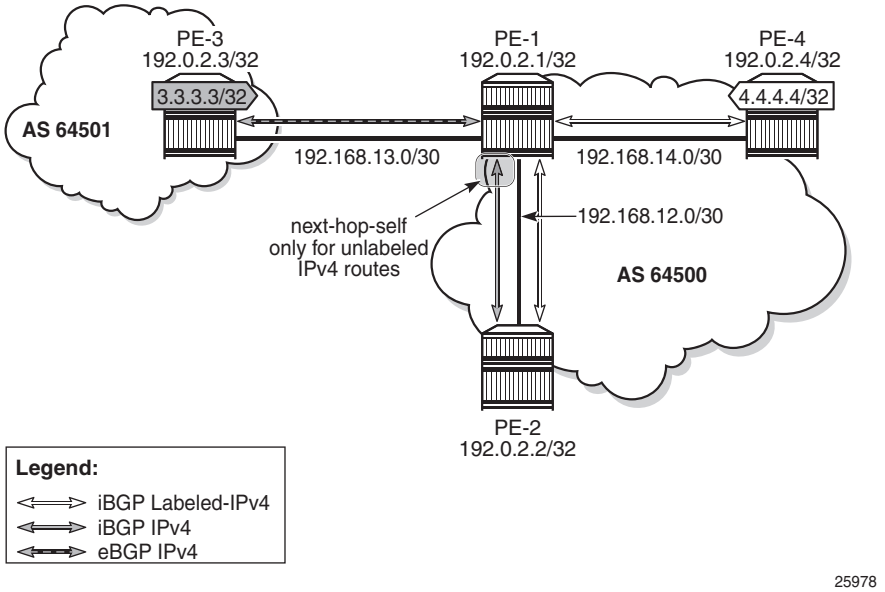
Figure 93 shows that PE-1 applies next-hop-self for BGP updates toward PE-2.

Figure 93 **PE-1 Applies Next-Hop-Self toward Neighbor PE-2**

On PE-1, next-hop-self is enabled for neighbor PE-2 only, as follows:

```
*A:PE-1# configure router bgp group "iBGP" neighbor 192.0.2.2 next-hop-self
```

This applies to both address families. The next hop for unlabeled route 3.3.3.3/32 will be 192.0.2.1, as follows:



```
*A:PE-2# show router bgp routes 3.3.3.3/32
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500

===============================================================================
*A:PE-2#
```

Figure 94 shows that next-hop-self is applied to unlabeled IPv4 routes only.

Figure 94 **Applying Next-Hop-Self to Unlabeled IP-4 Routes to Neighbor PE-2**

An export policy is configured to ensure that next-hop-self is only applied for address family ipv4. The route policy is configured as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "export-nhs"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                        next-hop-self
                    exit
                exit
                entry 20
                    from
                        protocol bgp-label
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

The next-hop-self configuration for neighbor PE-2 is replaced by export policy "export-nhs", as follows:

```
*A:PE-1# configure router bgp group "iBGP" neighbor 192.0.2.2 no next-hop-self
*A:PE-1# configure router bgp group "iBGP" neighbor 192.0.2.2 export "export-nhs"
```

With this export policy, only the unlabeled route 3.3.3.3/32 will have next hop 192.0.2.1, while the labeled-unicast route 4.4.4.4/32 will have next hop 192.0.2.4, as follows:

```
*A:PE-2# show router bgp routes 3.3.3.3/32
===============================================================================

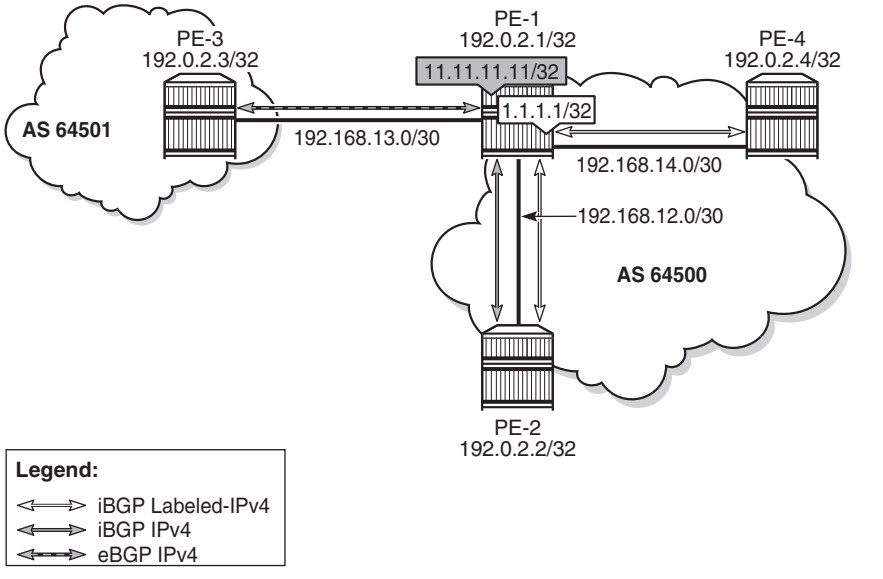
*A:PE-2#
```



The export policy "export-nhs" toward neighbor PE-2 is removed as follows:

```
*A:PE-1# configure router bgp group "iBGP" neighbor 192.0.2.2 no export
```

Export Policy to Advertise Route as Labeled/ Unlabeled

Figure 95 shows that two loopback addresses are configured in PE-1 to be advertised: prefix 1.1.1.1/32 and 11.11.11.11/32. Initially, there is no route policy applied for a selective export as labeled or unlabeled route.

Figure 95 **PE-1 Advertises Prefixes 1.1.1.1/32 and 11.11.11.11/32**

By default, these prefixes will be advertised as both labeled and unlabeled routes toward dual-family neighbor PE-2. On PE-2, the unlabeled IPv4 RIB contains prefixes 1.1.1.1/32 and 11.11.11.11/32, as follows:

```
*A:PE-2# show router bgp routes
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500
===============================================================================
 Legend -
 Status codes  : u - used, s - suppressed, h - history, d - decayed, * - valid
                 l - leaked, x - stale, > - best, b - backup, p - purge
 Origin codes  : i - IGP, e - EGP, ? - incomplete
===============================================================================
BGP IPv4 Routes
===============================================================================
Flag  Network                                              LocalPref   MED
      Nexthop (Router)                                     Path-Id     Label
      As-Path
-------------------------------------------------------------------------------
u*>i  1.1.1.1/32                                           100         None
      192.0.2.1                                            None        -
      No As-Path
---snip---
u*>i  11.11.11.11/32                                       100         None
      192.0.2.1                                            None        -
      No As-Path
---snip---
```

The labeled-IPv4 RIB on PE-2 also contains prefixes 1.1.1.1/32 and 11.11.11.11/32, as follows:

```
*A:PE-2# show router bgp routes label-ipv4
===============================================================================
 BGP Router ID:192.0.2.2        AS:64500       Local AS:64500
===============================================================================

*>i   1.1.1.1/32                                           100         None
      192.0.2.1                                            None        262136
      No As-Path
---snip---
*>i   11.11.11.11/32                                       100         None
      192.0.2.1                                            None        262135
      No As-Path
---snip---
```

In many cases, it is not required to advertise both a labeled route and an unlabeled route. The following policy is configured to advertise prefix 1.1.1.1/32 as a labeled-IPv4 route and prefix 11.11.11.11/32 as an unlabeled IPv4 route:

```
configure
    router
        policy-options
            begin
            prefix-list "1.1.1.1/32"
                prefix 1.1.1.1/32 exact
            exit
            prefix-list "11.11.11.11/32"
                prefix 11.11.11.11/32 exact
            exit
            policy-statement "export-bgp1"
                entry 10
                    from
                        prefix-list "1.1.1.1/32"
                    exit
                    to
                        protocol bgp-label
                    exit
                    action accept
                    exit
                exit
                entry 30
                    from
                        prefix-list "11.11.11.11/32"
                    exit
                    to
```

```
                    protocol bgp
                exit
                action accept
                exit
            exit
            default-action drop
            exit
        exit
        commit
```

This policy is applied on PE-1 as an export policy for neighbor PE-2, as follows:

```
*A:PE-1# configure router bgp group "iBGP" neighbor 192.0.2.2 export "export-bgp1"
```

Prefix 11.11.11.11/32 is received as an unlabeled route on PE-2 and stored in the unlabeled RIB, but prefix 1.1.1.1/32 is not, as follows:

```
*A:PE-2# show router bgp routes
===============================================================================

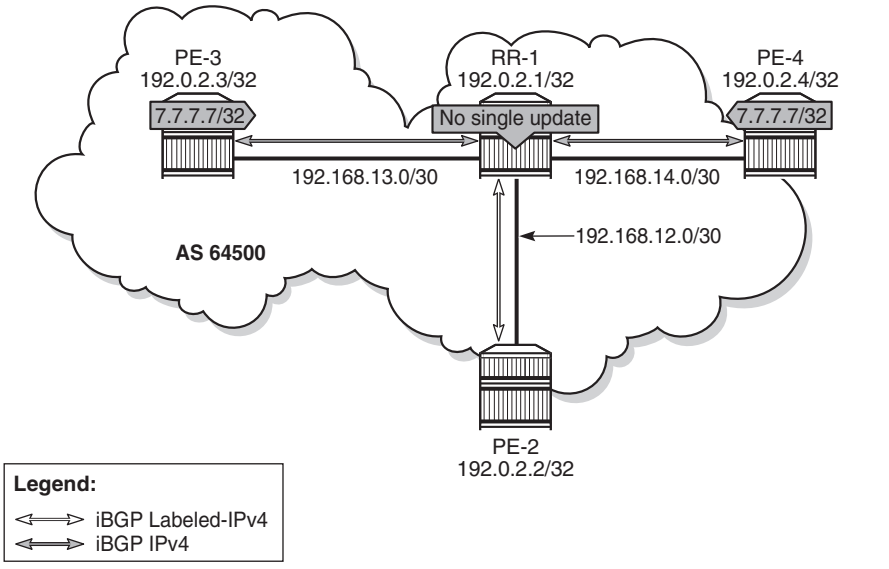
This selective route advertisement from PE-1 reduces the memory usage for the RIBs on PE-2.

RR Behavior with a Mix of Labeled and Unlabeled BGP Sessions

Figure 96 shows a slightly different setup, with all PEs in the AS 64500 and RR-1 acting as the RR for all PEs. There are no dual-family connections. PE-3 and PE-4 have an unlabeled BGP session with RR-1 and PE-2 has a labeled BGP connection with RR-1. RR-1 has add-path=2 capability configured for neighbor PE-2. RR-1 receives the same prefix 7.7.7.7/32 from two neighbors: PE-3 and PE-4.

Figure 96 **RR with Labeled and Unlabeled BGP Sessions**

On RR-1, BGP is configured as follows:



```
configure
    router
        bgp
            min-route-advertisement 1
            split-horizon
            group "iBGP"
                cluster 192.0.2.1
                export "export-bgp"
                peer-as 64500
                neighbor 192.0.2.2
                    family label-ipv4
                    add-paths
                        label-ipv4 send 2 receive
                    exit
                exit
                neighbor 192.0.2.3
                    family ipv4
                exit
                neighbor 192.0.2.4
                    family ipv4
                exit
            exit
        exit
    exit
exit
```

RR-1 receives the prefix 7.7.7.7/32 from neighbors PE-3 and PE-4, as follows:

```
*A:RR-1# show router bgp routes 7.7.7.7/32
===============================================================================

===============================================================================
*A:PE-2#
```

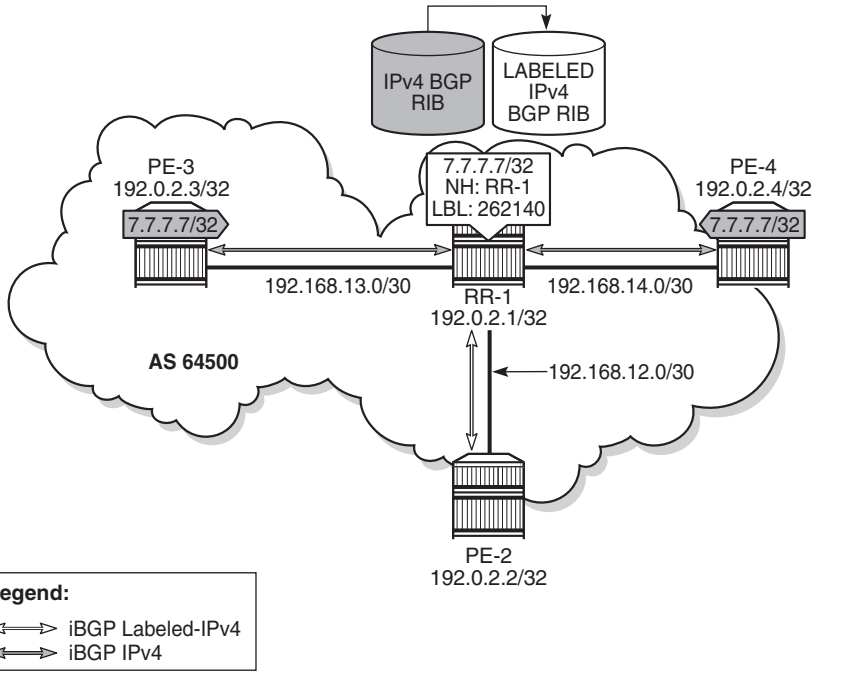
A route policy is created on RR-1 to accept both labeled and unlabeled routes, as follows:

```
configure
    router
        policy-options
            begin
            policy-statement "import-all"
                entry 10
                    from
                        protocol bgp
                    exit
                    action accept
                    exit
                exit
                entry 20
                    from
                        protocol bgp-label
                    exit
                    action accept
                    exit
                exit
            exit
            commit
```

This policy accepts all routes, labeled and unlabeled. For route 7.7.7.7/32 to be advertised to the labeled peer PE-2, it is sufficient to have a policy with only entry 10 that says from protocol bgp action accept. However, the preceding policy can also be used to import labeled routes to be advertised to unlabeled peers.

The following policy is applied as route-table-import policy in BGP RIB management, both for unlabeled IPv4 routes and labeled-IPv4 routes on RR-1:



```
configure
    router
        bgp
            rib-management
                ipv4
                    route-table-import "import-all"
                exit
                label-ipv4
                    route-table-import "import-all"
                exit
            exit
        exit
```

```
    exit
exit
```

For allowing unlabeled route 7.7.7.7/32 to be advertised on a labeled session, it is sufficient to have a route-table-import for labeled-IPv4 only. However, the configuration allows for RIB leaking in both ways: from unlabeled IPv4 BGP RIB to labeled-IPv4 BGP RIB and vice versa.

Figure 98 shows this RIB leaking process.

Figure 98 **RIB Leaking from IPv4 BGP RIB to Labeled-IPv4 BGP RIB**

After applying this RIB leaking, RR-1 will advertise prefix 7.7.7.7/32 to PE-2. Therefore, RR-1 needs to add a label to the route and RR-1 needs to set next-hop-self. RR-1 advertises only one labeled route for prefix 7.7.7.7/32, with next hop 192.0.2.1, as follows:

```
*A:RR-1# show router bgp neighbor 192.0.2.2 label-ipv4 advertised-routes
===============================================================================
 BGP Router ID:192.0.2.1        AS:64500       Local AS:64500
===============================================================================
 Legend -

```

Conclusion

The BGP RIB architecture in SR OS release 14.0.R4, and later, with separate RIBs for unlabeled and labeled-unicast routes supports unlabeled sessions and labeled sessions in parallel. By default, labeled routes are not advertised to unlabeled sessions and vice versa. Route-table import policies for RIB management allow route leaking between separate RIBs: unlabeled BGP RIB and labeled-unicast BGP RIB.

MPLS

In This Section

This section provides MPLS configuration information for the following topics:

- Automatic Bandwidth Adjustment in P2P LSPs
- Automatic Creation of RSVP-TE LSPs
- Class-Based Forwarding
- DiffServ Traffic Engineering
- Entropy Label
- IGP Shortcuts
- Inter-Area TE Point-to-Point LSPs
- LDP FEC to BGP Label Route Stitching
- LDP over RSVP Using OSPF as IGP
- LDP Point-to-Point LSPs
- LDP-SR Stitching for IPv4 Prefixes (IS-IS)
- MPLS LDP FRR using ISIS as IGP
- MPLS Transport Profile
- Multicast Label Distribution Protocol
- RSVP Point-to-Point LSPs
- RSVP Signaled Point-to-Multipoint LSPs
- Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP
- Segment Routing with IS-IS Control Plane
- Shared Risk Link Groups for RSVP-Based LSP
- Static Point-to-Point LSPs
- Tunneling of ICMP Reply Packets over MPLS LSPs
- Unnumbered Interfaces in RSVP-TE and LDP

Automatic Bandwidth Adjustment in P2P LSPs

This chapter provides information about automatic bandwidth adjustment in P2P LSPs.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This note is applicable to all 7x50 chassis. At a minimum chassis mode C must be used (and for 7450 ESS, at least chassis mode D). The feature was first introduced in 8.0.R4. Initially, this chapter was written for release 13.0.R2, but the CLI in the current edition corresponds to release 14.0.R1.

Overview

Automatic bandwidth adjustment refers to the capability of an ingress label edge router (iLER) to dynamically adjust the bandwidth of a resource reservation protocol (RSVP) label switched path (LSP) tunnel based on active measurement of the traffic rate into the tunnel. The bandwidth assigned to an RSVP LSP tunnel is taken into account by the control plane, to verify that sufficient bandwidth is available for a new LSP or for an increase or decrease in bandwidth for an existing LSP. The actual bandwidth in the data plane is not capped by this setting. QoS mechanisms can be set up to filter and police the traffic in the data plane, but that is beyond the scope of this chapter.

Auto-bandwidth adjustment uses the existing LSP egress statistics feature to track the bandwidth on a specific LSP. When egress statistics are enabled, the control processing module (CPM) collects statistics from all IOMs forwarding traffic belonging to the LSP (whether the traffic is currently leaving the ingress LER via the primary path, a secondary path, or an FRR detour/bypass path). The egress statistics have counts for the number of packets and bytes forwarded per LSP on a per-forwarding class, per priority (in-profile versus out-of-profile) basis.

For the actual bandwidth adjustment, Make-Before-Break (MBB) is used. No traffic interruption is noticed. If an auto-bandwidth attempt fails, there will be 5 retries and, if they all fail, the bandwidth remains unchanged. The next attempt may occur with the next trigger.

Retries follow the retry-limit (5 in this case), retry-timer (by default 30s), and exponential back-off timer, if enabled in MPLS.

Auto-bandwidth adjustment can be triggered in four different ways:

1. Periodic trigger

   The iLER determines at the end of each adjust-interval whether to attempt an auto-bandwidth adjustment.
2. Overflow or underflow trigger

   The measured bandwidth of an LSP has increased or decreased significantly since the start of the current adjust-interval. It may be preferable to adjust the bandwidth of the LSP after a number of overflow/underflow samples, rather than wait for the adjust-interval to end (default: 24 h).
3. Manual trigger

   An operator launches a tools command to trigger an auto-bandwidth adjustment.
4. Active path change

   The LSP has a primary and one or more secondary paths. When there is a change from the primary path to a secondary path without the LSP going down, an auto-bandwidth MBB is triggered. When the primary path becomes active again, another auto-bandwidth MBB is triggered.

Periodic Trigger

Figure 99 shows the different time intervals and bandwidths defined in the auto-bandwidth adjustment implementation. In this example, there will be an auto-bandwidth attempt when the adjust-interval elapses (periodic trigger). If the auto-bandwidth algorithm is met, the current bandwidth is increased. The parameters are explained after the figure.

Figure 99 **Auto-Bandwidth Adjustment Implementation**

The time intervals are:

- Collection interval in minutes. This is a global parameter to be set in an accounting policy. Range: 5 to 120 minutes. Default: 5 minutes.

  For this kind of record type, the minimum interval is 5 minutes. For policies using a record type of SAA or PM, the minimum is 1 minute.

```
*A:PE-1# configure log accounting-policy 10 collection-interval
  - collection-interval <minutes>
  - no collection-interval

 <minutes>            : [1..120]

*A:PE-1# configure log accounting-policy 10 collection-interval 1
MAJOR: LOG #1076 Except for policies using a record type of SAA or PM the minimum
interval is 5 mins
```

  - Sample interval: sample-multiplier * collection interval
  - Sample-multiplier is configurable globally in the MPLS context or per LSP. Default value: 1. In Figure 99, the sample multiplier equals 2 for a sample interval of 2 * 5 minutes = 10 minutes.

- Adjust-interval: adjust-multiplier * collection interval
  - Nokia recommends that the adjust-multiplier is an integer multiple of the sample-multiplier.

– Adjust-multiplier is configurable globally in the MPLS context or per LSP. Default value: 288 (288 * 5 minutes = 1440 minutes = 24 h). In Figure 99, the adjust multiplier equals 10 for an adjust-interval of 10 * 5 minutes = 50 minutes.

```
*A:PE-1# configure router mpls auto-bandwidth-multipliers
  - auto-bandwidth-multipliers sample-multiplier <number1> adjust-multiplier <number2>
  - no auto-bandwidth-multipliers

 <number1>            : [1..511]
 <number2>            : [1..16383]

*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth multipliers
  - multipliers sample-multiplier <num1> adjust-multiplier <num2>
  - no multipliers

 <num1>               : [1..511]
 <num2>               : [1..16383]
```

The different bandwidths are:

- Minimum bandwidth: configured minimum bandwidth in Mbps that the auto-bandwidth adjustment can signal for the LSP. Granularity: 1 Mbps. Default: 0 Mbps.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth min-bandwidth
  - min-bandwidth <mbps>
  - no min-bandwidth

 <mbps>               : [0..100000]
```

- Maximum bandwidth: configured maximum bandwidth in Mbps that the auto-bandwidth adjustment can signal for the LSP. Granularity: 1 Mbps. Default: 100 Mbps.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth max-bandwidth
  - max-bandwidth <mbps>
  - no max-bandwidth

 <mbps>               : [0..100000]
```

- Current bandwidth or operational bandwidth (O): currently reserved bandwidth in Mbps for the LSP in the control plane. This is the operational bandwidth that is maintained in the Management Information Base (MIB) and is the bandwidth that will be auto-adjusted. Granularity: 1 Mbps.
- Sampled bandwidth (S): average data rate for the last sample interval.

- Measured bandwidth (M): maximum averaged (per sample interval) data rate in the current adjust-interval. The SR OS keeps track of the maximum average data rate of each LSP since the last reset of the adjust-count.
- Signaled bandwidth: bandwidth in Mbps that is provided to the CSPF algorithm and signaled in the RSVP SENDER_TSPEC and FLOWSPEC objects, when an auto-bandwidth adjustment is attempted. Granularity: 1 Mbps.

The other auto-bandwidth parameters for periodically triggered auto-bandwidth adjustment are:

- Up% (adjust-up in percent): minimum increase in bandwidth from current to measured bandwidth, expressed as a percentage of the current bandwidth. Default: 5%.
- Up (adjust-up bw): minimum increase in bandwidth as absolute bandwidth in Mbps. Up = measuredBW – currentBW. Granularity: 1 Mbps. Default: 0 Mbps.

```
*A:PE-1>config>router>mpls>lsp>auto-bandwidth# adjust-up
  - adjust-up <percent> [bw <mbps>]
  - no adjust-up

 <percent>            : [0..100]
 <mbps>               : [0..100000]
```

- Down% (adjust-down in percent): minimum decrease in bandwidth from current to measured bandwidth, expressed as a percentage of the current bandwidth. Default: 5%.
- Down (adjust-down bw): minimum decrease in bandwidth as absolute bandwidth in Mbps. Down = currentBW – measuredBW. Granularity: 1 Mbps. Default: 0 Mbps.

```
*A:PE-1>config>router>mpls>lsp>auto-bandwidth# adjust-down
  - adjust-down <percent> [bw <mbps>]
  - no adjust-down

 <percent>            : [0..100]
 <mbps>               : [0..100000]
```

In Figure 99, the minimum and maximum bandwidths mark the bandwidth range where auto-bandwidth adjustments are allowed. The sample interval is two collection intervals long (2 * 5 minutes = 10 minutes). The adjust-interval is 10 collection intervals long (10 * 5 minutes = 50 minutes). Initially, the current bandwidth (O) equals the configured bandwidth for the primary path. It is good practice to give that same value to the minimum bandwidth for auto-bandwidth. The system doesn’t confirm this and these bandwidths are independent from each other.

In this example, the sampled bandwidth exceeds the current bit rate in most of the sample intervals. The maximum sampled bandwidth in the current adjust-interval corresponds to the measured bandwidth (M). When auto-bandwidth adjustment is triggered at the end of the adjust-interval, this measured bandwidth will be signaled and, after a successful adjustment, will be the new current bandwidth. After the auto-bandwidth adjustment, a new adjust-interval starts and the measured bandwidth is reset to 0. As long as the first sample interval of the new adjust-interval is not finished, the measured bandwidth equals 0 and auto-adjustment would be impossible even when triggered manually.

The auto-bandwidth attempt follows these rules:

- When measuredBW ≥ currentBW
  - if {(measuredBW / currentBW – 1) ≥ up%} &&{(measuredBW – currentBW) ≥ up
    then signaledBW = max{(min(measuredBW, maxBW)), minBW}
- When measuredBW ≤ currentBW
  - if {(1 – measuredBW/currentBW) ≥ down%} && {(currentBW – measuredBW) ≥ down}
    then signaledBW = min{(max(measuredBW, minBW)), maxBW}

CLI configured bandwidths have a granularity of 1 Mbps, while the threshold calculations with measured bandwidth are performed at full precision. This means that the signaled bandwidth in the RSVP message is rounded up to the nearest integer multiple of 1 Mbps.

Overflow/Underflow Trigger

Auto-bandwidth adjustment can also be triggered by overflow or underflow. When the bandwidth changes drastically, the bandwidth can be auto-adjusted after a number of consecutive overflow/underflow samples. In this case, there is no need to wait for the adjust-interval to end (by default: 24 h).

The parameters used in case of overflow are:

- Overflow sample: a sample interval counts as an overflow sample if the sampled bandwidth is higher than the current bandwidth by at least the configured overflow thresholds.
- Overflow-limit/overflow-count: an auto-bandwidth adjustment occurs after this number of consecutive overflow samples.
- Threshold%: minimum difference between sampled bandwidth and current bandwidth, expressed as a percentage of the current bandwidth.

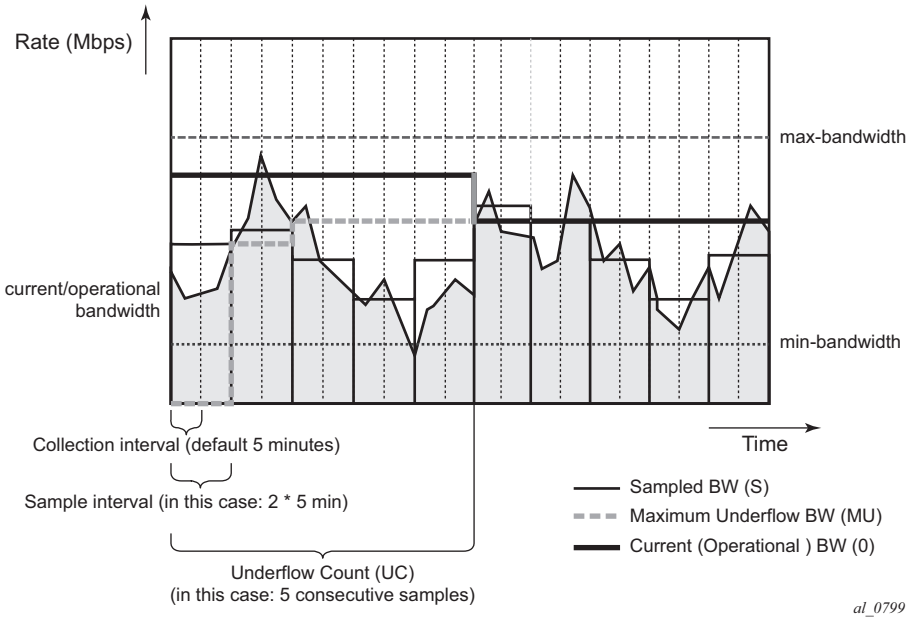
- Threshold bw: minimum difference between sampled bandwidth and current bandwidth in Mbps. Default value: 0.

```
A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth overflow-limit
  - overflow-limit <number> threshold <percent> [bw <mbps>]
  - no overflow-limit

 <number>             : [1..10]
 <percent>            : [0..100]
 <mbps>               : [0..100000]
```

The rules for overflow-triggered auto-bandwidth adjustment are as follows:

- Overflow sample: {(sampledBW / currentBW – 1) ≥ threshold%} && {(sampledBW – currentBW) ≥ thresholdBW}
- The signaled bandwidth will be:
  - if (measuredBW ≥ maxBW) then signaledBW = maxBW
  - if (measuredBW ≤ minBW) then signaledBW = minBW
  - else signaledBW = measuredBW



Underflow triggers were introduced in 12.0.R1. The parameters used in case of underflow are:

- Underflow sample: a sample interval counts as an underflow sample if the sampled bandwidth is lower than the current bandwidth by at least the configured underflow thresholds.
- Underflow-limit/underflow-count: an auto-bandwidth adjustment occurs after this number of consecutive underflow samples.
- Threshold%: minimum difference between current bandwidth and sampled bandwidth, expressed as a percentage of the current bandwidth.
- Threshold bw: minimum difference between current bandwidth and sampled bandwidth in Mbps. Default value: 0.
- Maximum underflow bandwidth (MU): maximum sampled bandwidth in the consecutive underflow samples.

```
A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth underflow-limit
  - underflow-limit <number> threshold <percent> [bw <mbps>]
  - no underflow-limit

 <number>             : [1..10]
 <percent>            : [0..100]
 <mbps>               : [0..100000]
```

Figure 100 **Underflow-Triggered Auto-Bandwidth Implementation**

In Figure 100, the adjust-interval is not displayed. It is assumed to be the default of 288 collection intervals (24 h). The figure only shows five consecutive underflow samples. The underflow-limit equals 5. In each of the samples, the sample bandwidth is below the underflow threshold. The maximum sampled bandwidth of these five samples corresponds to the maximum underflow bandwidth. This bandwidth will be signaled when auto-bandwidth adjustment is triggered because the underflow count is reached.

The rules for underflow-triggered auto-bandwidth adjustment are as follows:

- Underflow sample:
  - {(1 - sampledBW / currentBW) ≥ threshold%} && {(currentBW – sampledBW) ≥ thresholdBW}
- Underflow count/underflow limit: after that many consecutive underflow samples, an auto-bandwidth adjustment is triggered.
- The signaled bandwidth will be:
  - if (maxUnderflowBW ≥ maxBW) then signaledBW = maxBW
  - if (maxUnderflowBW ≤ minBW) then signaledBW = minBW
    else signaledBW = maxUnderflowBW

If the adjustment is successful, the sample counter within the adjust-interval is reset, along with other parameters, such as the maximum underflow bandwidth, the measured bandwidth, and the underflow count. The next adjust-interval will elapse in 24 h.

If the adjustment fails, there will be 5 retries. If they all fail, only the underflow count and the maximum underflow bandwidth are reset. The current adjust-interval continues.

Manual Trigger

Besides the periodic trigger and the overflow/underflow trigger, an operator can launch a tools command to trigger an auto-bandwidth adjustment.

```
A:PE-1# tools perform router mpls adjust-autobandwidth
```

This tools command can be launched with or without explicit LSP name. In the latter case, all active LSPs are attempted for auto-bandwidth.

```
A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
  - adjust-autobandwidth [lsp <lsp-name> [force [bandwidth <mbps>]]]

 <lsp-name>           : [64 chars max]
 <force>              : keyword
 <mbps>               : [0..100000]

A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
```

This command (without the keyword force) triggers a new auto-bandwidth calculation according to the rules of periodic triggered type. If the LSP already has the correct reserved bandwidth, the following message is returned.

```
A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
MINOR: CLI lsp LSP-PE-1-PE-2 active path is already at the requested value 12 Mbps.
```

If the keyword force is added without a specific value for the bandwidth, there is no threshold checking. The bandwidth can also be adjusted if the difference in bandwidth is below the thresholds. The granularity remains 1 Mbps.

```
A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2" force
```

The rules for the signaled bandwidth are unchanged:

- if (measuredBW ≥ maxBW) then signaledBW = maxBW
- if (measurealedBdBW ≤ minBW) then signaledBW = minBW
  else signW = measuredBW

If the keyword force with bandwidth (in Mbps) option is given, the signaled bandwidth is set to this configured bandwidth, even if it is a value below the minimum or higher than the maximum bandwidth.

```
A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2" force
bandwidth 30
```

After a manually triggered auto-bandwidth MBB, no counters are reset. The ongoing adjust-interval is not aborted.

A clear command resets all counters and timers associated with auto-bandwidth adjustment on a specified LSP.

```
A:PE-1# clear router mpls lsp-autobandwidth "LSP-PE-1-PE-2"
```

This command clears the parameters that are shown in bold in the following example. The parameters will be explained in the configuration section.

```
A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth

A:PE-1#
```

Passive Monitoring

The system offers the option to measure the bandwidth of an LSP without taking any action to adjust the bandwidth reservation.

```
A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth monitor-bandwidth
```

Auto-Bandwidth Based on Forwarding Class

From 11.0.R4 onward, the bandwidth can be calculated as a weighted sum of all the traffic in the eight forwarding classes. By default, all forwarding classes have the same weight: 100%, but that sampling weight is configurable.

```
A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth fc
  - fc <fc-name> sampling-weight <sampling-weight>
  - no fc <fc-name>

 <fc-name>            : be|l2|af|l1|h2|ef|h1|nc
 <sampling-weight>    : [0..100]
```

Active Path Change

From 12.0.R4 onward, auto-bandwidth adjustment is also supported on LSPs that have secondary paths. If the secondary path is standby, an auto-bandwidth MBB can be triggered when the active path changes from primary to secondary. The secondary/standby path is only initialized at its configured bandwidth when it is established, and the bandwidth is adjusted only when it becomes active. This happens when the primary path goes down or becomes degraded. When another path becomes active, the bandwidth used to signal the auto-bandwidth MBB will be the operational bandwidth of the previous path.

The definition for current bandwidth is modified for this feature:

- Current bandwidth: last known reserved bandwidth for the LSP. This may be for a different path than the active one.

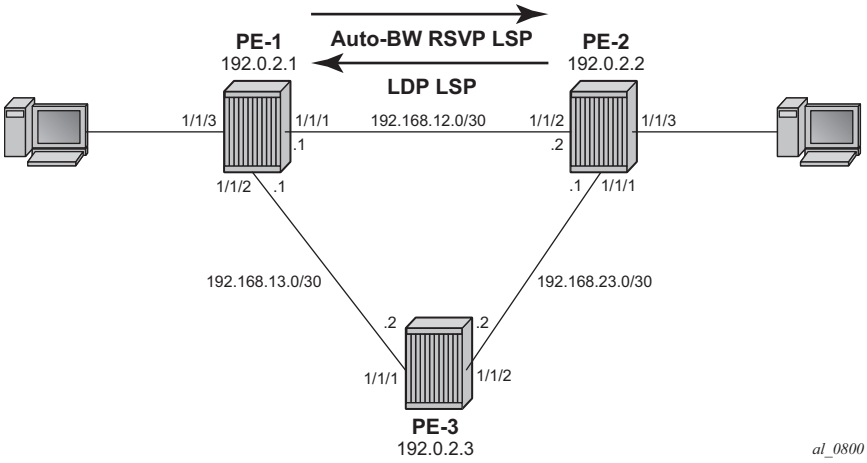
  Auto-bandwidth adjustment will only take place on the active path. When the active path changes, the current bandwidth is updated to the operational bandwidth of the new active path.

- For a secondary path that is signaled as standby, if the active path for an LSP changes without the LSP going down, an auto-bandwidth MBB is triggered on the new active path. The signaled bandwidth is the operational bandwidth of the previous path. The reserved bandwidth of the new active path will be its configured bandwidth until the MBB succeeds.
- For a secondary path where the active path goes down, the LSP will go down temporarily until the secondary path is set up. When the LSP goes down, all statistics and counters are cleared, so the previous path operational bandwidth is lost. There will be no immediate bandwidth adjustment on the secondary path.

The following rules apply to determine the signaled bandwidth of the new active path.

- For a path that is operationally down, signaledBW = configuredBW.
- For the first 5 MBB attempts on the path that just became active,
  signaledBW = currentBW (operational bandwidth of the previous path).

For the remaining MBB attempts, signaledBW = operationalBW.



- For all MBBs other than auto-bandwidth MBB on the active path,
  MBB signaledBW = operationalBW.
- For an MBB on the inactive (standby) path, MBB signaledBW = configuredBW.

When the system reverts from a secondary standby path to the primary path, a Delayed Retry MBB is attempted to bring the bandwidth on the standby path back to the configured bandwidth. MBB is attempted once, and if it fails, the standby is torn down. A Delayed Retry MBB has the highest priority among MBBs, so it will take precedence over any other MBB in progress on the standby path, such as configuration change or pre-emption.

Configuration

Figure 101 shows the example setup. The focus will be on the RSVP LSP from PE-1 to PE-2.

Figure 101 **Example Setup for Auto-Bandwidth Point-to-Point LSPs**

Base Configuration

The cards, MDAs and ports need to be configured.

Configure the interfaces on all nodes. For PE-1:

```
configure router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-3"
            address 192.168.13.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
```

As an IGP, OSPF or IS-IS can be used. In this example, OSPF is configured. Traffic engineering should be enabled. For PE-1:

```
configure router
        ospf
            traffic-engineering
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-PE-3"
```

```
                    interface-type point-to-point
                exit
            exit
        exit
```

Optionally, enable LDP on all interfaces. Link-layer LDP is not a pre-requisite for using auto-bandwidth RSVP LSPs. In this example, the SDP from PE-2 to PE-1 uses an LDP LSP, but it could have been an RSVP-TE LSP instead. For PE-2:

```
configure router ldp
            interface-parameters
                interface "int-PE-2-PE-1"
                exit
                interface "int-PE-2-PE-3"
                exit
            exit
            targeted-session
            exit
```

Enable MPLS and RSVP on all nodes.

```
configure router mpls no shutdown
configure router rsvp no shutdown
```

Add all interfaces to the MPLS context. They will automatically be added to the RSVP context. For PE-1:

```
configure router
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-3"
            exit
        exit
```

Configure a path with no explicitly defined hops and LSP LSP-PE-1-PE-2 on PE-1:

```
configure router mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                primary "loose"
                exit
                no shutdown
            exit
```

In the example, traffic needs to be injected into the LSP tunnel. For that, a VPLS service is created. For PE-1, an SDP using the RSVP LSP to PE-2 is created.

```
configure service
        sdp 212 mpls create
            description "SDP-PE-1-PE-2-overRSVP-TE"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
```

On PE-2, an SDP using LDP is created toward PE-1.

```
configure service
        sdp 121 mpls create
            description "SDP-PE-2-PE-1-overLDP"
            far-end 192.0.2.1
            ldp
            no shutdown
        exit
```

On PE-1 and PE-2, a VPLS is created. For PE-1:

```
configure service vpls 100 customer 1 create
            sap 1/1/3 create
            exit
            spoke-sdp 212:100 create
            exit
            no shutdown
            exit
```

The configuration on PE-2 is similar.

Pre-requisites for Auto-Bandwidth LSP Configuration

Enable constrained shortest path first (CSPF) on the LSP by adding the keyword **cspf**.

```
configure router mpls lsp “LSP-PE-1-PE-2” cspf
```

The bandwidth of the LSP will be adjusted in a make-before-break (MBB) manner. Enable MBB on the LSP by adding the keyword adaptive to the primary path.

```
configure router mpls lsp “LSP-PE-1-PE-2” primary “loose” adaptive
```

Enter a value for the bandwidth in Mbps for the primary path. It is good practice to configure the same value as for the minimum bandwidth in the auto-bandwidth settings.

```
configure router mpls lsp "LSP-PE-1-PE-2" primary "loose" bandwidth 2
```

Auto-Bandwidth LSP Configuration

MPLS auto-bandwidth adjustment allows the ingress LER to dynamically adjust the bandwidth of an RSVP tunnel based on active measurements of the traffic rate into the tunnel. Therefore, LSP egress statistics need to be enabled on the iLER.

Auto-bandwidth adjustment requires an accounting policy to be defined and operational. The accounting policy specifies the collection interval for LSP statistics collection, which is fundamental to the auto-bandwidth algorithm. The minimum interval for this type of collection is 5 minutes, which is the default value.

```
configure log
        accounting-policy 10
            record combined-mpls-lsp-egress
            to no-file
            no shutdown
       exit
```

An accounting policy of record type **combined-mpls-lsp-egress** doesn't need a reference to a specific file ID.

From the moment auto-bandwidth is enabled with an LSP context, the record combined-mpls-lsp-egress inside the accounting policy will also take bandwidth measurements.

```
configure log accounting-policy 10 to no-file
```

When the no-file is configured, no LSP statistics are stored anymore. The MPLS auto-bandwidth feature retrieves it LSP statistics information directly from the statistics module.

However, the accounting policy can reference a file and, therefore, a CF card. An additional CF card may be required in each node as a storage location. For releases prior to 10.0.R4, this is mandatory.

```
configure log
        file-id 66
            location cf1:
            rollover 15 retention 1
```

```
        exit
        accounting-policy 66
            record combined-mpls-lsp-egress
            to file 66
            no shutdown
        exit
```

In the remainder of the example, the accounting policy will reference to no-file.

After the accounting policy has been created, egress statistics can be enabled on the LSP.

```
configure router mpls lsp "LSP-PE-1-PE-2"
         egress-statistics
            no shutdown
            collect-stats
            accounting-policy 10
         exit
```

The system does not verify whether egress statistics have been enabled on the LSP. When a user configures auto-bandwidth adjustment, but without enabling egress statistics, no auto-bandwidth measurements and adjustments are performed. The operational state of auto-bandwidth (AB OpState) is down.

Enable auto-bandwidth with default settings by adding the keyword auto-bandwidth to the LSP.

```
configure router mpls lsp LSP-PE-1-PE-2 auto-bandwidth
```

The actual values are shown in the following output. They are explained after the output.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth

===============================================================================
*A:PE-1#
```

The plus sign (+) indicates that the value is inherited from the global MPLS settings (AB Adj Mul: 288+ and AB Samp Mul: 1+). The sample-multiplier and the adjust-multiplier can both be configured globally in the MPLS context or overruled by the settings per LSP. In this example, nothing has been configured in the MPLS context or in the LSP. Therefore, the default values as defined in the MPLS context are applicable.

Auto-Bandwidth – Periodic Trigger (Normal)

The default collection interval is 5 minutes. The sample-multiplier is 1, by default. The sample interval equals 1 * 5 minutes = 5 minutes. The adjust-multiplier is 288, by default 288. The adjustment interval equals 288 * 5 minutes = 1440 minutes (24 hours).

The auto-bandwidth settings for the LSP are modified as follows:

```
configure router mpls lsp LSP-PE-1-PE-2
                auto-bandwidth
                    multipliers sample-multiplier 1 adjust-multiplier 3
                    adjust-up 10 bw 1
                    adjust-down 5 bw 0  ## default
                    max-bandwidth 20
                    min-bandwidth 2
                exit
```

In the example, the bandwidth of the LSP can be auto-adjusted every 15 minutes (after 3 intervals of 5 minutes). For a decrease in bandwidth, the default settings apply and no explicit command is required in this example. That means that the current bandwidth will be reduced when the difference in bandwidth is at least 5%. There is no absolute decrease (in Mbps) defined. For an increase in bandwidth, there

will only be an adjustment when the increase is at least 10% and at least 1 Mbps. The minimum bandwidth is 2 Mbps. This equals the bandwidth set in the path in the LSP (recommended). The maximum bandwidth equals 20 Mbps. The system will not compare the minimum or maximum bandwidth to the configured bandwidth for the path.

Display the actual auto-bandwidth data after 5, 10, and 15, minutes.

There are different bandwidths displayed:

- The AB Curr BW is the operational bandwidth during the adjustment interval. It is initially the configured bandwidth of the path in the LSP, but it can be auto-adjusted. This bandwidth is taken into account in the control plane when an LSP is set up or modified in case of MBB. The real data rate in the data plane may exceed this operational bandwidth.
- The ABMaxAvgRt is the measured bandwidth, meaning the maximum averaged bandwidth (calculated every sample interval of 5 minutes) in the adjustment interval of 15 minutes (AB Adj Time: 15 Min).
- The AB Lst AvgRt is the sampled bandwidth, averaged over the latest sample interval of 5 minutes (AB Samp Intv: 5 Mins).

After 5 minutes, one collection interval has elapsed within the adjust-interval (AB Adj Cnt = 1) and the next adjustment time is in 10 minutes (AB Next Adj = 10 Min). The current bandwidth equals 2 Mbps, while the measured and the sampled bandwidths are much higher: 12 Mbps.

*A:PE-1#
```

The periodic trigger type rules for auto-bandwidth are:

- When measuredBW ≥ currentBW
  - if {(measuredBW / currentBW – 1) ≥ up%} &&{(measuredBW – currentBW) ≥ up

    then signaledBW = max{(min(measuredBW, maxBW)), minBW}

In this case, the measuredBW (13 Mbps) is greater than the currentBW (2 Mbps). The increase is at least 10% (up%) and at least 1 Mbps (up). The bandwidth will be adjusted. The new bandwidth that will be signaled is calculated as follows:

```
signaledBW= max{(min(measuredBW, maxBW)), minBW}
signaledBW= max {(min (13 Mbps, 20 Mbps)), 2 Mbps}
signaledBW= max {13 Mbps, 2 Mbps}
signaledBW= 13 Mbps
```

Whenever an auto-bandwidth adjustment is performed, a message is stored in log 99.

```

```

Auto-Bandwidth - Passive Monitoring

When passive monitoring is enabled, no automatic bandwidth adjustments occurs. When the maximum bandwidth is again raised to 20 Mbps, the bandwidth will not be auto-adjusted even if the measured bandwidth is high enough.

```
configure router mpls lsp LSP-PE-1-PE-2 auto-bandwidth max-bandwidth 20
configure router mpls lsp LSP-PE-1-PE-2 auto-bandwidth monitor-bandwidth
```

The system monitors the bandwidth, but without taking action at the end of the adjust-interval.

```

```

The value for the parameter **AB Monitor BWis True**

For the remainder of the chapter, there is no passive monitoring. The settings are restored to normal:

```
configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth no monitor-bandwidth
```

Auto-Bandwidth – Overflow and Underflow Trigger Type

With default settings, the adjustment interval is 24 hours. If the bandwidth changes significantly since the start of the current adjust-interval, overflow and underflow triggers can be used. This will speed up the auto-bandwidth adjustment. Overflow triggers are supported from 8.0.R4 onward and underflow triggers from 12.0.R1 onward.

Stop auto-bandwidth in order to force a MBB attempt toward the configured primary path bandwidth (2Mbps in this example).

```
configure router mpls lsp "LSP-PE-1-PE-2" no auto-bandwidth
```

Check the operational bandwidth of the LSP.

```

*A:PE-1#
```

Enable auto-bandwidth with similar settings as before and add overflow and underflow triggers. The multipliers are default. Therefore, a periodically triggered auto-adjustment will only take place once every 24 hours.

```
configure router mpls lsp LSP-PE-1-PE-2 auto-bandwidth
                    multipliers sample-multiplier 1 adjust-multiplier 288
                    adjust-up 10 bw 1
                    max-bandwidth 20
                    min-bandwidth 2
                    overflow-limit 1 threshold 10 bw 2
                    underflow-limit 3 threshold 10 bw 2
                exit
```

The overflow count indicates the number of consecutive times that the overflow condition is detected at the end of a sample interval. Auto-bandwidth adjustment occurs after that number of overflow samples is reached, in this case, after the first overflow sample (overflow-limit = 1). The conditions for an overflow sample are:

{(sampledBW / currentBW – 1) ≥ threshold%} && {(sampledBW – currentBW) ≥ thresholdBW}

{(11 Mbps/2Mbps – 1) ≥ 0,1} && {(11Mbps – 2Mbps) ≥ 2Mbps}

The signaled bandwidth will be:

- if (measuredBW ≥ maxBW) then signaledBW = maxBW
- if (measuredBW ≤ minBW) then signaledBW = minBW
  else signaledBW = measuredBW
- if (11 Mbps ≥ 20 Mbps) then signaledBW = 20 Mbps;
- if (11 Mbps ≤ 2 Mbps) then signaledBW = 2 Mbps;
  else signaledBW = 11 Mbps

Display the auto-bandwidth data. The **AB Adj Cause** is now **overflow**. The overflow limit is the configured value of 1 (**AB Ovfl Lmt**). The overflow count has been reset after the auto-bandwidth was adjusted (**AB Ovfl Cnt = 0**), along with the **ABMaxAvgRt** and **the AB Adj Cnt**. This is the start of a new adjust-interval of 24 hours.

===============================================================================
*A:PE-1#
```

In the following example, the current bandwidth is 13 Mbps, but the bandwidth dropped from 10 Mbps and the conditions for underflow are met. At the end of a sample interval, the sampled bandwidth is reduced by at least 10% and at least 2 Mbps, and this becomes an underflow sample. The conditions for an underflow sample are:

{(1 - sampledBW / currentBW) ≥ threshold%} && {(currentBW – sampledBW) ≥ thresholdBW}

{(1 - 10 Mbps / 13 Mbps) ≥ 0,1} && {(13Mbps – 10Mbps) ≥ 2Mbps}

Since the underflow limit equals 3, an auto-bandwidth adjustment can only take place after the third consecutive underflow sample. The new bandwidth will equal the **maximum sampled underflow bandwidth (ABMaxUndflBW)**. This is the maximum sampled bandwidth in the three consecutive underflow samples.

The signaled bandwidth will be:

- if (maxUnderflowBW ≥ maxBW) then signaledBW = maxBW
- if (maxUnderflowBW≤ minBW) then signaledBW = minBW
  else signaledBW = maxUnderflowBW
- if (10 Mbps≥ 20 Mbps) then signaledBW = 20 Mbps;
- if (10 Mbps ≤ 2 Mbps) then signaledBW = 2 Mbps;
  else signaledBW = 10 Mbps

The following output shows the auto-bandwidth data after two consecutive underflow samples (**AB Underfl Cnt: 2**). The maximum sampled underflow bandwidth equals 10 Mbps. No bandwidth adaptation can take place until there are three consecutive underflow samples (**AB UndflLmt: 3**).

===============================================================================
*A:PE-1#
```

If the overload or underload trigger condition is met at the end of an adjust-interval, the auto-bandwidth adjustment is normal, based on the periodic trigger. Overflow and underflow auto-bandwidth adjustments only take place when the adjust-interval is not yet completed.

Auto-Bandwidth – Manual Trigger Type

The auto-bandwidth adjustment can be triggered manually at all times by the following command (with or without the keyword force).

```
tools perform router mpls adjust-autobandwidth
tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2" force
```

When no specific LSP is referred to, auto-bandwidth will be attempted on all LSPs. If the LSP already has the requested bandwidth, the following output is returned.

```
*A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
MINOR: CLI No Thresholds crossed for lsp LSP-PE-1-PE-2.
```

By adding the keyword **force**, there is no check whether the thresholds are crossed. However, the granularity is 1 Mbps. In this case, it is not possible to signal a bandwidth that is at least 1 Mbps different, so the following error message is returned.

```
*A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2" force
MINOR: CLI lsp LSP-PE-1-PE-2 active path is already at the requested value 13 Mbps.
```

If the first sample interval has not yet expired, the following error message is returned.

```
*A:PE-1# tools perform router mpls adjust-autobandwidth lsp "LSP-PE-1-PE-2"
MINOR: CLI No Autobandwidth Averages computed for lsp LSP-PE-1-PE-2.
```

If the tools command is launched after the first sample interval has expired (**ABMaxAvgRt** is filled in), the overflow trigger rules can be applied. In this example, the traffic is reduced and the thresholds are crossed.

The **AB Adj Cause** is manual.

```

*A:PE-1#
```

Manually triggered auto-bandwidth adjustments are also performed using MBB procedures.

Auto-Bandwidth Adjustment Based on Forwarding Class Subset

With the configuration applied so far, there is no distinction between traffic from different forwarding classes (FCs). The average data rate is the sum of the traffic from all eight FCs. From 11.0.R4 onward, it is possible to provide a sampling weight for each Forwarding Class (FC) for each auto-bandwidth LSP. The average data rate is now the weighted sum of the traffic from all FCs.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" auto-bandwidth fc
  - fc <fc-name> sampling-weight <sampling-weight>
  - no fc <fc-name>

 <fc-name>            : be|l2|af|l1|h2|ef|h1|nc
 <sampling-weight>    : [0..100]

===============================================================================
*A:PE-1#
```

The sampling-weight values can be changed while auto-bandwidth is enabled. The auto-bandwidth algorithm will be reset on the LSP at the end of the current collection interval. At that time, the current bandwidth will not be adjusted and the following counters will be reset to 0: sample count, adjust count, overflow count, underflow count, max average data rate, and max average underflow data rate.

Auto-Bandwidth on LSPs with Secondary Paths

This feature is supported from 12.0.R4 onward.

When the active path goes down or becomes degraded, the bandwidth used to signal the auto-bandwidth MBB will be the operational bandwidth of the previous active path. The parameter current-bandwidth requires a modified definition:

Current-bandwidth — The last known reserved bandwidth for the LSP (this may be for a different path than the active one).

When the active path changes, the current bandwidth is updated to the operational bandwidth of the new active path. While the auto-bandwidth MBB on the active path is in progress, a statistics sample might be triggered because the intervals aren't reset when the active path changes. It is possible that an auto-adjustment is needed. The in-progress auto-bandwidth MBB will be restarted with retry attempts to 0 and signaled bandwidth equal to the new measured bandwidth. If after five attempts, auto-bandwidth MBB fails, the current bandwidth and secondary **oper-bw** remain unchanged.

For a secondary/standby path, if the active path changes without the LSP going down, an auto-bandwidth MBB is triggered for the new active path. The bandwidth used to signal the MBB is the operational bandwidth of the previous active path (current bandwidth).

If the primary path is not currently active, but it has not gone down, then any MBB should use the configured bandwidth for the primary path.

Create two new strict paths and assign them to the LSP. The primary path is the direct strict path from PE-1 to PE-2. There are two secondary paths: **path-PE-1-PE-3-PE-2** and **loose**. The first one is standby, the latter is not.

```
configure router mpls
            path path-PE-1-PE-2
                hop 10 192.0.2.2 strict
                no shutdown
            exit
            path path-PE-1-PE-3-PE-2
                hop 10 192.0.2.3 strict
                hop 20 192.0.2.2 strict
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                cspf
                fast-reroute facility
                    no node-protect
                exit
                primary loose shutdown
                no primary loose
                primary path-PE-1-PE-2
                    adaptive
                    bandwidth 2
                exit
                secondary path-PE-1-PE-3-PE-2
                    adaptive
                    bandwidth 2
                    standby
                exit
                secondary loose
                    adaptive
                    bandwidth 2
                exit
                no shutdown
            exit
```

Stop the auto-bandwidth MBB to have the current bandwidth equal to the bandwidth configured for the primary path (2 Mbps).

```
configure router mpls lsp "LSP-PE-1-PE-2" no auto-bandwidth
```

Configure auto-bandwidth with the following settings:

```
configure router mpls lsp "LSP-PE-1-PE-2"
               auto-bandwidth
                   multipliers sample-multiplier 1 adjust-multiplier 288
                   adjust-up 10 bw 1
                   max-bandwidth 20
                   min-bandwidth 2
                   overflow-limit 2 threshold 10
                   underflow-limit 3 threshold 10
                   fc be sampling-weight 50
                   fc af sampling-weight 80
               exit
```

Initially, the current bandwidth is the configured bandwidth of the primary path: 2 Mbps, but in case of overflow, it will be increased after two overflow samples (10 minutes).

```

Conclusion

Auto-bandwidth adjustment can be enabled on point-to-point LSPs in order to make a realistic bandwidth reservation, based on active iLER traffic monitoring. A user has control over how the bytes count for the different FCs by providing a sampling-weight factor. This can influence the average data rate over the sample interval.

The bandwidth is taken into account in the control plane when LSPs are established or when they change their bandwidth using MBB. The bandwidth in the data plane is not restricted by this setting.

Auto-bandwidth adjustment can be triggered in different ways: periodically, in case of overflow/underflow, manually, and in case of an active path change. It is also possible to have passive monitoring where no adjustment is done.

Automatic Creation of RSVP-TE LSPs

This chapter provides information about automatic creation of resource reservation protocol with traffic engineering (RSVP-TE) label switched paths (LSPs).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This feature is applicable to 7750 SR-7/12, 7750 SR-12e, 7450 ESS-7/12, XRS-20/16c, and 7750-c4/12 with no hardware constraints as this is a control-plane feature only.

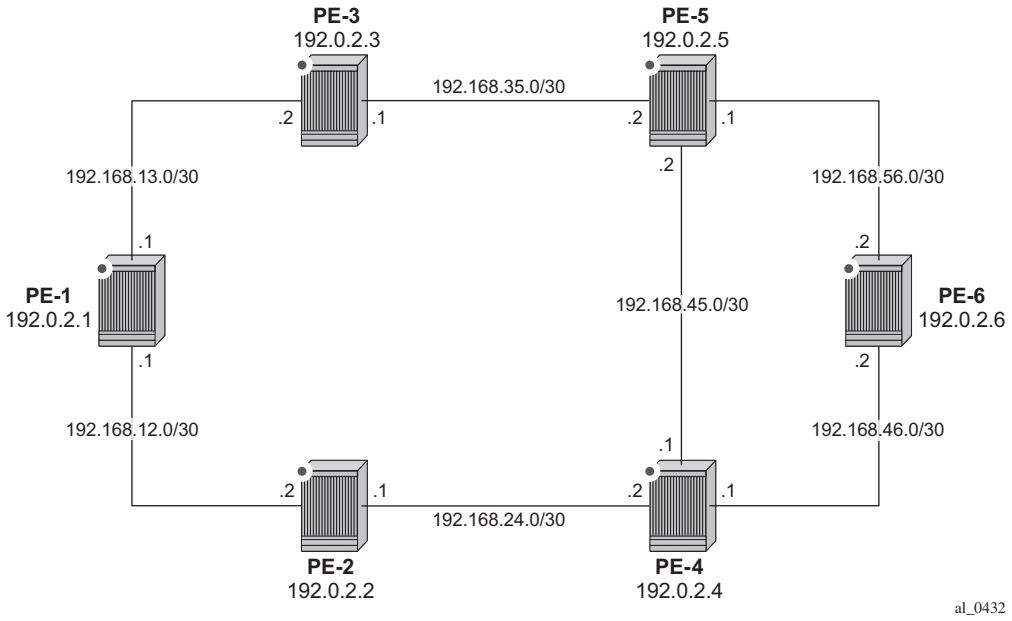
This chapter was originally written for and tested on SR OS release 11.0.R6, but the CLI in this edition corresponds to release 14.0.R1.

Overview

Automatic creation of RSVP-TE LSPs enables the automated creation of point-to-point RSVP-TE LSPs within a single interior gateway protocol (IGP) intermediate system to intermediate system (IS-IS) level or open shortest path first (OSPF) area that can subsequently be used by services and/or IGP shortcuts. The feature is divided into two components: creation of an RSVP-TE LSP mesh, and creation of single-hop RSVP-TE LSPs. Although both can be used simultaneously, it is likely that one or the other is used.

When creating an RSVP-TE LSP mesh, the mesh can be full or partial, the extent of which is governed by a prefix-list containing the system addresses of all nodes that should form part of the mesh. When using single-hop RSVP-TE LSPs, point-to-point LSPs are established to all directly connected neighbors. The purpose of these single-hop LSPs is to allow for equal cost multi-path (ECMP) load-balancing of traffic using LDP-over-RSVP, which is not possible using native RSVP LSPs.

The use of automatically created RSVP-TE LSPs avoids manual configuration of RSVP-TE LSP meshes. Even when provisioning tools (such as 5620 SAM) are used to automatically provision these LSPs, auto-mesh still provides a benefit by avoiding increased configuration file sizes.



The use of automatically created targeted label distribution protocol (LDP) sessions is also described when using the automatically created RSVP LSPs for Layer 2 services.

Configuration

Example Topology

The example topology is shown in Figure 102. All routers participate in a single IS-IS Level-2 area that has traffic engineering enabled. Multiprotocol label switching (MPLS) and RSVP are enabled on every interface, but no LSPs are initially provisioned. All routers are border gateway protocol (BGP) speakers and form part of autonomous system (AS) 64496. PE-5 is a route reflector and the remaining routers are IBGP clients for the VPN IPv4 and L2-VPN address families. The objective of this example is to demonstrate how to automatically create transport LSPs using RSVP or LDP-over-RSVP, and then create services that utilize those LSPs. The exchange of BGP routes is needed for those services.

Figure 102 **Example Topology**

Automatic Creation of an RSVP-TE LSP Mesh

To start the process of automatically creating an RSVP-TE LSP mesh, the user must create a route policy referencing a prefix-list. This prefix-list contains the system addresses of all nodes that are required to be in the mesh, and can be entered as a series of /32 addresses, or simply as a range as shown configured below. This range encompasses all of the system addresses of the nodes in the test topology as the requirement is to make a full-mesh.

```
configure
    router
        policy-options
            begin
            prefix-list "System-Addresses"
                prefix 192.0.2.0/24 prefix-length-range 32-32
            exit
            policy-statement "Remote-PEs"
                entry 10
                    from
                        prefix-list "System-Addresses"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

After the route policy is created, the user must create an **lsp-template** containing the common parameters which are used to establish all point-to-point LSPs within the mesh. For an RSVP-TE LSP mesh, the **lsp-template** must be suffixed with the creation-time attribute **mesh-p2p**. Upon creation of the template, CSPF is automatically enabled (and cannot be disabled), and the template must reference a **default-path** before it can be placed in a **no shutdown** state. In the example contained in the following output, the template refers to a path named “loose” that has no strict or loose hops defined, meaning the system will dynamically calculate the path whilst considering other specified constraints. The **lsp-template** in this output also stipulates **fast-reroute facility** bypass protection. The default behavior is no node-protect, therefore this configuration requests link protection only. FRR one-to-one protection is not supported for automatically created RSVP-TE LSPs; therefore facility bypass is the only form of protection supported. Finally the template is placed in a no shutdown state.

Next, the user must associate the lsp-template with the previously defined route-policy, and this is accomplished using the **auto-lsp lsp-template** command. In this example, the lsp-template “Full-Mesh” is associated with the policy-statement “Remote-PEs” that in turn references a prefix-list containing all system addresses in the test topology. Up to five policies can be associated with a given lsp-template at the same time. If a policy associated with an lsp-template is modified in order to add or remove prefixes, the system immediately re-evaluates the policy and the prefix-list to determine if one or more LSPs need to be established, or one or more LSPs need to be torn down.

```
configure
    router
        mpls
            path "loose"
                no shutdown
            exit
            lsp-template "Full-Mesh" mesh-p2p
                default-path "loose"
                cspf
                fast-reroute facility
                exit
                no shutdown
            exit
            auto-lsp lsp-template "Full-Mesh" policy "Remote-PEs"
            no shutdown
        exit
```

Once the **auto-lsp lsp-template** command is entered, the system commences the process of establishing the point-to-point LSPs. The prefixes defined in the prefix-list are checked, and if a prefix corresponds to a router-id that is present in the traffic engineering database, the system instantiates a CSPF computed primary path to that prefix using the parameters specified in the lsp-template. With the previously

defined configuration applied at PE-6, the existence of point-to-point RSVP LSPs to every node in the test topology can be verified as shown in the following output. The LSP name is automatically constructed as TemplateName-DestIPv4Address-TunnelId. The LSP name signaled in the Session Attribute object concatenates the LSP name with the path name (for example Full-Mesh-192.0.2.1-61441::loose).

```

LSPs : 5
===============================================================================
*A:PE-6#
```

The lsp-template requests fast-reroute link protection. At PE-6, this protection can be verified by querying each primary LSP. In the following output, the primary LSP to PE-1 (Full-Mesh-192.0.2.1-61441) is signaled through PE-5 (192.0.2.5) and PE-3 (192.0.2.3), and the presence of the @ indicator after each hop denotes that link protection is available to the primary path.

```
*A:PE-6# show router mpls lsp path "Full-Mesh-192.0.2.1-61441" detail | match

*A:PE-6#
```

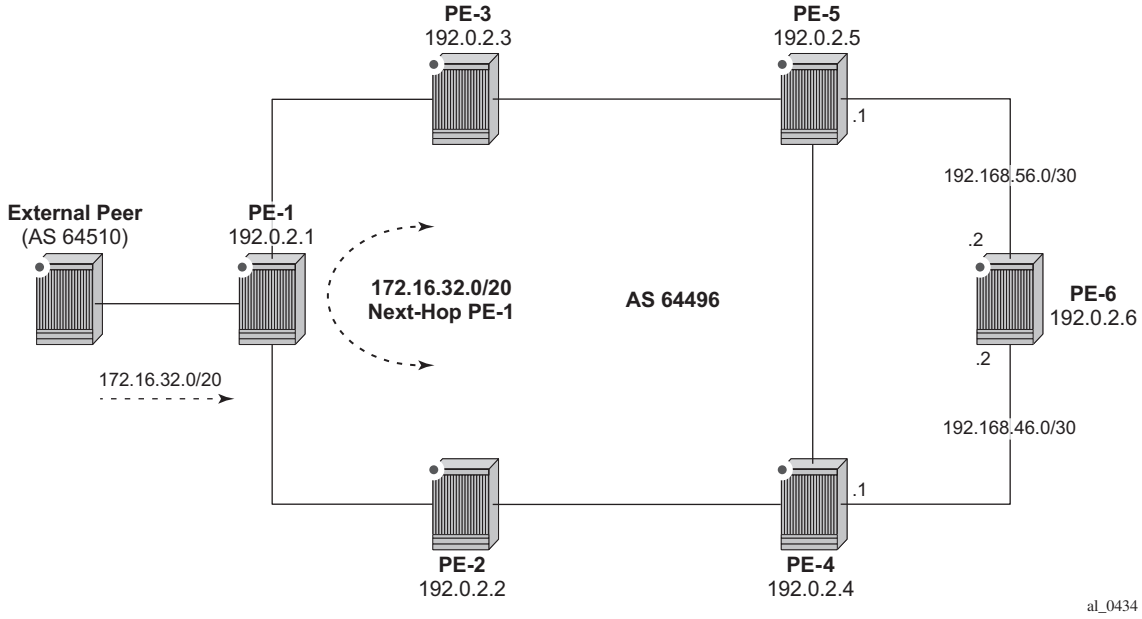
Once the lsp-template is in use and LSPs are instantiated, it is necessary to place the template into a shutdown state to change any parameters that cannot be handled as a *Make-Before-Break* (MBB). This essentially includes all LSP parameters with the exception of bandwidth and fast-reroute without node-protection. Modification of any other parameters requires a shutdown of the lsp-template and a re-signal of the LSP once the lsp-template is placed in the no shutdown state again. MBB is supported for timer-based and manual re-signaling of the automatically created LSPs.



Service and Application Verification

With the RSVP-TE LSP mesh in place, it is now possible to create services and applications to utilize those LSPs. These applications and services include Layer 2 and Layer 3 VPNs, resolution of BGP labeled routes and resolution of BGP, IGP, and static routes. However, the automatically created LSPs are not available for explicit binding in a statically provisioned service distribution point (SDP).

IGP Shortcuts

Figure 103 demonstrates the use of IGP shortcuts. Prefix 172.16.32.0/20 is advertised to PE-1 from an external peer in AS 64510, which PE-1 subsequently advertises into IBGP, imposing Next-Hop-Self in the process. For more details on IGP shortcuts, see chapter IGP Shortcuts.

Figure 103 **IGP Shortcuts with RSVP-TE Auto-Mesh**

The objective is for PE-6 to use the automatically created LSP to PE-1 as an IGP shortcut (typically implemented in order to maintain a “BGP-free” core). IGP shortcuts for BGP are enabled under the main BGP context using the command **next-hop-resolution shortcut-tunnel** with options for **rsvp**, **ldp** or **bgp**. Since the example topology only has (automatically created) RSVP-TE LSPs, this option is selected. In fact, there are three more options: sr-isis, sr-ospf, and sr-te. These are related to segment routing, which is beyond the scope of this chapter.

```
configure router bgp next-hop-resolution shortcut-tunnel family
  - family <family>

 <family>             : ipv4

 [no] disallow-igp    - Allow/Disallow IGP shortcuts
     resolution      - Configure resolution state of BGP unlabelled routes to tunnels
      resolution-fil* + Configure specific tunnels to be used for resolving BGP
unlabelled routes

configure router bgp next-hop-resolution shortcut-tunnel family ipv4 resolution-filter
  - resolution-filter

 [no] bgp             - Use BGP tunnelling for next hop resolution
 [no] ldp             - Use LDP tunnelling for next hop resolution
 [no] rsvp            - Use RSVP tunnelling for next hop resolution
 [no] sr-isis         - Use sr-isis for next hop resolution
 [no] sr-ospf         - Use sr-ospf for next hop resolution
 [no] sr-te           - Use sr-te for next hop resolution
```

```
configure
    router
        bgp
            next-hop-resolution
                shortcut-tunnel
                    family ipv4
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                exit
            exit
```

Once the shortcuts are enabled, the route-table (and FIB) can be validated to ensure that the programmed next hop is the advertising BGP speaker (as opposed to the IGP next hop), and that traffic is tunneled to that next hop through an RSVP LSP. In this case the RSVP LSP is the LSP with Tunnel-Id 61441, which is the LSP to PE-1.

```
*A:PE-6# show router route-table 172.16.32.0/20

===============================================================================
```

Layer 3 VPN

Layer 3 VPNs can utilize the automatically created LSPs by using the **auto-bind-tunnel** feature configured with the **rsvp** option (possibly in combination with LDP). The option to include both rsvp and ldp, allows the system to use an RSVP LSP if one exists, and if not, to revert to an LDP-based LSP. A virtual private routed network (VPRN) is configured in this manner at PE-1 and PE-6. PE-1 is configured with a loopback address of 172.16.1.1/24 and advertises the VPN IPv4 prefix 172.16.1.0/24 into IBGP, whilst PE-6 is configured with a loopback address of 172.16.6.1/24 and advertises the VPN IPv4 prefix 172.16.6.0/24 into IBGP. The next output illustrates the configuration at PE-6. The only difference at PE-1 is the IP address assigned to the loopback interface.

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                    rsvp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "loopback" create
                address 172.16.6.1/24
                loopback
            exit
            no shutdown
        exit
```

Before a VPN IPv4 prefix is considered **valid**, the receiving SR OS PE router must be able to resolve the BGP next hop to an LSP in the tunnel table (if not, the prefix is held in routing information base RIB-In and flagged as **invalid**). At PE-6, it is possible to verify that the VPN IPv4 prefix 172.16.1.0/24 received from PE-1 is correctly resolved by looking at the VPRN-specific route table. In the following output, the VPN IPv4 prefix 172.16.1.0/24 with a next hop of PE-1 (192.0.2.1) is correctly resolved to an RSVP LSP with a tunnel ID of 61441.

```
*A:PE-6# show router 1 route-table 172.16.1.0/24

===============================================================================
```

Layer 2 VPN

As previously described, automatically created RSVP LSPs cannot be referenced by statically provisioned SDPs. Without the ability for SDPs to explicitly reference automatically created RSVP LSPs, there is little value in manually defining SDPs within Layer 2 service constructs (there is little point in referring to an SDP that cannot bind to the underlying RSVP mesh). Therefore, in order to deliver Layer 2

services there is a requirement to adopt a model within the service construct that permits automatic creation of SDP bindings, and this is achieved using a pseudowire-template dictating the characteristics of the SDP. The secondary effect of using pseudowire-templates to dynamically create SDPs is that these automatically created SDPs can currently only use LDP or BGP as a transport tunnel, not RSVP. The solution is to enable LDP-over-RSVP.

This can be implemented using static provisioning of peers as shown in the next output, or it can be done using automatic creation of T-LDP sessions. Regardless of the method, a reciprocal configuration must exist at both peer endpoints. The static per-peer configuration is applied in the **targeted-session** context specifying the remote peer system IP address, and the keyword **tunneling,** which enables tunneling of LDP FECs over RSVP LSPs with a far-end address matching that of the T-LDP peer. At a global level, the **prefer-tunnel-in-tunnel** command is shown, but is only required when a next hop router advertises a FEC over link-level LDP and T-LDP. In this case, by default the system would prefer the link-level LDP tunnel, so the **prefer-tunnel-in-tunnel** instructs the system to prefer an LDP-over-RSVP tunnel if it is available. Although link-layer LDP is not present in the test topology, the command is included because the presence of link-layer LDP is common.

```
configure
    router
        ldp
            prefer-tunnel-in-tunnel
            interface-parameters
            exit
            targeted-session
                peer 192.0.2.1
                    tunneling
                    exit
                exit
            exit
            no shutdown
        exit
```

The next output provides an example demonstrating the automatic creation of T-LDP sessions. Here, no explicit reference is made to specific peers, but rather a **peer-template** is configured containing the parameters which apply to all T-LDP sessions spawned by this template. In this example, only the **tunneling** command is required. A **peer-template-map** is then used to create a mapping between the **peer-template** (TLDP-Mesh) and a **policy** defining the IP addresses of remote nodes to which T-LDP sessions should be established. In this example, the policy “Remote-PEs” is the same policy previously used by the auto-created RSVP LSP mesh.

```
configure
    router
        ldp
            prefer-tunnel-in-tunnel
            interface-parameters
            exit
            targeted-session
```

```
            peer-template "TLDP-Mesh"
                tunneling
            exit
            peer-template-map peer-template "TLDP-Mesh" policy "Remote-PEs"
        exit
        no shutdown
    exit
```

Regardless of whether T-LDP sessions are explicitly provisioned, or dynamically created using a peer-template, the result is that a targeted LDP session is established which can be used for advertising address and service FECs, and which is capable of tunneling LDP over RSVP.

```

To create VPLS services using dynamically-created SDPs, BGP auto-discovery (BGP-AD) must be used together with LDP (or BGP) pseudowire signaling, for more details see LDP VPLS using BGP-Auto Discovery.

In the following output PE-6 uses BGP-AD and LDP signaling. The same configuration is applied at PE-1. The **vpls-id** is configured in the **bgp-ad** context. The **vpls-id** is a network-wide identifier assigned to all VPLS switch instances (VSIs) belonging to the same VPLS, and is carried in VPLS network layer reachability information (NLRI) as an extended community attribute. A second parameter used for BGP-AD and carried in the VPLS NLRI is the VSI-ID, which uniquely identifies

each VSI. The VSI-ID is automatically derived from the global ASN, the VPLS service ID, and the system IP address. To automatically create SDPs, the **bgp** context of the VPLS service refers to a **pw-template** defining the parameters of the pseudowire. In this example, the use of the hash (entropy) label is enabled in the pseudowire template, and a **split-horizon-group,** SHG, is applied.

```
configure
    service
        pw-template 2 create
            hash-label
            split-horizon-group "SHG"
            exit
        exit
        vpls 2 customer 1 create
            bgp
                pw-template-binding 2
                exit
            exit
            bgp-ad
                vpls-id 64496:2
                no shutdown
            exit
            sap 1/1/4:2 create
            exit
            no shutdown
        exit
```

The following service information provides the BGP and BGP-AD operational parameters, and shows that an SDP of type **BgpAd** (17407:4294967295) has been automatically created. Both the SDP and the SAP are operationally up.

```

```

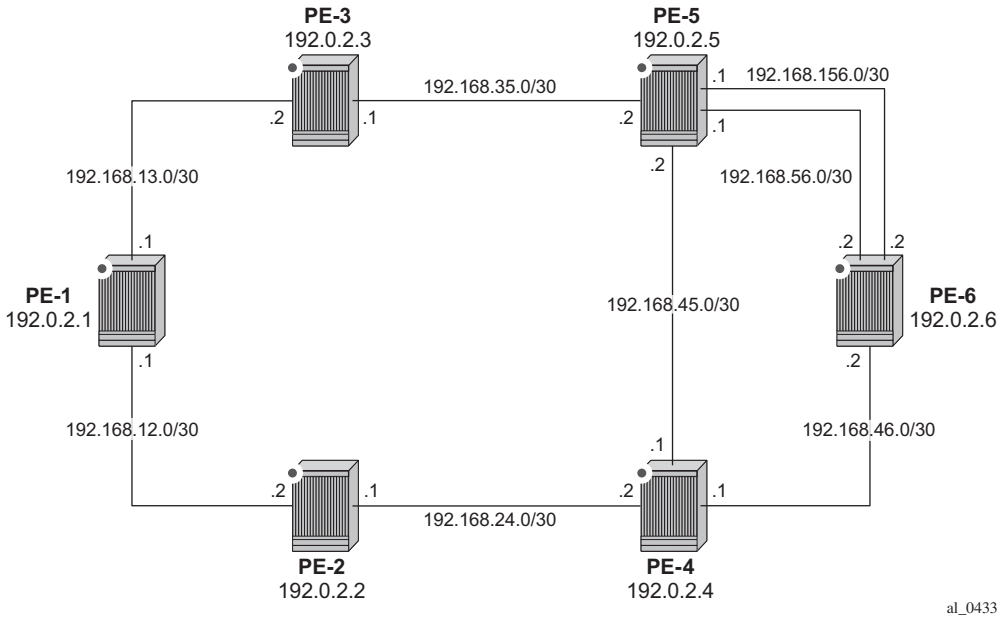
To create Epipe services using dynamically created SDPs, two options exist. Either LDP FEC 129 signaling can be used, which in turn dictates the presence of pseudowire routing information, or BGP-VPWS based signaling can be used, for more details see BGP Virtual Private Wire Services. This example illustrates the use of BGP VPWS, but in either case, only single-segment pseudowires are supported. The next output shows the configuration requirements for a basic BGP-based Epipe service at PE-6. Once again a **pw-template** is used to define the characteristics of the pseudowire, and this template is referenced in the **bgp** context of the Epipe service. The **bgp** context is also where the **route-distinguisher** and **route-target** values are configured, which are carried in the VPWS NLRI and extended communities respectively. The **ve-name**, **ve-id**, and **remote-ve-name** are all configured in the **bgp-vpws** context. The **ve-id** is carried in the VPWS NLRI, and when a PE router receives a VPWS NLRI to try to establish an Epipe service, the **ve-id** from the NLRI is validated against the **ve-id** configured in the **remote-ve-name**. These must match before the Epipe becomes operational.

```
configure
    service
        pw-template 3 create
            hash-label
        exit
        epipe 3 customer 1 create
            bgp
                route-distinguisher 64496:3
                route-target export target:64496:3 import target:64496:3
                pw-template-binding 3
                exit
            exit
            bgp-vpws
                ve-name "PE-6"
                    ve-id 6
                exit
                remote-ve-name "PE-1"
```

```
                ve-id 1
            exit
            no shutdown
        exit
        sap 1/1/4:3 create
        exit
        no shutdown
    exit
```

The basic service information is truncated to show only the relevant information in order to verify that the service is operational. SDP (17406:4294967294) has been automatically created and is of type **BgpVpws**. Both the SDP and the SAP are operationally up.



```

Automatic Creation of RSVP Single-Hop LSPs

As previously discussed, the purpose of a single-hop LSP mesh is to allow for ECMP load-balancing of traffic using LDP-over-RSVP. ECMP load-balancing could be implemented using LDP over a partial or full mesh of RSVP-TE LSPs, but the use of single-hop LSPs additionally allows for load-balancing across a number of parallel RSVP LSPs between nodes. To illustrate ECMP load-balancing over multiple parallel RSVP LSPs the example topology of Figure 102 is modified to include a parallel link between PE-6 and PE-5 as shown in Figure 104. In addition, all routers are enabled for ECMP=2.

```
configure router ecmp 2
```

Figure 104 **Test Topology for Single-Hop LDP-over-RSVP with ECMP**

Unlike the automatically created RSVP-TE LSP mesh previously discussed, the automatically created single-hop RSVP-TE LSPs have no requirement for a prefix-list to be referenced containing the prefixes of the remote nodes that form part of the mesh. In the case of automatically created single-hop LSPs the TE database keeps track of each TE link which comes up to a directly connected IGP neighbor. The system then establishes a single-hop LSP with a destination address matching the router-id of the neighbor and with a strict hop consisting of the address of the interface used by the TE link.

The first requirement is to create an **lsp-template** containing the common parameters used to establish each single-hop LSP. For a single-hop LSP mesh the **lsp-template** must be suffixed with the creation-time attribute **one-hop-p2p**. Upon creation of the template, **cspf** is automatically enabled (and cannot be disabled), and the **hop-limit** is set to a value of **2**. The hop-limit defines the number of nodes the LSP may traverse, and since these are single-hop LSPs to adjacent neighbors a limit of 2 is sufficient. The template must also reference a **default-path** before it can be placed in the no shutdown state. The following example references a path named “loose” that has no strict or loose hops defined. When the RSVP PATH message is actually generated to create the one-hop LSP, it contains one strict-hop to the interface address of the neighbor; and as destination the system address of the adjacent node.

The next requirement is to trigger the creation of single-hop LSPs, and this is achieved using the **auto-lsp lsp-template** command. In this example, the lsp-template “Single-Hop” is referenced, and the command is completed with the keyword **one-hop** to indicate the creation of single-hop LSPs. Unlike an RSVP-TE mesh there is no requirement to reference a route-policy. In the example, the auto-lsp with lsp-template “Full-Mesh” is removed.

```
configure router mpls no auto-lsp lsp-template "Full-Mesh"

configure
    router
        mpls
            path "loose"
                no shutdown
            exit
            lsp-template "Single-Hop" one-hop-p2p
                default-path "loose"
                cspf
                hop-limit 2
                no shutdown
            exit
            auto-lsp lsp-template "Single-Hop" one-hop
            no shutdown
        exit
    exit
exit
```

Once the **auto-lsp lsp-template** command is entered, the system starts the process of establishing the single-hop LSPs. A check is made of the TE database for every TE link to a directly connected IGP neighbor, and a single-hop LSP is established across each TE link. The following output is taken from PE-6 and shows the automatically created single-hop LSPs. The LSP names are automatically constructed as TemplateName-DestIPv4Address-TunnelId. The LSP name signaled in the session attribute object concatenates the LSP name with the path name (for example Single-Hop-192.0.2.4-61499::loose). Recall from Figure 104 that PE-6 has a single TE-enabled link to PE-4, and two TE-enabled links to PE-5, therefore with ECMP=2, there is one LSP to PE-4 (192.0.2.4) and two LSPs to PE-5 (192.0.2.5). However, if ECMP=1, only one single-hop LSP would be signaled to PE-5.

```

```

As the purpose of single-hop LSPs is to enable ECMP load-balancing using LDP-over-RSVP, there is a requirement to configure T-LDP sessions between RSVP LSP endpoints. This can be implemented using static peer provisioning, or it can be done using automatic creation of T-LDP sessions, both of which have been previously described and they are therefore not repeated. In this example, the automatic creation of T-LDP sessions approach is used, and T-LDP sessions are created to adjacent neighbors that are capable of tunneling inside RSVP.

```
*A:PE-6# show router ldp session

*A:PE-6#
```

To validate the ECMP load-balancing capability, PE-5 is configured to advertise prefix 172.16.5.0/24 to PE-6. In turn, PE-6 is configured for **ibgp-multipath** to enable load-balancing over IGP links to the BGP next hop address, **next-hop-resolution shortcut-tunnel resolution-filter ldp** to enable tunneling of traffic destined toward the BGP next hop in MPLS, and **ecmp 2**.

```
configure
    router
        bgp
            ibgp-multipath
            next-hop-resolution
                shortcut-tunnel
                    family ipv4
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                exit
            exit
            no shutdown
```

The prefix 172.16.5.0/24 advertised by PE-5 is learned at PE-6 and installed in the RIB/FIB with PE-5's system address (192.0.2.5) as next hop.

Conclusion

Automatic creation of RSVP-TE LSPs provides a good solution for reducing the amount of provisioning activity required when configuring RSVP LSPs. However, there are some constraints with regard to the way that services are deployed on top of those LSPs. SDPs cannot explicitly reference automatically created RSVP LSPs, which means that automatically created SDPs need to be used for Layer 2 services. In turn, automatically created SDPs can only use LDP or BGP as a transport tunnel (not RSVP), therefore in order to use the automatically created RSVP mesh, LDP over RSVP must be used. These caveats need to be fully understood before considering deployment of automatically created RSVP-TE LSPs.

Class-Based Forwarding

This chapter provides information about class-based forwarding

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and was initially written for release 13.0.R7. The CLI in this edition corresponds to release 14.0.R1.

Before SR OS 13.0.R6, class-based forwarding (CBF) was only applicable to resource reservation protocol (RSVP) label switched paths (LSPs) in multi-LSP service distribution points (SDPs) used by services. In release 13.0.R6, CBF of label distribution protocol (LDP) prefix packets over interior gateway protocol (IGP) shortcuts was introduced. Both implementations are described in this chapter.

Overview

In large networks, services are typically required from any PE to any other PE, and can traverse multiple domains. Within a service, different traffic classes can coexist, each with different requirements for latency and jitter.

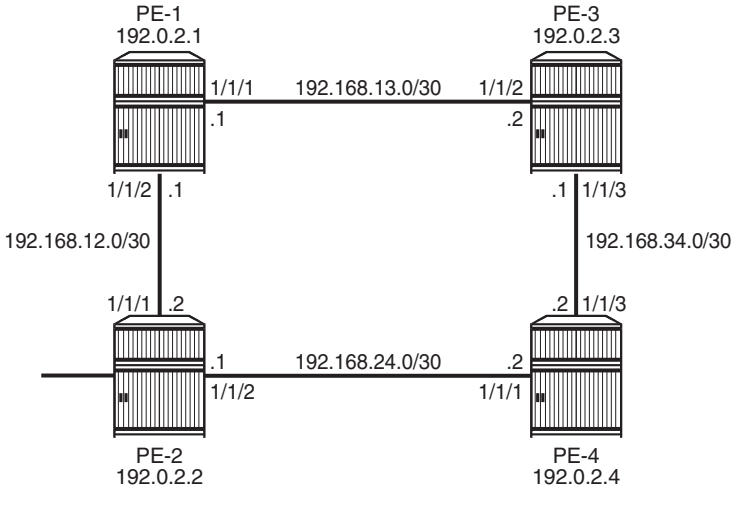
With CBF, packets with different forwarding classes (FCs) can be forwarded on different LSPs. When equal-cost multipath (ECMP) routing without CBF is used, packets are distributed over the whole set of LSPs, without any distinction for the FC. CBF is based on FC, not on the traffic being in-profile or out-of-profile, and is a local decision, which makes it easier for interoperability.

This feature may be useful when certain links have less bandwidth and should only be used for high priority traffic. A service provider might decide to send real-time traffic over a shorter path with less bandwidth, while the bulk of the traffic takes a longer path with more bandwidth.

Configuration

The initial implementation for CBF was based on RSVP LSPs. This is described first, followed by CBF of LDP prefix packets over IGP shortcuts.

CBF over RSVP LSPs



CBF over RSVP LSPs allows a service packet to be forwarded over a specific RSVP LSP, part of an SDP, based on its service ingress determined FC, typically controlled by a default or operator-defined **sap-ingress** policy. A default LSP is configured for all traffic that does not match the FCs that are explicitly configured in the SDP. CBF over RSVP LSPs is also used to forward a received packet that has been classified at the ingress service access point (SAP) into an FC, if the LSP that supports its FC is not available.

Note: CBF can also be enabled on static LSPs in the same way, but that scenario is not common.

A multicast LSP is configured for broadcast, unknown, and multicast (BUM) traffic. When no multicast LSP is defined, BUM traffic uses the default LSP. Because there are multiple LSPs per SDP, CBF over RSVP LSPs increases the number of RSVP sessions.

The test topology is shown in Figure 105. This topology will be extended in a subsequent use case.

Figure 105 **Test Topology for CBF on RSVP LSPs**

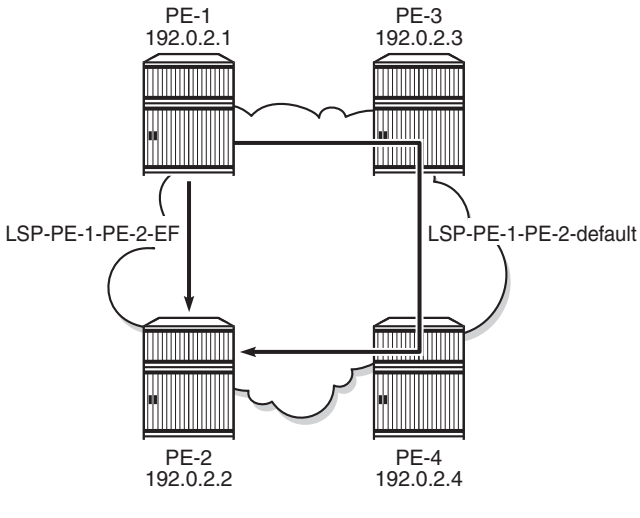
Initial Configuration

All nodes have the following initial configuration:

- Cards, media dependent adapters (MDAs), ports
- Router interfaces
- IGP open shortest path first (OSPF) or intermediate system to intermediate system (IS-IS)
- Multiprotocol label switching (MPLS) enabled on all router interfaces
- RSVP enabled
- RSVP LSPs

As an example, the configuration on PE-1 is shown. The configuration for PE-2 is similar.

```
*A:PE-1# configure router
        interface "int-PE-1-P-3"
            address 192.168.13.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
```



```
*A:PE-1# configure router
        ospf
            traffic-engineering
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-P-3"
                    interface-type point-to-point
                exit
            exit
        exit
*A:PE-1# configure router
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-P-3"
            exit
            no shutdown
        exit
*A:PE-1# configure router rsvp no shutdown
```

The RSVP LSPs use paths with strict hops:

```
*A:PE-1# configure router
        mpls
            path "direct-PE-1-PE-2"
                hop 10 192.168.12.2 strict
                no shutdown
            exit
            path "indirect-PE-1-PE-2"
                hop 10 192.168.13.2 strict
                hop 20 192.168.34.2 strict
                hop 30 192.168.24.1 strict
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2-EF"
                to 192.0.2.2
                primary "direct-PE-1-PE-2"
                exit
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2-default"
                to 192.0.2.2
                primary "indirect-PE-1-PE-2"
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The configured RSVP LSPs are shown in Figure 106.

Figure 106 **LSPs with Direct and Indirect Path toward PE-2**

Configure SDPs

In the initial configuration, the traffic is by default sent on LSP "LSP-PE-1-PE-2-default", except when the FC is expedited forwarding (EF). The traffic with FC EF is sent over LSP "LSP-PE-1-PE-2-EF". Both LSPs are assigned to SDP 122 on PE-1:

```
*A:PE-1# configure service
        sdp 122 mpls create
            description "SDP-PE-1-PE-2"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2-EF"
            lsp "LSP-PE-1-PE-2-default"
            path-mtu 1514
            class-forwarding default-lsp "LSP-PE-1-PE-2-default"
                fc "ef" lsp "LSP-PE-1-PE-2-EF"
                no shutdown
            exit
            no shutdown
        exit
```

Note: A change in the CBF configuration may result in a change of forwarding behavior.

The configuration of SDP 212 from PE-2 to PE-1 is similar.

For the SDPs to get operational up, targeted-LDP (T-LDP) must be enabled on the PE nodes:

```
*A:PE-1# configure router ldp no shutdown
```

The state of the SDP can be verified as follows:

```
*A:PE-1# show service sdp
===============================================================================
Services: Service Destination Points
===============================================================================

===============================================================================
*A:PE-1#
```

Some Considerations

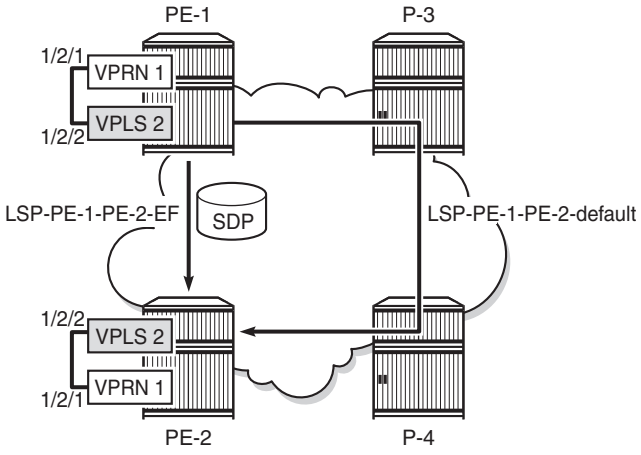
- When CBF is enabled, a default LSP must be configured. An error is raised when class-forwarding is enabled without a default LSP:

```
*A:PE-1>config>service>sdp# class-forwarding
MINOR: CLI Default LSP must be specified.
```

- Only one LSP can be configured as the default LSP in the SDP context. Configuring another LSP as the default LSP overwrites the originally configured LSP.
- Only one LSP can be assigned to an FC in the SDP context. Configuring another LSP for an FC overwrites the originally configured LSP.
- An LSP can be assigned to multiple FCs in the SDP context.
- The default LSP can also be assigned to one or more FCs in the SDP context.

```
*A:PE-1>config>service# info
----------------------------------------------
        sdp 122 mpls create
            description "RSVP-SDP-PE-1-PE-2"
            far-end 192.0.2.2
            lsp "LSP-PE-1-PE-2-EF"
            lsp "LSP-PE-1-PE-2-default"
            path-mtu 1514
            keep-alive
                shutdown
            exit
            class-forwarding default-lsp "LSP-PE-1-PE-2-default"
                fc "af" lsp "LSP-PE-1-PE-2-default"
                fc "be" lsp "LSP-PE-1-PE-2-default"
```

```
            fc "ef" lsp "LSP-PE-1-PE-2-EF"
            multicast-lsp "LSP-PE-1-PE-2-default"
            no shutdown
        exit
        no shutdown
    exit
```



- The SDP goes down when the default LSP goes down.
- When CBF is configured on the LSP/LSP template as well as on the SDP, the configuration on the LSP/LSP template is ignored. Configuring CBF in the LSP/LSP template context is required in another use case: CBF of LDP Prefix Packets over IGP Shortcuts. This is described later in this chapter.

Configure Services for Traffic Verification

To verify that EF traffic is sent over the direct link while traffic with a different FC is sent over the longer path, two services are configured on PE-1 and PE-2.

To generate traffic, ping messages will be sent in virtual private routed network 1 (VPRN 1). The outgoing traffic is sent to virtual private LAN service 2 (VPLS 2) where the FC can be modified to EF if needed. VPLS 2 has the spoke SDP with the different LSPs and CBF. This is shown in Figure 107.

Figure 107 **CBF on RSVP LSPs - Services**

```
*A:PE-1# configure service
        vprn 1 customer 1 create
            route-distinguisher 64496:11
```

```
            vrf-target target:64496:1
            interface "loopback1" create
                address 172.31.1.1/32
                loopback
            exit
            interface "int-PE-1-PE-2-VPRN1" create
                address 192.168.112.1/30
                sap 1/2/1 create
                exit
            exit
            static-route-entry 172.31.2.1/32
                next-hop 192.168.112.2
                    no shutdown
                exit
            exit
            no shutdown
        exit
*A:PE-1# configure service
        vpls 2 customer 1 create
            description "VPLS to modify FC for traffic from VPRN 1"
            sap 1/2/2 create
            exit
            spoke-sdp 122:2 create
            exit
            no shutdown
        exit
```

The configuration of the services on PE-2 is similar.

The operational state of the spoke SDP can be verified as follows:

```
*A:PE-1# show service sdp-using
===============================================================================
SDP Using

```

Verify CBF on LSP for Specific FC

To verify that EF traffic is sent out on "LSP-PE-1-PE-2-EF", via port 1/1/2 on PE-1, the configuration of VPLS 2 needs to be modified. The default FC is set to EF.

The SAP ingress policy to set the FC to EF is applied in VPLS 2 on PE-1 as follows:

```
*A:PE-1# configure qos sap-ingress 2 create
```

```
            default-fc ef
            exit
*A:PE-1# configure service
        vpls 2
            sap 1/2/2 create
                ingress qos 2
            exit
        exit
```

The configuration is identical for PE-2.

First, the port statistics are cleared.

```
*A:PE-1# clear port 1/1/[1..2] statistics
```

One thousand ping messages will be sent from VPRN 1 on PE-1 to the loopback address in VPRN 1 on PE-2:

```
*A:PE-1# ping router 1 172.31.2.1 rapid count 1000
```

The port statistics are verified. The FC is equal to EF, so the LSP "LSP-PE-1-PE-2-EF" is used and the traffic is sent via port 1/1/2.

```
*A:PE-1# show port 1/1/1 statistics
===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                    Ingress         Ingress         Egress          Egress
Id                      Packets          Octets         Packets         Octets
-------------------------------------------------------------------------------
1/1/1                        21            1740              21            1708
===============================================================================
*A:PE-1# show port 1/1/2 statistics
===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                    Ingress         Ingress         Egress          Egress
Id                      Packets          Octets         Packets         Octets
-------------------------------------------------------------------------------
1/1/2                      1033          126954            1033          126898
===============================================================================
```

Note: The traffic on the unused port (1/1/1) is not strictly equal to zero and the traffic on the used port (1/1/2) is not strictly equal to 1000, because of other traffic, such as OSPF messages.

Verify CBF on Default LSP

The SAP ingress policy to define the FC is removed from SAP 1/2/2 of VPLS 2. Traffic that enters a SAP where no SAP ingress policy with FC is defined always gets FC best effort (BE). Traffic with FC BE will be sent on the default LSP "LSP-PE-1-PE-2-default" on port 1/1/1 on PE-1, not on the direct link to PE-2.

```
*A:PE-1# configure service vpls 2 sap 1/2/2 ingress no qos 2
*A:PE-1# clear port 1/1/[1..2] statistics
*A:PE-1# ping router 1 172.31.2.1 rapid count 1000
```

The port statistics are verified. The FC is not equal to EF, so the default LSP is used and the traffic is sent via port 1/1/1.

```
*A:PE-1# show port 1/1/1 statistics
===============================================================================
Port Statistics on Slot 1
===============================================================================

Id                      Packets          Octets         Packets          Octets
-------------------------------------------------------------------------------
1/1/2                        12            1068              12            1068
===============================================================================
```

Because no LSP has been configured to transport packets of classes other than EF, the default LSP will be used for all traffic classes different from EF. A similar outcome occurs when the FC of the ping messages is set to assured forwarding (AF), or any other FC different from EF.

The SAP ingress policy to set the FC to AF is applied in VPLS 2 on PE-1 as follows:

```
*A:PE-1# configure qos sap-ingress 2 create
            default-fc af
            exit
*A:PE-1# configure service
        vpls 2
            sap 1/2/2 create
                ingress qos 2
            exit
        exit
```

The configuration is identical for PE-2.

The port statistics are cleared and ping messages are sent. The result shows that the same port (that is, 1/1/1) is used for the generated traffic:

```
*A:PE-1# clear port 1/1/[1..2] statistics
*A:PE-1# ping router 1 172.31.2.1 rapid count 1000
*A:PE-1# show port 1/1/1 statistics
===============================================================================

Id                      Packets          Octets         Packets          Octets
-------------------------------------------------------------------------------
1/1/2                        10             846              10             864
===============================================================================
*A:PE-1#
```

As indicated, the default LSP is used for all traffic with an FC that is not mapped to a specific LSP, which includes the case where a mapping FC-to-LSP has been defined but the LSP is not available. In the current example, all traffic with FC EF will be sent on LSP "LSP-PE-1-PE-2-EF", unless that LSP is unavailable. The default LSP will carry traffic with FC EF in that latter case.

The SAP ingress policy to assign the FC EF is applied in VPLS 2 on PE-1 as follows:

```
*A:PE-1# configure qos sap-ingress 2 create
            default-fc ef
            exit
*A:PE-1# configure service
        vpls 2
            sap 1/2/2 create
                ingress qos 2
            exit
        exit
```

The configuration is identical for PE-2.

To make the LSP "LSP-PE-1-PE-2-EF" unavailable, it is put in the shutdown state on PE-1. LSP "LSP-PE-2-PE-1-EF" on PE-2 is also put in the shutdown state.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2-EF" shutdown
*A:PE-2# configure router mpls lsp "LSP-PE-2-PE-1-EF" shutdown
```

The port statistics are cleared and ping messages are sent. The packets are classified as FC EF in VPLS 2:

```
*A:PE-1# clear port 1/1/[1..2] statistics
*A:PE-1# ping router 1 172.31.2.1 rapid count 1000
```

Because LSP "LSP-PE-1-PE-2-EF" (which uses port 1/1/2) is not operational, the traffic is sent on the default LSP on port 1/1/1 instead:

```
*A:PE-1# show port 1/1/1 statistics
===============================================================================
Port Statistics on Slot 1
===============================================================================
Port                    Ingress         Ingress         Egress          Egress

-------------------------------------------------------------------------------
1/1/2                        14            1046              14           1046
===============================================================================
```

The LSP "LSP-PE-1-PE-2-EF" is re-enabled and the default LSP is now disabled. In this case, the SDP goes down. Ping messages will time out. The SAP ingress quality of service (QoS) policy in VPLS 2 is removed and the FC of the ping messages will no longer be changed to EF.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2-EF" no shutdown
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2-default" shutdown
*A:PE-1# configure service vpls 2 sap 1/2/2 ingress no qos 2
```

The SDP is operational down when the default LSP is down, as can be verified:

```
*A:PE-1# show service sdp-using
===============================================================================
SDP Using

===============================================================================
*A:PE-1#
```

The default LSP is re-enabled.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2-default" no shutdown
```

Define Multicast LSP for BUM Traffic

The multicast LSP specifies the LSP in the SDP to use to forward BUM traffic. The LSP name must exist and must have been associated with this SDP. In this example, the default LSP is configured as the multicast LSP.

```
*A:PE-1# configure service sdp 122 class-forwarding multicast-lsp "LSP-PE-1-PE-2-
default"
*A:PE-2# configure service sdp 212 class-forwarding multicast-lsp "LSP-PE-2-PE-1-
default"
```

The SAP ingress policy to set the default FC to EF is enabled on SAP 1/2/2 in VPLS 2 in PE-1 and PE-2.

```
*A:PE-1# configure service vpls 2 sap 1/2/2 ingress qos 2
```

Ping messages are classified as FC EF in VPLS 2. This traffic is sent over "LSP-PE-1-PE-2-EF". However, if the traffic is unknown, it will be sent over the multicast LSP, which is "LSP-PE-1-PE-2-default". To get unknown traffic, the forwarding database (FDB) is cleared and MAC learning is disabled in VPLS 2 on PE-1.

```
*A:PE-1# clear service id 2 fdb all
*A:PE-1# configure service vpls 2 disable-learning
```

Clear port statistics and launch one thousand rapid ping messages in VPRN 1 on PE-1.

```
*A:PE-1# clear port 1/1/[1..2] statistics
*A:PE-1# ping router 1 172.31.2.1 rapid count 1000
```

Verify the port statistics. BUM traffic is sent on the multicast LSP "LSP-PE-1-PE-2-default" and the egress port on PE-1 is 1/1/1:

```
*A:PE-1# show port 1/1/1 statistics
===============================================================================
Port Statistics on Slot 1

===============================================================================
FC Mapping Table
===============================================================================
FC Name             LSP Name
-------------------------------------------------------------------------------
ef                  LSP-PE-1-PE-2-EF
===============================================================================
---snip---
```

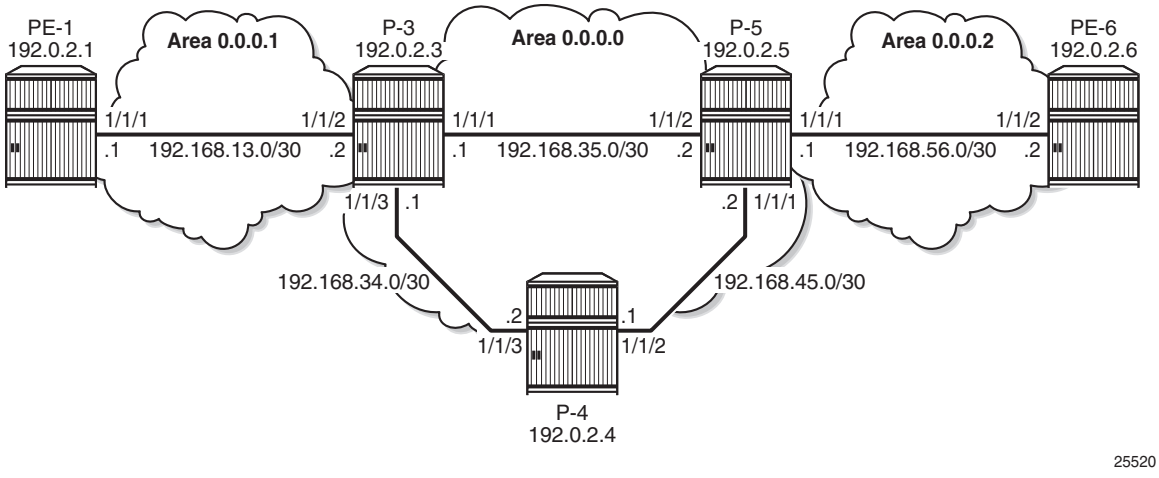
The detailed information for the SDP contains all the LSPs configured in the SDP. CBF is enabled with default LSP "LSP-PE-1-PE-2-default". The multicast LSP is "LSP-PE-PE-2-default", but the name is truncated. The FC mapping table lists all FCs that have an LSP assigned. Each FC can only have one LSP assigned. Different FCs can have the same LSP assigned. In this example, only the FC EF has an LSP assigned.

Traffic statistics can be displayed per service per SDP. These statistics are not per LSP, so no distinction can be made between the different FCs.

```
*A:PE-1# show service id 2 sdp 122 detail
---snip---
Statistics            :
```

```
I. Fwd. Pkts.      : 9003                  I. Dro. Pkts.      : 0
I. Fwd. Octs.      : 882180                I. Dro. Octs.      : 0
E. Fwd. Pkts.      : 9001                  E. Fwd. Octets     : 882060
---snip---
```

Note: In this configuration example, the service using the SDP with CBF is a VPLS. The SDP can be used in a similar way by a VPRN.



Note: An epipe service using CBF must have ingress shared-queuing enabled on access/ SAP to work correctly.

CBF of LDP Prefix Packets over IGP Shortcuts

For this implementation, a more complex test topology is needed. Different OSPF areas are used.

In this example, traffic will be sent from VPRN 3 in PE-1 in OSPF area 0.0.0.1 to VPRN 3 in PE-6 in OSPF area 0.0.0.2. Most nodes used in the previous use case are reused, but some reconfiguration is required (router interfaces, OSPF areas, LSPs). For simplicity, PE-2 is not used anymore. The test topology is shown in Figure 108.

Figure 108 **Test Topology for CBF of LDP Prefix Packets over IGP Shortcuts**

Initial Configuration

All nodes have the following initial configuration:

- Cards, MDAs, ports
- Router interfaces
- IGP (here: OSPF) - PE-1 is now in OSPF area 0.0.0.1 instead of 0.0.0.0 in the preceding use case. P-3 and P-5 have interfaces in different areas:

```
*A:P-3# configure router
        ospf
            traffic-engineering
            area 0.0.0.0
                interface "system"
                exit
                interface "int-P-3-P-4"
                    interface-type point-to-point
                exit
                interface "int-P-3-P-5"
                    interface-type point-to-point
                exit
            exit
            area 0.0.0.1
                interface "int-P-3-PE-1"
                    interface-type point-to-point
                exit
            exit
            no shutdown
        exit
```

- MPLS enabled on all router interfaces
- RSVP enabled
- RSVP LSPs:
  - Between PE-1 and P-3 in area 0.0.0.1 and between PE-6 and P-5 in area 0.0.0.2.
  - Between P-3 and P-5 in area 0.0.0.0, there are two LSPs in each direction: one LSP uses the direct strict path and the other LSP uses an indirect strict path via P-4. On P-3, the LSP "LSP-P-3-P-4-P-5" with indirect path will be used as the default LSP, while the LSP "LSP-P-3-P-5" with the direct path will be used for traffic with FC EF. For simplicity, there are no LSPs configured to or from P-4.

```
*A:P-3# configure router
        mpls
            path "path-P-3-PE-1"
                hop 10 192.168.13.1 strict
                no shutdown
            exit
            path "path-P-3-P-5"
                hop 10 192.168.35.2 strict
                no shutdown
```

```
            exit
            path "path-P-3-P-4-P-5"
                hop 10 192.168.34.2 strict
                hop 20 192.168.45.2 strict
                no shutdown
            exit
            lsp "LSP-P-3-PE-1"
                to 192.0.2.1
                primary "path-P-3-PE-1"
                exit
                no shutdown
            exit
            lsp "LSP-P-3-P-5"
                to 192.0.2.5
                primary "path-P-3-P-5"
                exit
                no shutdown
            exit
            lsp "LSP-P-3-P-4-P-5"
                to 192.0.2.5
                primary "path-P-3-P-4-P-5"
                exit
                no shutdown
            exit
            no shutdown
        exit
```

Configure IGP Shortcuts

IGP shortcut or forwarding adjacency must be enabled in one or more IGP instances. In the example, IGP shortcuts (RSVP shortcuts) are configured on all nodes:

- IGP shortcut:

```
*A:PE-1# configure router ospf rsvp-shortcut
```

- Forwarding adjacency (not configured in the example):

```
*A:PE-1# configure router ospf advertise-tunnel-link
```

By default, all LSPs are eligible for IGP shortcut. However, it is possible to exclude a specific RSVP LSP from being used in IGP shortcut as follows (this is not required in this example):

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-P-3" no igp-shortcut
```

For more information on IGP Shortcuts, see chapter “IGP Shortcuts”.

Configure ECMP

ECMP must be enabled in the global routing instance. Nokia recommends that ECMP is set to a value that is at least equal to the number of FCs used by the packets forwarded using the LDP over RSVP tunnel.

In this case, two traffic flows are distinguished: traffic with FC EF takes one LSP while all other traffic takes the default LSP. Here, ECMP should be at least equal to 2. For simplicity, ECMP equal to 2 is only configured on P-3 and P-5:

```
*A:P-3# configure router ecmp 2
```

Note: The selection of ECMP LSPs is done regardless of class-forwarding assignments, if any. The total number of LSPs with same cost, the number of those which have class-forwarding assignments, and the max-ecmp-routes parameter value influence the final set of LSPs, the consistency (from a CBF perspective) of which will be verified. These three factors must be carefully configured so as to ensure that the final set is consistent from a CBF perspective.

Enable LDP over RSVP

LDP over RSVP must be enabled between all PE routers and all P routers within the same area and between all P routers in the area 0:

```
*A:PE-1# configure router
        ldp
            targeted-session
                peer 192.0.2.3
                    tunneling
                    exit
                exit
            exit

*A:P-3# configure router
        ldp
            targeted-session
                peer 192.0.2.1
                    tunneling
                    exit
                exit
                peer 192.0.2.5
                    tunneling
                    exit
                exit
            exit
```

Note: The LSP names configured in the tunneling context (if any) are not directly used by LDP when the rsvp-shortcut option is enabled. With IGP shortcuts, the set of tunnel next-hops is always provided by IGP in the routing table manager (RTM). The class-based forwarding rules will not apply to these named LSPs unless they are populated by IGP in the RTM as next-hops for a prefix.

Note: The option prefer-tunnel-in-tunnel must be disabled (which is the default) for CBF to apply to LDP prefixes which are the endpoints of tunnels.

There is no need to enable LDP over RSVP on the LSPs. It is enabled by default, as can be verified with the following command:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2-EF" detail | match LdpOverRsvp
LdpOverRsvp : Enabled                          VprnAutoBind   : Enabled
```

For more information on LDP over RSVP, see chapter “LDP over RSVP Using OSPF as IGP”.

Configure CBF of LDP Prefix Packets over IGP Shortcuts

Enable CBF of LDP prefix packets over IGP shortcuts with the following command in the LDP context on P-3 and P-5:

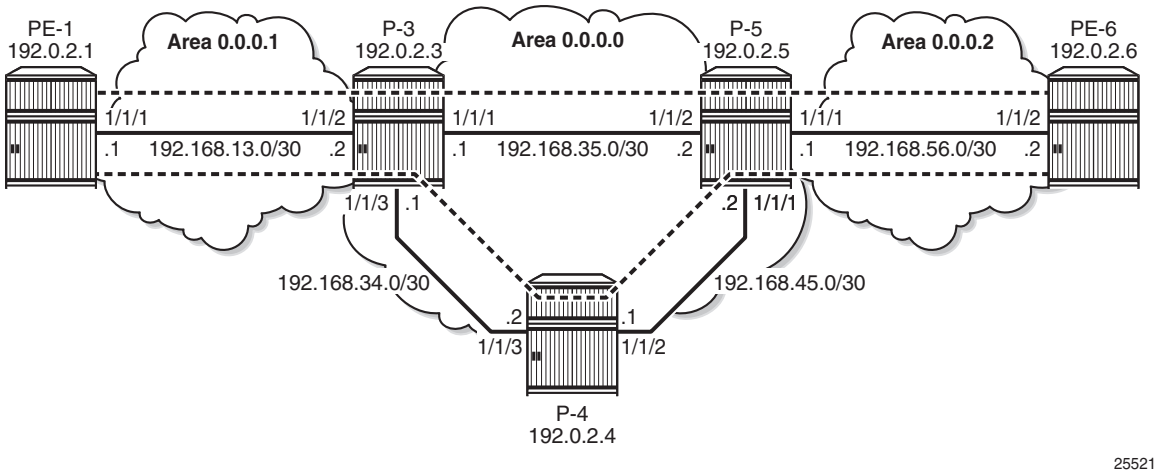
```
*A:P-3# configure router ldp class-forwarding
```

In this example, the PEs only have one path to the P routers. There is no need to enable class-forwarding.

When CBF is enabled, LDP prefixes resolved to a set of ECMP tunnel next-hops will have their packets forwarded to the LSP configured to carry the forwarding class that the packet was classified to at the ingress SAP, access interface, or network interface.

In release 13.0.R6, this command is applicable for LSRs forwarding LDP forwarding equivalence class (FEC) prefix packets over a set of MPLS LSPs using IGP shortcuts. It is not supported for LER forwarding.

Note: The command configure router ldp class-forwarding applies to the following contexts:



1. LER forwarding of packets of VPRN and L2 services that use auto-binding to LDP when the LDP FEC is resolved to a set of MPLS LSPs using IGP shortcuts. This is not supported in 13.0.R6.
2. LER forwarding of shortcut packets over LDP FEC that is resolved to a set of MPLS LSPs using IGP shortcuts. This is not supported in 13.0.R6.
3. LSR forwarding LDP FEC prefix packets over a set of MPLS LSPs using IGP shortcuts. This is supported in 13.0.R6.

This command does not apply to the following contexts:

- LER forwarding of VPRN and L2 services over a user-provisioned SDP of type LDP when the LDP FEC is resolved to a set of MPLS LSPs using IGP shortcuts.

In this use case, the direct link from P-3 to P-5 should only be used for traffic with FC EF. The default LSP will take the longer path from P-3 via P-4 to P-5. The two different paths are shown in Figure 109.

Figure 109 **Different Paths for Different FCs**

The LSPs can be configured as follows:

```
*A:P-3# configure router
        mpls
           lsp "LSP-P-3-P-5"
                class-forwarding
                    fc ef
                exit
            exit
            lsp "LSP-P-3-P-4-P-5"
                class-forwarding
```

```
                default-lsp
            exit
        exit
```

All traffic with an FC that is not mapped to a specific LSP will be mapped to the default LSP. The default LSP will also be used for traffic with FC EF, in case the dedicated LSP for that traffic is no longer available. It is possible to configure more than one default LSP, but only one will be used at a time.

The same LSP can be assigned to one or more FCs and be the default LSP at the same time.

```
*A:P-3# configure router
        mpls
            lsp "LSP-P-3-P-4-P-5"
            class-forwarding
                fc be
                default-lsp
            exit
        exit
```

The consistency of the configuration among the tunnel next-hops of an LDP FEC can only be verified by LDP at the time the FEC is resolved to IGP shortcuts. An example of an inconsistent configuration would be when class-forwarding is enabled while all tunnel next-hops for an LDP FEC have neither **fc** nor **default-lsp** assigned to them. LDP will then revert to ECMP routing for that FEC.

In this example, only P-3 and P-5 have ECMP equal to 2 and class-forwarding enabled.

Multiple LSPs can have the same FC assigned. Only one of these LSPs will be used to forward packets of this FC. That LSP is the one with the lowest tunnel ID.

Multiple LSPs can have the default-lsp configuration assigned, but only one of those will be the default LSP carrying all the traffic that should get the default treatment. That LSP is the one with the lowest tunnel ID.

If at least one LSP (amongst the ECMP set of LSPs) has an FC assigned, but no LSP has the default-lsp configuration, a single LSP will be automatically designated by LDP, even if all eight FCs have been mapped. A default LSP is needed to carry packets of an FC for which no explicit mapping to an LSP exists. The LSP with the lowest tunnel ID will be selected.

Note: If none of the LSPs has an FC or default LSP configuration, the set is inconsistent and no CBF happens.

When the active LDP bindings are displayed, FECs resolved with CBF can be recognized by the (C) after the prefix:

```
*A:P-3# show router ldp bindings active prefixes prefix 192.0.2.6/32

-------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 4
===============================================================================
*A:P-3#
```

Only the entries that correspond to swap operations get the (C) added. The entries that correspond to push operations do not get the (C) because CBF is not supported for LERs in 13.0.R6.

Traffic that is sent from PE-1 to PE-6 will be forwarded on P-3 based on the FC, while traffic that originates on P-3 will not be subjected to CBF.

LSP 2 uses the direct path from P-3 to P-5 while LSP 3 uses the indirect path from P-3 to P-5 via P-4. This can be verified in the tunnel table:

```
*A:P-3# show router tunnel-table
===============================================================================

-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:P-3#
```

The LSP that uses the direct path to P-5 has the lowest tunnel ID. When both LSPs are configured as default LSP, the LSP with the lowest tunnel ID will effectively be used as the default LSP. In the current configuration, only the LSP using the indirect path is configured as the default LSP.

Verify CBF

Traffic will be sent from a VPRN on PE-1 to a VPRN on PE-6 and back.

Configure VPRN

On PE-1 and PE-6, a VPRN service needs to be configured. BGP will be used to exchange VPN routes.

Import and export policies are configured as follows:

```
*A:PE-1# configure router
        policy-options
            begin
            community "VPN3" members "target:64496:3"
            policy-statement "VPN3-export"
                entry 10
                    from
                        protocol direct
                    exit
                    to
                        protocol bgp-vpn
                    exit
                    action accept
                        community add "VPN3"
                    exit
                exit
            exit
            policy-statement "VPN3-import"
                entry 10
                    from
                        protocol bgp-vpn
                        community "VPN3"
                    exit
                    action accept
```

```
                exit
            exit
        exit
        commit
    exit
```

The VPRN is configured using auto-bind-tunnel with resolution-filter ldp, as follows:

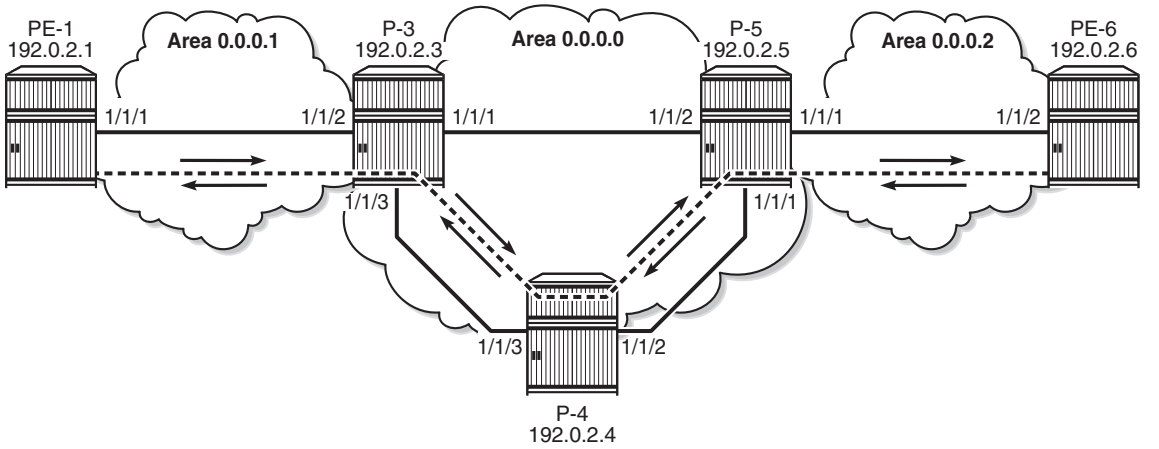
```
*A:PE-1# configure service
    vprn 3 customer 1 create
        vrf-import "VPN3-import"
        vrf-export "VPN3-export"
        route-distinguisher 64496:31
        auto-bind-tunnel
            resolution-filter
                ldp
            exit
            resolution filter
        exit
        interface "loopback3" create
            address 172.31.1.3/32
            loopback
        exit
        no shutdown
    exit
```

For BGP, P-5 is used as route reflector. The address family is VPN-IPv4.

```
*A:PE-1# configure router
    autonomous-system 64496
    bgp
        family vpn-ipv4
        group "internal"
            peer-as 64496
            neighbor 192.0.2.5
            exit
        exit
        no shutdown
    exit

*A:P-5# configure router
    bgp
    autonomous-system 64496
        family vpn-ipv4
        cluster 1.1.1.1
        group "internal"
            peer-as 64496
            neighbor 192.0.2.1
            exit
            neighbor 192.0.2.3
            exit
            neighbor 192.0.2.4
            exit
            neighbor 192.0.2.6
            exit
        exit
        no shutdown
```

```
        exit
```



The routes are learned, as can be verified with the following command:

```
*A:PE-1# show router 3 route-table
===============================================================================
Route Table (Service: 3)

Verify Traffic Flow - Default LSP

When ping messages are sent from the VPRN on PE-1 to the VPRN on PE-6, the traffic will be forwarded according to the FC at the LSRs. The FC is not manipulated yet. For P-3, the traffic will be sent on the default LSP to P-5 via P-4. On node P-3, the ingress port for traffic destined to PE-6 is 1/1/2 and the egress port to P-4 is 1/1/3. The ping replies will follow the reverse path. The traffic flow is shown in Figure 110.

Figure 110 **Traffic on Default LSP**

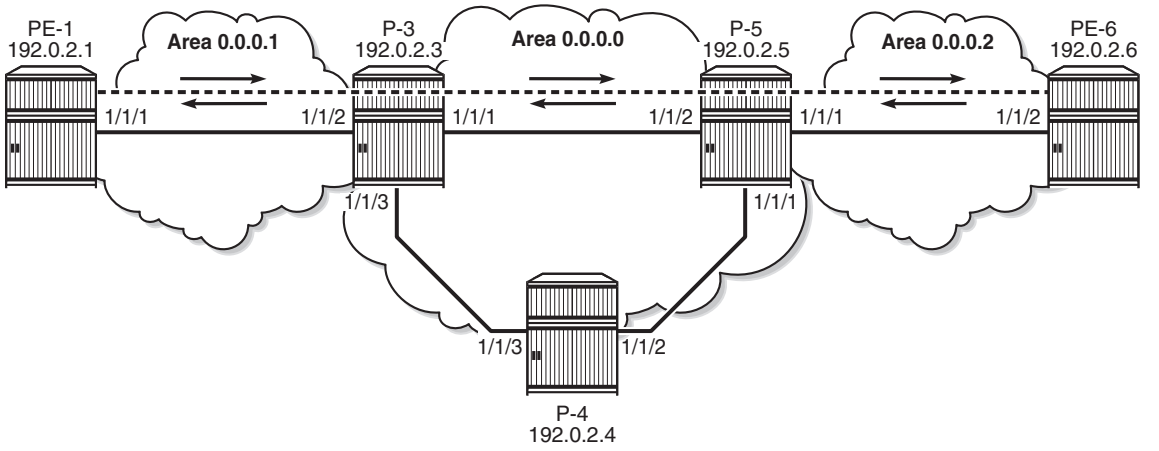
1/1/3                     1037          118074            1040          118648
===============================================================================
*A:P-3#
```

With the same commands, the traffic flow on the other nodes can be verified. P-4 has traffic on port 1/1/3 (to P-3) and on port 1/1/2 (to P-5). P-5 has traffic on port 1/1/1 (to P-4) and port 1/1/3 (to PE-6).



Verify Traffic Flow - LSP for FC EF

On nodes P-3 and P-5, the FC is set to EF at the ingress of the interface to the PE router.

```
*A:P-3# configure qos
        network 2 create
            ingress
                default-action fc ef profile in
            exit
        exit
*A:P-3# configure router interface "int-P-3-PE-1" qos 2
```

When the FC is modified to EF, the traffic takes the direct path between P-3 and P-5. On node P-3, traffic will be sent to and received from P-5 on port 1/1/1, as shown in Figure 111.

Figure 111 **Traffic with FC EF on Direct Path**

```
*A:P-3# clear port 1/1/[1..3] statistics
*A:PE-1# ping router 3 172.31.6.3 rapid count 1000

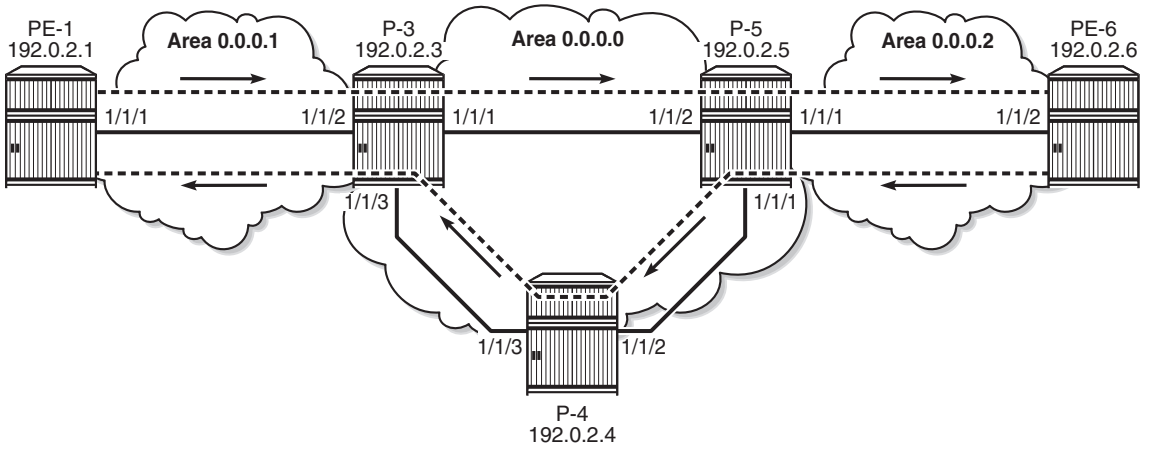
*A:P-3#
```



The original configuration is restored by removing the QoS network policy from the interface to the PE as follows:

```
*A:P-3# configure router interface "int-P-3-PE-1" no qos
```

Verify Traffic Flow - Multiple LSPs Configured as Default LSP on P-3

The FC is not manipulated anymore. On P-3, LSP "LSP-P-3-P-4-P-5" was configured as default LSP. Additionally, also LSP "LSP-P-3-P-5" is configured as a default LSP. So "LSP-P-3-P-5" becomes the used default LSP, because the tunnel ID (equal to 2) is lower than the tunnel ID of the LSP using the long path from P-3 to P-5 via P-4 (equal to 3). When this is configured on P-3, without changing anything to the configuration at P-5, the behavior is asymmetric. Incoming traffic on port 1/1/2 is forwarded to P-5 via port 1/1/1, while the ping replies still take the long path using ingress port 1/1/3 on P-3 The traffic flow is shown in Figure 112.

Figure 112 **Traffic on Default LSP with Lowest ID on P-3**

```
*A:P-3# configure router
        mpls
            lsp "LSP-P-3-P-5"

-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:P-3#
```

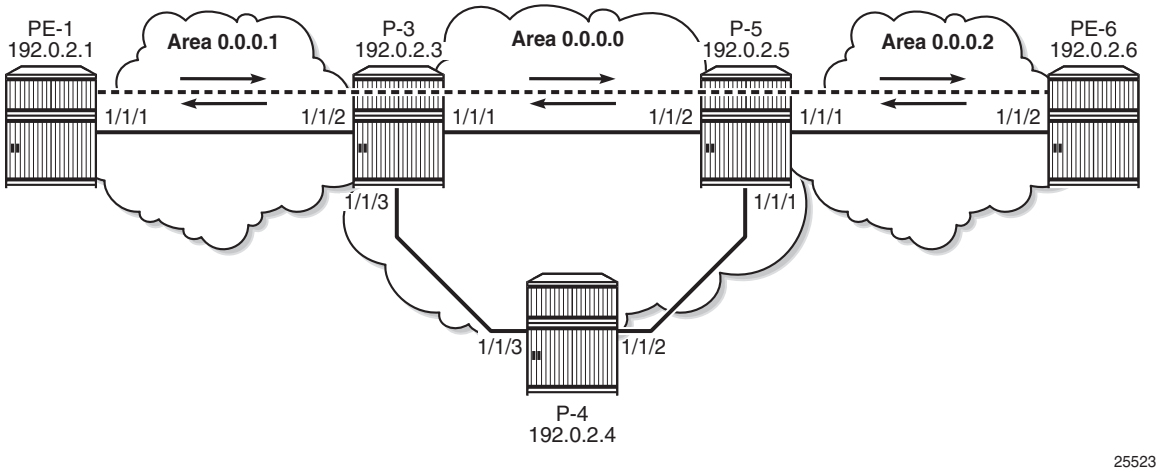
The original configuration is restored. The LSP with the direct path will only be used for traffic with FC EF ("LSP-P-3-P-5" remained an EF LSP even when it became a default LSP):

```
*A:P-3# configure router mpls lsp "LSP-P-3-P-5" class-forwarding no default-lsp
```

Verify Traffic Flow - No Default LSP Configured

When the class-forwarding configuration for the different LSPs always has one or more FCs and no default LSP, the system will select a default LSP itself. This can be tested by removing the default LSP configuration from all LSPs on P-3 and P-5 and adding FC AF instead. FC AF does not correspond to the FC of the ping messages; therefore, a default LSP will be required.

```
*A:P-3# configure router mpls lsp "LSP-P-3-P-4-P-5" class-forwarding no default-lsp
*A:P-3# configure router mpls lsp "LSP-P-3-P-4-P-5" class-forwarding fc af
*A:P-5# configure router mpls lsp "LSP-P-5-P-4-P-3" class-forwarding no default-lsp
*A:P-5# configure router mpls lsp "LSP-P-5-P-4-P-3" class-forwarding fc af
```



The actual CBF configuration does not include any default LSPs anymore:

```
*A:P-3>config>router>mpls# info
----------------------------------------------
---snip---
            lsp "LSP-P-3-P-5"
                to 192.0.2.5
                class-forwarding
                    fc ef
                exit
                primary "path-P-3-P-5"
                exit
                no shutdown
            exit
            lsp "LSP-P-3-P-4-P-5"
                to 192.0.2.5
```

```
            class-forwarding
                fc af
            exit
            primary "path-P-3-P-4-P-5"
            exit
            no shutdown
        exit
```

The system selects the LSP with the lowest tunnel ID as the default LSP, in this case the LSP using the direct path between P-3 and P-5, as shown in Figure 113.

Figure 113 **Traffic on System-Selected Default LSPs with Lowest Tunnel ID**

The tunnel ID can be verified in the tunnel table. The tunnel table for P-3 has already been shown in the preceding section.

On P-5, the LSP to P-3 with the tunnel ID 2 has next hop 192.168.35.1, as can be verified in the tunnel table. This corresponds to LSP "LSP-P-5-P-3". The LSP with tunnel ID 3 and next hop 192.168.45.1 corresponds to LSP "LSP-P-5-P-4-P-3".

```

*A:P-3#
```

No CBF in Case of Inconsistent Configuration

The FC LSP and default LSPs are removed from P-3 and P-5. Class-forwarding remains enabled, but the configuration is inconsistent and the forwarding behavior reverts to ECMP routing.

```
*A:P-3# configure router mpls lsp "LSP-P-3-P-4-P-5" class-forwarding no default-lsp
*A:P-3# configure router mpls lsp "LSP-P-3-P-4-P-5" class-forwarding no fc af
*A:P-3# configure router mpls lsp "LSP-P-3-P-5" class-forwarding no fc ef
*A:P-5# configure router mpls lsp "LSP-P-5-P-4-P-3" class-forwarding no default-lsp
*A:P-5# configure router mpls lsp "LSP-P-5-P-4-P-3" class-forwarding no fc af
*A:P-5# configure router mpls lsp "LSP-P-5-P-3" class-forwarding no fc ef
*A:P-3>config>router>mpls# info
----------------------------------------------
---snip---
            lsp "LSP-P-3-P-5"
                to 192.0.2.5
```

```
            class-forwarding
            exit
            primary "path-P-3-P-5"
            exit
            no shutdown
        exit
        lsp "LSP-P-3-P-4-P-5"
            to 192.0.2.5
            class-forwarding
            exit
            primary "path-P-3-P-4-P-5"
            exit
            no shutdown
        exit
        no shutdown
```

ECMP equals 2, so the traffic flows will be distributed over the two LSPs between P-3 and P-5, as can be verified in the routing tables at P-3 and P-5:

```
*A:P-3# show router route-table
===============================================================================
Route Table (Router: Base)

The ECMP hashing algorithm will hash on the source and destination IP address. As long as they are the same for each packet, the traffic will be sent on the same link. Therefore, different traffic flows need to be generated in parallel from PE-1 to PE-6. It is possible to create additional loopback interfaces in VPRN 3, but for this test, the system IP addresses of PE-1 and PE-6 can also be used. The ping messages are not sent after one another, but parallel in two different sessions with PE-1.

Figure 114 shows that different traffic flows are sprayed over the different LSPs. The returning traffic need not take the same path.

Figure 114 **Inconsistent CBF Configuration. Revert to ECMP Forwarding**

*A:P-3#
```

In this case, all traffic from PE-1 to PE-6 for both traffic flows takes the LSP "LSP-P-3-P-4-P-5". The returning traffic is distributed over the LSPs "LSP-P-5-P-3" and "LSP-P-5-P-4-P-3". ECMP works, but there are not enough traffic flows to show it more clearly.

Conclusion

Within a service, traffic with different FCs can be forwarded using different paths, depending on the requirements for latency and jitter. This is also the case for services traversing multiple domains.

CBF is a local decision and need not be enabled on all intermediate routers. This allows for better interoperability.

DiffServ Traffic Engineering

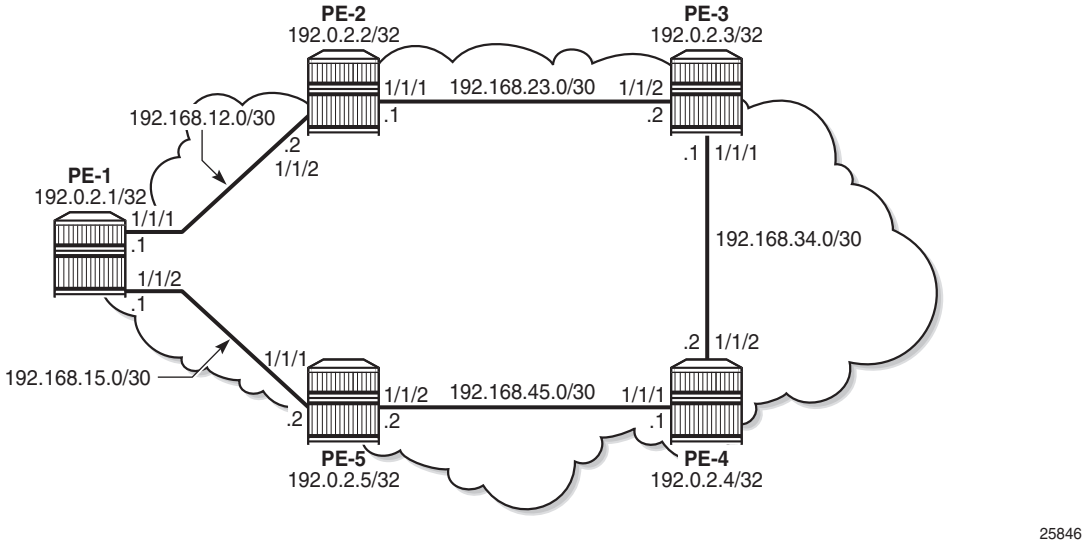
This chapter provides information about DiffServ traffic engineering.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R2.



Overview

Differentiated services (DiffServ) is a mechanism to classify and manage network traffic to provide quality of service (QoS). DiffServ traffic engineering (DiffServ TE) reserves bandwidth for label switched paths (LSPs) on resource reservation protocol (RSVP) interfaces on a per TE class basis.

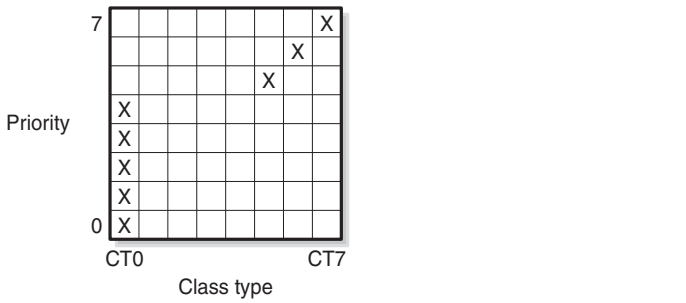
Example Topology

Figure 115 shows the example topology that contains five 7750 SRs in a ring topology.

Figure 115 **Example Topology**

Definitions

The following definitions are used in this chapter:



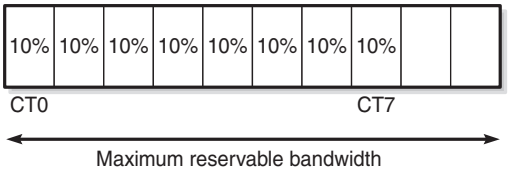
- Forwarding classes (FCs) classify micro-flows into macro-flows. FCs can be mapped to class types (CTs).
- A CT is macro-flow crossing a link governed by a specific bandwidth constraint (BC). The BC is defined on a per-link and per-CT basis. A CT can be considered as a network-wide FC, advertised by the IGP (OSPF opaque link state advertisement (LSA), IS-IS TE type length value (TLV)).
  - IGP-TE can reserve bandwidth per CT on a link (BC).
  - RSVP-TE can reserve bandwidth per LSP path, based on TE class.
- A TE class is a combination of a CT and a preemption priority.

There are eight FCs that can be mapped to CTs. The CTs range from CT0 (lowest) to CT7 (highest) and each gets a percentage of the bandwidth of the link. Each CT has eight different priority levels that are used for preemption. Even though there are 64 different potential combinations of CT and priority, only eight different combinations can be defined for TE classes. All CTs and priorities must be manually configured.

The system allows up to eight TE classes to be configured. The more TE classes are defined, the more RSVP LSPs need to be configured for each service. TE classes are consistently configured on all TE-aware label switching routers (LSRs) throughout the network and advertised through the IGP.

The following shows a DiffServ TE configuration where each CT can reserve up to 10% of the maximum reservable bandwidth meaning that 20% of the bandwidth is not allocated to any CT. MPLS needs to be shut down when DiffServ TE is configured. Figure 116 shows the mapping of the TE classes.

Figure 116 **Mapping of TE Classes**



```
*A:PE-1# configure router
        mpls
            shutdown
        exit

                te-class 0 class-type 0 priority 0
                te-class 1 class-type 0 priority 1
                te-class 2 class-type 0 priority 2
                te-class 3 class-type 0 priority 3
                te-class 4 class-type 0 priority 4
                te-class 5 class-type 5 priority 5
                te-class 6 class-type 6 priority 6
                te-class 7 class-type 7 priority 7
                fc af class-type 0
                fc be class-type 0
                fc ef class-type 5
                fc h1 class-type 6
                fc h2 class-type 0
                fc l1 class-type 0
                fc l2 class-type 0
                fc nc class-type 7
            exit
        exit
        mpls
            no shutdown
```

```
        exit
```

This configuration is applied on all TE-aware LSRs for consistency.

Figure 117 shows the bandwidth reservation for the CTs.

Figure 117 **Bandwidth Reservation for the CTs**

Eight TE classes are defined, each with a different priority, using four CTs (0, 5, 6 and 7). There is no need to assign any bandwidth to the unused CTs. The configuration in this example is not a recommendation. In this example, the BC for each CT is 10% of the maximum reservable bandwidth.

On each node, the RSVP status shows whether DiffServ TE is enabled and how it is configured, as follows:

```
*A:PE-1# show router rsvp status

```

In the preceding output, only the output for the interface between PE-2 and PE-3 is shown; the output is similar for the other interfaces. On each interface between nodes, there will be eight BCs for the eight CTs: from BC0 to BC7. In this example, each of the BCs has the same constraint of 1 Gb/s, which corresponds to 10% of the 10 Gb/s interfaces. As long as no LSP is configured with a CT and a bandwidth, no bandwidth will be reserved. The BCs for an interface, such as the interface between PE-1 and PE-2, can be shown as follows:

```
*A:PE-1# show router rsvp interface "int-PE-1-PE-2" detail

===============================================================================
*A:PE-1#
```

In this example, all BCs for the CTs are equal to 1 Gb/s, which is 10% of the maximum reservable bandwidth of 10 Gb/s. Currently no bandwidth is reserved for any of the TE classes. The unreserved bandwidth equals 1 Gb/s for TE0 through TE7.

The maximum bandwidth that can be allocated depends on the bandwidth of the link and the subscription percentage. When the subscription percentage is doubled to 200%, the BCs will be doubled too, as follows:

```
*A:PE-1# configure router rsvp interface "int-PE-1-PE-2" subscription 200
*A:PE-1# show router rsvp interface "int-PE-1-PE-2" detail

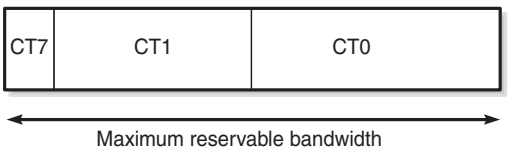
```

The subscription percentage is restored to its default value of 100% as follows:

```
*A:PE-1# configure router rsvp interface "int-PE-1-PE-2" no subscription
```

Bandwidth Constraint Models



Two models are available for the bandwidth calculation that is required during the LSP setup: the maximum allocation model (MAM) and the Russian doll model (RDM). Table 13 shows a comparison between the two models.

Table 13 **Comparison Bandwidth Constraint Models**

Maximum allocation model (MAM)	Russian doll model (RDM)
Fixed BC per CT. No bandwidth sharing between CTs.	Maps one BC to one or more CTs. Lower CTs are allowed to reserve from the unused bandwidth of the pools defined for higher CTs.
Achieves isolation between CTs and guaranteed bandwidth to CTs without the need for preemption.	No isolation between CTs. Requires preemption to guarantee bandwidth to CTs other than the premium.
Bandwidth may be wasted.	Efficient use of bandwidth.
Easy to manage.	More complex.

Figure 118 shows the reserved bandwidth for the different class types according to the MAM model. In this example, there is only bandwidth reserved for CT0, CT1, and CT2.

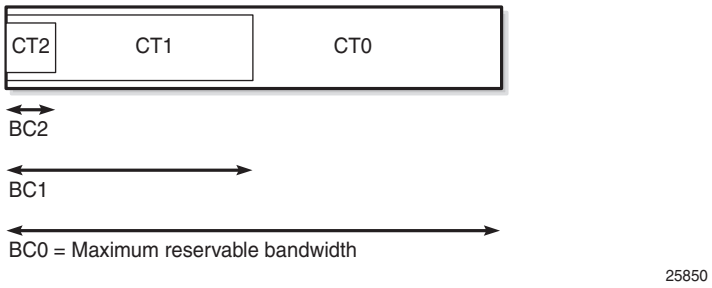


Figure 118 **Bandwidth Reservation in Maximum Allocation Model for Three CTs**

Bandwidth that is reserved for a specific CT cannot be used by any other CT. Therefore, bandwidth may be wasted.

The Russian doll model is more flexible: when CT1 has some spare bandwidth that might be used by CT0, this is allowed. Depending on the configured setup priority and hold priority, this may be reversed when CT1 requires the bandwidth. The bandwidth reservation in the Russian doll model is shown in Figure 119.

Figure 119 **Bandwidth Reservation in Russian Doll Model for Three CTs**

Backup Class Types

The main CT is defined at LSP level or primary path level. The main CT is used at the first attempt for the initial establishment and re-signal make-before-break (MBB) of the LSP primary path. Re-signaling of the LSP path can be triggered manually or timer-based. Subsequent retries use the backup CT, which is configured on the primary path level. Secondary paths are always signaled with the main CT. There is no verification whether the backup CT is lower than the main CT. This applies to CSPF and non-CSPF LSPs. An example of an LSP with main CT1 and backup CT0 is as follows:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-withBackupCT"
                to 192.0.2.3
                cspf
                class-type 1
                primary "dyn"
                    bandwidth 50
                    priority 4 4
                    backup-class-type 0
                exit
                no shutdown
            exit
```

Possible triggers for using the backup CT are:

- Local interface failure or control plane failure (hello timeout)

- Received Resv message with the local-protection-in-use flag set (global revertive trigger)
- Received Patherr message with fast reroute (FRR) protection active notification (global revertive trigger)
- Received Patherr message with error code 34 (Reroute) and value 1 (soft preemption trigger)
- Received Patherr message with Preemption pending flag set (soft preemption trigger)
- Received ResvTear message

When the reservable bandwidth for a CT (including the bandwidth for the inner dolls in case of RDM) is insufficient, this does not trigger the backup CT to be used. If possible, an alternate path will be used for the LSP requiring this bandwidth.

Priorities

Two different priorities are linked to an LSP in a range from 0 to 7, where 0 is the highest priority and 7 the lowest. These values are important when preemption occurs, as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" primary "dyn" priority
  - no priority
  - priority <setup-priority> <hold-priority>
 <setup-priority>     : [0..7]
 <hold-priority>      : [0..7]
```

The following shows an LSP with both priorities equal to 4:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3"
                to 192.0.2.3
                cspf
                primary "dyn"
                    bandwidth 50
                    priority 4 4
                exit
                no shutdown
            exit
```

- The first priority in the configuration is the setup priority. When an LSP is signaled and there is not enough bandwidth available on the Ethernet label edge router (eLER) or LSR, the LSP can preempt an established LSP with a hold priority lower than this setup priority. For a setup priority of 4, existing LSPs with a hold priority of 5, 6, or 7 can be preempted in case of insufficient bandwidth.

- The second priority in the configuration is the hold priority. When this LSP is established and a new LSP needs to be established, and there is insufficient bandwidth, this LSP can only be preempted by an LSP with a higher setup priority than this hold priority. For a hold priority of 4, the LSP can be preempted by any LSP with a setup priority of 0, 1, 2, or 3.

The default values are a setup priority of 7 and a hold priority of 0. A low setup priority of 7 means the LSP cannot preempt any LSP. A high hold priority of 0 implies that the LSP cannot be preempted by any other LSP.

The setup priority needs to be lower than or equal to the hold priority to avoid preemption loops. Nokia recommends that the setup priority and the hold priority are set to equal values.

Bandwidth, CT information, and priorities are shown as follows:

```

---snip---
```

Configuration

The setup consists of five 7750 SRs in a ring topology, as shown in Figure 115.

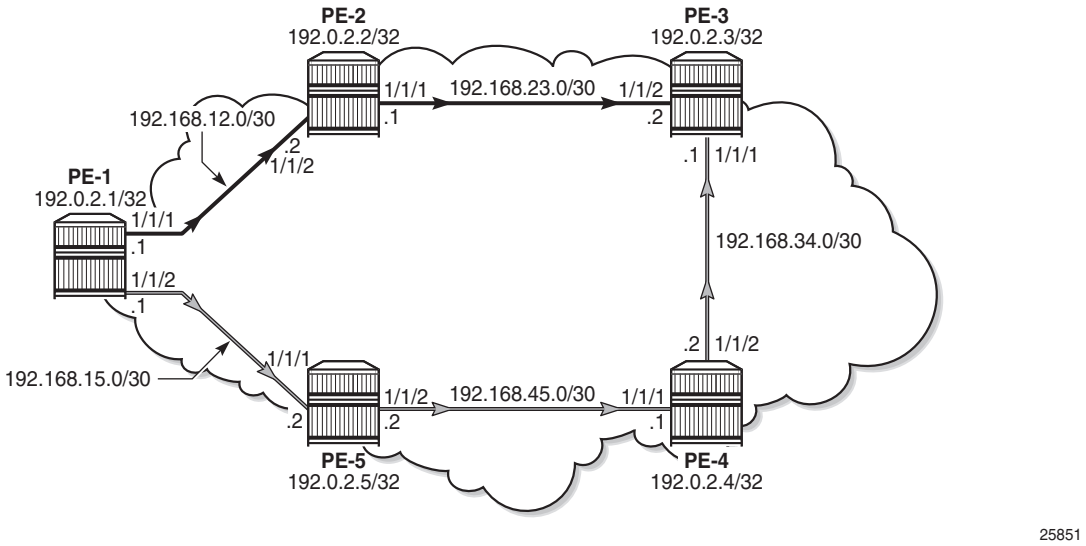
Initial Configuration

The nodes have the following initial configuration:

- Cards, MDAs, ports
- Router interfaces. For PE-1:

```
*A:PE-1# configure router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-5"
            address 192.168.15.1/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.1/32
        exit
```

- IGP: OSPF (alternatively, IS-IS could have been used) with TE enabled. For PE-1:



```
*A:PE-1# configure router
       ospf
            traffic-engineering
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-PE-5"
                    interface-type point-to-point
                exit
            exit
        exit
```

- MPLS and RSVP enabled on all interfaces. For PE-1:

```
*A:PE-1# configure router
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-5"
            exit
            no shutdown
        exit
        rsvp
            no shutdown
        exit
```

LSPs will be established from PE-1 to PE-3 with the short path via PE-2 as preferred. If insufficient bandwidth is available on the short path via PE-2, the longer path via PE-5 and PE-4 is taken, as shown in Figure 120.

Figure 120 **Paths from PE-1 to PE-3**

Initially, the default BC model, which is MAM, is enabled. Different LSPs will be created with different class type and priority. When an LSP is established, the bandwidth reservation is verified on the interfaces of PE-1. The same LSPs will later be established for the second BC model, RDM, where the bandwidth reservation is more efficient. For simplicity, FRR is not enabled on the LSPs.

Maximum Allocation Model

Enable DiffServ MAM

DiffServ TE can only be configured when MPLS is shutdown. This is something to consider during migration. An error is raised when MPLS is not shutdown, as follows:

```
*A:PE-1# configure router rsvp diffserv-te mam
MINOR: RSVP #1005 Invalid operation for RSVP instance -
 Diffserv can be enabled only when MPLS is shutdown
*A:PE-1#
```

The DiffServ TE configuration must be consistent on all the nodes in the setup. In this example, DiffServ TE is configured as follows:

```
*A:PE-1# configure router
        mpls
            shutdown
        exit
        rsvp
            diffserv-te mam
                class-type-bw ct0 50 ct1 40 ct2 0 ct3 0 ct4 0 ct5 0 ct6 0 ct7 10
                te-class 0 class-type 0 priority 7
                te-class 1 class-type 0 priority 4
                te-class 2 class-type 1 priority 7
                te-class 3 class-type 1 priority 4
                te-class 4 class-type 2 priority 7
                te-class 5 class-type 2 priority 2
                fc af class-type 1
                fc be class-type 0
                fc nc class-type 2
            exit
        exit
        mpls
            no shutdown
        exit
```

The bandwidth percentage for each CT must be configured. For unused CTs, the bandwidth percentage must be set to 0. An error is raised if unused CTs are missing , as follows:

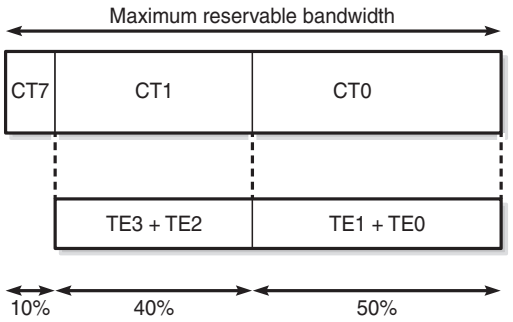
```
*A:PE-1# configure router rsvp diffserv-te class-type-bw ct0 50 ct1 50
                                                                 ^
Error: Missing parameter
```

The sum of bandwidth percentages can be lower than, but must not exceed 100%, as follows:

```
*A:PE-1# configure router rsvp diffserv-te class-type-
bw ct0 50 ct1 50 ct2 0 ct3 0 ct4 0 ct5 0 ct6 0 ct7 10
```

```
MINOR: RSVP #1005 Invalid operation for RSVP instance -
 Total CT percent (110) exceeds 100
```

Fewer than eight classes can be configured, as in this example.



In the example, only three CTs are used by the TE classes: CT0, CT1, and CT2. However, 10% of the maximum reservable bandwidth is allocated to CT7. Because the MAM model does not allow bandwidth allocated to a CT to be used by other CTs, only 90% of the bandwidth can be reserved: 50% to be divided between TE0 and TE1, and 40% to be divided between TE2 and TE3. TE4 and TE5 do not have any bandwidth allocated. The bandwidth allocated to CT7 is completely wasted. This is just an example, not a recommendation.

The same settings will be repeated in the RDM model, where the bandwidth will not be wasted. The following bandwidth information can be seen on any interface:

```
*A:PE-1# show router rsvp interface "int-PE-1-PE-2" detail

---snip---
```

Figure 121 shows the bandwidth allocation for the CTs and TE classes.

Figure 121 **MAM Bandwidth Allocation**

Establishing LSPs

TE class 5 corresponds to CT2 and priority 2. No bandwidth can be reserved for an RSVP LSP with CT2, setup priority 2, and hold priority 2. This can be verified by configuring an empty path and an LSP, as follows:

```
*A:PE-1# configure router
        mpls
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-3-TE5"
                to 192.0.2.3
                cspf
                class-type 2
                primary "dyn"
                    bandwidth 1000
                    priority 2 2
                exit
                no shutdown
            exit
```

CSPF must be enabled. The class type is by default CT0, but can be changed to CT2 by configuration. The class type can be configured in the LSP context, as shown here, or in the primary path context. The setup priority and hold priority are configured in the primary path context.

The LSP cannot be established, because no bandwidth is allocated to TE class 5, as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE5" path detail | match "Failure Code"
Failure Code     : noCspfRouteToDestination
```

No bandwidth is reserved on the RSVP interfaces, as follows:

```
*A:PE-1# show router rsvp interface
===============================================================================
RSVP Interfaces
===============================================================================
Interface                       Total    Active    Total BW  Resv BW   Adm Opr
                                Sessions Sessions  (Mbps)    (Mbps)
-------------------------------------------------------------------------------
system                          -        -         -         -         Up  Up
int-PE-1-PE-2                   0        0         10000     0         Up  Up
int-PE-1-PE-5                   0        0         10000     0         Up  Up
-------------------------------------------------------------------------------
Interfaces : 3
===============================================================================
*A:PE-1#
```

Bandwidth can be reserved for an LSP with CT1 and priorities 4, as for the following LSP:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-TE3"
                to 192.0.2.3
                cspf
                primary "dyn"
                    bandwidth 2000
                    priority 4 4
                    class-type 1
                exit
                no shutdown
            exit
```

In the example, the CT is configured in the primary path context while the CT in the previous example was configured in the LSP context.

The path is set up via PE-2 to PE-3, as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE3" path detail
===============================================================================

```

Figure 122 shows the bandwidth reservation for CT1 on interface int-PE-1-PE-2 on PE-1 and on interface int-PE-2-PE-3 on PE-2.

Figure 122 **Reserved and Unreserved Bandwidth**

An additional LSP is configured with CT1 and priority 4 and with CT0 as backup CT. The backup CT will not be used when the amount of unreserved bandwidth for CT1 is insufficient, as in the following case where int-PE-1-PE-2 and int-PE-1-PE-5 have insufficient unreserved bandwidth for CT1:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-TE3-backupTE1"
                to 192.0.2.3
                cspf
                primary "dyn"
                    bandwidth 5000
                    priority 4 4
                    class-type 1
                    backup-class-type 0
```

```
            exit
            no shutdown
        exit
```

The LSP will not come up, as follows:

```
*A:PE-1# show router mpls lsp
===============================================================================
MPLS LSPs (Originating)
===============================================================================
LSP Name                            To              Tun     Fastfail  Adm  Opr
                                                    Id      Config
-------------------------------------------------------------------------------
LSP-PE-1-PE-3-TE5                   192.0.2.3       3       No        Up   Dwn
LSP-PE-1-PE-3-TE3                   192.0.2.3       4       No        Up   Up
LSP-PE-1-PE-3-TE3-backupTE1         192.0.2.3       5       No        Up   Dwn
-------------------------------------------------------------------------------
LSPs : 3
```

The bandwidth requirement is lowered, as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE3-backupTE1" primary "dyn"
bandwidth 2500
```

Interface int-PE-1-PE-2 does not have sufficient bandwidth for CT1, but the longer path via PE-5 and PE-4 has sufficient unreserved bandwidth for CT1. The LSP will be operationally up, as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE3-backupTE1" path detail

```

Figure 123 shows the reserved and unreserved bandwidth on the RSVP interfaces on PE-1.

Figure 123 **Reserved and Unreserved Bandwidth on PE-1**

Trigger Backup Class-Type

This mechanism is described for MAM, but it is also supported in RDM.

Port 1/1/2 is shut down. The long path via PE-5 and PE-4 can no longer be used. However, the LSP has a backup CT (CT0), which is triggered by the port being down, as follows:

```
*A:PE-1# configure port 1/1/2 shutdown
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE3-backupTE1" path detail
===============================================================================

TE7->  Resv. Bw   : 0                  Unresv. Bw        : 0
---snip---
```

Figure 124 shows the bandwidth reservation on interface int-PE-1-PE-2. The bandwidth reservation on interface int-PE-2-PE-3 on PE-2 is identical.

Figure 124 **Bandwidth Reservation**

The preceding examples illustrate that bandwidth can be wasted in the MAM model. The bandwidth allocated to CT7 cannot be used because there is no TE class configured with CT7. The bandwidth cannot be shared between CTs. The next section explains how the same LSPs will be used in the RDM model. They will be established one-by-one and, therefore, they are shut down, as follows:

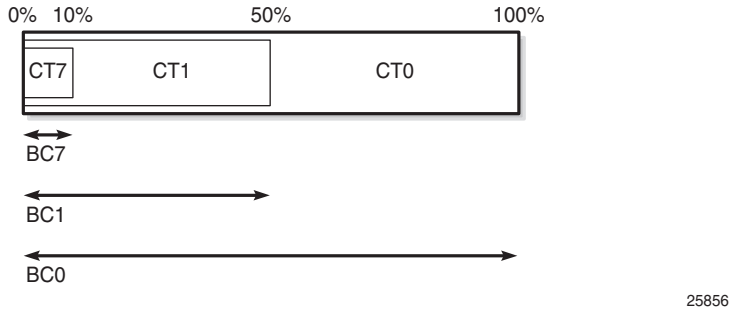
```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE5" shutdown
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE3" shutdown
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE3-backupTE1" shutdown
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE1" shutdown

*A:PE-1# configure port 1/1/2 no shutdown
```

Russian Doll Model

Enable DiffServ RDM

The DiffServ TE configuration needs to be consistent on all the nodes in the network, as follows:



```
*A:PE-1# configure router
        mpls
            shutdown
```

```
exit
rsvp
    diffserv-te rdm
        class-type-bw ct0 50 ct1 40 ct2 0 ct3 0 ct4 0 ct5 0 ct6 0 ct7 10
        te-class 0 class-type 0 priority 7
        te-class 1 class-type 0 priority 4
        te-class 2 class-type 1 priority 7
        te-class 3 class-type 1 priority 4
        te-class 4 class-type 2 priority 7
        te-class 5 class-type 2 priority 2
        fc af class-type 1
        fc be class-type 0
        fc nc class-type 2
    exit
exit
mpls
    no shutdown
exit
```

In this example, three FCs are mapped to CTs. FC BE corresponds to CT0, FC AF to CT1, and FC NC to CT2. CT0 can be mapped to TE class 0 for priority 7, and to TE class 1 for priority 4. The mapping is similar for CT1 (with priorities 7 and 4), and CT2 (with priorities 7 or 2).

The RDM model allows the outer dolls (lower CT) to use the unused bandwidth allocated to the inner dolls (higher CT), as shown in Figure 125.

Figure 125 **Russian Doll Model for Three Class Types**

The calculation of the BCs takes into account the BCs of the inner dolls, as shown in the OSPF LSAs in the opaque database, as follows:

```
*A:PE-1# show router ospf opaque-database adv-router 192.0.2.1 detail

```

Six TE classes are defined:

- TE0 and TE1 are defined for CT0. They can reserve all the available bandwidth, if it is not required by the other TE classes (100% = 50% for CT0 + 40% for CT1 + 10% for CT7)
- TE2 and TE3 are defined for CT1. They can reserve 50% of the bandwidth (50% = 40% for CT1 + 10% for CT7)
- TE4 and TE5 are defined for CT2. They can reserve 10% of the bandwidth, even though the configured bandwidth percentage for CT2 is 0. The 10% allocated to higher class CT7 can be used.

Bandwidth is more efficiently used in RDM than in MAM.

The BCs and bandwidth per TE class type show that bandwidth can be shared with the outer dolls, as follows:

```

Establishing LSPs

LSP-PE-1-PE-3-TE5 could not be established in the MAM model, because there was no bandwidth assigned to TE5 (CT2). However, in the RDM model, TE5 can use the bandwidth of the inner doll CT7 and the LSP will be operationally up, as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE5" path detail
===============================================================================

---snip---
```

This LSP uses all the available bandwidth for CT7. Because TE5 is defined with the best priority (2) of all TE classes, this LSP will not be preempted when a new LSP is enabled. Therefore, this bandwidth is subtracted from the amount of unreserved bandwidth. The remaining unreserved bandwidth is for CT0 and CT1 only. LSPs with other CTs cannot be established on this interface. Figure 126 shows the reserved bandwidth on interface int-PE-1-PE-2 for this LSP.

Figure 126 **Reserved Bandwidth for LSP with CT2 (One Session)**

Another LSP is established: LSP-PE-1-PE-3-TE3, with CT1 and priority 4, as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3-TE3" no shutdown
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3-TE3" path detail

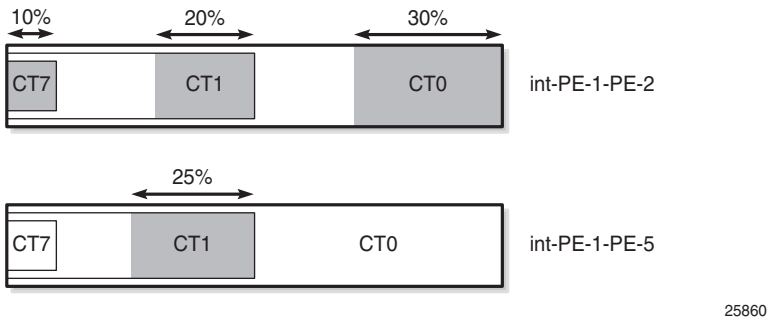
Figure 128 shows the reserved bandwidth on both interfaces of PE-1.

Figure 128 **Reserved Bandwidth on Both Interfaces of PE-1 (3 Sessions)**

The following LSP is configured on PE-1:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-TE1"
                to 192.0.2.3
                cspf
                primary "dyn"
                    bandwidth 3000
                    priority 4 4
                exit
                no shutdown
            exit
```



The class type is by default 0. CT0 and priority 4 corresponds to TE1. There is sufficient bandwidth available on the short path via PE-2. The bandwidth reservation on RSVP interface int-PE-1-PE-2 is as follows:

```
*A:PE-1# show router rsvp interface "int-PE-1-PE-2" detail
---snip---
Bandwidth for TE Class Types (Kbps)
TE0->  Resv. Bw   : 0                  Unresv. Bw        : 4000000
TE1->  Resv. Bw   : 3000000            Unresv. Bw        : 4000000
TE2->  Resv. Bw   : 0                  Unresv. Bw        : 2000000
TE3->  Resv. Bw   : 2000000            Unresv. Bw        : 2000000
TE4->  Resv. Bw   : 0                  Unresv. Bw        : 0
TE5->  Resv. Bw   : 1000000            Unresv. Bw        : 0
TE6->  Resv. Bw   : 0                  Unresv. Bw        : 0
TE7->  Resv. Bw   : 0                  Unresv. Bw        : 0
---snip---
```

None of the established LSPs can be preempted. Therefore, the sum of the reserved and unreserved bandwidth does not exceed the total bandwidth.

Figure 129 shows the bandwidth reservation on both interfaces.

Figure 129 **Reserved Bandwidth on Both Interfaces on PE-1 (4 Sessions)**

The following LSP with CT0 and priority 7 is configured on PE-1:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-TE0"
                to 192.0.2.3
                cspf
                primary "dyn"
                    bandwidth 4000
                    priority 7 7
                exit
                no shutdown
            exit
```

The bandwidth is reserved in TE class 0. There is sufficient bandwidth on the short path to PE-3. The bandwidth is now reserved for 100%, as follows:

```
*A:PE-1# show router rsvp interface

---snip---
```

Even though the sum of the reserved bandwidth equals the maximum reservable bandwidth on the link, there is still unreserved bandwidth for specific TE classes. When an additional LSP is established requiring bandwidth in TE3 or TE1 (which have setup priority 4), it can preempt another LSP with a lower hold priority. LSPs requiring bandwidth in TE class TE2 have a setup priority 7 and cannot preempt any other LSP. The setup priority in TE1 and TE3 is 4, which is higher than the hold priority in TE2 and TE0 (7 is the lowest priority). There are no LSPs in TE2, so the only LSPs to preempt have bandwidth reserved in TE0.

Figure 130 shows the bandwidth reservation on the interfaces of PE-1.

Figure 130 **Reserved Bandwidth on Both Interfaces of PE-1 (5 Sessions)**

Preemption

The following LSP is configured with CT1, setup priority 4, and hold priority 4, which corresponds to TE class 3:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3-TE3-2nd"
                to 192.0.2.3
                cspf
                class-type 1
                primary "dyn"
                    bandwidth 750
                    priority 4 4
                exit
                no shutdown
            exit
```

Because the setup priority 4 exceeds the hold priority 7 of LSP-PE-1-PE-3-TE0, this LSP will preempt the existing one. The following output shows that the next hop for LSP-PE-1-PE-3-TE0 is 192.168.15.2 (PE-5), while the next hop for LSP-PE-1-PE-3-TE3-2nd is 192.168.12.2 (PE-2):

```

---snip---
```

Figure 131 shows the bandwidth reservation on both interfaces on PE-1 for the six sessions.

Figure 131 **Reserved Bandwidth on Both Interfaces on PE-1 (6 Sessions)**

Preemption can also be within the same CT. An LSP with CT0 and priority 4 (TE1) could have preempted the LSP with CT0 and priority 7 (TE0) equally well.

Bandwidth Availability Check

A tools command can be launched to verify the available bandwidth toward a node for a specific class type (by default CT0) and priority (by default setup priority 7 and hold priority 0). The options for this command are as follows:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3
  - cspf to <ip-addr> [from <ip-addr>] [bandwidth <bandwidth>] [include-
bitmap <bitmap>] [exclude-bitmap <bitmap>] [hop-limit <limit>] [exclude-
address <excl-addr> [<excl-addr>...(upto 8 max)]] [use-te-metric] [strict-
srlg] [srlg-group <grp-id>...(upto 8 max)] [exclude-node <excl-node-id> [<excl-node-
id>..(upto 8 max)]] [skip-interface <interface-name>] [ds-class-type <class-
type>] [cspf-reqtype <req-type>] [least-fill-min-thd <thd>] [setup-
priority <val>] [hold-priority <val>]
 <ip-addr>            : a.b.c.d
 <bandwidth>          : [1..100000] in Mbps
 <bitmap>             : [0..4294967295] - accepted in decimal, hex(0x) or binary(0b)
 <limit>              : [2..255]
 <excl-addr>          : a.b.c.d (outbound interface)
 <use-te-metric>      : keyword
 <strict-srlg>        : keyword
 <grp-id>             : [0..4294967295]
 <excl-node-id>       : [a.b.c.d] (outbound interface)
 <interface-name>     : [max 32 chars]
 <class-type>         : [0..7]
 <req-type>           : all|random|least-fill : keywords
 <thd>                : [1..100]
 <priority>           : [0..7]
```

The following verifies whether an LSP can be set up from PE-1 to PE-3 requesting 100 Mb/s with CT0 (default) and both priorities equal to 4:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 bandwidth 100 setup-
priority 4 hold-priority 4
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/
(DiffServ = RDM) class: 0 , setup Priority 4, Hold Priority 4 TE Class: 1
CSPF Path
To        : 192.0.2.3
Path 1    : (cost 20)
    Src:   192.0.2.1   (= Rtr)
    Egr:   192.168.12.1     -> Ingr:   192.168.12.2    Rtr:   192.0.2.2   (met 10)
    Egr:   192.168.23.1     -> Ingr:   192.168.23.2    Rtr:   192.0.2.3   (met 10)
    Dst:   192.0.2.3   (= Rtr)
*A:PE-1#
```

The short path via PE-2 has sufficient bandwidth for an LSP with these TE requirements (TE class 1 with CT0 and both priorities 4). This is different for TE class 5 (CT2 and priorities 2), where the bandwidth is completely reserved. The following shows that the longer path via PE-5 and PE-4 must be taken:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 bandwidth 100 ds-class-
type 2 setup-priority 2 hold-priority 2
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/
(DiffServ = RDM) class: 2 , setup Priority 2, Hold Priority 2 TE Class: 5
CSPF Path
To        : 192.0.2.3
Path 1    : (cost 30)
    Src:   192.0.2.1   (= Rtr)
    Egr:   192.168.15.1     -> Ingr:   192.168.15.2    Rtr:   192.0.2.5   (met 10)
    Egr:   192.168.45.2     -> Ingr:   192.168.45.1    Rtr:   192.0.2.4   (met 10)
```

```
    Egr:   192.168.34.2     -> Ingr:   192.168.34.1    Rtr:   192.0.2.3   (met 10)
    Dst:   192.0.2.3   (= Rtr)
*A:PE-1#
```

This tools command can only be launched when a TE class is defined with the requested CT and priority. An error is raised when the request cannot be fulfilled, as follows:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 setup-priority 5
MINOR: CLI No Te class mapped to Class Type 0 , Setup Priority 5.
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 setup-priority 4
MINOR: CLI No Te class mapped to Class Type 0 , Hold Priority 0.
```

Conclusion

DiffServ TE enforces different BCs for different classes of traffic. DiffServ TE controls overbooking and supports preemption. Two BC models are described in this chapter: MAM and RDM.

Entropy Label

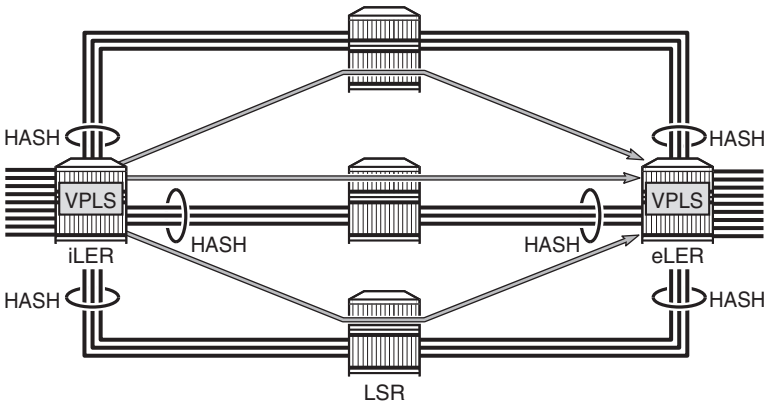
This chapter provides information about the entropy label (EL).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

The information and configuration in this chapter is based on SR OS release 14.0.R4.



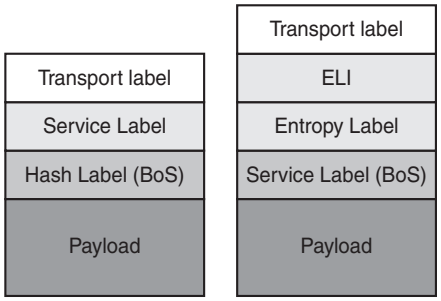
RFC 6391 hash label or flow-aware transport label is supported in SR OS release 8.0.R1, and later. RFC 6790 entropy labels (ELs) are supported on RSVP and BGP tunnels in release 14.0.R1, and later, and supported on LDP tunnels in release 14.0.R4, and later. Chassis-mode D is required.

Overview

Entropy is the degree of disorder or uncertainty in a system. SR OS supports both the MPLS EL and the hash label, but they are mutually exclusive. These labels allow label switched routers (LSRs) to load-balance labeled packets in a granular way without the need to inspect the IPv4 or IPv6 header. The hash label is applicable to services such as Epipe VLL, VPLS, IES (spoke-SDP), and VPRN services. The main advantage of the EL compared to the hash label is that the EL can be applied to a wider range of services, such as EVPN, BGP VPWS, Fpipe VLL, Ipipe VLL, H-VPLS, and BGP RFC 3107 tunnels.

Figure 132 shows that different flows from an ingress label edge router (iLER) are load-balanced across different paths in the MPLS network toward the egress label edge router (eLER).

Figure 132 **Load-Balancing of Flows Based on Hash Label or Entropy Label**



The EL is inserted below the innermost tunnel label (TL) in the label stack, along with the entropy label indicator (ELI), which is a special purpose MPLS label with a value of 7 to indicate that the next label in the stack is an EL. As with the hash label, the value of the EL is calculated based on a hash of the packet payload header (IP and Layer 4). The EL is inserted as deep as possible in the stack to ensure preservation for as far as possible through the network. When the EL and ELI are present, load-balancing on the transit LSRs can be configured to only take into account the EL label for LAG and ECMP. Load-balancing on the LSR can be configured to take into account the IP header also, but that is not required when the EL and ELI are present. The eLER removes the EL and ELI before forwarding the packet to its final destination.

The EL requires two additional labels in the label stack, which might result in an unsupported label stack depth in an intermediate (possibly third-party) LSR. SR OS allows control of the EL and ELI insertion and accounting of extra labels in the tunnel table. The supported label stack depth is 12 in SR OS release 14.0, including transport, service, hash, and OAM labels.

Figure 133 shows a comparison between a label stack with a hash label and a label stack with an EL and ELI.

Figure 133 **Label Stack with Hash Label versus Label Stack with EL and ELI**

Hash labels or ELs are inserted by the iLER, based on the incoming packet header. The iLER creates a unique label per conversation, based on the incoming packet header (IP and Layer 4). The hash label is a single label that is inserted at the bottom of the stack, below the service label. The EL is inserted together with the ELI below the innermost tunnel label, but above the service label. The entropy and hash label value is outside of the range for MPLS label values, because the most significant bit equals 1 for entropy and hash labels and 0 for MPLS labels.

The EL is used as part of the LSR hashing algorithm for spraying packets over multi-port LAGs, ECMP, or BGP tunnels with multiple downstream interfaces. The packet ordering is preserved because one label is used per conversation. Hashing based on a label stack containing an EL per service will become more granular than when based on a standard label stack alone.

Figure 134 shows how the eLER signals its EL capability to the iLER.

Figure 134 **Downstream LERs Signal EL Capability to ILER**

The entropy label capability (ELC) is signaled by the eLER and indicates the ability to receive and process the ELs. This can be advertised for LDP and RSVP. However, ELC signaling is not supported for BGP tunnels, because no agreed standard exists in the IETF. RFC 6790 introduced the ELC BGP attribute that can be signaled by the eLER to indicate that it supports EL. According to RFC 6790, LSRs incapable of processing ELs must remove the ELC BGP attribute, but this requirement could not be guaranteed; therefore, the ELC BGP attribute has been deprecated in RFC 7447.

As a workaround, at the iLER, an override of the ELC for a BGP tunnel can be manually configured. After this ELC has been overridden, the BGP sender assumes that the receiver is capable of receiving and processing the ELs, regardless of the signaled ELC. The iLER inserts an EL on a tunnel for which the ELC is confirmed by the downstream peer or when the ELC is overridden by configuration.

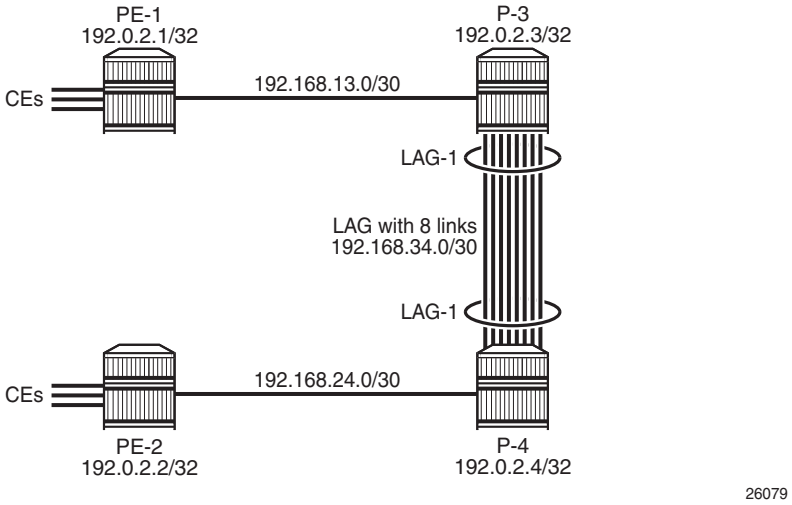
ELC signaling can be enabled for LDP on the LERs, as follows:

```
*A:PE-2# configure router ldp entropy-label-capability
```

ELC signaling for RSVP can be enabled as follows:

```
*A:PE-2# configure router rsvp entropy-label-capability
```

As previously described, the lack of an IETF standard for BGP tunnels means that ELC is ignored by the receiving LER, and no EL is inserted. Therefore, an override is required that assumes that the far-end LER has ELC, and allows insertion of the EL. The override is enabled as follows:



```
*A:PE-1# configure router bgp override-tunnel-elc
```

When the ELC is overridden for BGP, the iLER assumes that the receiver can handle the EL.

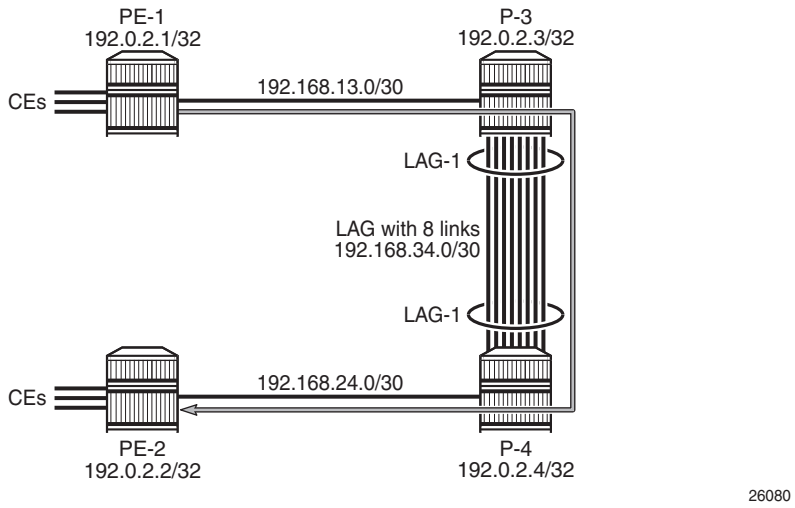
Configuration

In this section, an EVPN-VPLS will be configured on PE-1 and PE-2 to illustrate LAG hashing based on EL. Figure 135 shows the topology used for this example. Load-balancing of the traffic will be performed in the P-routers that are connected by a LAG with eight links.

Figure 135 **Example Topology**

The initial configuration of the PE/P-routers includes the following:

- Cards, MDAs, ports
- LAG with eight network links between P-3 and P-4
- Router interfaces
- IGP (IS-IS or OSPF)
- LDP enabled on all interfaces
- MPLS enabled on all interfaces. RSVP enabled.
- iBGP configured with P-3 as route reflector (RR)



For the configuration of EVPN-MPLS, the BGP configuration needs to include the address family EVPN, as follows. See chapter EVPN for MPLS Tunnels for more information.

```
configure
    router
        bgp
            min-route-advertisement 1
            rapid-update evpn
            group "iBGP"
                family evpn
                peer-as 64500
                neighbor 192.0.2.3
                exit
            exit
        exit
```

EVPN Service Using RSVP Tunnel with EL

Figure 136 shows LSP "LSP-PE-1-PE-2" from PE-1 to PE-2 via core routers P-3 and P-4.

Figure 136 **RSVP LSP "LSP-PE-1-PE-2" from PE-1 to PE-2 via P-3 and P-4**

The LSP "LSP-PE-1-PE-2" is configured on PE-1, as follows:

```
configure
    router
        mpls
            path "path-PE-1-PE-2"
                hop 10 192.168.13.2 strict
                hop 20 192.168.34.2 strict
                hop 30 192.168.24.1 strict
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                primary "path-PE-1-PE-2"
                exit
                no shutdown
            exit
        exit
    exit
exit
```

The configuration for LSP "LSP-PE-2-PE-1" on PE-2 is similar.

ELC is disabled by default, and needs to be enabled for RSVP on the eLERs, as follows:

```
*A:PE-2# configure router rsvp entropy-label-capability
```

The EL can be disabled (force-disable) or enabled in the MPLS context on the iLER, as follows:

```
*A:PE-1# configure router mpls entropy-label
  - entropy-label rsvp-te <rsvp-te>

 <rsvp-te>            : <force-disable | enable>
```

The EL can also be disabled (force-disable) or enabled per LSP, but there is a third option to inherit the EL settings from the MPLS context, as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" entropy-label
  - entropy-label {force-disable | inherit | enable}

 <force-disable | i*> : force-disable|inherit|enable
```

By default, the EL on the LSP inherits the EL settings in the MPLS context, as follows:

```
*A:PE-1# configure router mpls
*A:PE-1>config>router>mpls#  info detail
----------------------------------------------
            ---snip---
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                ---snip---
                entropy-label inherit
                ---snip---
```

When LSP templates are used, EL can be configured within the LSP template context for single-hop and mesh point-to-point LSPs, as follows:

```
*A:PE-1# configure router mpls lsp-template "LSPtemplate1" one-hop-p2p entropy-
label
  - entropy-label {force-disable | inherit | enable}

 <force-disable | i*> : force-disable|inherit|enable

*A:PE-1# configure router mpls lsp-template "LSPtemplate2" mesh-p2p entropy-label
  - entropy-label {force-disable | inherit | enable}

 <force-disable | i*> : force-disable|inherit|enable
```

When the EL settings are modified, for example, from inherit to enabled, the changes only take effect after the LSP has been cleared or MPLS has been bounced, using shutdown/no shutdown. The following message is raised when the configuration is modified for an LSP in no shutdown state:

```
*A:PE-1>config>router>mpls>lsp# entropy-label enable
INFO: MPLS #1029 Entropy Label change is not operational - LSP must be bounced
```

The following command shows that EL is enabled in MPLS:

```
*A:PE-1# show router mpls status | match Label
Entropy Label RSVP-TE     : Enabled
*A:PE-1#
```

The following command shows that EL is enabled in RSVP:

```
*A:PE-1# show router rsvp status | match Label
Implicit Null Label: Disabled           Node-id in RRO     : Exclude
DiffServTE AdmModel: Basic              Entropy Label      : Enabled
*A:PE-1#
```

The following command shows that EL is enabled and operational in LSP "LSP-PE-1-PE-2":

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" detail | match Label
Entropy Label   : Enabled                   Oper Entropy Label   : Enabled
*A:PE-1#
```

In this case, the EL was configured to be enabled on the LSP, instead of the default behavior, which would have been displayed as "Inherited", as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" detail | match Label
Entropy Label   : Inherited                   Oper Entropy Label   : Enabled
*A:PE-1#
```

The following command shows that the LSP "LSP-PE-1-PE-2" has the flag "entropy-label-capable" in the RSVP tunnel table:

```
*A:PE-1# show router tunnel-table protocol rsvp detail

===============================================================================

Number of tunnel-table entries with LFA : 0
===============================================================================
*A:PE-1#
```

EL is supported on many Layer 2 and Layer 3 services. In this example, VPLS 1 is configured on PE-1 with BGP EVPN-MPLS, as follows:

```
configure
    service
        vpls 1 customer 1 create
            bgp
            exit
            bgp-evpn
                evi 1
                mpls
                    entropy-label
                    auto-bind-tunnel
                        resolution-filter
                            rsvp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            sap 1/1/2:1 create
            exit
            no shutdown
```

Auto-bind-tunnel is resolved to the RSVP LSP "LSP-PE-1-PE-2". A similar configuration is applied on PE-2.

The following command shows that the EL is enabled for BGP-EVPN, as follows:

```
*A:PE-1# show service id 1 bgp-evpn

*A:PE-1#
```

The iLER PE-1 will add the EL and ELI to the label stack. Traffic load-balancing will be performed in P-3 where the traffic will be sprayed over all eight links of the LAG. By default, the load-balancing settings on P-3 are as follows:

```
*A:P-3>config>system>load-balancing# info detail
----------------------------------------------
            no l4-load-balancing
            no lsr-load-balancing
            no system-ip-load-balancing
            no mc-enh-load-balancing
            no service-id-lag-hashing
----------------------------------------------
```

When the EL and ELI are included in the stack, only the EL label is used for the load-balancing. It is not required to inspect the IP header or any other header. The options for LSR load-balancing are the following:

```
*A:P-3# configure system load-balancing lsr-load-balancing
  - lsr-load-balancing <hashing-algorithm>
  - no lsr-load-balancing

 <hashing-algorithm>  : lbl-only | lbl-ip | ip-only | eth-encap-ip
```

The option **lbl-only** is preferred when the EL is present, and is configured as follows:

```
*A:P-3# configure system load-balancing lsr-load-balancing lbl-only
```

For the reverse path, PE-2 is the iLER, and P-4 will do the spraying of the packets over all links of the LAG. Therefore, LSR load-balancing with lbl-only is also configured on P-4.

EVPN Service Using LDP Tunnel with EL

ELC is disabled by default for LDP, as follows:

```
*A:PE-1# show router ldp status
```

```

-------------------------------------------------------------------------------
---snip---
```

The following EVPN-VPLS uses an LDP transport tunnel and has EL enabled:

```
configure
    service
        vpls 2 customer 1 create
            bgp
            exit
```

```
            bgp-evpn
                evi 2
                mpls
                    entropy-label
                    auto-bind-tunnel
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                    no shutdown
                exit
            exit
            sap 1/1/2:16 create
            exit
            no shutdown
```

The configuration on PE-1 and PE-2 is similar.

EL is enabled in this service, as follows:

```
*A:PE-2# show service id 2 bgp-evpn

LSR Load-Sharing Based on EL

The LSR load-sharing based on the EL results in a granular load-sharing, as shown in the following test results. In each direction, 9000 flows were generated; each flow with four unique variables: source IP address, destination IP address, source UDP port, and destination UDP port. For this test, an EVPN-VPLS with RSVP tunnel was used. Each flow gets a unique EL and the P-nodes distribute the load over all eight links in the LAG, based on the hashing algorithm "lbl-only", as follows:

```
A:P-4# monitor lag 1 rate
===============================================================================
Monitor statistics for LAG ID 1

```

The flows are evenly spread in each direction.

Conclusion

The EL is a standard-compliant way to maintain packet ordering within a conversation while load-balancing across multiple ECMP paths or links in a LAG. The EL is supported for both Layer 2 and Layer 3 services and is, therefore, a more general solution than the MPLS hash label.

IGP Shortcuts

This chapter provides information about IGP shortcuts.

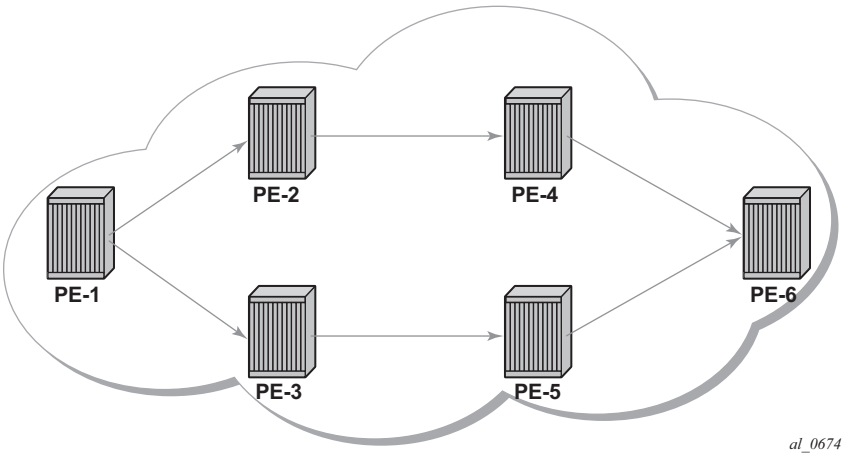
Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS when the feature is not related to BGP.There are no other pre-requisites for this configuration. This chapter was originally written for release 12.0.R3, but the CLI in this edition corresponds to release 14.0.R1.

Overview



Interior gateway protocols (IGPs) are routing protocols that operate inside an autonomous system (AS). An AS is a network domain that is managed under a single administration. Because the scope of operation of an IGP is usually within an AS, IGPs are also called intra-AS protocols. The purpose of an IGP is to provide reachability information to destination nodes that are inside the domain. IGPs can be one or more of a variety of protocols, including routing protocols such as routing information protocol (RIP) version 1 or 2, open shortest path first (OSPF), and intermediate system to intermediate system (IS-IS).

IGPs such as OSPF and IS-IS are link-state protocols that use a shortest path first (SPF) algorithm to compute the shortest path tree to all nodes in a network. The results of such computations indicate the destination node, next hop address, and output interface, where the output interface is a physical interface. Optionally, multiprotocol label switching (MPLS) label switched paths (LSPs) can be included in the SPF algorithm on the node performing the calculations, as LSPs behave as

logical interfaces directly connected to remote nodes in the network. Because the SPF algorithm treats the LSPs in the same way as a physical interface (being a potential output interface), the computation results could be to select a destination node together with an output LSP, using the LSP as a shortcut through the network to the destination node.

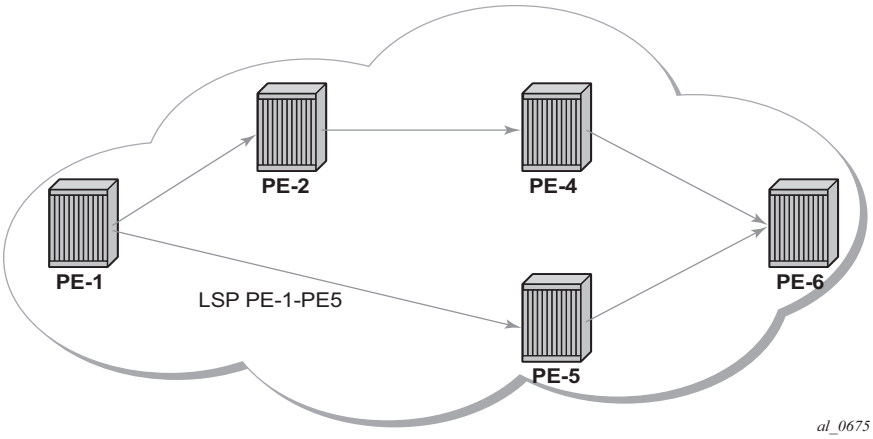


Figure 137 shows a normal SPF tree sourced by PE-1 (Provider Edge-1).

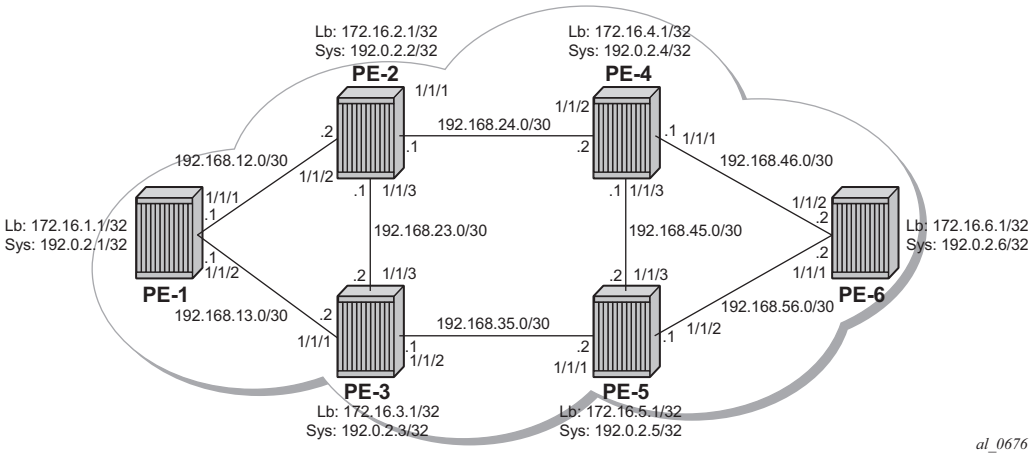
Figure 137 **Normal SPF Tree Sourced by PE-1**

If there is an LSP that connects PE-1 to PE-5, and IGP shortcuts are configured on PE-1, the SPF tree will be as shown in Figure 138.

Figure 138 **SPF Tree Sourced by PE-1 Using LSP Shortcuts**



IGP shortcuts are enabled on a per router basis; SPF computations are independent and irrelevant to other routers, so there is no need to enable shortcuts on every single router.

The example topology used in this example is displayed in Figure 139. The setup consists of six 7750 service routers. There is a single AS and a single IGP area. The following configuration tasks should be completed first:

- IS-IS or OSPF on all interfaces within the AS (configuration has been done using IS-IS but using OSPF shows exactly the same behavior).
- Label distribution protocol (LDP) and resource reservation protocol (RSVP) on all interfaces within the AS.

Figure 139 **Example Topology**

In all figures, **Lb** stands for Loopback and **Sys** stands for the system IP addresses.

Configuration

The first step is to configure the IGP (IS-IS) on all nodes, where IS-IS redistributes route reachability to all routers. To facilitate IS-IS configuration, all routers are L2-L1 capable within the same IS-IS area-id so there is only a single topology area in the network (all routers share the same topology). Traffic engineering (TE) is enabled on the IGP as it is a requirement for RSVP. The metric is using the default values: since no reference bandwidth command is used, the default metric of 10 is applicable on all interfaces. The configuration for PE-2 is displayed below.

```
*A:PE-2# configure router
```

```
        interface "int-PE-2-PE-1"
            address 192.168.12.2/30
            port 1/1/2
        exit
        interface "int-PE-2-PE-3"
            address 192.168.23.1/30
            port 1/1/3
        exit
        interface "int-PE-2-PE-4"
            address 192.168.24.1/30
            port 1/1/1
        exit
        interface "system"
            address 192.0.2.2/32
        exit

*A:PE-2# configure router
        isis
            area-id 49.0001
            traffic-engineering
            interface "system"
                passive
            exit
            interface "int-PE-2-PE-1"
                interface-type point-to-point
            exit
            interface "int-PE-2-PE-4"
                interface-type point-to-point
            exit
            interface "int-PE-2-PE-3"
                interface-type point-to-point
            exit
```

The configuration for the other nodes is similar. The IP addresses can be derived from Figure 139.

The global route table (GRT) for PE-2 is as follows:

```
*A:PE-2# show router route-table
===============================================================================
Route Table (Router: Base)

===============================================================================
*A:PE-2#
```

LDP and RSVP Shortcuts

Interface label distribution protocol (iLDP) is enabled on all interfaces (except system interfaces, which is not allowed) in all routers. The configuration on all nodes is similar and the IP addresses are derived from Figure 139. The configuration of PE-4 is as follows:

```
*A:PE-4# configure router ldp
            interface-parameters
                interface "int-PE-4-PE-2"
                exit
                interface "int-PE-4-PE-5"
                exit
                interface "int-PE-4-PE-6"
                exit
            exit
```

With iLDP enabled, PE-4 establishes iLDP sessions with its directly connected neighbors, as follows:

```
*A:PE-4# show router ldp session
===============================================================================
LDP IPv4 Sessions
===============================================================================

===============================================================================
*A:PE-4#
```

The following tunnel table shows that there is a label switched path (LSP) to every other router. The reason is that the LDP label distribution mode is downstream unsolicited (DU) by default, originating label bindings for system addresses only (which are used by iLDP as transport address by default). The command also shows the preference of the LSPs (where the preference is 9 for LDP) and the metric of the LSPs (the metric is inherited from the IGP, each hop counts as a metric of 10), as follows. The metric to destinations PE-1 and PE-3 is 20 because there are two hops in between (PE-4 is two hops away from PE-1 and PE-3).

```
*A:PE-4# show router tunnel-table

*A:PE-4#
```

In order to configure RSVP shortcuts, RSVP must be enabled on all interfaces where traffic engineering is required. For simplicity, RSVP is configured on all interfaces of the network, including system interfaces. When RSVP is in **no shutdown**, it is automatically configured on the interfaces where MPLS is configured. The configuration for PE-6 is as follows.

```
*A:PE-6# configure router mpls no shutdown
*A:PE-6# configure router rsvp no shutdown

*A:PE-6# configure router
        mpls
            interface "int-PE-6-PE-4"
            exit
            interface "int-PE-6-PE-5"
            exit
```

The configuration of the other nodes is similar. The IP addresses can be derived from Figure 139. Because there are no RSVP LSPs configured yet, the tunnel-table has no RSVP LSPs and only contains LDP LSPs.

LDP Static Route (IP Tunneled in LDP Tunnel)

Using LDP LSP shortcuts for static route resolution enables forwarding of IPv4 packets over LDP LSPs instead of using a regular IP next hop. In other words, the traffic to the resolved static routes is forwarded using MPLS LDP LSP rather than plain IP.

The configuration defines a static route pointing to the destination PE (remote loopback, which is an indirect next hop in the example), and explicitly indicates that it should use LDP rather than IGP. Taking PE-1 and PE-6 as an example, two loopback interfaces are configured (172.16.X.1/32), where X = PE number, and a static route is defined according to the explanation above. The following shows the configuration on PE-1.

```
*A:PE-1# configure router
        interface "loopback"
            address 172.16.1.1/32
            loopback
        exit
        static-route-entry 172.16.6.1/32
            indirect 192.0.2.6
                tunnel-next-hop
                    resolution-filter
                        ldp
                    exit
                    disallow-igp
                    resolution filter
                exit
                no shutdown
            exit
        exit
```

Looking at the GRT or forwarding information base (FIB), there are two new entries corresponding to the two configured loopback interfaces. One entry is has the protocol set to local (the local loopback on the PE), and the other entry has the protocol set to static, where the next hop is reached using an LDP LSP.

```
*A:PE-1# show router fib 1
===============================================================================
FIB Display
===============================================================================
Prefix [Flags]                                          Protocol
    NextHop
-------------------------------------------------------------------------------
172.16.1.1/32                                           LOCAL
```

```
    172.16.1.1 (loopback)
172.16.6.1/32                                                 STATIC
    192.0.2.6 (Transport:LDP)
---snip---
```

The next output shows that a ping sourced by the loopback interface on PE-1 is able to reach the loopback interface on PE-6, and traceroute demonstrates that the traffic is following the LDP LSP. The ping and traceroute traffic cannot follow the IGP path because the static route command states that the IGP is disallowed when no LDP LSP towards PE-6 is available (also, the loopback interfaces are not enabled on IS-IS).

```
*A:PE-1# ping 172.16.6.1 source 172.16.1.1

  3  172.16.6.1 (172.16.6.1)    1.69 ms  3.24 ms  2.46 ms
*A:PE-1#
```

With the traceroute command, there are three hops from PE-1 to PE-6. There is no information regarding IP for the first two hops because the traffic is encapsulated in an MPLS LSP. The reason why the hops are displayed even when there is an MPLS LSP tunnel is because by default, the SR router propagates (copies) the time to live (TTL) from the IP header in the MPLS header. This is known as uniform mode.

However, a service provider might not want to show how many MPLS hops (nodes) there are in their network if a **traceroute** command is executed from outside their network. To prevent internal hops being shown, **no propagate** commands are needed in the LDP configuration, as shown below. This is known as pipe mode.

```
*A:PE-1# configure router ldp
            no shortcut-local-ttl-propagate
            no shortcut-transit-ttl-propagate
            exit
```

Once TTL propagation is disabled, the hops are not displayed any longer when running the **traceroute** command.

```
*A:PE-1# traceroute 172.16.6.1 source 172.16.1.1
traceroute to 172.16.6.1 from 172.16.1.1, 30 hops max, 40 byte packets
```

```
  1  172.16.6.1 (172.16.6.1)    2.36 ms  2.24 ms  2.25 ms
*A:PE-1#
```

For more information about uniform mode and pipe mode, see chapter Tunneling of ICMP Reply Packets over MPLS LSPs.

RSVP Static Route (IP Tunneled in RSVP Tunnel)

Using RSVP LSP shortcuts for static route resolution enables forwarding of IPv4 packets over RSVP LSPs instead of using a regular IP next hop. In other words, the traffic to the resolved static routes is forwarded using an MPLS RSVP LSP rather than plain IP.

The configuration defines a static route pointing to a destination PE (remote loopback, which is an indirect next hop in the example), and explicitly indicates that it should use RSVP rather than IGP. Taking PE-6 and PE-1 as an example, two loopback interfaces are configured (172.16.X.1/32), where X = PE number, and a static route is defined according to the explanation above. The following shows the configuration on PE-6.

```
*A:PE-6# configure router
        interface "loopback"
            address 172.16.6.1/32
            loopback
            no shutdown
        exit
        static-route-entry 172.16.1.1/32
            indirect 192.0.2.1
                tunnel-next-hop
                    resolution-filter
                        rsvp-te
                        exit
                    exit
                    disallow-igp
                    resolution filter
                exit
                no shutdown
            exit
        exit
```

Also, an RSVP LSP needs to be configured with the system interface of PE-1 as the destination:

```
*A:PE-6# configure router mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-6-PE-1"
                to 192.0.2.1
                primary "loose"
```

```
            exit
            no shutdown
        exit
```

In the LSP tunnel table, an RSVP LSP is created:

```
*A:PE-6# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop         Metric
-------------------------------------------------------------------------------
192.0.2.1/32      rsvp      MPLS  1         7        192.168.46.1    30
192.0.2.1/32      ldp       MPLS  65553     9        192.168.46.1    30
192.0.2.2/32      ldp       MPLS  65552     9        192.168.46.1    20
192.0.2.3/32      ldp       MPLS  65540     9        192.168.56.1    20
192.0.2.4/32      ldp       MPLS  65551     9        192.168.46.1    10
192.0.2.5/32      ldp       MPLS  65541     9        192.168.56.1    10
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-6#
```

The default RSVP preference is 7 (preferred over that of LDP, which is 9) and the metric reflects that this LSP spans 3 hops (for a dynamic LSP not using constrained shortest path first (CSPF), the metric is inherited from IGP). See RSVP Shortcut for IGP Route Resolution for more details about the metric applied in LSPs.

The RSVP LSP is used to resolve the indirect next hop (PE-1 system address) in the static route (the LSP used is identified with the tunnel ID, in this case 1), hence the GRT is modified with the following entry:

```
*A:PE-6# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
172.16.1.1/32                                   Remote  Static    00h00m21s  5
       192.0.2.1 (tunneled:RSVP:1)                                     1

---snip---
-------------------------------------------------------------------------------
No. of Routes: 16
```

As in the LDP shortcut with static route example, between PE-6 and PE-1, TTL propagation is disabled.

```
*A:PE-6# configure router mpls
            no shortcut-local-ttl-propagate
            no shortcut-transit-ttl-propagate
```

The output is the following when running a traceroute:

```
*A:PE-6# traceroute 172.16.1.1 source 172.16.6.1
traceroute to 172.16.1.1 from 172.16.6.1, 30 hops max, 40 byte packets
  1  172.16.1.1 (172.16.1.1)    2.22 ms  2.04 ms  2.18 ms
*A:PE-6#
```

The two static routes that have been defined to use the LDP and RSVP shortcuts follow the static routes default values and have a preference of 5 and a metric of 1.

LDP Shortcut for IGP Route Resolution

Using LDP shortcuts for IGP route resolution enables forwarding of packets to IGP learned routes over an LDP LSP. The default is to disable the LDP shortcut across all interfaces in the node.

When LDP shortcuts are enabled, LDP populates the route table manager (RTM) with next hop entries corresponding to all prefixes for which it activated an LDP forwarding equivalence class (FEC). For a given prefix, two route entries are populated in RTM. One corresponds to the LDP shortcut next hop and has an owner of LDP. The other one is the regular IP next hop. The LDP shortcut next hop always takes preference over the regular IP next hop for forwarding user packets and specific control packets over a given outgoing interface to the route next hop.

Once LDP has activated a FEC for a given prefix and programmed the RTM, it also programs the ingress tunnel table in the line card with the LDP tunnel information.

When an IPv4 packet is received on an ingress network interface, a subscriber Internet enhanced service (IES) interface, or a regular IES interface, the lookup of the packet by the ingress line card results in the packet being sent labeled with the label stack corresponding to the next hop label forwarding entry (NHLFE) of the LDP LSP when the preferred RTM entry corresponds to an LDP shortcut. If the preferred RTM entry corresponds to an IP next hop, the IPv4 packet is forwarded unlabeled. The activation of the FEC by LDP is done by performing an exact match with an IGP route prefix in RTM but it can also be done by performing a longest prefix match with an IGP route in RTM if the aggregate-prefix-match option is enabled globally in LDP.

Handling of Control Packets

All control plane packets will not see the LDP shortcut route entry in RTM with the exception of the following control packets which will be forwarded over an LDP shortcut when enabled:

- A locally generated or in transit ICMP ping and UDP traceroute of an IGP route. The transit message appears as a user packet to the ingress LER node.
- A locally generated response to a received ICMP ping or UDP traceroute message.

All other control plane packets that require an RTM lookup and have knowledge of which destination is reachable over the LDP shortcut will continue to be forwarded over the IP next hop route in RTM.

Handling of Multicast Packets

LDP shortcuts apply to unicast FEC types and are used for forwarding IP unicast packets in the data path. IP multicast packets forwarded over an multicast label distribution protocol (mLDP) point-to-multipoint (P2MP) LSP make use of a multicast FEC and thus cannot make use of the LDP unicast shortcut.

ECMP Considerations

When equal cost multi-path (ECMP) is enabled and multiple equal cost next hops exist for the IGP route, the ingress line card will spray the packets for this route based on the hashing routine supported for IPv4 packets. When the preferred RTM entry corresponds to an LDP shortcut route, spraying is performed across the multiple next hops for the LDP FEC. The FEC next hops can either be direct link LDP neighbors or T-LDP (targeted LDP) neighbors reachable over RSVP LSPs in the case of LDP-over-RSVP but not both. This is as per ECMP for LDP in the existing implementation. When the preferred RTM entry corresponds to a regular IP route, spraying will be performed across regular IP next hops for the prefix. Spraying across regular IP next hops and LDP shortcut next hops concurrently is not supported.

Configuring IGP LDP shortcuts is straightforward, and only applies to the node where there is interest to provision the LDP shortcut. In this example, only PE-1 is provisioned with LDP shortcuts, as follows:

```
*A:PE-1#configure router ldp-shortcut
```

Now, all tunnel LSPs that resolve an IGP next hop will replace the IP next hops, as shown in the following output:

```
*A:PE-1# show router route-table
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
```

```

```

Applying LDP IGP shortcuts only on PE-1 implies that IP traffic from PE-1 to any of the system addresses of the rest of nodes will use the LDP shortcut, however, the traffic replied from any PE back to PE-1 will be native IP since IGP shortcuts have not been provisioned in the other nodes.

RSVP Shortcut for IGP Route Resolution

Using RSVP LSP shortcuts when resolving IGP routes enables forwarding of packets to IGP learned routes over an RSVP LSP. The use of RSVP shortcut for resolving IGP routes is enabled at the IS-IS (or OSPF) routing protocol level or at the LSP level, and instructs IS-IS and OSPF to include RSVP LSPs originating on this node and terminating on the system address (router-id) of a remote node and considers them as direct links. RSVP LSPs with a destination address corresponding to an interface address or any other loopback interface address of a remote node are automatically not considered by IS-IS or OSPF.

By default, **rsvp-shortcut** is disabled in all IGP instances.

RSVP LSPs are included in the IGP SPF computation with the following characteristics:

- RSVP LSP is modeled as a point-to-point link IP interface and its metric is used in the computation of the shortest path of IGP routes
- Next hop and interface include the NHLFE of the shortcut LSP when the IGP path cost using the RSVP LSP is the best.
- Shortcuts are not used when the destination RSVP LSP is in a different IGP area. In addition, IGP adjacencies across an RSVP LSP are not supported.

The next output shows the configuration commands:

```
configure router isis rsvp-shortcut
```

The configuration can be done at the IGP level or per LSP level. When rsvp-shortcut is enabled at the IGP instance level, all RSVP LSPs originating on this node are eligible by default. The user can, however, exclude a specific RSVP LSP from being used as a shortcut for resolving IGP routes by entering the command

```
*A:PE-6# configure router mpls lsp "LSP-PE-6-PE-1" no igp-shortcut
```

As RSVP shortcuts can coexist with LDP shortcuts or IP next hops, SPF computation and path selection follows the procedures in RFC 3906:

- SPF picks the RSVP shortcut next hop if there is an RSVP LSP directly to that address regardless of the path cost compared to the IGP next hop.
- SPF picks the RSVP shortcut next hop or the IGP next hop based on path lowest cost if there is an IGP path to the prefix that does not go via the tail-end of the LSP.
- If the IGP next hop is picked, then it can be an LDP shortcut next hop or a regular IP next hop. The LDP shortcut next hop always has preference over the regular IP next hop.

Handling of Control Packets

All control plane packets requiring an RTM lookup and whose destination is reachable over the RSVP shortcut are forwarded over the shortcut. This is because RTM keeps a single route entry for each prefix except if there is ECMP over different outgoing interfaces. Interface bound control packets are not impacted by the RSVP shortcut since RSVP LSPs with a destination address different than the router-id are not included by IGP in its SPF calculation.

Important note: RSVP shortcuts for IGP shortcut resolution should only be used with CSPF LSPs and/or with fully explicit path non-CSPF LSP. RSVP hop-by-hop Path messages will try to use the shortcut and consequently LSPs without CSPF enabled, or that use a loose/empty hop path, will not come up. However, LSPs with CSPF enabled or using a strict hop path will come up. This is because in the former case the RTM lookup to get the next hop results in using the shortcut and so the path messages are sent directly to the destination of the LSP, where they are dropped. With CSPF enabled, the next hop (and the entire path) is provided by CSPF and the path messages are sent unlabeled to the directly connected neighbor which corresponds to the next hop of the destination of the LSP. Similar processing occurs if a strict hop path is used, as is the case in the following example.

Handling of Multicast Packets

IP multicast packets cannot be forwarded over an RSVP shortcut, they can only be forwarded over an RSVP P2MP LSP. However, RSVP shortcut routes appear in RTM and are seen by all applications when they are the best route. When the reverse path forwarding (RPF) check for the source of the multicast packet matches an RSVP shortcut route, the check will pass if both the RSVP shortcut and the multicast-import options are enabled in the IGP, as shown below, as the RTM is populated with next hops only and not with tunnels (RPFs will fail for source prefixes resolved to a tunnel NH).

```
*A:PE-6# configure router isis multicast-import
  - multicast-import [both]
  - multicast-import [ipv4]
  - multicast-import [ipv6]
  - no multicast-import [both]
  - no multicast-import [ipv4]
  - no multicast-import [ipv6]

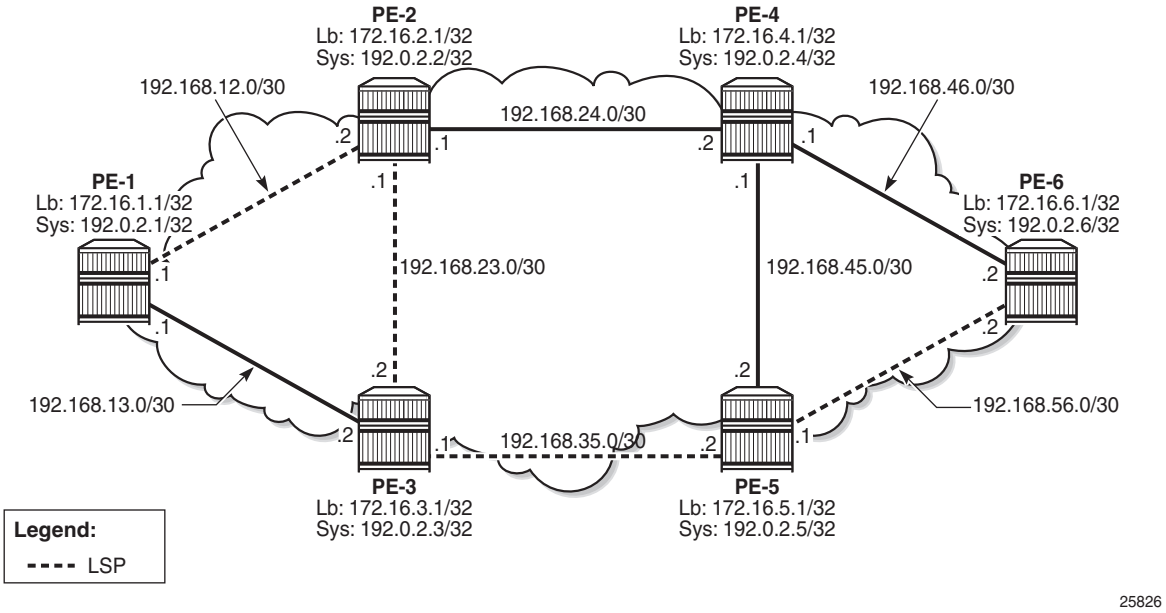
 <ipv4>               : keyword
 <ipv6>               : keyword
 <both>               : keyword

*A:PE-6#
```

The unicast RTM can still use the tunnel next hop for the same prefix. SPF keeps track of both the direct first hop and the tunneled first hop of a node which is added to the Dijkstra tree.

ECMP Considerations

When ECMP is enabled and multiple equal cost paths exist for the route over a set of tunnel next hops based on the hashing routine supported for IPv4 packets, there are two possibilities:



- Destination is tunnel endpoint: the system selects the tunnel with lowest tunnel ID (IP next hop is never used).
- Destination is different from the tunnel endpoint: it selects tunnel endpoints when the LSP metric is not greater than the IGP cost and it prefers tunnel endpoint over IP next hop.

ECMP is not performed across the IP and tunnel next hops simultaneously.

RSVP Shortcuts Configuration

Configuring RSVP LSP shortcuts is straightforward, and only applies to the node where there is interest to provision the RSVP shortcut. Two LSPs, from PE-6 to PE-1 and from PE-1 to PE-6, with strict hops, are provisioned according to Figure 140.

Figure 140 **LSPs Between PE-1 and PE-6**

The configuration on PE-1 and PE-6 is similar (replacing the IP addresses), so only the configuration for PE-6 is shown:

```
configure router isis rsvp-shortcut

configure router mpls
    path "path-to-PE-1"
        hop 10 192.0.2.5 strict
        hop 20 192.0.2.3 strict
        hop 30 192.0.2.2 strict
        hop 40 192.0.2.1 strict
        no shutdown
    exit
    lsp "LSP-PE-6-PE-1-strict"
        to 192.0.2.1
        primary "path-to-PE-1"
        exit
        no shutdown
    exit
```

The GRT output shows the change in the next hop, using an RSVP shortcut:

```
*A:PE-6# show router route-table

===============================================================================

===============================================================================
*A:PE-6#
```

The RSVP LSP in the output has a metric of 16777215, the LSP administrative metric matches the maximum value allowed for an IS-IS link using the wide-metric (24-bit value with a range of [0 — 16777215]). The following metric rules apply:

- A dynamic strict path non-CSPF LSP has the maximum metric (16777215).
- A dynamic CSPF LSP has a metric equal to the cumulative IGP cost.
  - If the user enabled the use of the TE metric on this LSP (configure router mpls lsp cspf use-te-metric), then the metric for the LSP is the maximum (16777215).

  - If the user enabled the use of the TE metric on this LSP (configure router mpls lsp cspf use-te-metric) and provisioned a specific metric on the lsp (configure router mpls lsp metric <metric>:<0..16777215>), then the metric for the LSP is the one provisioned. When configuring the metric of an LSP, the parameter “use-te-metric” is not required.
- A static LSP has a maximum metric (16777215).
- Manual and dynamic bypass LSPs have the maximum metric (16777215).

The RSVP shortcuts section detailed the importance of the LSP metric when using CSPF LSPs or when importing RSVP tunnel links into the IGP. The LSP metric can be inherited from the IGP, or can be manually modified by configuring a specific LSP metric or relative-metric offset. Because IP and LDP FECs resolve to RSVP LSPs when the metric is equal or lower compared to the regular routing metric, configuring a specific static LSP metric (lower than the IGP metric) or relative-metric offset is strongly recommended when using RSVP shortcuts, so that the GRT and LDP FEC resolution will always prefer the RSVP LSP shortcuts when the CSPF path computation is not using the shortest path.

For the example above, the first rule applies.

Advertising RSVP LSP Tunnel Links in the IGP: Forwarding Adjacency Feature

If configured, an RSVP LSP can also be advertised into the IGP similar to regular links so that other routers in the network can include that RSVP LSP into their SPF computations. The forwarding adjacency feature can be enabled independently from the RSVP shortcut feature in CLI. If both are configured for a given IGP instance, the forwarding adjacency takes precedence. An RSVP LSP must exist in the reverse direction in order for the advertised link to pass the bi-directional link check and be usable by other routers in the network. However, this is not required for the node which originates the LSP. The LSP is advertised as an unnumbered point-to-point link and the link state protocol data unit (LSP) and link state advertisement (LSA) have no traffic engineering opaque sub-TLVs as per RFC 3906.

Reusing the RSVP IGP shortcuts set up previously (PE-1 and PE-6 RSVP IGP shortcut example according to Figure 140), the outcome is a route linked with an RSVP LSP as next hop, as seen below:

```
*A:PE-6# show router route-table 192.0.2.1/32
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                            Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
```

```
192.0.2.1/32                                    Remote  ISIS      00h02m37s  15
       192.0.2.1 (tunneled:RSVP:2)                                    16777215
-------------------------------------------------------------------------------
No. of Routes: 1
```

The route tunneled through RSVP has a metric of 16777215, so it is not used by PE-6 GRT to reach any other routes since the metric is very high. After enabling the forwarding adjacency feature (tunnel links) to use shortcuts in the configuration, PE-1 and PE-6 have a direct connection through the RSVP LSP (as a virtual link). This configuration command must be executed in both routers.

```
configure router isis advertise-tunnel-link
```

Once the shortcut is advertised by IS-IS, the route will disappear from the RTM as the metric of the shortcut is greater than the IGP cost.

```
*A:PE-6# show router route-table 192.0.2.1/32
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h00m04s  15
       192.168.46.1                                                30
-------------------------------------------------------------------------------
No. of Routes: 1
```

If the LSP is reconfigured to use a metric equal to or smaller than the IGP cost, the router PE-6 will use the RSVP shortcut again. In the example, the LSP is reconfigured with a metric of 30:

```
*A:PE-6# configure router mpls lsp "LSP-PE-6-PE-1-strict" metric 30
```

Now the shortcut shows up as the preferred next hop to reach PE-1 from PE-6.

```
*A:PE-6# show router route-table 192.0.2.1/32
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h00m06s  15
       192.0.2.1 (tunneled:RSVP:2)                                 30
-------------------------------------------------------------------------------
No. of Routes: 1
```

As explained earlier, this could be combined together with ECMP, so if ECMP is configured to 2, the system shows the two equal cost paths.

```
*A:PE-6# configure router ecmp 2
```

```
*A:PE-6# show router route-table 192.0.2.1/32
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age         Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h00m05s  15
       192.0.2.1 (tunneled:RSVP:2)                                    30
192.0.2.1/32                                    Remote  ISIS      00h00m05s  15
       192.168.46.1                                                   30
-------------------------------------------------------------------------------
No. of Routes: 2
```

Checking GRT on PE-4, it displays the route to reach PE-1 (192.0.2.1/32) with a metric of 20 via PE-2 as next hop. Although now PE-6 is announcing the RSVP LSP-PE-6-PE-1 to the other routers, the LSP shortcut is not used by PE-4 because the metric to reach PE-6 (10) plus the metric of the LSP shortcut from PE-6 to PE-1 (metric 30) is greater than 20.

```
*A:PE-4# show router route-table
===============================================================================
Route Table (Router: Base)

       192.168.45.2                                                   20
-------------------------------------------------------------------------------
```

```
No. of Routes: 14
```

If the metric of the LSP LSP-PE-6-PE-1 is modified to a value between 1 and 9, there is a better metric (less than 20) so that PE-4 will change the next hop via PE-6. First the metric of the LSP is modified to 9:

```
*A:PE-6# configure router mpls lsp "LSP-PE-6-PE-1-strict" metric 9
```

And checking PE-4´s GRT the next hop to reach PE-1 has changed, from next hop PE-2 to next hop PE-6 (hence, using the LSP shortcut), and the metric is 19 (10 to reach PE-6 plus metric 9 of the LSP PE-6-PE-1 shortcut):

```
*A:PE-4# show router route-table 192.0.2.1/32
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                    Remote  ISIS      00h00m07s  15
       192.168.46.2                                                 19
-------------------------------------------------------------------------------
No. of Routes: 1
```

Because the metric of the LSP shortcut was modified to a value of 9, when displaying the GRT of PE-6 it is noted that the next hops of several routes have changed and are also using the shortcut LSP PE-6-PE-1 because the metric is better than the regular IS-IS metric. It is important to emphasize that IGP shortcuts will not be used to resolve prefixes downstream of the LSP endpoint when the LSP metric is higher than the underlying IGP cumulative metric.

There are also cases where an LDP FEC can resolve to an RSVP LSP, if the user enables the LDP-over-RSVP feature or IGP shortcut feature when prefer-tunnel-in-tunnel is enabled in LDP and the endpoint of the RSVP LSP matches the FEC prefix. For those cases, the metric to the prefix is the sum of the RSVP LSP metric + remaining IGP path cost.

Table 14 provides a summary of the outcome when configuring the forwarding adjacency, LDPoRSVP and RSVP shortcut options at both the IGP instance level and at the LSP level.

Table 14 **RSVP LSP Role As Outcome of LSP Level and IGP Level Configuration Options**

	IGP Instance Level Configurations					
LSP Level Configuration	advertise-tunnel-link enabled/ rsvp-shortcut enabled/ldp-over-rsvp enabled	advertise-tunnel-link enabled/ rsvp-shortcut enabled/ldp-over-rsvp disabled	advertise-tunnel-link enabled/ rsvp-shortcut disabled/ldp-over-rsvp disabled	advertise-tunnel-link disabled/ rsvp-shortcut disabled/ldp-over-rsvp disabled	advertise-tunnel-link disabled/ rsvp-shortcut enabled/ldp-over-rsvp enabled	advertise-tunnel-link disabled/ rsvp-shortcut disabled/ldp-over-rsvp enabled
igp-shortcut enabled/ldp-over-rsvp enabled	Forwarding Adjacency	Forwarding Adjacency	Forwarding Adjacency	None	IGP Shortcut	LDP-over-RSVP
igp-shortcut enabled/ldp-over-rsvp disabled	Forwarding Adjacency	Forwarding Adjacency	Forwarding Adjacency	None	IGP Shortcut	None
igp-shortcut disabled/ldp-over-rsvp enabled	None	None	None	None	None	LDP-over-RSVP

Table 14 **RSVP LSP Role As Outcome of LSP Level and IGP Level Configuration Options**

	IGP Instance Level Configurations					
igp-shortcut disabled/ldp-over-rsvp disabled	None	None	None	None	None	None

LSP Relative Metric

It is possible to use relative metrics for IGP shortcuts as per RFC 3906, *Calculating Interior Gateway Protocol (IGP) Routes Over Traffic Engineering Tunnels*, with the following command:

```
*A:PE-6# configure router mpls lsp "LSP-PE-6-PE-1-loose" igp-shortcut relative-metric
  - igp-shortcut [lfa-protect | lfa-only][relative-metric [offset]]
  - no igp-shortcut

 <lfa-protect>        : keyword
 <lfa-only>           : keyword
 <relative-metric>    : keyword
 <offset>             : [-10..10]
```

When this feature is enabled, IGP applies the shortest IGP cost between the endpoints of the LSP, plus the value of a configured offset when computing the cost of the prefix that is resolved to the LSP.

The offset value is optional and can have a value between -10 and 10, and defaults to zero (0). An offset value of zero (0) is used when the relative-metric option is enabled without specifying the offset parameter value. The minimum net cost for the prefix is capped to the value of one (1) after applying the offset:

Prefix cost = max (1, IGP Cost + relative metric offset)

The **relative-metric** option is ignored when advertise-tunnel-link is enabled in IS-IS or OSPF. In that case, the IGP advertises the LSP as a P2P unnumbered link using the LSP operational metric.

The **relative-metric** option is mutually exclusive with the **lfa-protect** (loop-free alternat (LFA)) or the **lfa-only** options. An LSP with **relative-metric** option enabled cannot be included in the LFA SPF and vice-versa when the **rsvp-shortcut** option is enabled in the IGP (see chapter LDP/IP FRR LFA for IGP Shortcut Using IS-IS/OSPF for more information).

The offset can be used to enforce the preference of the shortcut path over the other paths for the prefix. Using an example, a new CSPF LSP with empty path and relative metric of -10 is created between PE-6 and PE-1. While the operational or absolute metric is 30 (IGP cost and populated in the Tunnel Table Manager, TTM), the metric that the RTM shows is 20 after applying the offset:

```
*A:PE-6# configure router mpls
            lsp "LSP-PE-6-PE-1-loose"
                to 192.0.2.1
                cspf
                igp-shortcut relative-metric -10
                primary "loose"
                exit
                no shutdown
            exit

LDP/IP FRR LFA for IGP Shortcut Using IS-IS/OSPF

MPLS LDP/IP FRR LFA for IGP shortcuts allows for the use of RSVP-LSP-based IGP shortcuts as a Loop-Free Alternate (LFA) backups, this way expanding the coverage of the IP Fast-Reroute (FRR) and the LDP FRR capabilities for IS-IS and OSPF prefixes. For a detailed description about IP and LDP FRR, see chapter MPLS LDP FRR using ISIS as IGP.

When an RSVP LSP is used as a shortcut by IS-IS or OSPF, it is included by the SPF as a P2P link and it can also be optionally advertised into the rest of the network by the IGP.

Two LSP-level configuration options are provided:

- The lfa-protect option includes the RSVP LSP in both the main SPF and the LFA SPFs. If the prefix primary next hop (NH) is tunneled, no LFA NH is computed. The protection in this case is provided by RSVP FRR. If the prefix primary NH is direct, then an LFA NH is computed. A direct LFA NH is preferred over a tunneled LFA NH. Within each LFA NH type, node-protection is preferred over link-protection. The configuration command is:

```
configure router mpls lsp <lsp-name> igp-shortcut lfa-protect
```

- The lfa-only option includes the LSP in the LFA SPFs only so that the introduction of IGP shortcuts does not impact the main SPF decision. The prefix primary NH is always direct and the prefix LFA NH is computed. A direct LFA NH is preferred over a tunneled LFA NH. Within each LFA NH type, node-protection is preferred over link-protection. The configuration command is:

```
configure router mpls lsp <lsp-name> igp-shortcut lfa-only
```

LDP/IP FRR is a local decision, so it can be enabled per node and there are no interoperability issues with other nodes. In the topology, PE-2 is provisioned with IS-IS LFA (OSPF configuration for the rest of this section is similar):

```
A:PE-2# configure router isis loopfree-alternate
```

The second item to configure is whether LDP or IP FRR is provisioned. To configure ip-fast-reroute, the command is:

```
A:PE-2# configure router ip-fast-reroute
```

IP FRR feature for IS-IS/OSPF prefixes is supported on 7950 XRS, on 7750 SR-7/12/12e in chassis mode D, on the 7450 ESS-6/6v/7/12 in chassis mode D with or without mixed-mode, and 7750 SR-c4/c12.

To configure LDP FRR (no chassis dependency), this command is used:

```
A:PE-2# configure router ldp fast-reroute
```

Although not shown, it is recommended to enable IGP-LDP synchronization per interface to avoid possible traffic blackholes.

Once LFA is enabled in all routers of the topology, looking at PE-2 (the configuration is done only on this node), the following command shows the LFA coverage where 4/5 nodes and 7/10 IPv4 prefixes are protected (IPv6 is not configured). The output shows L1 and L2 because this node is provisioned as an L1-L2 IS-IS router. PE-2, PE-3, PE-4 and PE-5 share the same results, whereas only PE-1 and PE-6 have a 100% of coverage.

```

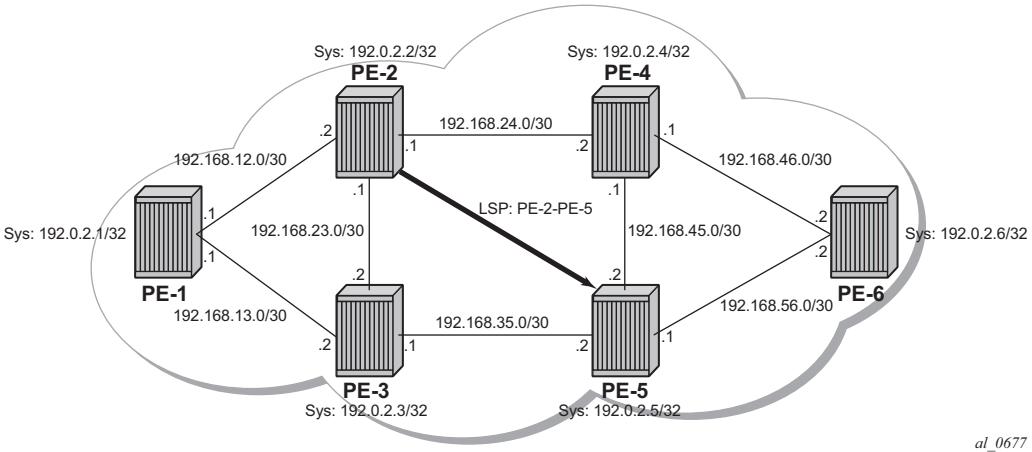
*A:PE-1#
```

Taking a deeper look into the IS-IS LFA on PE-2, it can be seen that the node which is not protected is PE-4 (system address 192.0.2.4, since it is the one missing):



```
*A:PE-2# show router route-table alternative | match LFA pre-lines 2
192.0.2.1/32                                  Remote  ISIS      02h22m46s  15
       192.168.12.1                                                 10

       192.168.23.2                                                 20
       192.168.12.1 (LFA)                                           30
192.168.56.0/30                               Remote  ISIS      02h22m17s  15
       192.168.23.2                                                 30
```

```
       192.168.24.2 (LFA)                                          30
Flags: n = Number of times nexthop is repeated
       Backup = BGP backup route
       LFA = Loop-Free Alternate nexthop
*A:PE-2#
```

LFA is improved by taking advantage of RSVP shortcuts when it is properly provisioned. The reason why PE-4 cannot be protected with an LFA path is because the direct NH is using the direct link between PE-2 and PE-4 (the shortest IGP) and the intended LFA path through PE-3 is not valid (when LFA tries to find an alternate path via PE-3, the IGP cost from PE-3 to PE-4 is the same going via PE-5 as the path back via PE-2, invalidating that LFA calculation because there is a loop). This is normal because PE-2, PE-3, PE-4 and PE-5 are forming a ring. LFA coverage is increased by adding a link between PE-2 and PE-5, which can be done using a physical link or a virtual link with an RSVP shortcut. From the two possible options (lfa-only and lfa-protect), a new LSP “LSP-PE-2-PE-5” is configured with igp-shortcut lfa-only.

```
*A:PE-2# configure router mpls
            path "path-to-PE-5"
                hop 10 192.0.2.3 strict
                hop 20 192.0.2.5 strict
                no shutdown
            exit
            lsp "LSP-PE-2-PE-5"
                to 192.0.2.5
                igp-shortcut lfa-only
                primary "path-to-PE-5"
                exit
                no shutdown
            exit
```

Figure 141 **RSVP Shortcuts LFA Use Case Example**

Now the coverage is 100% as shown by the output:

```
*A:PE-2# show router isis lfa-coverage

===============================================================================
*A:PE-2#
```

The GRT details the prefix information after the new LFA calculation using the lfa-only option (the shortcut is used by LFA SPF). The metric from PE-2 to PE-4 is the maximum plus the IGP cost (16777215 + 10) and the shortcut is also used to protect the rest of the previously unprotected prefixes:

```
*A:PE-2# show router route-table alternative | match LFA pre-lines 2

       192.168.24.2                                                     20
       192.0.2.5 (LFA) (tunneled:RSVP:1)                                16777235
192.168.56.0/30                                 Remote  ISIS      02h27m30s  15
       192.168.23.2                                                     30
       192.168.24.2 (LFA)                                               30
Flags: n = Number of times nexthop is repeated
       Backup = BGP backup route
```

```
       LFA = Loop-Free Alternate nexthop
*A:PE-2#
```

The tunnel table shows the RSVP LSP used as a shortcut and its operational metric.

```
*A:PE-2# show router tunnel-table 192.0.2.5
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop         Metric
-------------------------------------------------------------------------------
192.0.2.5/32      rsvp      MPLS  1         7        192.168.23.2    16777215
192.0.2.5/32      ldp       MPLS  65540     9        192.168.23.2    20
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-2#
```

If the LSP “LSP-PE-2-PE-5” is provisioned with lfa-protect instead of lfa-only, the result is that the LSP "LSP-PE-2-PE-5“ is used by normal SPF to define the primary NH and it is not used by LFA SPF anymore.

```
A:PE-2# configure router mpls lsp "LSP-PE-2-PE-5" igp-shortcut lfa-protect
```

The coverage when lfa-protect is used also shows a 100% for nodes. The 112% coverage for prefixes shown below is not correct and should be 100% since the IGP shortcut used as a primary next hop to reach PE-5 from PE-2 is providing protection for prefixes reachable via PE-5. The display issue will be fixed in a later release and will be referenced by [201872] in the release notes.

```
*A:PE-2# show router isis lfa-coverage

Rules Determining the Installation of Shortcuts into RTM

Although it was already mentioned in the RSVP-TE LSP shortcut for IGP route resolution section, the rules determining how shortcuts are installed into RTM are (sorted by higher priority):

- RSVP shortcut.
- LDP shortcut.
- IGP route with regular IP next hop.
- The implementation is compliant with RFC3906.

To check the rules, the network configuration is iLDP in all interfaces with LDP shortcuts enabled, there is also an RSVP LSP from PE-6 to PE-3 available but RSVP shortcuts are disabled. The topology is shown in Figure 142.

Figure 142 **Network Topology to Verify Installation of Shortcuts into RTM**

The following RSVP LSP is needed between PE-6 and PE-3.

```
configure router ldp-shortcut

configure router isis no rsvp-shortcut

configure router mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-6-PE-3"
                to 192.0.2.3
                cspf
                primary "loose"
                exit
                no shutdown
            exit
```

Displaying relevant info in PE-6, the routes are:

```
*A:PE-6# show router route-table
===============================================================================
Route Table (Router: Base)
```

```

       192.168.56.1 (tunneled)                                         10
192.168.12.0/30                                 Remote  ISIS      00h00m08s  15
       192.0.2.3 (tunneled:RSVP:4)                                     40
192.168.13.0/30                                 Remote  ISIS      00h00m08s  15
       192.0.2.3 (tunneled:RSVP:4)                                     30
192.168.23.0/30                                 Remote  ISIS      00h00m08s  15
       192.0.2.3 (tunneled:RSVP:4)                                     30
-------------------------------------------------------------------------------
No. of Routes: 7
```

The GRT shows that PE-6 is using an LDP shortcut to reach PE-5, but PE-6 is using the RSVP shortcut to reach not only PE-3's system address, but also PE-1 and PE-2 routes (including all interfaces) which were behind the RSVP LSP shortcut.

In summary, the behavior is:

1. When resolving a prefix, SPF picks the RSVP shortcut next hop if there is an RSVP LSP directly to that address regardless of the IGP path cost compared to the IGP next hop. When multiple RSVP LSPs to that address exist and all have the same lowest metric, if ECMP is enabled on the system, the LSP with the lowest tunnel ID is chosen. In this example, if LSP "LSP-PE-6-PE-3" is provisioned with a metric of 100 (IGP metric is 20), the GRT shows that the PE-3 system address is reachable via the LSP.

```
*A:PE-6# show router route-table 192.0.2.3
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.3/32                                    Remote  ISIS      00h00m12s  15
       192.0.2.3 (tunneled:RSVP:4)                                     100
-------------------------------------------------------------------------------
No. of Routes: 1
```

2. SPF also picks the RSVP LSP shortcut if both the LSP path and the IGP path to the prefix are via the tail-end of the LSP. This is regardless of the path cost compared to the IGP next hop. When paths over multiple RSVP shortcuts have the same lowest cost, if ECMP is enabled on the system, the LSP with the lowest tunnel ID is chosen. In this example, 192.168.13.0 and 192.168.23.0 are using the shortcut but 192.168.12.0 is not.

```

LDP/RSVP LSP Shortcut for BGP NH Resolution

Using LDP/RSVP LSP shortcuts for resolving BGP next hops allows IPv4 packet forwarding to routes resolved via a BGP next hop using an LDP/RSVP LSP instead of using a regular IP next hop. In the network topology of Figure 139, both PE-3 and PE-6 have a single peer configured, initially without any shortcuts enabled under the BGP context. Also, one static route is configured in PE-3 and PE-6 and that is redistributed into BGP. The relevant configuration on PE-3 is the following:

```
*A:PE-3# configure router
        interface "static-route"
            address 172.16.33.1/30
            port 1/1/4:33
        exit
        autonomous-system 65536

        static-route-entry 10.10.10.0/24
            next hop 172.16.33.2
                no shutdown
            exit
        exit

        policy-options
            begin
            policy-statement "static-routes"
                description "export static-routes for I-BGP"
                entry 10
                    from
                        protocol static
                    exit
                    to
                        protocol bgp
                    exit
```

```
                action accept
                    next-hop-self
                exit
            exit
        exit
        commit
    exit

    bgp
        export "static-routes"
        group "ibgp"
            peer-as 65536
            neighbor 192.0.2.6
            exit
        exit
    exit
```

Checking the static route received on PE-6 via BGP, the next hop is the PE-3 system address:

```
*A:PE-6# show router bgp routes 10.10.10.0/24 detail

Three of the BGP peering configuration possibilities are LDP, RSVP, or BGP. The other resolution filter options are related to segment routing and are beyond the scope of this chapter. In case both LDP and RSVP are included in the filter, RSVP is preferred. Disabling the IGP is also allowed (meaning that unless there is a shortcut, the BGP peering will not fall back to IGP):

```
*A:PE-6# configure router bgp next-hop-resolution shortcut-tunnel family ipv4
resolution
  - resolution {any|filter|disabled}

*A:PE-6# configure router bgp next-hop-resolution shortcut-tunnel family ipv4
resolution-filter
  - resolution-filter

 [no] bgp             - Use BGP tunnelling for next hop resolution
 [no] ldp             - Use LDP tunnelling for next hop resolution
 [no] rsvp            - Use RSVP tunnelling for next hop resolution
 [no] sr-isis         - Use sr-isis for next hop resolution
 [no] sr-ospf         - Use sr-ospf for next hop resolution
 [no] sr-te           - Use sr-te for next hop resolution

*A:PE-6#
```

When enabling LDP shortcuts on PE-6, the output changes showing the detail of the received BGP route indicating that the next hop is resolved using LDP:

```
*A:PE-6# configure router bgp
            next-hop-resolution
                shortcut-tunnel
                    family ipv4
                        resolution-filter
                            ldp
                        exit
                        resolution filter
                    exit
                exit
            exit

*A:PE-6# show router bgp routes 10.10.10.0/24 detail

*A:PE-6#
```

After adding **resolution-filter rsvp** to the shortcut-tunnel configuration in the bgp context, the output shows that the BGP peer is reachable using an RSVP LSP (switched from LDP to RSVP since RSVP is preferred):

```
*A:PE-6# configure router bgp
            next-hop-resolution
                shortcut-tunnel
                    family ipv4
                        resolution-filter
                            ldp
                            rsvp
                        exit
                        resolution filter
                    exit
                exit
            exit

```

When the shortcut tunnel with resolution-filter rsvp is enabled at the BGP level, all RSVP LSPs originating on this node are eligible to be used by default as long as the destination address of the LSP corresponds to that of the BGP next hop for that prefix. It is also possible to exclude a specific RSVP LSP from BGP next hop resolution, similar to the exclusion of a specific RSVP LSP being used as a shortcut for resolving IGP routes. In this example, if the RSVP LSP LSP-PE-6-PE-3 is excluded to be eligible for BGP next hop resolution, it reverts back to LDP.

```
*A:PE-6# configure router mpls lsp "LSP-PE-6-PE-3"
               no bgp-shortcut
               no shutdown
               exit

*A:PE-6# show router route-table 10.10.10.0
===============================================================================
Route Table (Router: Base)
```

```
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
10.10.10.0/24                                   Remote  BGP       00h04m56s  170
       192.0.2.3 (tunneled)                                          0
-------------------------------------------------------------------------------
No. of Routes: 1
```

If the configuration is using **disallow-igp**, and neither LDP nor RSVP LSPs are available, the remote route received via BGP is removed from the GRT although the BGP peer session remains up. A field in the detailed show BGP route output indicates that the next hop is “Unresolved”:

```
*A:PE-6# configure router bgp
            next-hop-resolution
                shortcut-tunnel
                    family ipv4
                        resolution-filter
                            ldp
                            rsvp
                        exit
                        disallow-igp
                        resolution filter
                    exit
                exit
            exit

*A:PE-6# configure router ldp shutdown

*A:PE-6# show router bgp routes 10.10.10.0/24 detail

MPLS/GRE Shortcut for BGP NH Resolution within a VRF

Using RSVP/LDP or GRE shortcuts for resolving BGP next hops within a Virtual Private Routed Network (VPRN), also known as auto-bind-tunnel, allows a VPRN service to automatically resolve the BGP next hop for VPRN routes to an MPLS LSP or a GRE tunnel. Three possible mechanisms to provide transport tunnels for forwarding traffic between PE routers within an RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*, network exist:

- RSVP-TE protocol to create tunnel LSPs between PE routers.
- LDP protocol to create tunnel LSPs between PE routers.
- GRE tunnels between PE routers.

These transport tunneling mechanisms provide the flexibility to use dynamically created LSPs where the service tunnels are automatically bound (the “auto-bind-tunnel” feature), and the ability to provide certain VPN services with their own transport tunnels by explicitly binding SDPs if desired. All services using the auto-bind-tunnel feature use the same set of LSPs, which does not allow for alternate tunneling mechanisms (like GRE) or the ability to craft sets of LSPs with bandwidth reservations for specific customers, as is available with explicit SDPs for the service.

The auto-bind-tunnel configuration is as follows:

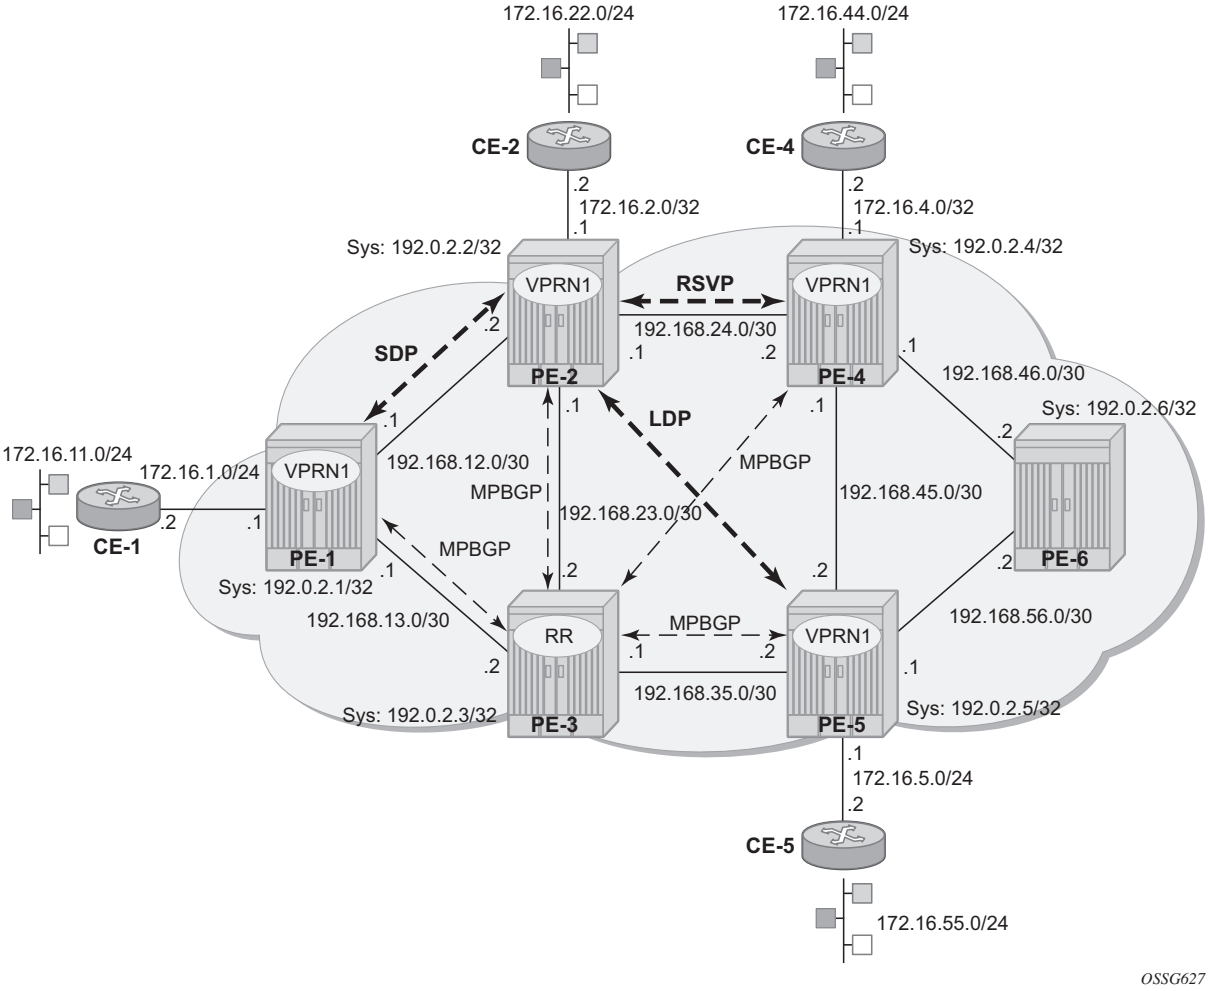
```
*A:PE-2# configure service vprn 1 auto-bind-tunnel resolution
  - resolution {disabled|any|filter}

 <disabled|any|filt*> : disabled|any|filter

*A:PE-2# configure service vprn 1 auto-bind-tunnel resolution-filter
  - resolution-filter

 [no] gre             - Enable/disable setting GRE type for auto-bind-tunnel
 [no] ldp             - Enable/disable setting LDP type for auto-bind-tunnel
 [no] rsvp            - Enable/disable setting RSVP-TE type for auto-bind-tunnel
 [no] sr-isis         - Enable/disable setting SR-ISIS type for auto-bind-tunnel
 [no] sr-ospf         - Enable/disable setting SR-OSPF type for auto-bind-tunnel
 [no] sr-te           - Enable/disable setting SR-TE type for auto-bind-tunnel
```

Parameter descriptions:



- **ldp** — Specifies LDP based LSPs should be used to resolve the BGP next hop for VPRN routes in an associated VPRN instance.
- **gre** — Specifies GRE based tunnels to be used to resolve the BGP next hop for VPRN routes in an associated VPRN instance. GRE is out of the scope regarding shortcuts, refer to SR OS documentation for further details.
- **rsvp** — Specifies RSVP-TE LSPs should be used to resolve the BGP next hop for VPRN routes in an associated VPRN instance.
- **ldp rsvp** — Chooses an existing RSVP-TE LSP if available, otherwise use LDP.
- **gre ldp rsvp** — When there are multiple tunnels to the BGP next hop address, the tunnel with the lowest tunnel-table preference value is selected (first RVSP, then LDP, then GRE).
- **sr-isis**— For segment routing with IS-IS (beyond the scope of this chapter)
- **sr-ospf** — For segment routing with OSPF (beyond the scope of this chapter)
- **sr-te** — For segment routing with TE (beyond the scope of this chapter)

In all cases, if an explicit spoke-sdp is specified in the VPRN, it is always preferred over automatically selected tunnels (even if the SDP is down, the route becomes inactive; there is no fallback to the automatic selection).

The network is configured according to the topology shown in Figure 6. Four PEs (PE-1, PE-2, PE-4 and PE-5) are connected forming a meshed IP-VPN (named VPRN 1), using a route reflector on PE-3 for MP-BGP peering. All PEs have LDP tunnels enabled so at a minimum all can establish LDP shortcut tunnels to the others. In order to have not only LDP but also RSVP-TE LSPs and static SDPs (using an RSVP LSP) in the network, a mix of tunneling methods is configured. For the sake of simplicity, the configuration of PE-2 only is given, providing the details about the

shortcuts created by auto-bind-tunnel. PE-2 has a static SDP (RSVP based) with PE-1, an RSVP LSP with PE-4, and an LDP LSP with PE-5. Every PE has a CE connected, so each PE has an interface connected to the CE as well as a static route to a CE LAN (although redistribution routing policies are needed, they are not shown for simplicity).

Figure 143 **Shortcuts Within a VRF Topology Network**

On PE-2, the following provides the configuration of VPRN1:

```
*A:PE-2# configure service
        sdp 1 mpls create
            far-end 192.0.2.1
            lsp "LSP-PE-2-PE-1"
            no shutdown
        exit
        vprn 1 customer 1 create
            vrf-import "VPN1-import"
```

```
            vrf-export "VPN1-export"
            route-distinguisher 65536:1
            auto-bind-tunnel
                resolution-filter
                    gre
                    ldp
                    rsvp
                exit
                resolution filter
            exit
            interface "to-CE-2" create
                address 172.16.2.1/24
                sap 1/1/4:1 create
                exit
            exit
            static-route-entry 172.16.22.0/24
                next-hop 172.16.2.2
                    no shutdown
                exit
            exit
            spoke-sdp 1 create
            exit
            no shutdown
        exit
```

As previously mentioned, regarding IP-VPN meshed connectivity, the configuration shows that there is a static SDP 1 (pointing to PE-1), and the rest of the configuration is just **auto-bind-tunnel.** On PE-2, the connectivity towards the other PEs in the network can be verified by checking VPRN 1:

```
*A:PE-2# show router 1 route-table

       192.0.2.1 (tunneled)                                         0
172.16.22.0/24                                  Remote  Static    00h20m27s  5
       172.16.2.2                                                   1
172.16.44.0/24                                  Remote  BGP VPN   00h00m27s  170
       192.0.2.4 (tunneled:RSVP:3)                                  0
172.16.55.0/24                                  Remote  BGP VPN   00h12m26s  170
       192.0.2.5 (tunneled)                                         0
-------------------------------------------------------------------------------
No. of Routes: 8
```

As can be seen, there are eight routes since every PE has two routes (one direct PE-CE interface and one static route), so six routes are received from other PEs via MP-BGP. The VPRN 1 routing table can be understood by looking at the tunnel table (active LSPs for remote system-ids):

```
*A:PE-2# show router tunnel-table

===============================================================================

       E = inactive best-external BGP route

===============================================================================

*A:PE-2#
```

The tunnel-table shows one entry per LSP per remote PE. The following tunnel selection rules apply:

- SDP has the lowest (best) preference, followed by RSVP and then by LDP.
- If the preference is the same, the lowest metric is selected (ECMP is possible with LDP).

PE-2 has three possibilities to reach PE-1 (192.0.2.1): an SDP Tunnel ID 1 with preference 5, an RSVP Tunnel ID 1 with preference 7, and an LDP LSP with preference 9. Because SDP Tunnel ID 1 has the lowest preference, it is the chosen option. PE-2 has three possibilities to reach PE-4 (192.0.2.4): an RSVP Tunnel ID 3 with preference 7 and metric 10, an RSVP Tunnel ID 4 with preference 7 and metric 16777215, and an LDP LSP with preference 9; hence RSVP Tunnel ID 3 is selected. PE-2 only has one option to reach PE-5 and PE-6 (192.0.2.5 and 192.0.2.6) using an LDP LSP.

As the VPRN 1 output does not show the details of the tunneling, displaying the FIB on router VPRN 1 provides more detailed information:

```
*A:PE-2# show router 1 fib 1
===============================================================================
FIB Display
```

```

    192.0.2.5 (VPRN Label:262136 Transport:LDP)
-------------------------------------------------------------------------------
Total Entries : 8
-------------------------------------------------------------------------------
```

The FIB shows the chosen transport tunnel, specifying SDP ID, RSVP Tunnel ID, and LDP, as well as service label information linked to the routes.

As static SDP tunnels are preferred over dynamic tunnels (RSVP or LDP auto-bind-tunnel), when the static SDP 1 is shut down with or the LSP goes down (there is no fallback to dynamic tunneling), the associated routes are removed:

```
*A:PE-2# configure service sdp 1 shutdown

*A:PE-2# show router 1 fib 1

```

To avoid this fallback issue, the configuration is modified and the manual spoke-sdps are removed from the configuration of PE-1 and PE-2, the rest of the configuration remains the same. Now the connectivity between PE-1 and PE-2 is using an RSVP LSP, as shown in the PE-1 following output (RSVP LSP which was used by SDP 1 has disappeared):

```
*A:PE-1# configure service vprn 1 no spoke-sdp 1
*A:PE-2# configure service vprn 1 no spoke-sdp 1

*A:PE-1# show router 1 route-table

Conclusion

IGP shortcuts provide a variety of shortcuts in IP, MPLS and IP-VPN scenarios to customers who want to use new options for building routing topologies. Because IGP shortcuts are enabled on a per router basis, SPF computations are independent and irrelevant to other routers, so there is no need to enable shortcuts globally. This network example shows the configuration of IGP shortcuts together with the associated show outputs which can be used for verification and troubleshooting.

Inter-Area TE Point-to-Point LSPs

This chapter describes inter-area TE point-to-point LSP configurations.

Topics in this chapter include:

- Applicability
- Summary
- Overview
- Configuration
- Conclusion

Applicability

Inter-Area Traffic Engineering (TE) point-to-point (P2P) label switched paths (LSPs) are supported on SR OS. This feature is supported on all IOM/IMM types. Initially, this chapter was written for release 11.0.R4, but the CLI in this edition corresponds to release 14.0.R1.

Summary

Multiprotocol label switching with traffic engineering (MPLS TE) is implemented on a wide scale in current ISP networks to steer traffic across their backbones to facilitate efficient use of available bandwidth between the routers and to guarantee fast convergence in case a link or node fails.

Regular TE LSPs in MPLS networks are confined to only a single interior gateway protocol (IGP) area/level. This is because the head-end has information in the TE database of only the local area (OSPF) or level (IS-IS). As the name implies, inter-area TE LSPs can cross the area/level borders of the IGP.

Inter-Area TE LSP Based On Explicit Route Expansion

Inter-area TE LSP using explicit route object (ERO) expansion enables the head-end to calculate the ERO path within its own area/level and keep the remaining ABRs of other areas/levels as loose hops in the ERO path. On receiving a PATH message with a loose hop ERO and based on local configuration, each area border router (ABR) does a partial constrained shortest path first (CSPF) calculation to the next ABR or a full CSPF calculation to reach the final destination.

Automatic selection of ABRs is supported so that the head-end node can work with an empty primary path. When the **to** field of an LSP definition is in an area/level different from the head-end node, CSPF will automatically compute the segment to the exit ABR router which advertised the prefix and which currently is the best path for resolving the prefix in route table manager (RTM).

ABR Protection

Link and node protection within the respective areas are supported through the TE capabilities of the IGP and resource reservation protocol (RSVP) in each area. To support ABR node protection, a bypass is required from the point of local repair (PLR; node prior to ABR) to the merge point (MP; next-hop node to ABR).

Two methods are possible: dynamic ABR protection and static ABR protection. Static ABR protection uses manual bypass tunnels (MBTs), statically configured by the operator between the PLR and the MP. For dynamic ABR protection, node ID propagation and signaling of an exclude route object (XRO) in RSVP PATH messages must both be supported.

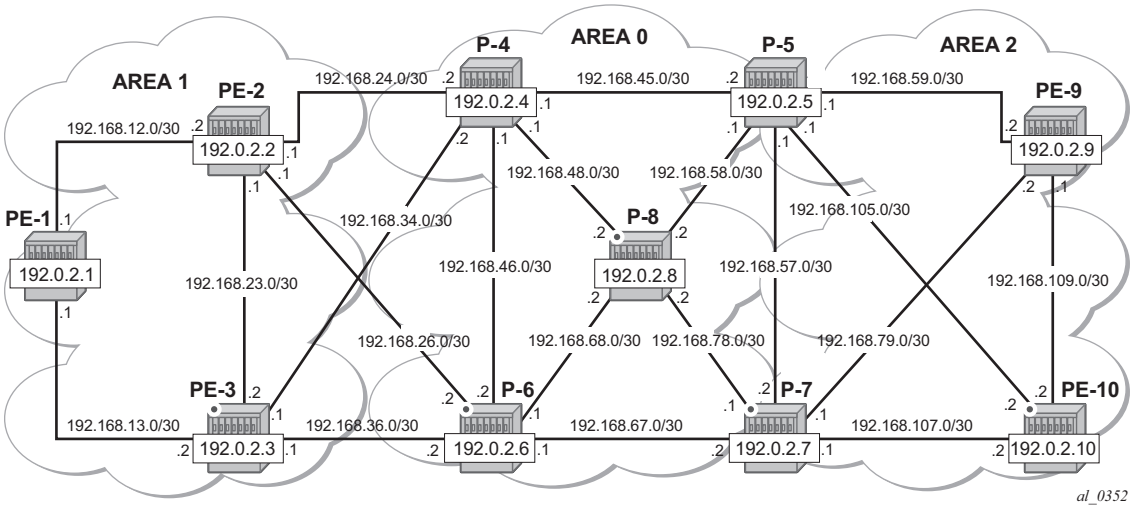
Since the record route object (RRO) Node ID sub-object description in RFC 4561 (*Definition of a Record Route Object (RRO) Node-Id Sub-Object*) is not clear about the format of the included node-address (S), interface-address (I) and label (L), the system supports multiple formats: IL, SL, ISL, SIL, SLI, ILSL and SLIL. The system uses the SLIL (node-address, label, interface-address, label) format to include the node-ID itself.

The exclude route object (XRO) inclusion (RFC 4874, *Exclude Routes - Extension to Resource ReserVation Protocol-Traffic Engineering*) in bypass RSVP PATH messages is required to exclude the protected ABR from the bypass path. The XRO object contains the ABRs system IP address.

Overview

The example setup in this chapter contains ten nodes in three areas. Figure 144 shows the physical topology of the setup.

Figure 144 **Inter-Area TE LSP Setup**



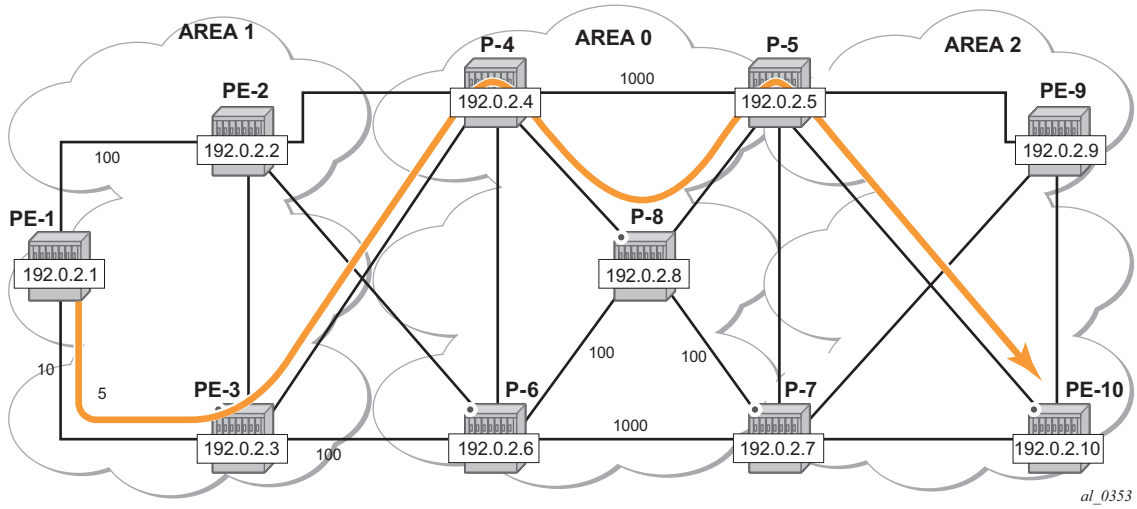


Figure 145 shows the LSP path intended to be set up through the network. An empty MPLS path is used. At the head-end node PE-1, the destination address PE-10 is learned via ABR node P-4 and ABR node P-5.

Figure 145 **Inter-Area TE LSP Path**

Configuration

The assumption is made that following base configuration has been implemented on the nodes:

- Cards, MDAs and ports configured
- Interfaces configured
- IGP areas configured and converged
- Traffic Engineering configured for the IGP
- MPLS and RSVP configured on all links in the network

OSPF or IS-IS can be configured as the IGP; OSPF is used in this chapter.

The following output shows the opaque database of PE-1:

```
A:PE-1# show router ospf opaque-database

-------------------------------------------------------------------------------
No. of Opaque LSAs: 19
===============================================================================
A:PE-1#
```

The information is only about routers that are part of area 0.0.0.1. PE-1 cannot calculate an end-to-end CSPF path to node PE-10 since this would require TE topology information from area 0.0.0.0 and area 0.0.0.2.

Each node announces its router ID and each attached link that is part of that area, hence the 19 opaque LSAs in area 0.0.0.1. The system interfaces of P-4 and P-6 are configured in backbone area 0.0.0.0, not in area 0.0.0.1.

In Figure 145, the LSP passes through node PE-3 and node P-8. In order to prefer a dynamic path from PE-1 to P-4 via PE-3 rather than via PE-2, it is necessary to configure on PE-1 a lower IGP metric on the interface to PE-3 (the default metric is derived from the interface speed; in this case the metric is 10 by default).

```
*A:PE-1# configure router ospf area 1 interface "int-PE-1-PE-3" metric 5
```

Similarly, in the core, the IGP metric between P-4 and P-5, and between P-6 and P-7 is increased to force the LSP to pass through the core P-8 node.

```
*A:P-4# configure router ospf area 0 interface "int-P-4-P-5" metric 1000

*A:P-6# configure router ospf area 0 interface "int-P-6-P-7" metric 1000
```

Other metrics have also been manipulated as indicated on Figure 145.

MPLS Path Configuration

Since automatic ABR selection is performed, an empty MPLS path is sufficient on the head-end node PE-1. Using an empty MPLS path will ease the provisioning process and brings consistency since this empty MPLS path can be used for both intra and inter-area/level type LSPs.

```
*A:PE-1# configure router mpls path "dyn" no shutdown
```

MPLS LSP Configuration

Configure an LSP on PE-1 to PE-10 and include the previously created MPLS path as primary path. Enable CSPF and fast reroute (FRR) facility on the LSP.

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-10"
                to 192.0.2.10
                cspf
                fast-reroute facility
                exit
                primary "dyn"
                exit
                no shutdown
            exit
```

At this stage the LSP is in an operational Down state with a failure code of badNode at failure node 192.168.34.2 (ABR P-4).

In order to get around the intra-area CSPF confinement, enable the ERO-expansion feature on all possible ABR nodes.

```
*A:P-4# configure router mpls cspf-on-loose-hop
*A:P-6# configure router mpls cspf-on-loose-hop

*A:P-7# configure router mpls cspf-on-loose-hop
*A:P-5# configure router mpls cspf-on-loose-hop
```

Cspf-on-loose-hop is only required if FRR or TE parameters are configured on the LSP. If any of these parameters is configured on the LSP while one of the ABRs along the path is not configured with cspf-on-loose-hop, the LSP will stay operationally down with failure code: badNode and an indication of the interface address of the failure node.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-10" path detail

---snip---

From        : 192.0.2.1                          To          : 192.0.2.10
Adm State   : Up                                 Oper State  : Down

---snip---

Failure Code     : badNode
Failure Node     : 192.168.34.2

---snip---
```

The LSP path can also contain other strict and/or loose hops. However, cspf-on-loose-hop must be configured inthe MPLS context whenever loose hops are configured in the MPLS path. This command enables ERO expansion and is only required for inter-area LSPs on all possible ABR nodes and all nodes not belonging to the area where the iLER is located, which have a loose hop reference in the MPLS path. However, for simplicity and consistency, it can be configured on all nodes without having a negative effect.

The following trace shows the ERO calculation on the head-end to the first ABR.

```
*A:PE-1# debug router rsvp packet path detail

ABR Node Protection

At this stage, the LSP is configured with facility FRR protection; link and node protection will be offered within each area, as was seen in the preceding output where there is no node protection for ABR P-4 because there is no bypass tunnel originating in PE-3 to offer node protection for the next hop. Likewise, there is no bypass tunnel originating in P-8 to offer node protection for ABR P-5. The bypass tunnels originating in PE-3 and P-8 only offer link protection. Dynamic ABR node protection requires the setup of a bypass tunnel from the PLR (node just upstream of the ABR) to the MP (node just downstream of the ABR). Two things are required for this:

- Firstly, the PLR node (part of area x) needs to know the system IP address of the MP node (part of area y) to set up the bypass. For this reason, the node-ID of the MP is included in the RESV message so that the PLR can link the manual bypass tunnel to the primary path to protect the ABR.
- Secondly, the other ABR node receiving the RSVP bypass PATH message for the protected ABR needs to do an ERO expansion toward the MP node. For this reason, the XRO object is included in the RSVP bypass PATH message, containing the node-ID of the protected ABR. As an example, a bypass PATH message is shown below on node PE-3.

The XRO object includes the system IP address of the protected ABR node P-4 and the ERO object has MP node P-8 as loose destination:

```
*A:PE-3# debug router rsvp packet path detail

1 2016/03/15 10:26:58.62 UTC MINOR: DEBUG #2001 Base RSVP
"RSVP: PATH Msg
Send PATH From:192.0.2.3, To:192.0.2.8
          TTL:17, Checksum:0xfddd, Flags:0x0

             Controlled BreakBit:0
"
```

Node-ID Inclusion in the RESV Message

P-8 will be the MP for the bypass of ABR P-4 and PE-10 will be the MP for the bypass of ABR P-5. So P-8 and PE-10 need to include their node-ID in the RESV message, inside the record route object (RRO).

```
*A:P-8# configure router rsvp node-id-in-rro include
*A:PE-10# configure router rsvp node-id-in-rro include
```

The default is **node-id-in-rro exclude**. As an example, the RESV message received on PLR node PE-3 is shown below. The RRO contains the MP node P-8 information in SLIL format:

```
*A:PE-3# debug router rsvp packet resv detail

7 2016/03/15 10:27:49.62 UTC MINOR: DEBUG #2001 Base RSVP
"RSVP: RESV Msg

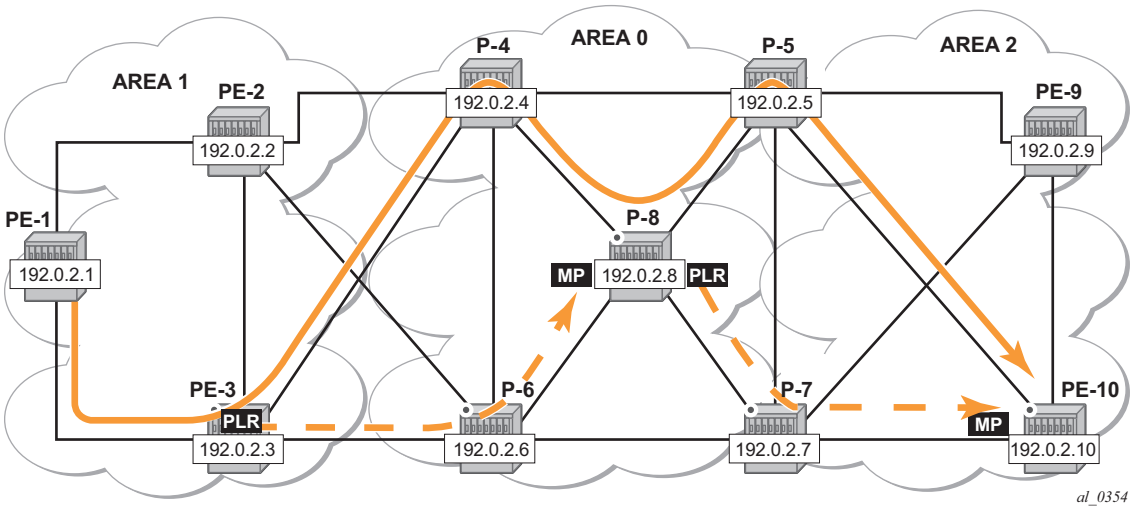
"
```

Bypass Configuration For ABR Protection

Since dynamic ABR protection is supported and used in this example, no explicit MBTs are configured to protect the ABRs. Each PLR first checks if an MBT tunnel exists between the PLR and the MP matching the constraints and protecting the ABR. If no MBT is available, the PLR will signal a bypass tunnel in a dynamic way toward the MP node.

Figure 146 shows the two dynamic ABR node protections that are signaled for this LSP.

Figure 146 **ABR Protection**



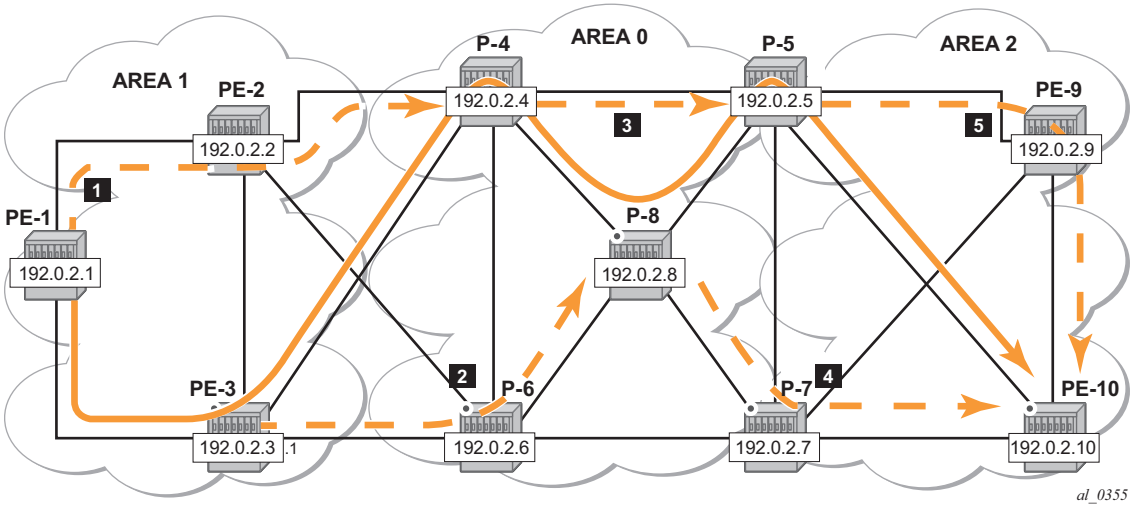


Figure 147 shows the complete picture of all the FRR protections and indicates each node/link protection in the setup.

Figure 147 **Protection of All Nodes/Links Along the LSP Path**

This can be seen in the detailed show output of the LSP path:

```

 -> 192.168.105.2                               Record Label        : 262143
---snip---
```

- The first bypass originates in PE-1 and protects node PE-3.
- The second bypass originates in PE-3 and protects node P-4.
- The third bypass originates in P-4 and protects node P-8.
- The fourth bypass originates in P-8 and protects node P-5. There are two entries for P-8: hop 192.0.2.8 and hop 192.168.48.2.
- The fifth bypass originates in P-5 and protects the link between P-5 and PE-10. There are two entries for P-5: hop 192.0.2.5 and hop 192.168.58.1.

There are two entries for P-8, P-5 and PE-10 in the ‘Actual Hops’ section in the previous output: one for the interface IP address and one for the system IP address. This is a consequence of configuring **node-id-in-rro include** on P-8, P-5 and PE-10.

The **node-id-in-rro include** command is not mandatory for this example on ABR node P-5, but to be able to cover cases where a new LSP is established in the network and P-5 acts as an MP node while the corresponding PLR node for that new LSP is in another area. This RSVP command can be executed on all possible MP nodes in the network.

The details of the bypass tunnel can be shown with the following command:

```
*A:PE-3# show router mpls bypass-tunnel protected-lsp detail
```

```

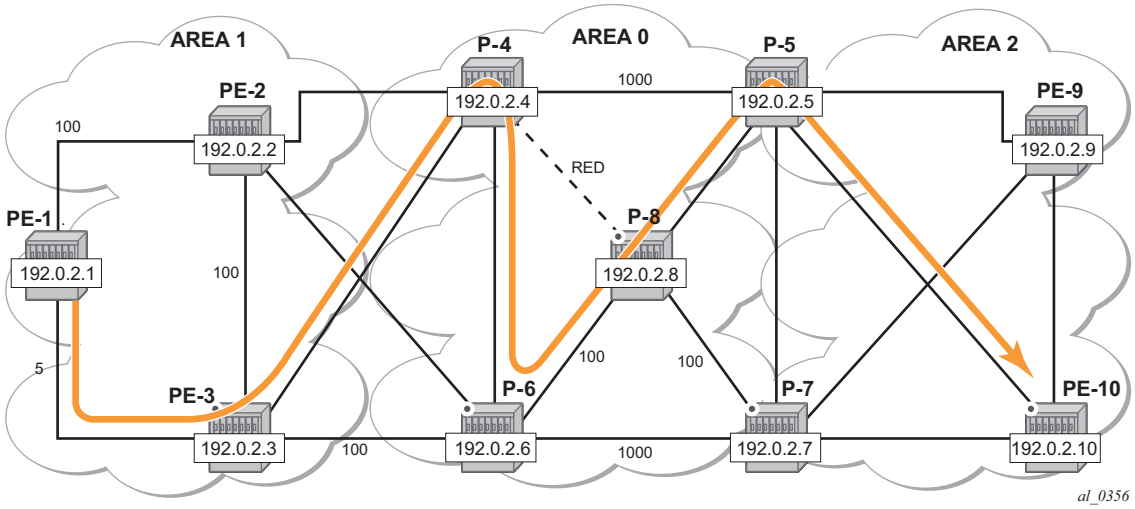
*A:PE-3#
```

The LSP could be protected with one or more additional secondary paths, pre-signaled or not, but this is outside the scope of this example.

When a link or node failure occurs along the LSP path, FRR protection kicks in and end-to-end path re-optimization is executed: a PATHERR message is forwarded to the head-end. Upon receiving the PATHERR message the head-end calculates a new path.



Admin Groups

The use of administrative groups is described in chapter RSVP Point-to-Point LSPs.

To support admin-groups for inter-area LSPs, the ingress node PE-1 must propagate the admin-groups within the session attribute object (SA) of the PATH message so that the ABRs along the path receive the admin group restrictions they have to take into account when further expanding the ERO in the PATH message.

In Figure 147 the LSP path avoids the link between P-4 and P-8. This is implemented by assigning admin group “red” to the link between P-4 and P-8 and then configuring the LSP to exclude the admin group “red”.

Figure 148 **Admin Group Example**

Admin Group Configuration

On P-4, configure admin group “red” and assign a group value. In this example group value 11 is used, but this can be any value between 0 and 31. Assign admin group “red” to the link to P-8.

This admin-group configuration is required on P-4 and on iLER PE-1. However, it is good practice to configure the admin group on all the nodes.

```
*A:Px# configure router if-attribute admin-group red value 11

*A:P-4# configure router
        mpls
            interface "int-P-4-P-8"
                admin-group "red"
            exit
```

On PE-1, change the LSP configuration as follows:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-10"
                exclude "red"
                propagate-admin-group
            exit
```

It is possible to have the same admin group constraint applied to the FRR bypass tunnels in the PLRs, but that is not the case here. The bypass tunnels ignore any admin group constraint. The **propagate-admin-group** command is required to include the admin group properties in the SA object of the PATH message. The admin-group value is mapped to a 32-bitmap. In this example, value 11 means that the 12th bit is set, which means in binary 100000000000 or hex 0x800.

```

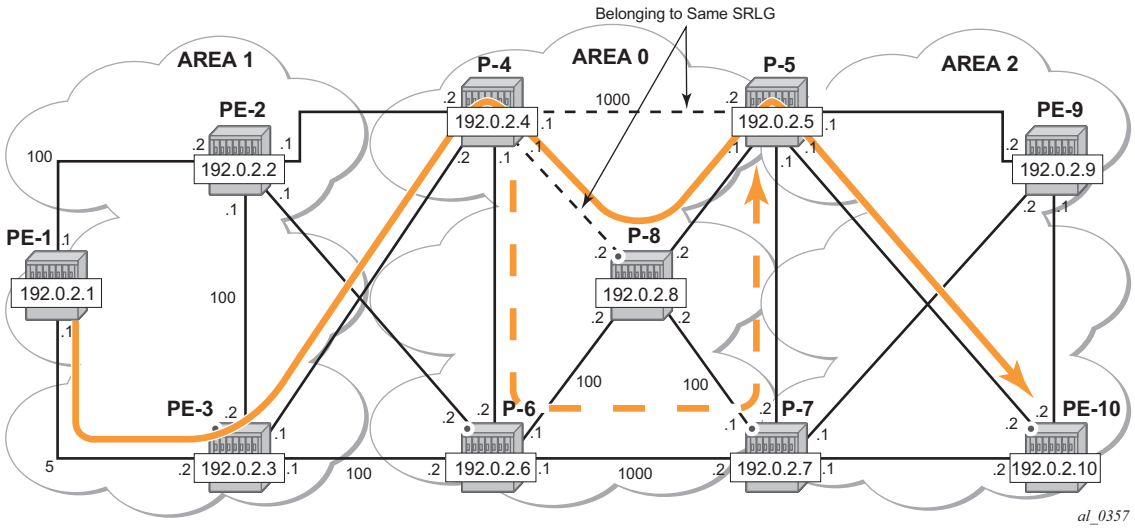
Shared Risk Link Groups (SRLG)

Shared risk link groups are explained in chapter Shared Risk Link Groups for RSVP-Based LSP.

SRLGs are also supported in the context of inter-area TE LSPs. SRLGs refer to situations where links in a network share a common fiber (or a common physical attribute). If one link fails, other links in the group may fail as well. Links in the group have a shared risk.



The MPLS TE SRLG feature enhances backup tunnel path selection so that a backup tunnel avoids using links that are in the same SRLG.

Consider the setup in Figure 149, where an inter-area LSP is set up from PE-1 to PE-10 and the path goes through P-8 because of a lower IGP metric. To protect against a node failure of P-8, P-4 (PLR) would normally set up an FRR backup directly to P-5 (MP), because of the lower IGP metric (P-4 to P-5:1000) compared to the IGP traffic via P-6 (P-4 to P-6 to P-7 to P-5:1020).

However, imagine that in this setup the link between P-4 and P-5 link and the link between P-4 and P-8 are part of the same transmission bundle. In this case a cut of that fiber bundle will bring down both the primary and the backup path.

This can be avoided by configuring these two links in the same SRLG group and enabling srlg-frr strict on P-4. In that case the backup will be set up via P-6 as indicated by the dotted line in Figure 149

Figure 149 **Share Risk Link Groups**

SRLG Configuration

On P-4 configure an SRLG group and add the link to P-5 and the link to P-8 to this SRLG group and enable srlg-frr strict.

The srlg-group configuration is required on all nodes that use srlg groups and on the ABR used by the inter-area TE LSP. In this example, it is configured on all nodes.

Note: Enabling or disabling SRLG for FRR is system-wide and requires the MPLS routing instance to be manually set to shutdown and then to no shutdown to activate the change. This may cause service outage. Nokia recommends that the operator incorporates the SRLG into the initial network design and implementation to minimize the traffic loss. In this case, it is sufficient to disable and re-enable RSVP on PE-1.

```
*A:Px# configure router if-attribute srlg-group bundle-red value 1

*A:P-4# configure router
        mpls
            srlg-frr strict
            interface "int-P-4-P-5"
                srlg-group "bundle-red"
            exit
            interface "int-P-4-P-8"
                srlg-group "bundle-red"
            exit

*A:PE-1# configure router rsvp shutdown
*A:PE-1# configure router rsvp no shutdown
```

LSP Configuration

Remove the admin group restriction from the LSP.

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-10"
                no exclude "red"
                no propagate-admin-group
            exit
```

Now check the LSP path on PE-1 and verify that FRR protection is in place.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-10"  path detail

Conclusion

Inter-area TE P2P LSPs can be set up based on ERO expansion. With this feature, the head-end does a partial CSPF calculation to its local ABR. On receiving a PATH message with a loose hop ERO, this ABR does a partial or full CSPF calculation to the next ABR to reach the final destination.

FRR protection within the area is available. FRR node protection of the ABR is possible through an MBT on the PLR (node just upstream of the ABR) to the MP (node just downstream of the ABR) or through a dynamically signaled bypass tunnel on the PLR. Dynamic ABR node protection requires that the node ID of the MP node is propagated in the RESV message and that an XRO object is included in the bypass PATH message which makes it possible for the ABR to calculate a path to an MP node.

TE features like BW, path prioritization, path pre-emption, graceful shutdown are supported, as well as propagation of the session attribute with affinity along the LSP path (admin groups) and SRLG.

LDP FEC to BGP Label Route Stitching

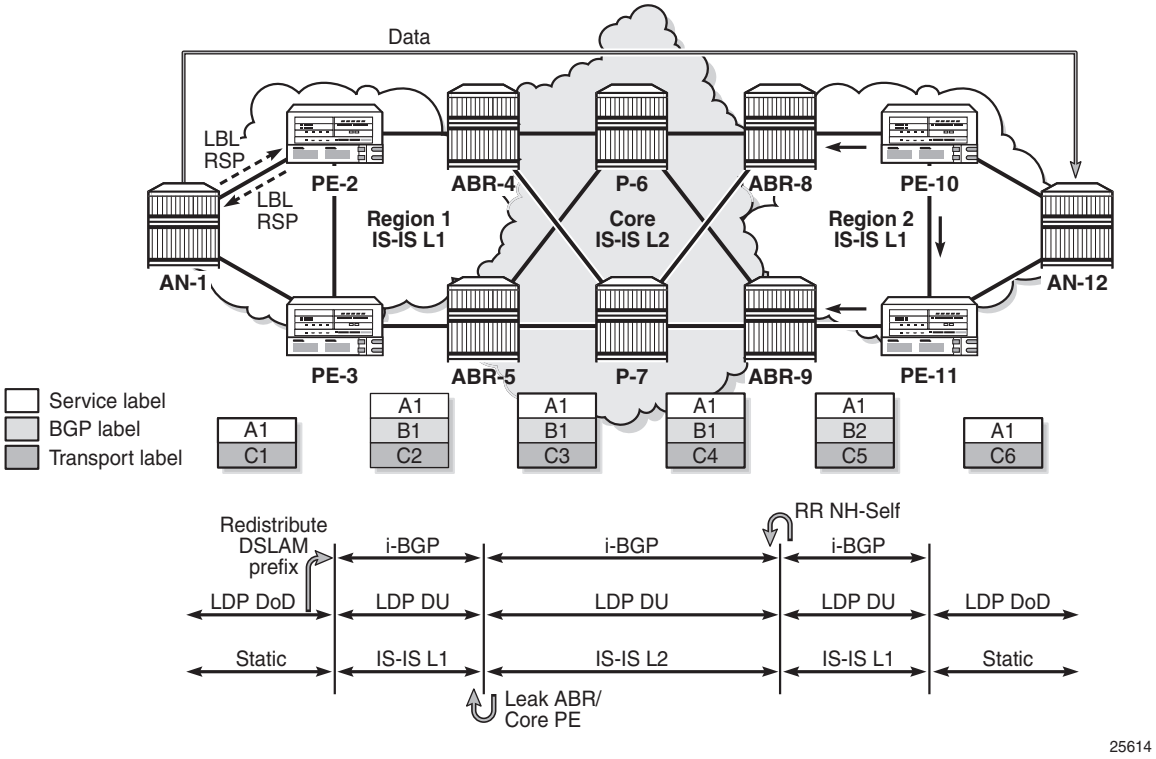
This chapter provides information about LDP FEC to BGP label route stitching.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and was initially written for release 13.0.R7. The CLI in the current edition corresponds to release 14.0.R1. Label distribution protocol (LDP) forwarding equivalence class (FEC) to border gateway protocol (BGP) label route stitching was first implemented in SR OS release 8.0.



Overview

Stitching of an LDP FEC to a BGP labeled route allows LDP-capable PE devices, such as digital subscriber line access multiplexers (DSLAMs), to offer services to LDP-capable PE devices in other areas or domains without the need to support BGP labeled routes. This feature is used in a large network to provide services across multiple areas or autonomous systems.

When BGP is used to distribute a particular route, it can at the same time be used to distribute a multiprotocol label switching (MPLS) label that is mapped to that route. The label mapping information for a particular route is appended to the same BGP update message that is used to distribute the route. This is described in RFC 3701, *Carrying Label Information in BGPv4*.

Figure 150 shows a network with a core area and regional areas. The components of the network are defined in the paragraphs that follow. For simplification, the control plane is displayed from right to left and the data plane from left to right.

Figure 150 **LDP FEC to BGP Label Route Stitching**

The access nodes (ANs) are DSLAMs that support LDP. In seamless MPLS networks, LDP downstream-on-demand (DoD) label advertisement can be used between the ANs and their next-hop PEs. Usually, MPLS routers implement LDP downstream unsolicited (DU) label distribution, advertising MPLS labels for all routes in their routing information base (RIB). The ANs do not need to have LDP bindings for all prefixes in the network. The ANs will request the LDP labels they need. LDP DoD improves scalability in large networks.

BGP route reflectors (RRs) can be used to improve scalability. The RR can be any node; it does not need to be an area border router (ABR) as in Figure 150. If the RR is not in the forwarding path, it does not need to be capable of forwarding MPLS packets.

There are different areas for IS-IS: routers in the core network have level 2 (L2) capability, while the routers in the regional areas have level 1 (L1) capability and the ABRs have both. In each ABR, an IS-IS export policy is defined to leak the routes from the core to the regional networks.

Passing L1 routes (regional) into L2 (core) is inherent to IS-IS and cannot be controlled through policy. Passing L2 routes to L1 can be controlled through policy.

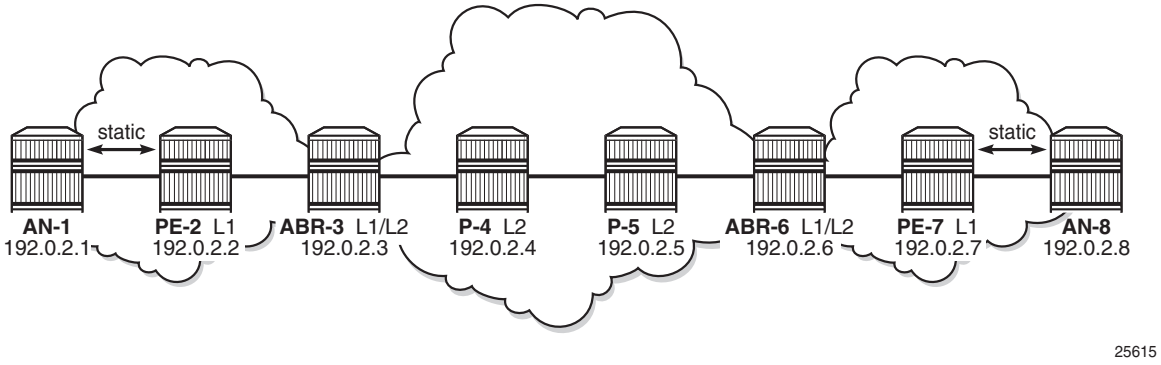
Only nodes within a regional area, and the ABR nodes in the same area, exchange LDP FECs. PE routers in a regional area learn the reachability of PE routers in other regional areas by way of RFC 3107 BGP labeled routes redistributed by the remote nodes.

The label stack contains three labels for packets sent in an Epipe service between the access nodes:

- The DSLAMs push a service label to the packets sent in the Epipe service. The service label remains unchanged end-to-end between the DSLAMs. The service label is popped by the remote DSLAM and is the inner label of the label stack.
- The BGP label is the middle label of the label stack and should be regarded as a transport label. The transport label stack has increased to two labels: BGP and LDP transport label. BGP labeled routes are not supported on the DSLAMs. The BGP label is pushed by the PE nearest to the local DSLAM and is swapped at the BGP next hop, which can be a BGP peer configured with next-hop-self or the PE that is the remote endpoint of the BGP tunnel. The BGP label is popped by the PE at the end of the BGP tunnel.
- The DSLAMs push an LDP transport label to the packets sent to the remote DSLAM. At the PE nearest to the local DSLAM, the LDP transport label is stitched to the BGP label. At the same time, that same PE pushes the LDP transport label to reach the BGP next hop. The LDP transport label is swapped in every label switching router (LSR) and popped by the PE nearest to the remote DSLAM. That PE also pops the BGP label, which is stitched to the LDP transport label that is pushed to the packets sent to the remote DSLAM. This LDP label is the top label of the label stack.

When PE-2 is an ingress label edge router (iLER) sending a service packet to the remote PE, PE-2 inserts the BGP route label to reach the remote PE and an LDP label to reach the next-hop router. In Figure 150, this is the remote ABR because it has set next-hop-self (NH-Self).

The access node AN-1, which is a DSLAM, can behave as a PE router for Epipe services. It will need to establish a pseudowire (PW) to a PE in a different regional area via LSR PE-2. In this case, PE-2 performs the following actions:



- Translates the LDP FEC it learned from AN-1 into a BGP labeled route and redistributes it using iBGP within its area. This is in addition to redistributing the FEC to its LDP neighbors in the same area.
- Translates the BGP labeled routes it learns through iBGP into an LDP FEC and redistributes it to its LDP neighbors in the same area. AN-1 requests the LDP FEC of the remote DSLAM (AN-12) using LDP DoD.

- When a data packet is received from AN-1 with destination AN-12, PE-2 swaps the LDP label into a BGP label and pushes the LDP label to reach the BGP next hop. When a data packet with destination AN-1 is received on PE-2 from the local ABR (ABR-4), the top transport label (LDP) is removed and the BGP label is swapped for the LDP label corresponding to AN-1.

Configuration

Figure 151 shows the example topology that is used in this chapter. An Epipe will be established between the access nodes AN-1 and AN-8. PE-2 and PE-7 will stitch the LDP FECs to BGP label routes. In the regional areas, IS-IS L1 capability is used while in the core area IS-IS L2 is used. The ABR nodes support both IS-IS L1 and L2 and export routes from L2 to L1. Static routes are configured between the access nodes and the next-hop PEs.

Figure 151 **Example Topology**

Initial Configuration

Note: In the example topology, all nodes are 7750 SRs, while the ANs should be access devices, such as DSLAMs. The limitation of this approach is that the ANs (SRs) in this setup can only request a label for the directly connected PE and not for their remote peer AN; however, DSLAMs do not have this limitation. Consequently, the Epipe service in this configuration will be operationally down because the transport tunnel is down.

All nodes have the following initial configuration:

- Cards, media dependent adapters (MDAs), ports

- Router interfaces

Note: The IP addresses for the link between node A and node B are in subnet 192.168.AB.0/0. The node with the lowest ID has IP address 192.168.AB.1/30 and the node with the highest ID has IP address 192.168.AB.2/30.

```
*A:PE-2# configure router
        interface "int-PE-2-ABR-3"
            address 192.168.23.1/30
            port 1/1/1
        exit
        interface "int-PE-2-AN-1"
            address 192.168.12.2/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.2/32
        exit
```

- Static routes are configured between AN-1 and PE-2 and between PE-7 and AN-8:

```
*A:AN-1# configure router
        static-route-entry 0.0.0.0/0
            next-hop 192.168.12.2
                no shutdown
            exit
        exit

*A:PE-2# configure router
 static-route-entry 192.0.2.1/32
            next-hop 192.168.12.1
                no shutdown
            exit
        exit
```

- IS-IS (alternatively, OSPF could have been used)
  - PE-2 and PE-7 have L1 capability.

```
*A:PE-2# configure router
        isis
            level-capability level-1
            area-id 49.0001
            interface "system"
            exit
            interface "int-PE-2-ABR-3"
                interface-type point-to-point
            exit
        exit
```

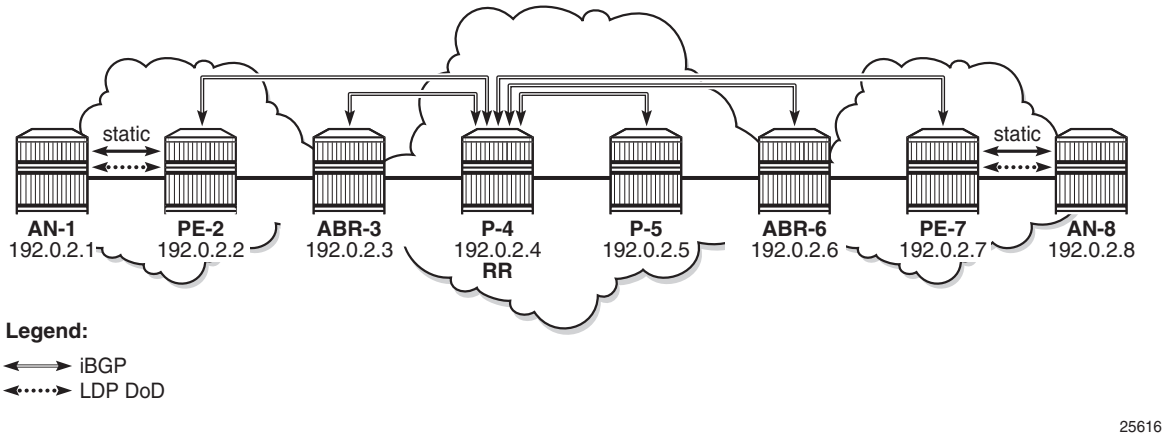
  - P-4 and P-5 have L2 capability.

– ABR-3 and ABR-6 have L1 capability on the interfaces toward the PE routers in the regional areas and L2 capability on the interfaces toward the P routers in the core area. A policy is applied to export the system IP addresses from L2 to L1:

```
*A:ABR-3# configure router
        policy-options
            begin
            prefix-list "systemIP"
                prefix 192.0.2.0/24 longer
            exit
            policy-statement "export-L2-to-L1"
                entry 10
                    from
                        protocol isis
                        prefix-list "systemIP"
                        level 2
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
        isis
            area-id 49.0001
            export "export-L2-to-L1"
            interface "system"
            exit
            interface "int-ABR-3-PE-2"
                level-capability level-1
                interface-type point-to-point
            exit
            interface "int-ABR-3-P-4"
                level-capability level-2
                interface-type point-to-point
            exit
        exit
```

• LDP

– Link LDP is enabled on all router interfaces on all nodes, including the ANs.



– On PE-2 and PE-7, DoD is enabled in the session parameters for the peering sessions with the ANs:

```
*A:PE-2# configure router
        ldp
            session-parameters
                peer 192.0.2.1
                    dod-label-distribution
                exit
            exit
            interface-parameters
                interface "int-PE-2-AN-1
                exit
                interface "int-PE-2-ABR-3"
                exit
            exit
```

Configure BGP

BGP is configured on all nodes except the ANs. Figure 152 shows that P-4 is the RR.

Figure 152 **BGP Enabled with P-4 as RR**

The initial BGP configuration on PE-2 is the following:

```
*A:PE-2# configure router
        autonomous-system 64496
        bgp
            group "internal"
                peer-as 64496
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
        exit
```

The configuration is identical for ABR-3, P-5, ABR-6, and PE-7. The initial BGP configuration on the RR P-4 is:

```
*A:P-4# configure router
        autonomous-system 64496
        bgp
            cluster 1.1.1.1
            group "internal"
                peer-as 64496
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.3
                exit
                neighbor 192.0.2.5
                exit
                neighbor 192.0.2.6
                exit
                neighbor 192.0.2.7
```

```
            exit
        exit
        no shutdown
    exit
```

The BGP sessions can be shown with the following command:

```
*A:P-4# show router bgp summary

*A:P-4#
```

Export Policies for BGP and LDP

LDP FEC to BGP label route stitching is established by configuring separate tunnel table route export policies in both protocols. At the local next-hop PE, the LDP FEC of the local AN must be translated into a BGP label and at the remote PE, the BGP label must be translated into an LDP FEC.

An export policy for the export from LDP to BGP must be defined on the PE nodes.

```
*A:PE-2# configure router
```

```
        policy-options
            begin
            prefix-list "local-AN"
                prefix 192.0.2.1/32 exact
            exit
            prefix-list "remote-AN"
                prefix 192.0.2.8/32 exact
            exit
            policy-statement "export-BGP"
                entry 10
                    from
                        protocol ldp
                        prefix-list "local-AN"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

On PE-7, the policy statement is identical, but the prefix lists are different.

This export policy must be applied in the BGP context: either in the general settings or per group or per neighbor.

```
*A:PE-2# configure router
        bgp
            group "internal"
                export "export-BGP"
            exit
        exit
```

In a similar way, BGP labels must be exported to LDP on the PE routers. The export policy is configured as follows, with the prefix list already defined earlier:

```
*A:PE-2# configure router
        policy-options
            begin
            prefix-list "remote-AN"
                prefix 192.0.2.8/32 exact
            exit
            policy-statement "export-LDP"
                entry 10
                    from
                        protocol bgp
                        prefix-list "remote-AN"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

This export policy is applied in the LDP context, as follows:

```
*A:PE-2# configure router
        ldp
            export-tunnel-table "export-LDP"
        exit
```

Advertise Labels in BGP Updates

BGP should evaluate the activated /32 LDP prefixes in the export policy. This needs to be configured on the endpoints of the BGP tunnel and on the RR:

```
*A:PE-2# configure router bgp group "internal" neighbor 192.0.2.4 advertise-
label ipv4 include-ldp-prefix
*A:PE-7# configure router bgp group "internal" neighbor 192.0.2.4 advertise-
label ipv4 include-ldp-prefix
*A:P-4# configure router
        bgp
            group "internal"
                neighbor 192.0.2.2
                    advertise-label ipv4 include-ldp-prefix
                exit
                neighbor 192.0.2.7
                    advertise-label ipv4 include-ldp-prefix
                exit
            exit
```

Configuring advertise-label with the include-ldp-prefix argument implies that all activated /32 LDP FEC prefixes will be sent to the remote BGP peer as an RFC 3107 formatted label.

Configuring advertise-label without the include-ldp-prefix argument implies that only core IPv4 routes learned from the route table manager (RTM) are advertised as RFC 3107 BGP labeled routes to this neighbor. No stitching of LDP FEC to the BGP labeled route will be performed for this neighbor, even if the same prefix was learned from LDP.

The BGP open messages contain address family AFI=1 and SAFI=1 between the RR and peers without the advertise-label argument. This address family is used for IPv4 unicast. See Cap_Code MP-BGP. Bytes 0x0 0x1 (AFI=1) 0x0 0x1 (SAFI=1).

```
*A:ABR-3# show debug
debug
    router "Base"
        bgp
            open
            update
        exit
    exit
exit
2 2016/03/30 08:02:25.73 UTC MINOR: DEBUG #2001 Base BGP
"BGP: OPEN
Peer 1: 192.0.2.4 - Received BGP OPEN: Version 4
```

```
   AS Num 64496: Holdtime 90: BGP_ID 192.0.2.4: Opt Length 16
   Opt Para: Type CAPABILITY: Length = 14: Data:

       Bytes: 0x0 0x0 0xfb 0xf0
"
```

The BGP update messages also show a difference. As expected, there is no label information between the RR and ABR-3 because the option to advertise labels is not enabled.

```
4 2016/03/30 08:07:22.58 UTC MINOR: DEBUG #2001 Base Peer 1: 192.0.2.4
"Peer 1: 192.0.2.4: UPDATE

```

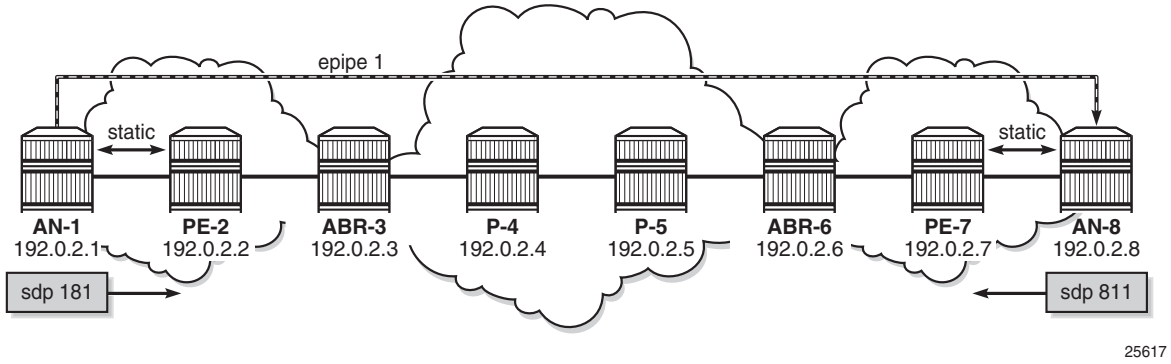
After applying the export policy from BGP to LDP and enabling the option in BGP to advertise labels for the LDP FEC prefixes, LDP will look for BGP route entries in the tunnel table. If a /32 BGP labeled route matches a prefix entry in the export policy, LDP originates an LDP FEC for this prefix, stitches it to the BGP labeled route, and redistributes the LDP FEC to its BGP neighbors. This can be shown on PE-7, as follows.



```
*A:PE-7# show router bgp inter-as-label
===============================================================================
BGP Inter-AS labels
Flags: B - entry has backup, P - entry is promoted
===============================================================================
NextHop                       Received       Advertised     Label
                              Label          Label          Origin
-------------------------------------------------------------------------------
192.0.2.8                     262143         262136         InternalLdp
-------------------------------------------------------------------------------
Total Labels allocated:   1
===============================================================================
*A:PE-7#
```

The label received from AN-8 is 262143. The label origin is InternalLdp. This LDP label is stitched to BGP label 262136 that will be advertised by PE-7 to its BGP peers, such as PE-2. Traffic sent from AN-1 toward AN-8 will be forwarded from PE-2 to its BGP NH PE-7 using BGP label 262136. In PE-7, the BGP label is stitched to LDP label 262143 that will be used to forward the packet to AN-8.

Configure SDP and Epipe

An end-to-end Epipe service is established between AN-1 and AN-8, as shown in Figure 153.

Figure 153 **End-to-End Epipe Service**

Note: : In this setup, ANs are simulated by 7750 SRs. Due to this limitation, the SDP used by the Epipe service will not become operational. 7750 SR only supports single-hop DoD, which implies that AN-1 can only request a label for the LSR ID of the directly connected router, PE-2, not of remote nodes, such as AN-8. Similarly, AN-8 cannot request a label for AN-1. Therefore, it is not possible to have an LDP LSP between the ANs and the SDP will be down because there is no transport tunnel.

The SDP is configured on AN-1, as follows:

```
*A:AN-1# configure service
        sdp 181 mpls create
            far-end 192.0.2.8
            ldp
            no shutdown
        exit
```

Epipe 1 is configured on AN-1, as follows:

```
*A:AN-1# configure service
        epipe 1 customer 1 create
            sap 1/2/1:1 create
            exit
            spoke-sdp 181:1 create
            exit
            no shutdown
        exit
```

The configuration of the SDP and Epipe on AN-8 is similar.

The SDP is down because there is no transport tunnel, which can be shown as follows:

```
*A:AN-1# show service sdp detail
===============================================================================
Services: Service Destination Points Details
```

```

```

LDP FEC Resolution at PE-2 for Traffic from AN-8 to AN-1

The following steps occur at PE-2 for the LDP FEC resolution for traffic from AN-1 toward AN-8. The situation is similar for PE-7.

Step 1. After receiving an LDP label binding message for LDP FEC for the system address of AN-1 (192.0.2.1/32), PE-2 installs this prefix in the label forwarding information base (LFIB). PE-2 programs a push and a swap next hop label forwarding entry (NHLFE) in the egress data path to forward packets to prefix 192.0.2.1/32.

Note: PE-2 installs this LDP FEC in the LFIB only if there is an exact match of the prefix 192.0.2.1/32 in the routing table or a longest match of the prefix in the routing table, in case aggregate-prefix-match is configured on PE-2. The advertising LDP neighbor (AN-1) must be the next hop to reach the FEC prefix.

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.1/32

BGP Labeled Route Resolution at PE-2 for Traffic from AN-1 to AN-8

The following steps occur at PE-2 for the BGP labeled route resolution for traffic from AN-1 toward AN-8. The situation is similar for PE-7.

Step 1. When there is an LDP LSP to the BGP neighbor advertising the route (PE-7) and PE-2 has received a BGP labeled route via iBGP for AN-8, PE-2 installs the prefix 192.0.2.8/32 in BGP. The LDP tunnel toward PE-7 is shown, then the BGP route toward AN-8, as advertised by PE-7.

```

LDP IPv4 Prefix Bindings (Active)
===============================================================================
Prefix                                    Op              IngLbl    EgrLbl
EgrNextHop                                EgrIf/LspId
-------------------------------------------------------------------------------
192.0.2.8/32(B)                           Swap            262135    262136
192.0.2.7                                 LspId 65542

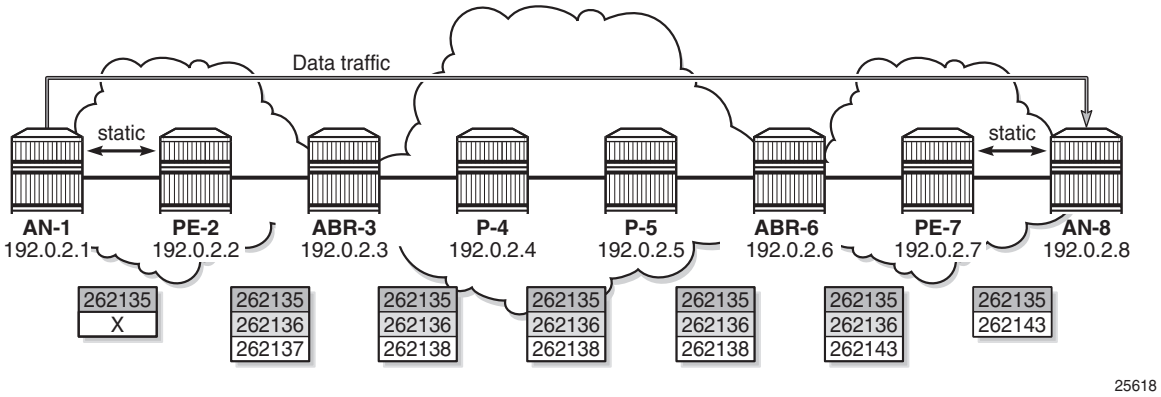
-------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 1
===============================================================================
*A:PE-2#
```

The (B) indicates that 192.0.2.8/32 is a BGP next hop. The ingress label is the LDP transport label from AN-1 for prefix 192.0.2.8/32. The LSP ID 65542 corresponds to the LDP LSP toward egress next-hop PE-7, as shown earlier in the tunnel table. The BGP egress label for traffic toward AN-8 is 262136.

Step 3. PE-2 programs a tunnel table entry for 192.0.2.8/32.

```
*A:PE-2# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop         Metric
-------------------------------------------------------------------------------
192.0.2.1/32      ldp       MPLS  65537     9        192.168.12.1    1
192.0.2.3/32      ldp       MPLS  65538     9        192.168.23.2    10
192.0.2.4/32      ldp       MPLS  65539     9        192.168.23.2    20
192.0.2.5/32      ldp       MPLS  65540     9        192.168.23.2    30
192.0.2.6/32      ldp       MPLS  65541     9        192.168.23.2    40
192.0.2.7/32      ldp       MPLS  65542     9        192.168.23.2    50
```

```
192.0.2.8/32      bgp       MPLS  262145    12       192.0.2.7      1000
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-2#
```



This is the only BGP tunnel in the tunnel table; all tunnels toward the other nodes are LDP tunnels. LDP routes have preference over BGP labeled routes, but there is no LDP route toward 192.0.2.8/32. Therefore, the BGP tunnel will be used for traffic destined to AN-8.

Step 4. PE-2 advertises a new FEC label binding for prefix 192.0.2.8/32 toward AN-1. This is only done after AN-1 requests a label for prefix 192.0.2.8/32, because LDP DoD is enabled. This is possible if the ANs are DSLAMs, but not in this setup with SRs.

Data Plane Overview for PE-2

Figure 154 shows the label stacks that are used for traffic from AN-1 to AN-8.

Figure 154 **Label Stacks for Traffic from AN-1 to AN-8**

Note: The LDP transport label that is pushed by AN-1 is not known because of the single-hop LDP DoD implementation in 7750 SR. AN-1 cannot request the LDP label for AN-8. Therefore, the LDP transport label is represented by "X".

The service label added for Epipe 1 on AN-1 for egress traffic to AN-8 is 262135. Ingress traffic on AN-1 has service label 262135. This can be shown as follows:

```
*A:AN-1# show service id 1 labels
===============================================================================

192.0.2.7                               LspId 65542

------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 1
==============================================================================
*A:PE-2#
```

The next hop is PE-7, which is the PE nearest to AN-8. The BGP label will not be swapped between PE-2 and PE-7 because there is no intermediate node that has set next-hop-self. An intermediate node with next-hop-self would become the next hop instead of PE-7. The BGP label is only added or removed by the next-hop PE.

On PE-2, when a service packet with destination AN-8 is received, the ingress LDP transport label X is swapped into BGP label 262136. To reach PE-7, which is the BGP next hop for traffic toward AN-8, another LDP transport label 262137 is pushed to the packet, as follows:

```
*A:PE-2# show router ldp bindings active prefixes prefix 192.0.2.7/32
==============================================================================
```

```

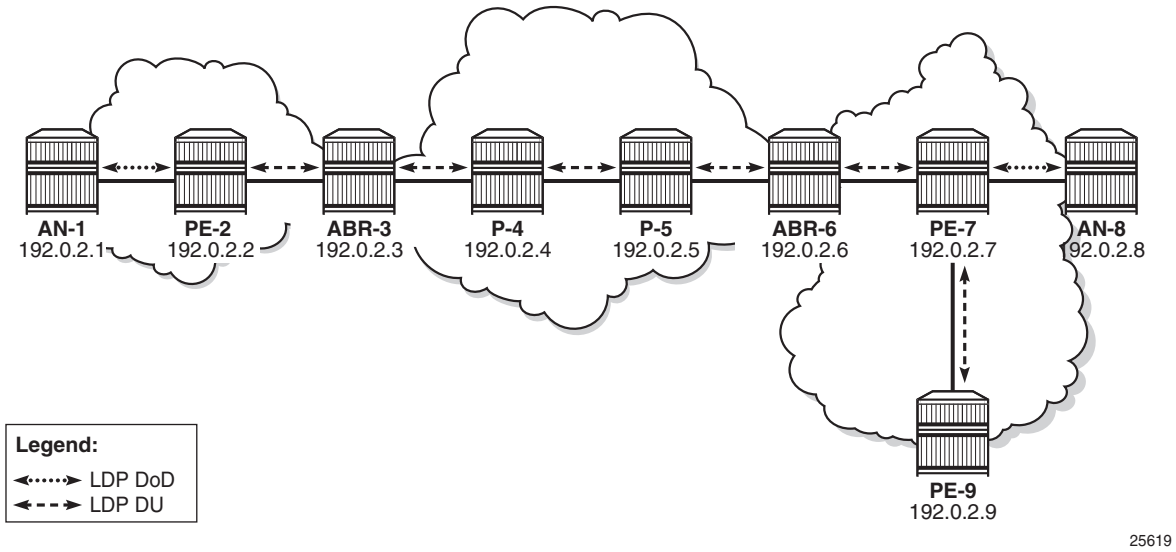
           label[1]=262143 protocol=3(LDP)
6  192.0.2.8  rtt=5.37ms rc=4(NoFECMapping) rsc=1
*A:PE-2#
```



Block BGP Label Bindings to LDP DU Peers

On a PE, labeled BGP prefixes are exported to LDP to allow LDP DoD peers to request these labels. LDP DU peers will also get all labeled BGP prefixes if not explicitly blocked by an LDP export policy, based on prefix lists. This can result in a high administrative and operational effort in large networks.

Blocking BGP label bindings to LDP DU peers is less labor-intensive because per-peer export policies are re-evaluated on NH type change (such as from BGP to LDP or to "unresolved state"), not only on a configuration change.

Figure 155 shows the extended topology used for this configuration. The additional PE router, PE-9, does not need to know the BGP labeled prefixes. LDP DU is used between PE-7 and PE-9.

Figure 155 **Block BGP Label Bindings to LDP DU Peer PE-9**

Blocking BGP label bindings to LDP DU peers can be achieved in two ways:

1. LDP export policy based on prefix list.
2. LDP export policy based on BGP NH type change. No prefix list is required.

To compare the two, both are described.

LDP Export Policy Based on Prefix List

Before applying the policy to block BGP label bindings from PE-7 to PE-9, the LDP bindings on PE-9 for prefix 192.0.2.1 are the following:

```
*A:PE-9# show router ldp bindings prefixes prefix 192.0.2.1/32
===============================================================================
LDP Bindings (IPv4 LSR ID 192.0.2.9)
             (IPv6 LSR ID ::)
===============================================================================
Legend: U - Label In Use,  N - Label Not In Use, W - Label Withdrawn

EgrNextHop
-------------------------------------------------------------------------------
192.0.2.1/32                                --                      262135
192.0.2.7:0                                 --
  --

-------------------------------------------------------------------------------
No. of IPv4 Prefix Bindings: 1
===============================================================================
*A:PE-9#
```

The following policy created on PE-7 is based on a prefix list that only contains the system address of the remote AN: 192.0.2.1.

```
*A:PE-7# configure router
        policy-options
            begin
            prefix-list "remote-AN"
                prefix 192.0.2.1/32 exact
            exit
            policy-statement "block-BGP-bindings-remote-AN"
                entry 10
                    from
                        prefix-list "remote-AN"
                    exit
                    action reject
                exit
            exit
            commit
        exit
```

The policy is applied on PE-7 in the LDP session-parameters context for peer 192.0.2.9.

```
*A:PE-7# configure router
        ldp
            session-parameters
                peer 192.0.2.9
                    export-prefixes "block-BGP-bindings-remote-AN"
                exit
            exit
        exit
```

After the policy is applied, there are no LDP bindings for prefix 192.0.2.1 on PE-9:

```
*A:PE-9# show router ldp bindings prefixes prefix 192.0.2.1/32

LDP Export Policy Based on BGP NH Type Change

The "from protocol bgp" argument will have a different meaning in the context of per-peer and targeted export policies. For those types of policies, policies are re-evaluated on NH type change; for example, from BGP to LDP or from LDP to "unresolved state". This requires less configuration because no prefix list needs to be specified. The following policy is configured on PE-7.

```
*A:PE-7# configure router
        policy-options
            begin
            policy-statement "block-BGP-to-LDP-DU"
                entry 10
                    from
                        protocol bgp
                    exit
                    action reject
                exit
            exit
            commit
        exit
```

The policy is applied in the LDP session-parameter context for peer 192.0.2.9.

```
*A:PE-7# configure router
        ldp
            session-parameters
                peer 192.0.2.9
                    export-prefixes "block-BGP-to-LDP-DU"
                exit
            exit
```

PE-7 will not send BGP label mapping information for prefix 192.0.2.1/32 to PE-9, or for any other prefix of a remote AN. In this example, AN-1 with prefix 192.0.2.1/32 is the only remote AN for PE-7.

```
*A:PE-9# show router ldp bindings prefixes prefix 192.0.2.1/32

```

Conclusion

LDP FEC to BGP label route stitching allows LDP-capable PE devices, such as DSLAMs, to offer services to LDP-capable PE devices in other areas or domains without the need to support BGP labeled routes. This feature can be used in a seamless MPLS environment.

LDP over RSVP Using OSPF as IGP

This chapter provides information about label distribution protocol (LDP) over resource reservation protocol with traffic engineering (RSVP-TE), also called LDPoRSVP, that uses RSVP label switched paths (LSPs) as a transport vehicle to carry the packets using LDP LSPs.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Additional Topics
- Conclusion

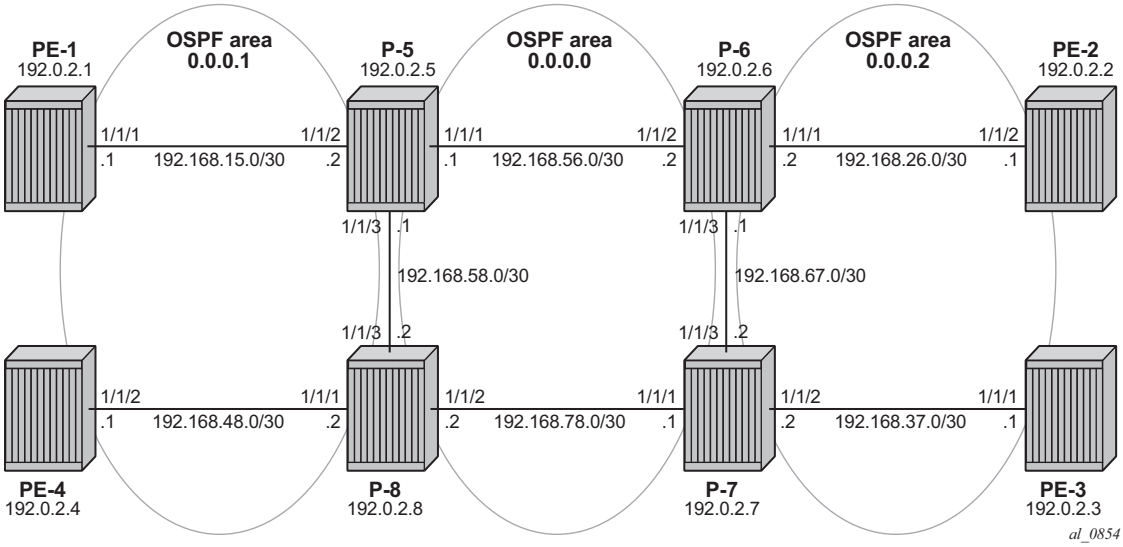
Applicability

This chapter is applicable to SR OS. Initially, it was written for and tested on 7.0.R5, but the CLI in this edition corresponds to release 14.0.R1. There are no prerequisites.

Overview

Introduction

Only user packets are tunneled over RSVP LSPs; targeted LDP (T-LDP) control messages are still sent unlabeled using the interior gateway protocol (IGP) shortest path. Since LDP does not have traffic engineering (TE), it can now benefit from the RSVP-TE features. LDP FRR is loopfree alternate (LFA), but with LDPoRSVP, it can use RSVP FRR detour or bypass tunnels.



The main advantage of LDPoRSVP is seen in large networks. A full mesh of intra-area RSVP LSPs between PE nodes (which in some cases is not scalable) is not needed anymore. While a label edge router (LER) may not have that many tunnels, any transit node will potentially have thousands of LSPs, and if each transit node also has to deal with detour tunnels or bypass tunnels, this number can make the label switching router (LSR) overly burdened.

LDPoRSVP can be configured in an intra-area domain and an inter-area domain. Any router in an area can be a stitching point for LDP over RSVP. LDPoRSVP introduces a new tunnel type, tunnel-in-tunnel (in addition to the existing LDP tunnel type and RSVP tunnel type). If multiple tunnel types match the destination PE forwarding equivalence class (FEC) lookup, LDP will prefer an LDP tunnel over an LDPoRSVP tunnel by default.

First, it is important to understand how LDP FEC resolution is working (with LDPoRSVP enabled). A more detailed explanation can be found later on in this chapter. The ingress LER receives an LDP label message including a FEC with prefix **P** and label **L** from a peer by a T-LDP session. LDP tries to resolve prefix **P** by performing a lookup in the routing table manager (RTM). The result of this is a next hop (NH) to the destination PE, either an intra-area PE (intra-area context) or an area border router (ABR) (inter-area context). When the NH matches the targeted LDP peer, LDP performs a second lookup for that NH in the tunnel table manager (TTM) which returns a user configured RSVP LSP with the best metric. If there are more than one configured RSVP LSPs with the best metric, LDP selects the first available RSVP LSP. If all user configured RSVP LSPs are down, no more action is taken. If the user did not configure any RSVP LSPs under the T-LDP context, the lookup in TTM will return the first available RSVP LSP which terminates on the ABR (inter-area) or intra-area PE with the lowest metric.

If the lookup in TTM results in no RSVP LSP, the system can fall back to link-level LDP (iLDP). In that way, it is possible that the NH is reachable using iLDP. Accordingly, the egress label will be installed on the ingress LER.

Figure 156 **Initial Topology**

OSPF area 0.0.0.1 and OSPF area 0.0.0.2 should be seen as two metro areas, connected to each other via a core area, represented by OSPF backbone area (area 0.0.0.0). Therefore, P-5, P-6, P-7 and P-8 are all acting as area border routers (ABRs). LDPoRSVP principles will be shown for intra-area PE communication (PE-1 <=> PE-4) and inter-area communication (PE-1 <=> PE-2).

Configuration

Step 1. Configuring the IP/MPLS network.

The system addresses and IP interface addresses are configured according to the Initial Topology. An interior gateway protocol (IGP) is needed to distribute routing information on all routers. In this case, the IGP is open shortest path first (OSPF) using the backbone area 0.0.0.0 in the core and normal areas (area 0.0.0.1 and area 0.0.0.2) in the two metro regions, connected toward the backbone area via ABRs. A configuration example is shown for PE-1 and P-5. A similar configuration can be derived for the other P and PE nodes.

```
A:PE-1# configure router ospf
            traffic-engineering
            area 0.0.0.1
                interface "system"
                exit
                interface "int-PE-1-P-5"
                    interface-type point-to-point
```

```
            exit
        exit
A:P-5# configure router ospf
        traffic-engineering
        area 0.0.0.0
            interface "system"
            exit
            interface "int-P-5-P-6"
                interface-type point-to-point
            exit
            interface "int-P-5-P-8"
                interface-type point-to-point
            exit
        exit
        area 0.0.0.1
            interface "int-P-5-PE-1"
                interface-type point-to-point
            exit
        exit
```

Because fast reroute will be enabled on the RSVP LSPs in the core area, traffic engineering is needed on the IGP. By doing this, OSPF will generate opaque link state advertisements (LSAs) which are collected in a traffic engineering database (TED), separate from the traditional OSPF topology database. OSPF interfaces are set up as type point-to-point to improve convergence, no designated router/backup designated router (DR/BDR) election process is performed. Convergence is beyond the scope of this document.

On all nodes originating and terminating a T-LDP session, an explicit **ldp-over-rsvp** parameter must be configured to enable this OSPF instance for LDPoRSVP. In the example, this becomes.

```
A:PE-[1..4]# configure router ospf ldp-over-rsvp
A:P-[5..8]# configure router ospf ldp-over-rsvp
```

To verify that OSPF neighbors are up (state:full), the **show router ospf neighbor** command is executed. To check if IP interface addresses/ subnets are known on all PEs, **show router route-table** or **show router fib** *IOM-card-slot* will display the content of the forwarding information base (FIB).

```
*A:PE-1# show router ospf neighbor

*A:PE-1#
```

The next step in the process of setting up the IP/MPLS network, is enabling the IP interfaces in the MPLS and RSVP context on all involved nodes (PE and P nodes). By default, the system interface is put automatically within the MPLS/RSVP context. When an interface is put in the MPLS context, the system also copies it into the RSVP context. Explicit enabling of MPLS and RSVP context is done by the **no shutdown** command. The following output displays the MPLS/RSVP configuration for PE-1.

```
A:PE-1# configure router rsvp no shutdown

A:PE-1# configure router mpls
            interface "system"
            exit
            interface "int-PE-1-P-5"
            exit
            no shutdown
```

Step 2. Configure the RSVP LSPs. In both metro areas, RSVP LSPs are set up from all PEs toward the ABRs, no intra-area PE-PE RSVP LSPs are needed. In the core/backbone, a full RSVP LSP mesh is required. To simplify the RSVP LSP configuration, no fast reroute is enabled on the RSVP LSPs in the metro areas, only in the backbone area. All RSVP paths are configured as **strict paths.** As an example, the configuration for PE-1 and P-5 is as follows:

```
*A:PE-1# configure router mpls
            path "path-PE-1-P-5"
                hop 1 192.168.15.2 strict
                no shutdown
            exit
            path "path-PE-1-P-5-P-8"
                hop 10 192.168.15.2 strict

===============================================================================
*A:P-5#
```

By default, the metric for strict LSPs configured without constrained shortest path first (CSPF) (RSVP LSPs in metro areas) is infinite (value = 16777215). The LSP metric for CSPF LSPs (RSVP LSPs in the core area) follows the IGP cost. LSP metrics can be explicitly set on the LSP level, see also in the Additional Topics section.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-P-5" metric
  - metric <metric>
  - no metric

 <metric>            : <0..16777215>
```

Whenever an RSVP LSP comes up it is by default, eligible for LDPoRSVP, meaning that RSVP will signal to the relevant IGP (OSPF in this case) that the LSP should be included in the IGP shortest path first (SPF) run. The destination of the LSP (192.0.2.5) will be considered as a potential endpoint in the FEC resolution. With the **info detail** command, all default settings of a context are shown.

```
A:PE-1# configure router mpls lsp "LSP-PE-1-P-5"
A:PE-1>config>router>mpls>lsp# info detail
----------------------------------------------
                to 192.0.2.5

*A:PE-1#
```

To make an RSVP LSP ineligible for LDPoRSVP, use the **exclude** command.

```
A:PE-1# configure router mpls lsp <LSP-name> ldp-over-rsvp exclude
```

Step 3. Create T-LDP sessions according to RSVP LSPs. It is a must that when configuring an RSVP LSP eligible for LDPoRSVP, also a T-LDP session is initiated. This must be done on all PE and P nodes.

```
*A:PE-1# configure router ldp
            targeted-session
                peer 192.0.2.5
                exit
                peer 192.0.2.8
                exit
```

```
            exit
*A:PE-1#

*A:PE-1# show router ldp session

-------------------------------------------------------------------------------
No Matching Entries Found
===============================================================================
*A:PE-1#
```

Step 4. Enable LDPoRSVP. This is done using the **tunneling** keyword inside the T-LDP session context. Configuration is needed on all PE and ABR nodes.

```
*A:PE-1# configure router ldp
            targeted-session
                peer 192.0.2.5
                    tunneling
                    exit
                exit
                peer 192.0.2.8
                    tunneling
                    exit
                exit
            exit
```

As a result of the **tunneling** command, the LDPoRSVP process of FEC resolving is initiated. As already stated in the introduction, FEC resolution is a three-step process. First run an SPF calculation to the destination, then select an endpoint close to that destination followed by a tunnel to that endpoint. The next two steps go more into detail on this FEC resolution process. Step 5 will handle inter-area FEC resolving and Step 6 will handle intra-area FEC resolving.

Step 5. Inter-area FEC resolving (ingress LER is PE-1, egress LER is PE-2)

i. Verification endpoint nodes and associated RSVP tunnels.

The first thing to do in the inter-area FEC resolving process is for PE-1 to perform an SPF calculation toward PE-2 with the purpose to search for an eligible endpoint, as close as possible to PE-2. An endpoint is eligible when a T-LDP session exists between PE-1 and the endpoint node, tunneling is configured on the endpoint node, PE-1 received a label for the destination FEC from the endpoint and an RSVP LSP exists between PE-1 and endpoint node that can be used for LDPoRSVP.

Endpoint node in OSPF area 1 can be either P-5 or P-8 (only those nodes have a T-LDP session toward PE-1). With **show router ldp bindings active prefixes prefix 192.0.2.2/32**, it can be concluded that P-5 will be the endpoint node (EgrNextHop).

```
*A:PE-1# show router ldp bindings active prefixes prefix 192.0.2.2/32

===============================================================================
*A:P-6#
```

Nodes P-5 and P-6 behave as stitching nodes to stitch RSVP LSPs. P-5 will stitch LSP-PE-1-P-5 and LSP-P-5-P-6 together while P-6 node will stitch LSP-P-5-P-6 and LSP-P-6-PE-2 together.

When the endpoints are defined, one corresponding RSVP LSP to those endpoints will be chosen (when ECMP=1). Selection criteria are as follows. When RSVP LSPs are configured under the T-LDP **tunneling** command (maximum 4), the one with the lowest LSP metric will be selected. When no RSVP LSPs are configured under the T-LDP **tunneling** command, LDP checks the TTM for all available RSVP LSPs. The RSVP LSP with the lowest metric and operational state up will be selected.

ii. Traffic verification using a virtual private routed network (VPRN) service.

Figure 157 **VPRN 1 with LDPoRSVP and No Intra-Area PE Connectivity**

VPRN service 1 is set up between three PE nodes (PE-1, PE-2, and PE-4) using the **auto-bind-tunnel resolution-filter ldp resolution filter** command. See also Figure 157 for the exact addressing scheme.

```
*A:PE-1# configure service vprn 1 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "int-PE-1-CE-1" create
                address 172.16.1.1/30
                sap 1/1/4:1 create
                exit
```

```
            exit
            static-route-entry 10.0.1.0/24
                next-hop 172.16.1.2
                    no shutdown
                exit
            exit
            no shutdown
            info
            exit all
```

In order to distribute VPRN information (vpn-ipv4 routes and VPRN service labels) across the service provider network, multi-protocol border gateway protocol (MP-BGP) is needed. MP-BGP is configured on PE-1, PE-2 and PE-4 with P-5 (192.0.2.5) being the route reflector (RR). In this way, no full BGP mesh between the three PE-nodes is needed, only a BGP peering toward RR.

```
*A:PE-1# configure router
        autonomous-system 64496
        bgp
            group "internal"
                family ipv4 vpn-ipv4
                peer-as 64496
                neighbor 192.0.2.5
                exit
            exit
            no shutdown

*A:P-5# configure router
        autonomous-system 64496
        bgp
            group "internal"
                family ipv4 vpn-ipv4
                peer-as 64496
                cluster 1.1.1.1
                neighbor 192.0.2.1
                exit
                neighbor 192.0.2.2
                exit
                neighbor 192.0.2.4
                exit
            exit
            no shutdown
```

If user traffic is monitored between PE-1 (ingress LER) and PE-2 (egress LER) three labels should be seen. The outer label is the transport label distributed using the RSVP protocol, the inner label is the service label distributed using MP-BGP. LDPoRSVP will add an extra MPLS label between transport and service label (distributed using LDP). This middle label is used to tell the endpoint nodes (P-5 and P-6 acting as ABR) what to do. The transport label stack contains two labels: an RSVP label and an LDP label.

Translated into show commands for traffic on ingress port 1/1/2 on ABR P-5 (PE-1<=>P-5 link):

RSVP transport label 262143 is added as the top label on each user packet

```

*A:P-6#
```

Service label 262133 is added as the inner MP-BGP label on each user packet.

Step 6. Intra-area FEC resolving (ingress LER is PE-1, egress LER is PE-4).

i. Verification endpoint node and associated RSVP tunnel.

The first thing to do in the intra-area FEC resolving process is for PE-1 to perform an SPF calculation toward PE4 to search for an eligible endpoint, as close as possible to PE-4. An endpoint is eligible when a T-LDP session exists between PE-1 and the endpoint node, tunneling is configured on the endpoint node, PE-1 received a label for the destination FEC from the endpoint and an RSVP LSP exists between PE-1 and endpoint node that can be used for LDPoRSVP.

First endpoint node in OSPF area 1 can be either P-5 or P-8 (only those nodes have a T-LDP session toward PE-1). With **show router ldp bindings active prefixes prefix 192.0.2.4/32** it can be concluded that P-5 will be the endpoint node.

===============================================================================
*A:P-5#
```

P-5 node acts as a stitching node to stitch RSVP LSPs. P-5 will stitch LSP-PE-1-P-5 and LSP-P-5-PE-4 together.

When the endpoint node (P-5) is defined, the corresponding RSVP LSP to this endpoint will be chosen. Selection criteria are as follows (when ECMP=1). When RSVP LSPs are configured under the T-LDP **tunneling** command (maximum 4), the one with the lowest LSP metric will be selected. When no RSVP LSPs are configured under the T-LDP **tunneling** command, LDP checks TTM for all available RSVP LSPs. The RSVP LSP with the lowest metric and operational state **up** will be selected.

ii. Traffic verification using a VPRN service (see VPRN 1 with LDPoRSVP and No Intra-Area PE Connectivity).

If user traffic between PE-1 (ingress LER) and PE-4 (egress LER) is monitored, three labels are seen. The outer label is the transport label (distributed using RSVP protocol), the inner label is the service label (distributed using MP-BGP). LDPoRSVP will add an extra MPLS transport label between outer and inner label (distributed using LDP). This middle label is used to tell the endpoint node (P-5) what to do.

Translated into show commands for traffic on ingress port 1/1/2 on P-5 node (PE-1<=>P-5 link):

Transport label 262143 is added as the top RSVP label on each user packet.

```

Service label 262133 is added as the inner MP-BGP label on each user packet.

Additional Topics

prefer-tunnel-in-tunnel

If the next-hop router advertised the same FEC over link-level LDP (iLDP), LDP will prefer the iLDP tunnel by default unless the user explicitly changed the default preference using the **prefer-tunnel-in-tunnel** command. In this case an LDPoRSVP tunnel will have precedence.

Until now, no RSVP LSPs are configured inside the **ldp targeted-session peer tunneling** context. Therefore, two additional strict non-CSPF RSVP LSPs are added between ingress LER PE-1 and egress LER P-5. Both LSPs will have an explicit metric setting and will be applied inside the **ldp tunneling** context. On the Layer 3 interface between PE-1 and P-5, iLDP is enabled.

```
A:PE-1# configure router ldp
            interface-parameters
                interface "int-PE-1-P-5"

---snip---

===============================================================================
```

Four LSPs are set up toward node P-5, three RSVP LSPs and one LDP LSP. Tunnel ID 1 is a reference to LSP-PE-1-P-5. Tunnel ID 3 is a reference to LSP-PE-1-P-5-metric100. Tunnel ID 4 is a reference to LSP-PE-1-P-5-metric200 and owner LDP is a reference to iLDP.

Taken into account the FEC resolution rules, iLDP prevails (no LDPoRSVP tunnel will be used).

Intra-PE Connectivity Will Change LDPoRSVP Behavior

Refer to Figure 158. In the two metro areas, both of the intra PEs are physically connected with each other. Compared with the previous figures, PE-1 is directly connected to PE-4 and PE-2 is directly connected to PE-3 (up to the OSPF level).

Figure 158 **VPRN 1 with LDPoRSVP and Intra-Area PE Connectivity**

The SPF path calculation on PE-1 toward destination (PE-4) will not point to node P-5 anymore (as was seen before) but will now point directly to PE-4 (shortest, lowest IGP metric). As a conclusion, it can be said that when possible intra-area endpoint nodes are not part of the calculated SPF path, LDPoRSVP will be not be preferred anymore. For this situation, it is advisable to configure iLDP on the intra-PE interfaces to have a fallback mechanism.

This is configured on PE-1 and PE-4 as follows:

```
*A:PE-1# configure router
        interface "int-PE-1-PE-4"
            address 192.168.14.1/30
            port 1/1/2
        exit

*A:PE-4# configure router
        interface "int-PE-4-PE-1"
            address 192.168.14.2/30
            port 1/1/1
```

```
        exit

*A:PE-1# configure router ospf
            area 0.0.0.1
                interface "int-PE-1-PE-4"
                    interface-type point-to-point
                exit
            exit

*A:PE-4# configure router ospf
            area 0.0.0.1
                interface "int-PE-4-PE-1"
                    interface-type point-to-point
                exit
            exit
```

From the moment iLDP is configured, an LDP LSP is set up. Intra-area PE traffic will flow over this LDP LSP.

```
*A:PE-1# configure router ldp
            interface-parameters
                interface "int-PE-1-PE-4"
                exit
            exit

*A:PE-4# configure router ldp
            interface-parameters
                interface "int-PE-4-PE-1"
                exit
            exit

===============================================================================
A:PE-1#
```

If user traffic is monitored, between PE-1 (ingress LER) and PE-4 (egress LER) only two labels are seen. The outer label is the transport label (distributed using LDP), the inner label is the service label (distributed using MP-BGP). No LDPoRSVP label is present anymore. Translated into show commands for traffic on ingress port 1/1/1 on PE-4 node (PE-1<=>PE-4 link):

LDP transport label 262141 is added as the outer label on each user packet.

Conclusion

LDPoRSVP allows tunneling of user packets toward an LDP far-end destination inside an RSVP LSP (with the benefits of RSVP LSPs, fast-reroute (FRR) and traffic engineering (TE)). The main application of this feature is for deployment of MPLS based services, for example, VPRN, virtual leased line (VLL), and virtual private LAN service (VPLS) services, in large networks where a full mesh of LSPs reaches the limits of scalability.

LDP Point-to-Point LSPs

This chapter provides information about label distribution protocol (LDP) point-to-point label switched paths (LSPs)

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was originally written for release 7.0.R5. The output in this edition corresponds to release 14.0.R1. There are no pre-requisites or conditions on the hardware for this configuration.

Overview

Due to the connectionless nature of the network layer protocol IP, packets travel through the network on a hop-by-hop basis with routing decisions made at each node. As a result, hyperaggregation of data on certain links may occur and it may impact the provider's ability to provide guaranteed service levels across the network end-to-end. To address these shortcomings, multiprotocol label switching (MPLS) was developed. The technology provides the capability to establish connection oriented paths, called label switched paths (LSPs), over a connectionless (IP) network. The LSP offers a mechanism to engineer network traffic independently from the underlying network routing protocol (mostly IP) to improve the network resiliency and recovery options and to permit delivery of new services that are not readily supported by conventional IP routing techniques (Layer 2 IP virtual private networks (VPNs)). These benefits are essential for today's communication network explaining the wide deployment base of the MPLS technology.

RFC 3031, *Multiprotocol Label Switching Architecture*, specifies the MPLS architecture while this document describes the configuration and troubleshooting of point-to-point LSPs on SR OS.

Packet Forwarding

As a packet of a connectionless network layer protocol travels from one router to the next, each router in the network makes an independent forwarding decision by performing the following basic tasks: first analyzing the packet's header, then referencing the local routing table to find the longest match based on the destination address in the IP header, and finally sending out the packet on the selected interface. In other terms, the first function partitions the entire set of possible packets into a set of forwarding equivalence classes (FECs). All packets associated to a particular FEC will be forwarded along the same logical path to the same destination. The second function maps each FEC to a next hop destination router. Each router along the packet's path performs these actions.

On the other hand, in MPLS, the assignment of a particular packet to a particular FEC is done just once, as the packet enters the network. In turn, the FEC is mapped to an LSP, which is established prior to packet forwarding. An MPLS label, representing the FEC to which the packet is assigned, is attached to the packet (push operation) and once labeled, the packet is forwarded to the next hop router along that LSP path. At subsequent hops, no analysis of the packet's network layer header is needed. Instead, the label is used as an index into a table which specifies the next hop and a new label. The old label is replaced with the new label (swap operation), and the packet is forwarded to its next hop. At the MPLS network egress, the label is removed from the packet (pop operation). If this router is the final destination (based on the remaining packet), the packet is handed to the receiving application (such as a virtual private LAN service (VPLS) domain). If this router is not the final destination of the packet, the packet will be sent into a new MPLS tunnel or forwarded by conventional IP forwarding towards the Layer 3 destination

Terminology

Figure 159 **Generic MPLS Network, MPLS Label Operations**

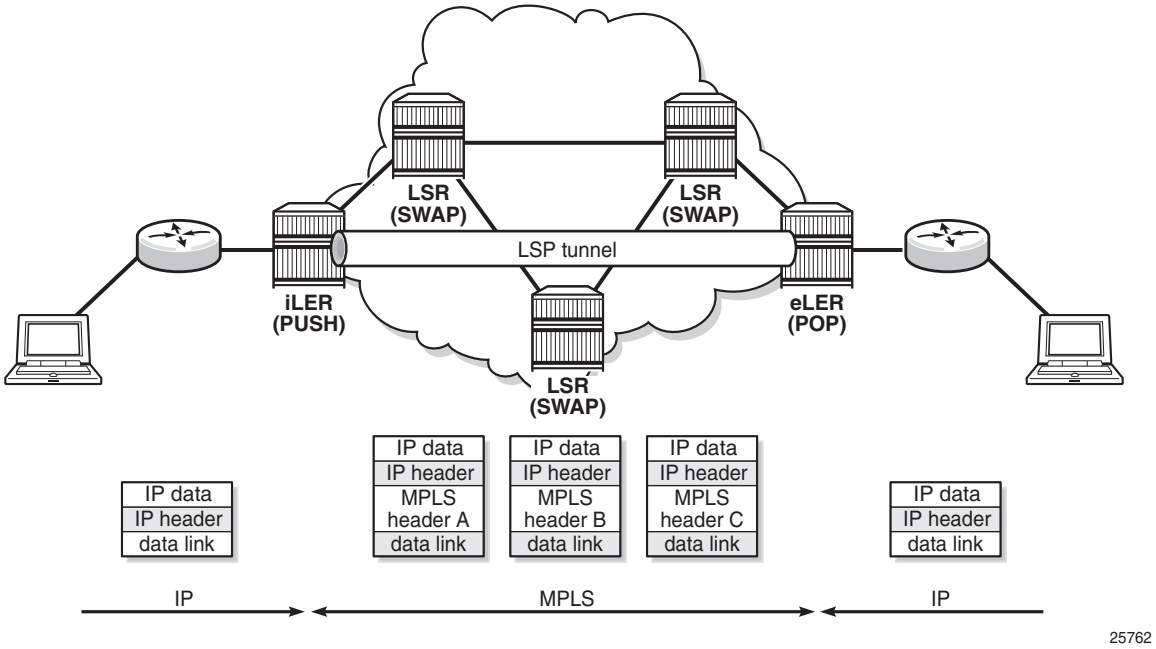

Figure 159 depicts a general network topology clarifying the MPLS-related terms. A label edge router (LER) is a device at the edge of an MPLS network, with at least one interface outside the MPLS domain. A router is usually defined as an LER based on its position relative to a particular LSP. The MPLS router at the head-end of an LSP is called the ingress label edge router (iLER). The MPLS router at the tail-end of an LSP is called the egress label edge router (eLER). The iLER receives unlabeled packets from outside the MPLS domain, then applies MPLS labels to the packets, and forwards the labeled packets into the MPLS domain. The eLER receives labeled packets from the MPLS domain, then removes the labels, and forwards unlabeled packets outside the MPLS domain. The eLER can signal an implicit-null label (numeric value 3). This informs the previous hop to send MPLS packets without an outer label and so is known as penultimate hop popping (PHP).

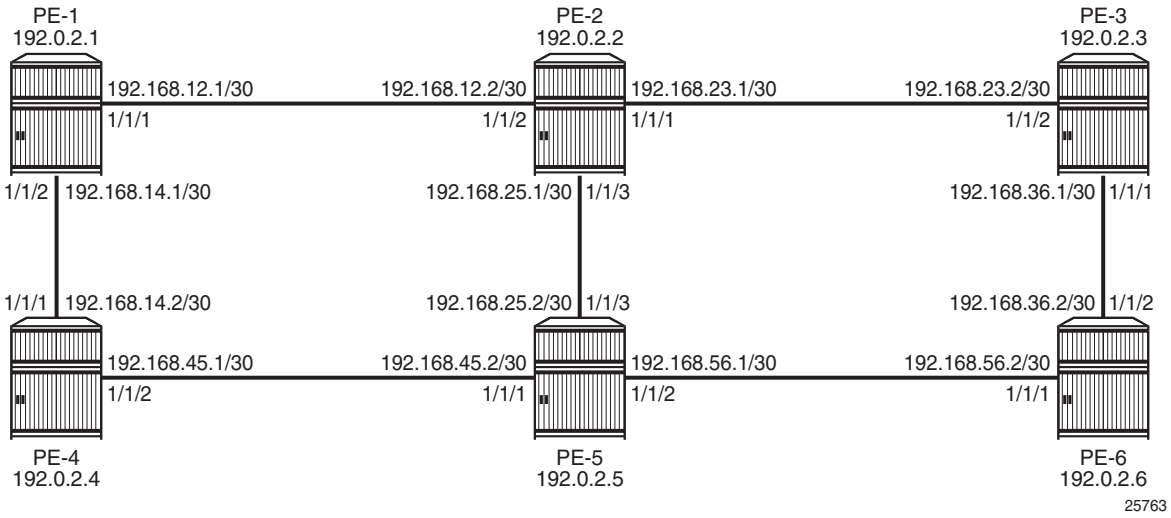
A label switching router (LSR) is a device internal to an MPLS network, with all interfaces inside the MPLS domain. These devices switch labeled packets inside the MPLS domain. In the core of the network, LSR ignore the packet's network layer (IP) header and simply forward the packet using the MPLS label swapping mechanism.

LSP Establishment

Prior to packet forwarding, the LSP must be established. In order to do so, labels need to be distributed for the path. Labels are usually distributed by a downstream router in the upstream direction (relative to the data flow). There are a number of ways used for label distribution: static, LDP, and RSVP. For static P2P LSPs, see chapter Static Point-to-Point LSPs; for RSVP-TE P2P LSPs, see chapter RSVP Point-to-Point LSPs.



LDP (RFC 5036, *LDP Specification*) can be considered as an extension to the network interior gateway protocol (IGP). As routers become aware of new destination networks, they advertise labels in the upstream direction that will allow upstream routers to reach the destination.

Fast reroute (FRR) allows for establishing backup paths before a failure takes place. This way traffic can flow almost continuously, without waiting for routing protocol convergence; see chapter MPLS LDP FRR using ISIS as IGP.

Example Topology

The example topology is displayed in Figure 160. The setup consists of six 7750 SR nodes located in a single autonomous system.

Figure 160 **MPLS Example Topology**

Configuration

As a general pre-requisite for the configuration of MPLS LSPs, a correctly working IGP is required. Open shortest path first (OSPF) or intermediate system to intermediate system (IS-IS) can be used as IGP.

LDP is a simple label distribution protocol with basic MPLS functionality (no traffic engineering). Fast Reroute is supported; see chapter MPLS LDP FRR using ISIS as IGP. LDP relies on the underlying routing information provided by an IGP in order to forward labeled packets. Each LDP configured LSR will originate a label for its system address and a label for each FEC for which it has a next-hop that is external to the MPLS domain, without the explicit need to manually configure the LSPs. When deviations from this default behavior are desired, import and export policies can be applied.

The configuration is as simple as enabling the LDP protocol instance and adding all network interfaces, for each node. As an example the configuration on node PE-1 is displayed below; similar configurations apply on the other nodes.

```
*A:PE-1# configure router
        ldp
            interface-parameters
                interface "int-PE-1-PE-2"
                exit
                interface "int-PE-1-PE-4"
                exit
```

The **show router ldp discovery** and **show router ldp session** commands can be used to verify the LDP hello adjacencies and sessions. The adjacency type (AdjType) needs to be **Link** while the state should be **Established**.

```
*A:PE-1# show router ldp discovery

===============================================================================
*A:PE-1#
```

In order to signal PHP with LDP, implicit-null must be configured on the eLER.

```
A:PE-6# configure router ldp implicit-null-label
```

The implicit-null is signaled immediately, all related labels are withdrawn and re-advertised with label value of 3. The new label would show up on PE-5 as a swap from the ingress label to an egress label of 3, although label 3 is not pushed on to the frame.

Import and Export Policies

The default label handling behavior is to originate label bindings for the system address and to propagate all FECs received. If this is not the desired behavior, an import/export policy can be applied. An LDP import policy impacts inbound filtering; an LDP export policy impacts outbound filtering. An export policy may be configured to control the set of LDP label bindings advertised by the LER (sending to LDP peers). As such, export policies are used to include additional FECs rather than filtering FECs from those advertised. An import policy can be used to control for which FECs a router will generate labels (accepting from LDP peers). This functionality is not unique to LDP; it can be used for RSVP-TE, OSPF, and IS-IS as well as others.

The policy can be global or LDP peer FEC prefix filtering, both for import and export. LDP peer FEC prefix filtering uses a similar policy context as the LDP global policies and works in addition to these global policies.

```
*A:PE-1# tree flat detail | match import-pref
configure router ldp session-parameters peer import-prefixes <policy-name>
                     [<policy-name>...(upto 5 max)]
configure router ldp session-parameters peer no import-prefixes
configure router ldp targeted-session import-prefixes <policy-name>
                     [<policy-name>...(upto 5 max)]
configure router ldp targeted-session no import-prefixes
*A:PE-1#
*A:PE-1# tree flat detail | match export-pref
configure router ldp session-parameters peer export-prefixes <policy-name>
                     [<policy-name>...(upto 5 max)]
configure router ldp session-parameters peer no export-prefixes
```

```
configure router ldp targeted-session export-prefixes <policy-name>
                     [<policy-name>...(upto 5 max)]
configure router ldp targeted-session no export-prefixes
*A:PE-1#
```

By default no labels are generated for directly connected (local) interfaces. To change this behavior, an export policy is created and applied to the LDP instance. There is no configuration difference in defining an import and export policy.

A policy starts with the keyword begin and contains a list of entries (of which each has a number), and ends with the keyword commit. An entry typically contains matching criteria (however, it is not required in cases where everything matches) and a corresponding action. Entries without an action are considered incomplete and are rendered inactive. When processing the policy, the router executes the specified action on the first matching statement; it does not process any further matches. For this reason, entries must be sequenced correctly from most to least specific.

The configuration of the LDP export policy for local interfaces is as follows:

```
*A:PE-1# configure router
        policy-options
            begin
            policy-statement "LDP-export"
                entry 10
                    from
                        protocol direct
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

There are 11 active LDP bindings before applying the export policy, as shown earlier.

The LDP export or import policy is applied to the LDP instance on the router, with the **export** or **import** keyword.

```
*A:PE-1# configure router ldp export "LDP-export"
```

When the export policy is applied, the active LDP binding table contains additional entries: the local interfaces of PE-x.

```
*A:PE-1# show router ldp bindings active ipv4

OAM

The following operations, administration, and maintenance operations can be launched on an LDP LSP:

- oam lsp-ping
- oam lsp-trace

The following options are supported for LSP ping:

```
*A:PE-1# oam lsp-ping
  - lsp-ping <lsp-name> [path <path-name>]
  - lsp-ping bgp-label prefix <ip-prefix/prefix-length> [path-destination <ip-
address> [interface
    <if-name> | next-hop <ip-address>]]
  - lsp-ping prefix <ip-prefix/prefix-length> [path-destination <ip-
address> [interface <if-name> |
    next-hop <ip-address>]]
  - lsp-ping static <lsp-name> [assoc-channel <ipv4|non-ip|none>] [dest-global-
id <global-id>
    dest-node-id <node-id>] [force] [path-type <active|working|protect>]
  - options common to all lsp-ping cases:  [detail] [fc <fc-
name> [profile <in|out>]] [interval
    <interval>] [send-count <send-count>] [size <octets>] [src-ip-address <ip-
address>] [timeout
    <timeout>] [ttl <label-ttl>]
 <octets>             : [1..9198] - Default: 1
 <label-ttl>          : [1..255] - Default: 255
 <timeout>            : [1..10] seconds - Default: 5
 <interval>           : [1..10] seconds - Default: 1
 <in|out>             : keywords - Default: out
 <send-count>         : [1..100] packets - Default: 1
 <path-name>          : [32 chars max]
 <detail>             : keyword - display detailed information
 <if-name>            : [32 chars max]
 <ip-address>         : ipv4-address   - a.b.c.d
                        ipv6-address   - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
 <static>             : keyword - use the Target FEC Stack sub-type 'Static LSP'
 <global-id>          : [0..4294967295] - Default: 0
 <node-id>            : a.b.c.d|<1..4294967295> - Default: 0
```

```
 <ipv4|non-ip|none>   : keywords - Default: non-ip
 <active|working|pr*> : keywords - Default: active
 <bgp-label>          : keyword - use the Target FEC Stack sub-
type 'BGP labeled IPv4 prefix'
 <force>              : keyword -
 start the test regardless of the local operational state of the LSP
                        path
 <lsp-name>           : [64 chars max]
 <ip-prefix/prefix-*> : <ipv4-prefix>/32 | <ipv6-prefix>/128
                        ipv4-prefix    - a.b.c.d
                        ipv6-prefix    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
 <fc-name>            : be|l2|af|l1|h2|ef|h1|nc - Default: be
*A:PE-1#
```

As an example, an LSP ping is sent from PE-1 to PE-6:

```
*A:PE-1# oam lsp-ping prefix 192.0.2.6/32
LSP-PING 192.0.2.6/32: 80 bytes MPLS payload
Seq=1, send from intf int-PE-1-PE-2, reply from 192.0.2.6
       udp-data-len=32 ttl=255 rtt=2.56ms rc=3 (EgressRtr)
---- LSP 192.0.2.6/32 PING Statistics ----
1 packets sent, 1 packets received, 0.00% packet loss
round-trip min = 2.56ms, avg = 2.56ms, max = 2.56ms, stddev = 0.000ms
*A:PE-1#
```

An LSP trace is sent from PE-1 to PE-6:

```
*A:PE-1# oam lsp-trace prefix 192.0.2.6/32
lsp-trace to 192.0.2.6/32: 0 hops min, 0 hops max, 104 byte packets
1  192.0.2.2  rtt=0.636ms rc=8(DSRtrMatchLabel) rsc=1
2  192.0.2.3  rtt=2.04ms rc=8(DSRtrMatchLabel) rsc=1
3  192.0.2.6  rtt=2.91ms rc=3(EgressRtr) rsc=1
*A:PE-1#
```

The return code (rc) is 8 for the LSRs and 3 for the eLER.

The detailed output for this LSP trace includes the interface IP address, the interface type, maximum receive unit (MRU), label and protocol; as follows:

```
*A:PE-1# oam lsp-trace prefix 192.0.2.6/32 detail
lsp-trace to 192.0.2.6/32: 0 hops min, 0 hops max, 104 byte packets
1  192.0.2.2  rtt=0.590ms rc=8(DSRtrMatchLabel) rsc=1
     DS 1: ipaddr=192.168.23.2 ifaddr=192.168.23.2 iftype=ipv4Numbered MRU=1564
           label[1]=262138 protocol=3(LDP)
2  192.0.2.3  rtt=1.01ms rc=8(DSRtrMatchLabel) rsc=1
     DS 1: ipaddr=192.168.36.2 ifaddr=192.168.36.2 iftype=ipv4Numbered MRU=1564
           label[1]=262143 protocol=3(LDP)
3  192.0.2.6  rtt=2.06ms rc=3(EgressRtr) rsc=1
*A:PE-1#
```

LDP Statistics

LDP-related statistics can be collected in files. First a file needs to be configured.

```
*A:PE-1# configure log
        file-id 1
            location cf1:
            rollover 5 retention 1
        exit
```

The next step is to configure an accounting policy that will define which statistics should be recorded.

```
*A:PE-1# configure log accounting-policy 1 record
  - no record
  - record <record-name>
 <record-name>        : aa-admit-deny|aa-app-group|aa-application|aa-partition|aa-
performance|
                        aa-protocol|aa-subscriber-application|aa-subscriber-
protocol|
                        com-bined-ldp-lsp-egress|combined-mpls-lsp-egress|combined-
mpls-lsp-ingress|
                        combined-network-ing-egr-octets|combined-queue-group|
                        combined-sdp-ingress-egress|combined-service-ing-egr-octets|
                        combined-service-ingress|compact-service-ingress-
octets|complete-pm|
                        complete-sdp-ingress-egress|complete-service-ingress-egress|
                        complete-subscriber-ingress-egress|custom-record-aa-sub|
                        custom-record-service|custom-record-subscriber|network-
egress-octets|
                        network-egress-packets|network-ingress-octets|network-
ingress-packets|
                        queue-group-octets|queue-group-packets|saa|service-egress-
octets|
                        ser-vice-egress-packets|service-ingress-octets|service-
ingress-packets|video|
                        complete-ethernet-port|extended-service-ingress-egress|
                        complete-network-ing-egr
*A:PE-1#
```

As an example, the following accounting-policy is configured:

```
*A:PE-1# configure log
        accounting-policy 1
            record combined-ldp-lsp-egress
            to file 1
            no shutdown
        exit
```

The collection of statistics for prefix 192.0.2.6/32 is enabled on PE-1 in the LDP context, as follows:

```
*A:PE-1# configure router
        ldp
```

```
            egress-statistics
                fec-prefix 192.0.2.6/32
                    collect-stats
                    accounting-policy 1
                    no shutdown
                exit
            exit
```

The following FEC egress statistics can be displayed:

```
*A:PE-1# show router ldp fec-egress-stats
  - fec-egress-stats [<ip-prefix/mask>]
  - fec-egress-stats [active] [family]
 <ip-prefix/mask>     : <ipv4-prefix>/32 | <ipv6-prefix>/128
                        ipv4-prefix    - a.b.c.d
                        ipv6-prefix    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
 <active>             : keyword
 <family>             : ipv4|ipv6
*A:PE-1#
```

The FEC egress stats for prefix 192.0.2.6/32 can be retrieved as follows:

```
*A:PE-1# show router ldp fec-egress-stats 192.0.2.6/32

===============================================================================
LDP IPv4 FEC Egress Statistics: 1
===============================================================================
*A:PE-1#
```

Statistics can be cleared as follows:

```
*A:PE-1# clear router ldp fec-egress-statistics 192.0.2.6/32
```

Debug

LDP debugging can be configured per LDP interface or per LDP peer, as follows:

```
*A:PE-1# debug router ldp
  - ldp
  - no ldp
 [no] interface       + Enable/disable and configure debugging for an LDP interface
 [no] peer            + Enable/disable and configure debugging for an LDP peer
*A:PE-1#
```

A particular peer is specified by its IPv4 or IPv6 address. It is possible to configure debugging for specific LDP events: bindings or messages, as follows:

```
*A:PE-1# debug router ldp peer 192.0.2.2
  - no peer <ip-address>
  - peer <ip-address>
 <ip-address>         : ipv4-address   - a.b.c.d
                        ipv6-address   - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                         x:x:x:x:x:x:d.d.d.d
                                         x - [0..FFFF]H
                                         d - [0..255]D
 [no] event           + Configure debugging for specific LDP events
 [no] packet          + Enable/disable debugging for specific LDP packets
*A:PE-1# debug router ldp peer 192.0.2.2 event
  - event
  - no event
 [no] bindings        - Enable/disable debugging for LDP bindings
 [no] messages        - Enable/disable debugging for LDP messages
*A:PE-1#
```

It is also possible to configure debugging for specific packets, such as label packets:

```
*A:PE-1# debug router ldp peer 192.0.2.2 packet
  - no packet
  - packet
 [no] hello           - Enable/disable debugging for LDP Hello packets
 [no] init            - Enable/disable debugging for LDP Init packets
 [no] keepalive       - Enable/disable debugging for LDP Keepalive packets
 [no] label           - Enable/disable debugging for LDP Label packets
```

The following debugging is configured on PE-1:

```
*A:PE-1# debug router ldp peer 192.0.2.2 packet label detail
```

Some label mapping packets sent to peer 192.0.2.2 are the following, with the label mapping for prefixes 192.0.2.1/32 and 192.0.2.4/32:

```
2 2016/02/18 14:18:59.71 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 7) to 192.0.2.2:0
Protocol version = 1
Label 262132 advertised for the following FECs
Prefix Address Family = 1 Prefix = 192.0.2.4/32
"
1 2016/02/18 14:18:59.71 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 6) to 192.0.2.2:0
Protocol version = 1
Label 262143 advertised for the following FECs
Prefix Address Family = 1 Prefix = 192.0.2.1/32
"
```

Conclusion

MPLS provides the capability to establish connection-oriented paths over a connectionless network.. LDP point-to-point LSPs are dynamically signaled and FRR is supported. This can greatly improve network resiliency. In this chapter, the configuration of several LDP point-to-point LSP features is given together with the associated show output which can be used to verify and troubleshoot.

LDP-SR Stitching for IPv4 Prefixes (IS-IS)

This chapter provides information about LDP-SR Stitching for IPv4 Prefixes (IS-IS).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

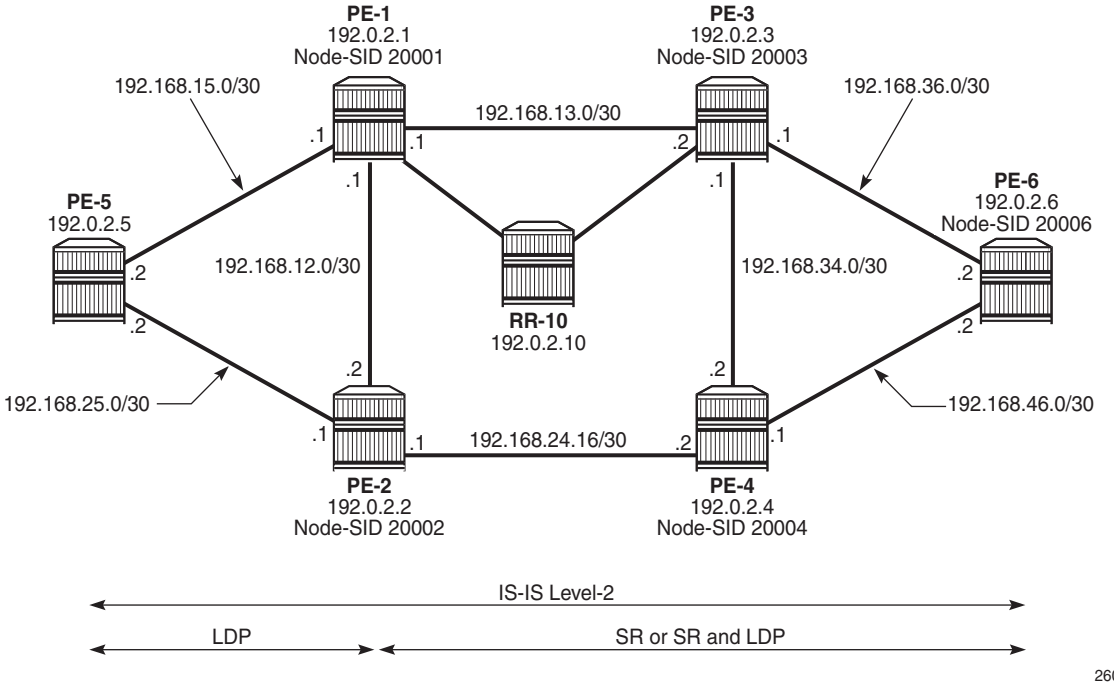
The information and configuration in this chapter is based on SR OS release 14.0.R5.

Overview

Segment Routing (SR) allows for the construction of source-routed Label Switched Paths (LSPs) where the series of hops to be taken through the network are indicated by one or more Segment Identifiers (SIDs) assigned at the ingress PE. In the case of an MPLS data plane, these SIDs are MPLS labels learned through extensions to the OSPF/IS-IS control plane. SR provides benefits to the MPLS data plane, such as high scalability (due to lack of soft-state), traffic engineering capability, and topology-independent fast reroute.

When SR is configured in an IP/MPLS network that runs the Label Distribution Protocol (LDP), it is possible that SR and LDP will coexist, in which case preference for LDP or SR is a local matter at the LSP head end. It is equally possible that not all devices will have the capability to support SR, in which case some kind of interworking between SR and LDP is necessary to create an end-to-end LSP. Fast reroute coverage can also benefit from this SR-LDP interworking function, where SR is used to increase Loop Free Alternate (LFA) coverage using Remote or Directed LFA.

This chapter describes the configuration requirements for the interworking of LDP and SR to form a single end-to-end LSP when using IS-IS as an IGP. The chapter shows how this interworking function can be used to extend fast reroute coverage for LDP-based LSPs.



Configuration

Example Topology

The topology shown in Figure 161 provides an example of SR-LDP interworking. All routers within the topology form part of Autonomous System 64496 and are IBGP clients of RR-10 for the VPN-IPv4 address family. All routers in the topology belong to the same IS-IS Level-2 area, and all link metrics are set to 100. RR-10 does not participate in any MPLS data plane, and signals the IS-IS overload bit to avoid being used for transit traffic.

PE-5 is a router that does not support SR and, therefore, runs only LDP to its connected peers PE-1 and PE-2. PE-1, PE-2, PE-3, PE-4, and PE-6 are capable of running both SR and LDP, but are initially configured to only run SR with the associated node-SIDs shown in Figure 161. When explicitly described, LDP will be enabled in conjunction with SR on these routers to show the difference between the two approaches, and to show how SR can be used as a fast reroute backup for SR primary LSPs.

Figure 161 **Example Topology**

The LDP configuration at PE-1 toward PE-5 is shown in the following output. The configuration at PE-2 is similar with the only exception being IP addressing.

```
configure
    router
        ldp
            interface-parameters
                interface "int-PE-1-PE-5" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            targeted-session
            exit
            no shutdown
        exit
```

PE-1, PE-2, PE-3, PE-4, and PE-6 run SR. The following output provides an example of the relevant SR configuration parameters at PE-1, with similar configurations on the remaining SR routers. For an explanation of these parameters, see chapter Segment Routing with IS-IS Control Plane.

```
configure
    router Base
        mpls-labels
            sr-labels start 20000 end 20099
        exit
        isis 0
            advertise-router-capability as
            interface "system"
                level-capability level-2
                ipv4-node-sid label 20001
                passive
                no shutdown
            exit
            segment-routing
                prefix-sid-range start-label 20000 max-index 99
                no shutdown
            exit
            no shutdown
        exit
```

SR Mapping Server

An SR Mapping Server (SR-MS) is an integral part of SR-LDP interoperability and has the responsibility for advertising prefixes to SID/label mappings on behalf of routers that do not support SR. When using IS-IS, a SID/label-binding TLV (TLV 149) containing a prefix-SID sub-TLV is used to advertise one or more SID index/labels and one or more prefixes. In the example topology, PE-4 is selected as the SR-MS and will advertise a prefix SID for the non-SR-capable router, PE-5.

The following output provides an example of the configuration required to implement SR-MS functionality. Under the **segment-routing** node, a **mapping-server** context is created that allows for origination of a SID/label-binding TLV and prefix-SID sub-TLV. The syntax begins with **sid-map node-sid** and is followed by an index. In SR OS, prefix-SIDs are always advertised with an index value (as opposed to an absolute label value), and the formula {start-label + SID index} is used to derive the label value. In this example, **index 5** is used and, therefore, the derived label value is {20000+5} 20005 for the PE-5 prefix 192.0.2.5/32.

An optional **range** argument allows for advertisement of a contiguous range of prefixes and associated SIDs using the configured index/prefix as the beginning of the range. Non-contiguous ranges require multiple entries and are advertised as separate SID/label-binding TLVs. An additional optional **set-flags s** argument can also be used to set the S-flag, which controls the flooding scope. When set, the flooding scope is the entire IS-IS domain. When not set, the flooding scope is the IS-IS level into which the TLV was advertised.

```
configure
    router
        isis 0
            segment-routing
                prefix-sid-range start-label 20000 max-index 99
         mapping-server
                    sid-map node-sid index 5 prefix 192.0.2.5/32
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The relevant part of the IS-IS LSP generated by PE-4, showing the SID/label-binding TLV, is shown in the following output:

```
*A:PE-4# show router isis database PE-4.00-00 detail
===============================================================================
Rtr Base ISIS Instance 0 Database (detail)
===============================================================================

---snip---
```

At other routers within the SR domain, the presence of the advertised prefix can be validated as shown in the following output taken at PE-1. The SRMS field is set to Y for prefix 192.0.2.5/32, indicating that the prefix was advertised by an SR-MS. (In the case of IS-IS, the prefix-SID is a sub-TLV of the SID/label-binding TLV and the "N" (node-SID) flag is set; therefore, it can be recognized as being advertised by a mapping server.) The Y is followed by an "(S)" flag, indicating that the SRMS prefix-SID is selected to be programmed. This indication is provided in case there are multiple advertisements for the same prefix and/or node-SID from different SR mapping servers that result in some kind of conflict or inconsistency. If there are multiple mapping servers advertising the same prefix-SID, the advertising router with the lowest system/router ID is preferred.

```

SR-LDP Interworking

Interworking SR and LDP essentially consists of stitching an LDP FEC and an SR node-SID route for the same prefix. In the example topology, PE-1 and PE-2 will act as the SR-LDP interworking nodes.

In the LDP-to-SR data plane direction, LDP uses an **export-tunnel-table** command under the **ldp** context to reference a policy that defines which prefixes should be redistributed from the IS-IS/SR domain into LDP. When applied, the LDP process monitors the tunnel-table until it locates a /32 SR tunnel of type sr-isis that matches a prefix defined in the export policy. LDP then programs an LDP Incoming Label Map (ILM) entry and stitches it to the SR node-SID tunnel endpoint. The LDP process also originates a FEC for the prefix and advertises that FEC to its peers.

The following output provides an example of the route policy and application of the policy at PE-1. In this policy, PE-1 advertises LDP FECs to PE-5 for PE-3 (192.0.2.3), PE-4 (192.0.2.4), and PE-6 (192.0.2.6), provided that PE-1 has a /32 SR tunnel of type sr-isis in the tunnel-table for those same prefixes. PE-1 also programs an LDP ILM entry for each prefix and stitches it to the appropriate SR tunnel. An identical configuration exists at PE-2.

```
configure
    router
        policy-options
            begin
            prefix-list "sr-domain"
                prefix 192.0.2.3/32 exact
                prefix 192.0.2.4/32 exact
                prefix 192.0.2.6/32 exact
            exit
            policy-statement "SR-to-LDP"
                entry 10
                    from
                        protocol isis
                        prefix-list "sr-domain"
                    exit
                    to
                        protocol ldp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

```
        ldp
            export-tunnel-table "SR-to-LDP"
            interface-parameters
                interface "int-PE-1-PE-5" dual-stack
                    ipv4
                        no shutdown
                    exit
                    no shutdown
                exit
            exit
            no shutdown
        exit
```

In the SR-to-LDP data plane direction, the **export-tunnel-table ldp** command within the **segment-routing** context is the only required configuration. Unlike the LDP-to-SR data plane direction, where policy is used to control which prefixes are stitched, in the SR-to-LDP direction, no policy is explicitly referenced because the SR-MS provides a network-wide policy for the prefixes that SR needs to stitch to a corresponding LDP FEC. With the **export-tunnel-table ldp** command applied, whenever a /32 LDP tunnel destination matches a prefix for which a prefix-SID sub-TLV was received from a mapping server, the SR ILM is stitched to the corresponding LDP tunnel endpoint.

The following output shows the configuration applied at PE-1 to implement SR-to-LDP data plane interworking:

```
configure
    router
        isis 0
            segment-routing
                export-tunnel-table ldp
                no shutdown
            exit
            no shutdown
        exit
```

With the required configuration in the SR-LDP interworking routers (PE-1 and PE-2), it is possible to validate the correct ILM entries. In the LDP-to-SR data plane direction, the following output shows the active LDP bindings at PE-1. Each of the entries for PE-3 (192.0.2.3), PE-4 (192.0.2.4), and PE-6 (192.0.2.6) have an "(I)" flag to indicate that the prefix has an SR-ISIS next-hop. Each entry also has an ingress label and an egress label. The ingress label represents the LDP FEC advertised for the corresponding prefix (in this case, advertised only to PE-5). The egress label represents the SR node-SID for the same prefix. Therefore, a mapping exists between LDP FEC and SR node-SID.

```

In the SR-to-LDP data plane direction, the following output, taken at PE-1, shows a dump of the SR database for next-hops resolved to LDP. There is a single entry with index 5 (label value 20005) advertised by the SR-MS for the PE-5 prefix 192.0.2.5. The final line of the entry shows that an LDP FEC is the SID next-hop for SR-LDP stitching. The tunnel LSP ID is 65537. The tunnel-table verifies that this is an LDP tunnel to PE-5 (192.0.2.5).

LDP = LDP FEC is the SID NH for SR-LDP stitching
===============================================================================
*A:PE-1#
```

To verify that the data plane is intact from end-to-end, a VPRN service is configured at the non-SR-capable PE-5 and the SR-capable PE-6, each with a locally configured subnet that is used to test IP connectivity. The configuration of the VPRN at PE-5 is shown in the following output. The **auto-bind-tunnel** configuration uses a resolution filter allowing only **ldp** to be used to resolve BGP next-hops for VPN-IPv4 routes. Usually, this could be configured for **resolution any**, but this configuration shows that LDP is being used. The local IP address at PE-5 is 172.31.5.1/24.

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
            auto-bind-tunnel
                resolution-filter
                    ldp
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "Local-Subnet" create
                address 172.31.5.1/24
                sap 1/1/1:1 create
                exit
            exit
            no shutdown
        exit
```

The configuration of the VPRN at PE-6 is shown in the following output. Again, the **auto-bind-tunnel** configuration uses a resolution filter, but this time it is configured for **sr-isis**. It could be set to **resolution any**, so that the tunnel-table preference would resolve an LSP with the lowest preference/metric, but the resolution filter configuration again shows that SR is being used. The **auto-bind-tunnel** context allows the transport mechanism to be a local decision at service level. The local IP address at PE-6 is 172.31.6.1/24.

Note: An alternative approach would be to configure the auto-bind-tunnel context for **resolution any**, then modify the tunnel-table preference for SR using the **tunnel-table-pref** command in the **segment-routing** context.

```
configure
    service
        vprn 1 customer 1 create
            route-distinguisher 64496:1
```

```
            auto-bind-tunnel
                resolution-filter
                    sr-isis
                exit
                resolution filter
            exit
            vrf-target target:64496:1
            interface "Local-Subnet" create
                address 172.31.6.1/24
                sap 1/1/2:1 create
                exit
            exit
            no shutdown
        exit
```

A VPRN ping between 172.31.5.1 at PE-5 and 172.31.6.1 at PE-6 verifies that the data plane is intact:

```
*A:PE-5# ping router 1 172.31.6.1 source 172.31.5.1

round-trip min = 6.54ms, avg = 7.47ms, max = 9.98ms, stddev = 1.26ms
```

SR and LDP Coexistence

The previous example demonstrates the use of SR-LDP interworking when the SR domain runs only SR. A more common scenario is that SR will coexist with LDP, because LDP is already deployed and the SR deployment will be added. In this sub-section, PE-1, PE-2, PE-3, PE-4, and PE-6 are configured to run LDP in conjunction with SR. PE-5 remains the same as the previous sub-section in that it runs only LDP to its connected peers PE-1 and PE-2.

In the SR-to-LDP data plane direction, there is no notable change when LDP coexists in the SR domain. Whenever a /32 LDP tunnel destination matches a prefix for which a prefix-SID sub-TLV was received from a mapping server, the SR ILM is stitched to the corresponding LDP tunnel endpoint.

In the LDP-to-SR data plane direction, there is a significant change. If only SR is running within the SR domain, the LDP process monitors the tunnel-table and when a /32 SR tunnel of type sr-isis is found that matches a prefix in the (**export-tunnel-table**) export policy, LDP programs an LDP ILM and stitches it to the SR node-SID tunnel endpoint. However, if an LDP FEC exists for the same /32 prefix, SR OS will resolve the LDP ILM entry to the LDP FEC. This is because LDP attempts to resolve the prefix in the route table first before looking in the tunnel-table and, therefore, prefers the LDP tunnel to the SR tunnel.

The following output is taken at PE-1 when LDP and SR coexist in the SR domain. The previous version of this output (when LDP was not running in the SR domain) showed the prefixes for PE-3, PE-4, and PE-6 as known via an SR-ISIS next-hop, and the egress labels as node-SIDs. When LDP is active in conjunction with SR, the egress labels resolve to an LDP FEC.

===============================================================================
```

That the LDP-to-SR data path resolves to LDP FECs rather than SR tunnels may result in an asymmetric data path. Taking the previously used VPRN service between PE-5 and PE-6 as an example:

- Traffic from PE-6 to PE-5 will use SR between PE-6 and one of the SR-LDP interworking gateways at PE-1 or PE-2, after which it will use LDP.
- Traffic from PE-5 to PE-6 will use LDP between ingress and egress. The interworking function between SR and LDP has no effect.

Both directions still use an MPLS data plane. However, the MPLS control plane differs in each direction.

LDP Fast Reroute using SR Tunnels

With the ability to interwork LDP and SR, primary LSPs signaled using LDP can select a remote LFA SR tunnel as backup. This provides the potential to increase fast reroute coverage. As with any other backup or fast reroute mechanism, the SR backup tunnel can be installed in the forwarding database before any failure, but can only be activated when the failure of the primary path has been detected.

The ability to detect a failure quickly forms a significant part of the overall recovergence time and may require the use of failure detection mechanisms, such as Bidirectional Forwarding Detection (BFD), the 802.3ah Ethernet in the First Mile (EFM), or just loss of signal (LoS). These mechanisms are beyond the scope of this chapter.

To use SR as a backup for LDP, the **fast-reroute backup-sr-tunnel** command must be configured in the **ldp** context. The **export-tunnel-table** command previously described should also be present, and should reference a policy including all of the prefixes for which backup is required. There is no requirement for an SR-MS when using SR tunnels for LDP backup, nor is there a requirement to enable SR-to-LDP interworking using the **export-tunnel-table ldp** command within the **segment-routing** context.

The following output shows the configuration applied at PE-6. When this configuration is applied, if the LFA SPF does not find an adjacent IP next-hop prefix for an LDP FEC, but can compute a remote LFA tunnel next-hop, LDP programs the LDP FEC using an LDP Next-Hop Label Forwarding Entry (NHLFE), and a backup next-hop using an LDP NHLFE pointing to the SR tunnel endpoint. The LDP packet is not tunneled over the SR tunnel, but rather the LDP label is stitched to the segment-routing label stack. This behavior is similar to the LDP-SR interworking function previously described within this chapter, but is modified such that the stitching of an LDP ILM entry to an SR tunnel only takes place if no adjacent LFA next-hop could be found for the prefix.

```
configure
    router Base
        isis
            loopfree-alternate remote-lfa
        exit
        ldp
            export-tunnel-table "SR-to-LDP"
            fast-reroute backup-sr-tunnel
        exit
        policy-options
            begin
            prefix-list "sr-domain"
                prefix 192.0.2.0/24 longer
            exit
            policy-statement "SR-to-LDP"
                entry 10
                    from
                        protocol isis
                        prefix-list "sr-domain"
                    exit
                    to
                        protocol ldp
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

With the preceding configuration in place at PE-6, it is possible to verify whether a backup exists for a specific prefix, using the command shown in the following output. In this example, the backup is displayed for the PE-6 adjacent neighbor PE-3 (192.0.2.3). There are two LSPs for the prefix 192.0.2.3/32; one is known via LDP and one is known via SR-ISIS, indicated in the protocol column. The entries are defined as follows:

- The first line of the LDP entry is the primary LSP with a next-hop of 192.168.36.1 using interface 1/1/2:100 (direct to PE-3).
- The second line of the LDP entry is the backup indicated by a "(B)" flag, with a next-hop of 192.168.46.1 using interface 1/1/1:100 (via PE-4). This backup is a basic LFA, which is possible to compute due to the example topology, or more explicitly the triangular mesh between PE-6, PE-4, and PE-3. Due to this topology, if the link between PE6 and PE3 fails, PE-6 can forward packets destined for PE-3 toward PE-4. PE-4 will then forward them directly toward PE-3, not return them to PE-6 (which would create a transient micro-loop until the next SPF is run).
- The first line of the SR-ISIS entry is the primary LSP with a next-hop of 192.168.36.1 using interface 1/1/2:100 (direct to PE-3).
- The second line of the SR-ISIS entry is the backup LSP indicated by the "(B)" flag, with a next-hop of 192.168.46.1 using interface 1/1/1:100 (via PE-4). Both the primary and backup LSPs use the label 20003, representing the PE-3 node-SID. As with the LDP backup entry, the SR-ISIS backup is a basic LFA.

```

To show the benefits that SR provides in increasing fast reroute coverage, the link between PE-4 and PE-3 is removed from the example topology, creating a ring topology. With this link removed, it is no longer possible for PE-6 to compute a basic LFA to PE-3 for the link between PE-6 and PE-3. If that link failed and PE-6 forwarded packets destined for PE-3 toward PE-4, PE-4 would return them to PE-6 until the next SPF was complete. Therefore, a backup tunnel is needed to a place in the network that will not loop packets back; essentially a remote LFA.

The following output at PE-6 shows the primary and backup LSPs for PE-3 (192.0.2.3) with the modified topology. Again there are two LSPs: one known through via LDP and one known via SR-ISIS. The entries are defined as follows:

- The first line of the LDP entry is the primary LSP with a next-hop of 192.168.36.1 using interface 1/1/2:100 (direct to PE-3).
- The second line of the LDP entry is the backup indicated by a "(B)" flag with a next-hop of 192.0.2.3 (PE-3), which uses an SR tunnel. The label of "3" (implicit-null) indicates that the LDP label is not tunneled through the SR tunnel, but rather popped before the primary LDP LSP is stitched to the backup SR LSP.
- The first line of the SR-ISIS entry is the primary LSP with a next-hop of 192.168.36.1 using interface 1/1/2:100 (direct to PE-3). This LSP assigns a single label of value 20003, representing the node-SID of PE-3.
- The second line of the SR-ISIS entry is the backup indicated by a "(B)" flag with a next-hop of 192.168.46.1 using interface 1/1/1:100 (via PE-4). There are two labels assigned to this backup tunnel. The upper label has a value of 20002, which represents the node-SID of PE-2. This is the remote LFA "PQ-node". The second label has a value of 20003, which represents the node-SID of the destination, PE-3.

  When this backup tunnel is operational, PE-6 encapsulates traffic destined for PE-3 to a point in the network where it will not be looped back toward the source. In the example topology, that node is PE-2. When traffic arrives at PE-2, it pops the top label (20002) and forwards traffic for PE-3 (with label 20003) on the shortest path toward the destination.

Conclusion

The SR control plane can (and likely will) coexist with other MPLS control plane clients, such as RSVP, LDP, or BGP. It is possible that these control plane clients will operate independently. However, where a mix of SR-capable and non-SR-capable routers exist within the same domain, SR-LDP interworking is necessary to form an end-to-end LSP. This chapter shows how that is possible using one or more SR mapping servers and one or more interworking routers.

SR-LDP interworking also provides an opportunity to increase fast reroute coverage in LDP-based networks. Before the introduction of SR-LDP interworking, a remote LFA could only be constructed using LDP-over-RSVP, which required the RSVP LSP to be manually configured and placed. When SR-LDP interworking is used, primary LDP LSPs can use a backup tunnel to a remote LFA signaled using SR. This requires no manual configuration, which provides the potential to greatly increase fast reroute coverage with minimal effort.

MPLS LDP FRR using ISIS as IGP

This chapter describes multiprotocol label switching (MPLS) label distribution protocol (LDP) fast reroute (FRR) using intermediate system to intermediate system (IS-IS) as the interior gateway protocol (IGP).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

MPLS label distribution protocol fast reroute (LDP FRR) is supported on all 7x50 platforms. This feature is supported on all input/output modules (IOMs), integrated media modules (IMMs), media dependent adapter (MDA), and compact media adapter (CMA) types that support network interfaces from 9.0.R4 and higher. This chapter was originally written for and tested on release 9.0.R6, but the CLI in this edition corresponds to release 14.0.R1. There are no prerequisites for this configuration.

Overview

LDP FRR improves convergence in case of a single link or single node failure in the network. Convergence times will be in the order of tens of milliseconds. This is important to some application services, such as voice over IP (VoIP), which are sensitive to traffic loss when running over the MPLS network.

Without FRR, link and/or node failures inside an MPLS LDP network result in traffic loss in the order of hundreds of milliseconds. The reason for that is that LDP depends on the convergence of the underlying IGP (IS-IS sending link state PDUs (LSPs) in this case). After IGP convergence, LDP itself needs to compute new primary next hop label forwarding entries (NHLFEs) for all affected forwarding equivalence classes (FECs). Finally, the different label forwarding information bases (LFIBs) are updated.

When FRR is configured on a node, the node pre-computes primary NHLFEs for all FECs and in addition it will pre-compute backup NHLFEs for all FECs. The backup NHLFE corresponds to the label received for the same FEC from a Loop-Free Alternate (LFA) next-hop (see also RFC 5286, *Basic Specification for IP Fast Reroute: Loop-Free Alternates*). Both primary NHLFEs and backup NHLFEs are programmed in the IOM/IMM which makes it possible to converge very quickly.

The SROS software has implemented Inequality 1 (link criterion) and Inequality 3 (node criterion) of RFC 5286. Similar to the shortest path tree (SPT) computation that is part of standard link-state routing functionality, also the LFA next-hop computation is based on the IGP metric.

The underlying LFA formulas appear in the following format:

Inequality 1:

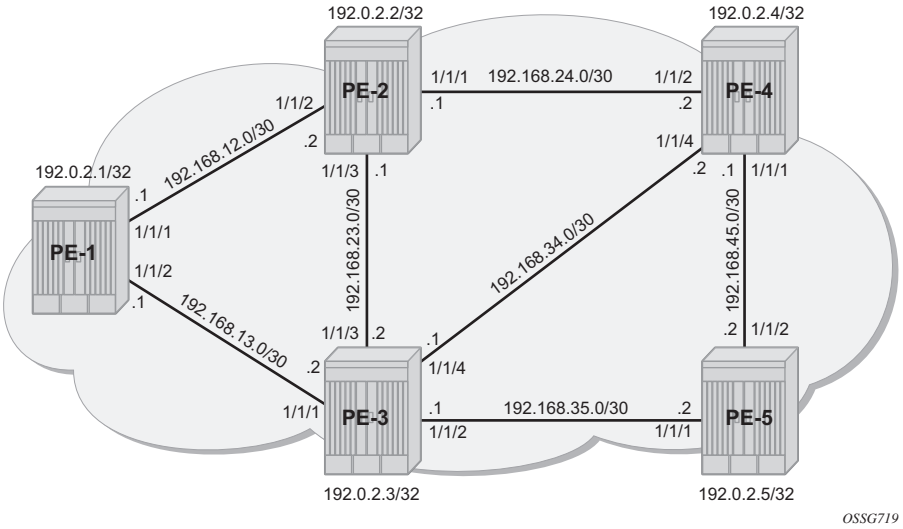
- SP(backup NHR, D) < {SP(backup NHR, S) + SP(S, D)}

Inequality 3:

- SP(backup NHR, D) < {SP(backup NHR, PN) + SP(PN, D)}

In these inequalities ‘SP’ is ‘shortest IGP metric path’, ‘NHR’ is ‘next hop router’, ‘D’ is ‘destination’, ‘S’ is ‘source node or upstream node doing the actual LFA next-hop computation’, and ‘PN’ is ‘protected node’. The inequality 3 rule is stricter than the inequality 1 rule. See Additional Topics for a practical example on these inequalities.

Configuration



This section provides information to configure:

- Configure the IP/MPLS network
- Enable LDP FRR and Verification
- Enable Synchronization Timer
- Data Path Verification

Additional topics include:

- Metric Change
- IS-IS Overload Bit

Figure 162 **Initial Topology**

Configure the IP/MPLS network

The system addresses and IP interface addresses are configured according to Figure 162. An interior gateway protocol (IGP) is needed to distribute routing information on all PEs. In our case, the IGP is IS-IS where each PE is acting as a level 2 router. A configuration example is shown for PE-1. Similar configurations can be derived for the other PEs.

```
*A:PE-1# configure router
        isis
            level-capability level-2
            level 2
                wide-metrics-only
            exit
            interface "system"
            exit
            interface "int-PE-1-PE-2"
                interface-type point-to-point
            exit
            interface "int-PE-1-PE-3"
                interface-type point-to-point
            exit
```

IS-IS interfaces are set up as type point-to-point to improve convergence since no designated router/backup designated router (DR/BDR) election process is done. To verify that IS-IS adjacencies are up, **show router isis adjacency** is performed. To check if IP interface addresses/subnets are known on all PEs, **show router route-table** or **show router fib** *slot-number* will display the content of the forwarding information base (FIB).

===============================================================================
*A:PE-1#
```

Initially, the default IS-IS Level 2 metric is applied on all interfaces (value 10).

```
*A:PE-1# show router isis status | match "L2 Default Metric"
L2 Default Metric    : 10
*A:PE-1#
```

The next step in the process of setting up the IP/MPLS network is setting up interface-LDP sessions on all interfaces. If the keyword dual-stack and ipv4 no shutdown isn't included in the command, as is the case for interface "int-PE-1PE-2", it will be added automatically.

```
*A:PE-1# configure router
        ldp
            interface-parameters
                interface "int-PE-1-PE-2"
                exit
```

```
                interface "int-PE-1-PE-3" dual-stack
                    ipv4
                        no shutdown
                    exit
                exit
            exit
            targeted-session
            exit
            no shutdown
        exit all
```

There is now a full mesh of LDP label switched paths (LSPs) set up between all system interfaces of the PEs, and the tunnel table on PE-1 will look like this:

```
*A:PE-1# show router tunnel-table

===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------

Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

The LDP LSP metric follows the IGP cost. Optionally, LSP metrics can be applied but that is out of the scope for this chapter.

Enable LDP FRR and Verification

Because LDP FRR is using LFA next-hop pre-computation by the IGP (as described in RFC 5286), the IGP CLI configuration is as follows:

```
*A:PE-1# configure router isis loopfree-alternate
*A:PE-1# show router isis status | match Loopfree
Loopfree-Alternate   : Enabled
*A:PE-1#
```

After enabling LFA inside the IGP context, FRR needs to be enabled within the LDP context:

```
*A:PE-1# configure router ldp fast-reroute
*A:PE-1# show router ldp status | match FRR
FRR                : Enabled              Mcast Upstream FRR   : Disabled
*A:PE-1#
```

This chapter describes FRR for unicast LDP. For multicast upstream FRR, see chapter Multicast Label Distribution Protocol. After these two CLI commands, the software pre-computes for each LDP FEC in the network both a primary and a backup NHLFE and uploads it to the IOM/IMM. The primary NHLFE corresponds to the label of the FEC received from the primary next-hop as per standard LDP resolution of the FEC prefix in the Routing Table Manager (RTM). The backup NHLFE corresponds to the label received for the same FEC from an LFA next-hop.

For point-to-point interfaces, when multiple LFA next-hops are found for a given primary next-hop, the following selection criteria are used:

- It will pick the node-protect type in favor of the link-protect type.
- If there is more than one LFA next-hop within the selected type, then it will pick one based on the lowest cost.
- If more than one LFA next-hop with the same cost, SPF will select the first one. This is not a deterministic selection and will vary following each SPF calculation.

Several show commands are possible to display LFA information:

The **show router isis statistics** command displays the number of LFA runs on a specific node.

```
*A:PE-1# show router isis statistics
===============================================================================
Rtr Base ISIS Instance 0 Statistics
===============================================================================
---snip---
LFA Statistics
LFA Runs          : 20
 Last scheduled   : 03/10/2016 08:58:54
Partial LFA Runs  : 1
 Last scheduled   : 03/10/2016 08:53:11

RLFA Statistics
RLFA Runs         : 0
---snip---
```

Remote LFA (RLFA) is related to segment routing and is described in chapter Segment Routing with IS-IS Control Plane.

The **show router isis lfa-coverage** command performs a mathematical calculation between the number of nodes and IPv4/IPv6 routes in the network versus present LFA next-hop protections. In our network (see Figure 162), all IS-IS links have a default level 2 metric of 10. This results in all four nodes and all IS-IS routes learned by PE-1 being 100% LFA protected (link or node). See the following output:

```
*A:PE-1# show router isis lfa-coverage
===============================================================================
Rtr Base ISIS Instance 0 LFA Coverage
===============================================================================
```

```

===============================================================================
*A:PE-1#
```

On PE-1, PE-4 (192.0.2.4/32) has a primary SPF next-hop pointing toward PE-2 (192.168.12.2) and an LFA next-hop pointing toward PE-3 (192.168.13.2).

Using the Inequality 3 formula on PE-1 for prefix 192.0.2.4/32, this becomes:

Inequality 3:

- [SP(backup NHR, D) < {SP(backup NHR, PN) + SP(PN, D)}] or
  [SP (PE-3, PE-4) < {SP (PE-3, PE-2) + SP(PE-2, PE-4)}] or
  [10 < {10 + 10}]

This means that Inequality 3 is met. The calculated LFA next-hop for prefix 192.0.2.4/32 on PE-1 is protecting node PE-2, see Figure 162 for a graphical representation.

The **show router ldp bindings** command displays the label information base (LIB). A BU flag is present in case the associated label is used as backup NHLFE for the given prefix. As an example, a display on PE-1 for prefix PE-4 is as follows.

This is only possible because the 7x50 LDP implementation is using liberal retention mode which means that every label mapping received by a peer is retained regardless of whether the LSR is the next-hop for the advertised mapping.

```
*A:PE-1# show router ldp bindings prefixes prefix 192.0.2.4/32

Enable Synchronization Timer

Within an MPLS network using LDP it is common practice to enable a synchronization timer between LDP and the IGP. Also when LDP FRR is enabled, a situation can occur in which a synchronization timer between IGP and LDP will help: the revert scenario. When the interface for the previous primary next hop is restored, IGP may re-converge before LDP completed the FEC exchange with its neighbor over that interface. This may cause LDP to remove the LFA next-hop from the FEC and blackhole traffic.

In order to avoid these situations, it is recommended to first enable IGP-LDP synchronization on the LDP interface. The time is expressed in seconds and can have a value between 1 and 1800 seconds. The LDP synchronization timer is enabled as follows:

```
*A:PE-1# configure router interface "int-PE-1-PE-2" ldp-sync-timer 10
*A:PE-1# configure router interface "int-PE-1-PE-3" ldp-sync-timer 10
```

The configuration on the other nodes is similar.

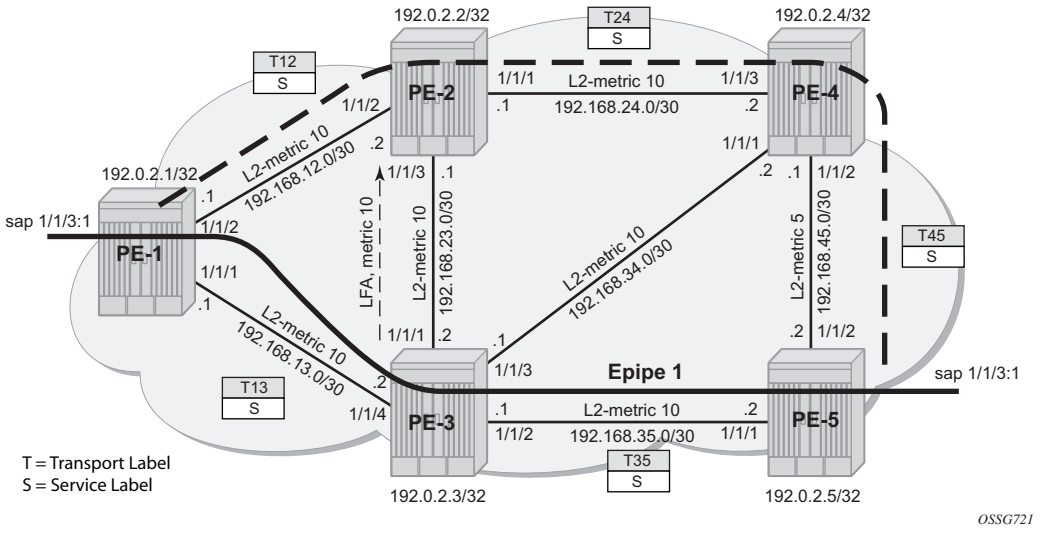
When this timer is enabled, it means that when an interface is restored again, the IGP will advertise this link in the network with an infinite metric. The **ldp-sync-timer** is started, LDP adjacencies are brought up together with a label exchange. After the **ldp-sync-timer** expires, the normal metric is advertised in the network again.

Data Path Verification

Data path verification is performed using a Layer 2/VLL service. Traffic generator ports are connected toward PE-1 and PE-5, and an Epipe service is created using an MPLS LDP based service distribution path (SDP) on both PE-1 and PE-5.

```
*A:PE-1# configure service
        sdp 15 mpls create
            far-end 192.0.2.5
            ldp
            no shutdown

*A:PE-1# configure service
        epipe 1 customer 1 create
            service-mtu 1450
            sap 1/1/3:1 create
            exit
            spoke-sdp 15:1 create
            exit
            no shutdown
```



A similar configuration is configured on PE-5.

The IS-IS Level 2 metric value on the interface between PE-4 and PE-5 is decreased to 5, see Figure 163.

```
*A:PE-4# configure router isis interface int-PE-4-PE-5 level 2 metric 5

*A:PE-5# configure router isis interface int-PE-5-PE-4 level 2 metric 5
```

Figure 163 **Data Verification, Direction PE-1 => PE-5 Using VLL Service**

In this setup, there is a loopfree alternate for prefix PE-5 from PE-1 that is protecting the node PE-3:

```

```

Additional Topics

Metric Change

Restore all the level 2 metrics back to their default value (10) before applying further changes:

```
*A:PE-4# configure router isis interface "int-PE-4-PE-5" level 2 no metric
*A:PE-5# configure router isis interface "int-PE-5-PE-4" level 2 no metric
```

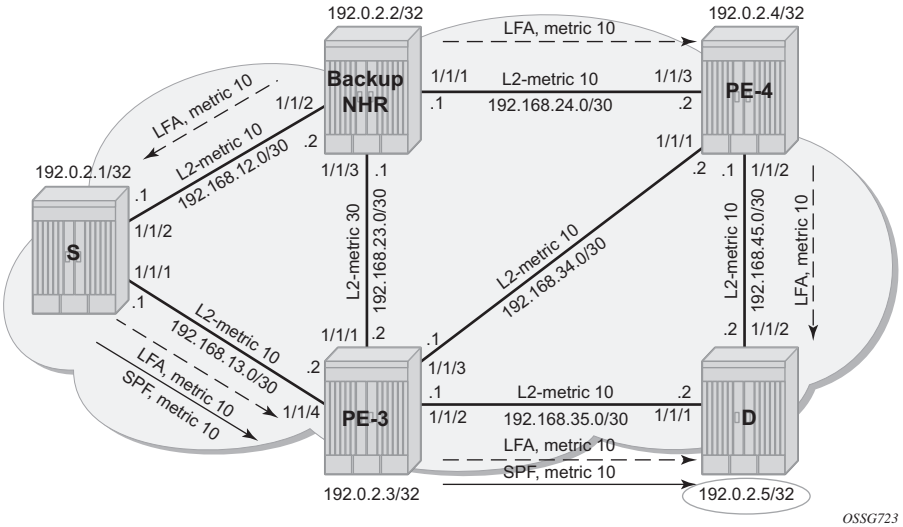
Suppose that the IS-IS level 2 metric between PE-2 and PE-3 changes to 30, then 100% LFA coverage is no longer possible. The IS-IS level 2 metric is modified as follows:

```
*A:PE-3# configure router isis interface "int-PE-3-PE-2" level 2 metric 30
*A:PE-2# configure router isis interface "int-PE-2-PE-3" level 2 metric 30
```

On PE-1, Inequality 3 formula will find LFA next-hop coverages for prefix PE-4 and PE-5. Inequality formula 1 will find LFA next-hop coverages for prefix PE-4, PE-5, and the subnet between PE-4 and PE-5.

Both inequality formulas are visualized in Figure 165 and Figure 164 for prefix 192.0.2.5/32 (= PE-5) on PE-1 which serves as the source node for LFA next-hop computation.

Figure 164 **LFA Computation, Inequality 1 for Prefix PE-5 (D) on PE-1 (S)**



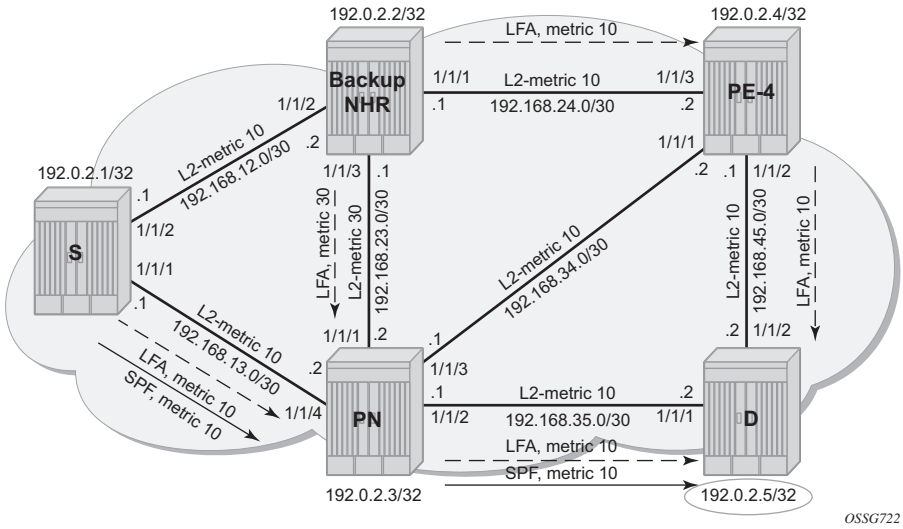


Figure 165 **LFA Computation, Inequality 3 for Prefix PE-5 (D) on PE-1 (S)**

Inequality 3 formula:

- [SP(backup NHR, D) < {SP(backup NHR, PN) + SP(PN, D)}]

For a node LFA next-hop calculation of prefix 192.0.2.5/32 (D) on PE-1, this means that the shortest path from backup next-hop router PE-2 toward destination PE-5 must be smaller than the sum of the shortest path from backup next-hop router PE-2 toward protected node PE-3 with the shortest path from protected node PE-3 to destination PE-5

The shortest path from backup next-hop router PE-2 toward destination PE-5 is going via PE-4, using IS-IS level 2 metric 10 for interface “int-PE-2-PE-4” and IS-IS level 2 metric 10 for interface “int-PE-4-PE-5”. The shortest path from backup next-hop router (PE-2) toward protected node (PE-3) uses IS-IS level 2 metric 30 for interface “int-PE-2-PE-3”. The shortest path from protected node (PE-3) to destination (PE-5) uses IS-IS level 2 metric 10 for interface “int-PE-3-PE-5”. The calculation is as follows:

```
Prefix 192.0.2.5/32: SP (PE-2, PE-5) < SP (PE-2, PE-3) + SP (PE-3, PE-5)
                           10 + 10  < 30 + 10 => OK
```

Inequality 1 formula:

- SP(backup NHR, D) < {SP(backup NHR, S) + SP(S, D)}

For a link LFA next-hop calculation of prefix 192.0.2.5/32 (D) on PE-1, this means that the shortest path from backup next-hop router PE-2 toward destination PE-5 must be smaller than the sum of the shortest path from backup next-hop router PE-2 toward source PE-1 with the shortest path from source PE-1 to destination PE-5.

The shortest path from backup next-hop router PE-2toward destination PE-5 is going over PE-4, using IS-IS level 2 metric 10 for interface “int-PE-2-PE-4” and IS-IS level 2 metric 10 for interface “int-PE-4-PE-5”. The shortest path from backup next-hop router PE-2 toward source PE-1 uses IS-IS level 2 metric 10 for interface “int-PE-2-PE-1”. The shortest path from source PE-1 to destination PE-5 follows the normal SPF calculation, going over PE-3, using IS-IS level 2 metric 10 for interface “int-PE-1-PE-3”, and IS-IS level 2 metric 10 for interface “int-PE-3-PE-5”.

The calculation is as follows:

```
Prefix 192.0.2.5/32 :  SP(PE-2,PE-5) < SP(PE-2,PE-1) + SP(PE-1,PE-5)
                          10 + 10    <    10 + (10 + 10)            => OK
```

For completeness, all the other Inequality 1 calculations on PE-1 are given:

```
Prefix 192.0.2.2/32 :  SP(PE-3,PE-2) < SP(PE-3,PE-1) + SP(PE-1,PE-2)
                             30     <      10 + 10                    => NOK
Prefix 192.0.2.3/32 :  SP(PE-2,PE-3) < SP(PE-2,PE-1) + SP(PE-1,PE-3)
                             30     <      10 + 10                    => NOK
Prefix 192.0.2.4/32 :  SP(PE-3,PE-4) < SP(PE-3,PE-1) + SP(PE-1,PE-4)
                             10     <      10 + (10 + 10)             => OK
Prefix 192.168.23.0/30 :  SP(PE-3,D) < SP(PE-3,PE-1) + SP(PE-1,D)
                             30     <      10 + (10 + 10)             => NOK
```

```
Prefix 192.168.24.0/30 :  SP(PE-3,D) < SP(PE-3,PE-1) + SP(PE-1,D)
                           30 + 10   <      10 + (10 + 10)               => NOK
Prefix 192.168.34.0/30 :  SP(PE-2,D) < SP(PE-2,PE-1) + SP(PE-1,D)
                           30 + 10   <      10 + (10 + 10)               => NOK
Prefix 192.168.35.0/30 :  SP(PE-2,D) < SP(PE-2,PE-1) + SP(PE-1,D)
                           30 + 10   <      10 + (10 + 10)               => NOK
Prefix 192.168.45.0/30 :  SP(PE-3,D) < SP(PE-3,PE-1) + SP(PE-1,D)
                           10 + 10   <      10 + (10 + 10 + 10)          => OK
```

Considering all inequality 1 calculations, only three of these are valid (OK).

In SR OS, the following summary command exists for LFA coverage on the router:

```
*A:PE-1# show router isis lfa-coverage
===============================================================================
LFA Coverage
===============================================================================

===============================================================================
*A:PE-1#
```

Restore all the IS-IS level 2 metrics back to the default value as follows:

```
*A:PE-2# configure router isis interface "int-PE-2-PE-3" level 2 no metric
*A:PE-3# configure router isis interface "int-PE-3-PE-2" level 2 no metric
```

IS-IS Overload Bit

As stated in RFC 3137, O*SPF Stub Router Advertisement*, sometimes it is useful and desirable for a router not to be a transit node. For those cases, it is also desirable not to have that router used as transit node during the LFA next-hop computation. Within IS-IS protocol this is achieved by setting the overload bit. When other routers detect that this bit is set, they will only use this router for packets destined to the overloaded router's directly connected networks and IP prefixes.

As an example, setting the IS-IS overload condition for a specific time on PE-2 provides following result on PE-1:

```
*A:PE-2# configure router isis overload
  - no overload
  - overload [timeout <seconds>] [max-metric]
```

```
 <seconds>            : [60..1800]

*A:PE-2# configure router isis overload timeout 60

*A:PE-1# show router isis lfa-coverage

```

On PE-1, only three Inequality 1 calculations are possible, as seen in the previous show commands. The Inequality 1 calculation on PE-1 for destination 192.168.24.0/30 is as follows:

```
[SP(backup NHR,D) < {SP(backup NHR,S) + SP(S,D)}]
      SP(PE-3,D) <  SP(PE-3,PE-1) + SP(PE-1,D)
        10 + 10  <       10 + (10 + 10)                 => OK
```

Figure 166 **IS-IS Overload on PE-2, Inequality 1 for 192.168.24.0/30 (D) on PE-1 (S)**

Conclusion

In production MPLS networks where FRR needs to be deployed, a trade off must be made between RSVP-TE FRR versus LDP FRR. The two main advantages of using LDP FRR compared to RSVP FRR are the simple configuration and the fact that LFA next-hop calculation is a local decision, which means there are no interoperability issues when working in a multi-vendor environment. The main disadvantage of using LDP FRR is that LFA next-hop calculation has to deal with the source-route paradigm (inequality formulas exclude a path going over the original source router).

MPLS Transport Profile

This chapter provides information about multiprotocol label switching transport profile (MPLS-TP).

Topics in this chapter include:

- Applicability
- Summary
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was originally written for release 12.0.R2. The CLI in the current edition corresponds to 14.0.R1. Multiprotocol label switching transport profile (MPLS-TP) requires a minimum of Flex Path 2 (FP2) or higher based hardware. A control processing module (CPM) 3 or higher is required for the highest bi-directional forwarding detection (BFD) scale using 10ms control packet timers.

The reader should be familiar with the configuration of IP/MPLS and virtual leased line (VLL) services in SR OS.

MPLS-TP was first introduced in SR OS release 11.0.R4 and further enhancements were added in subsequent releases.

Summary

MPLS-TP is intended to allow MPLS to be operated in a manner similar to existing transport technologies, with static configuration of transport paths (particularly with no requirement for a dynamic control plane), proactive in-band and on-demand operations and maintenance (OAM), and protection mechanisms that do not rely on a control plane (for example, resource reservation protocol with traffic engineering

(RSVP-TE)) to operate. The 7x50 can operate both as a label edge router (LER) and label switching router (LSR) for MPLS-TP LSPs, and as a terminating provider edge (T-PE) and switching provider edge (S-PE) for pseudowires (PWs) with MPLS-TP OAM. The 7x50 can therefore act as a node within an MPLS-TP network, or as a gateway between MPLS-TP and IP/MPLS domains.

Overview

MPLS can provide a network layer with packet transport services. In some operational environments it is desirable that the operation and maintenance of such an MPLS based packet transport network follows the operational models typically used in traditional optical transport networks (for example with SONET, SDH) while providing additional OAM, survivability and other maintenance functions targeted at that environment.

MPLS-TP defines a profile of MPLS targeted at transport applications. This profile defines specific MPLS characteristics and extensions required to meet the transport requirements, while retaining compliance with the standard IETF MPLS architecture and label-switching paradigm. The basic architecture and requirements for MPLS-TP are described by the IETF in RFC 5654, RFC 5921 and RFC 5960, in order to meet two objectives:

- To enable MPLS to be deployed in a transport network and operated in a manner similar to existing transport technologies.
- To enable MPLS to support packet transport services with a similar degree of predictability to that found in existing transport networks.

In order to meet these objectives, MPLS-TP has a number of high-level characteristics:

- MPLS-TP, including resilience and protection, operates in the absence of an IP control plane and IP. MPLS-TP does not modify the MPLS forwarding architecture, which is based on existing pseudowire and LSP constructs. Point-to-point LSPs may be unidirectional or bi-directional. Bi-directional LSPs must be congruent (i.e. co-routed and follow the same path in each direction) and are the only supported type on the 7x50. MPLS-TP is only supported on static LSPs and pseudowires (PWs). Also, there is no LSP merging.
- LSP and pseudowire monitoring is achieved using in-band OAM and does not rely on control plane or IP routing functions to determine the health of a path, for example, LDP hello failures do not trigger protection.

The system supports MPLS-TP on LSPs and PWs with static labels. MPLS-TP is not supported on dynamically signaled LSPs and PWs, although switching a static MPLS-TP PW to a targeted LDP (T-LDP) signaled PW is supported. MPLS-TP is supported for Epipe, Apipe and Cpipe VLLs, and Epipe spoke SDP termination on IES, VPRN and VPLS. Static PWs may use SDPs in addition to static MPLS-TP LSPs or RSVP-TE LSPs.

The following MPLS-TP OAM and protection mechanisms defined by the IETF are supported:

- MPLS-TP generic associated channel for LSPs and PWs (RFC 5586)
- MPLS-TP identifiers (RFC 6370)
- Proactive continuity check (CC), connectivity verification (CV), and remote defect indicator (RDI) using bi-directional forwarding detection (BFD) for LSPs (RFC 6428)
- On-demand CV for LSPs and PWs using LSP ping and LSP trace (RFC 6426)
- 1-for-1 Linear protection for LSPs (RFC 6378)
- Static PW status signaling (RFC 6478)

The system can play the role of an LER and an LSR for static MPLS-TP LSPs, and a PE/T-PE and an S-PE for static MPLS-TP PWs. It can also act as an S-PE for MPLS-TP segments between an MPLS network that strictly follows the transport profile and an MPLS network that supports both MPLS-TP and dynamic IP/MPLS.

Configuration

This section details the configuration steps for a set of simple MPLS-TP examples.

The following example network is used (Figure 167). It consists of four nodes and two Epipe VLL services. One service is used to transport traffic across a network domain consisting of only static MPLS-TP LSPs (Epipe 10) from PE-1 to PE-2. The other Epipe (Epipe 20) is used to transport traffic from PE-1 in the MPLS-TP domain to a VPLS service on PE-4 in an IP/MPLS domain. A static MPLS-TP LSP exists between PE-1 and PE-2, while a dynamic RSVP-TE LSP exists between PE-2 and PE-4.

Figure 167 **MPLS-TP Example Network Showing LSPs**

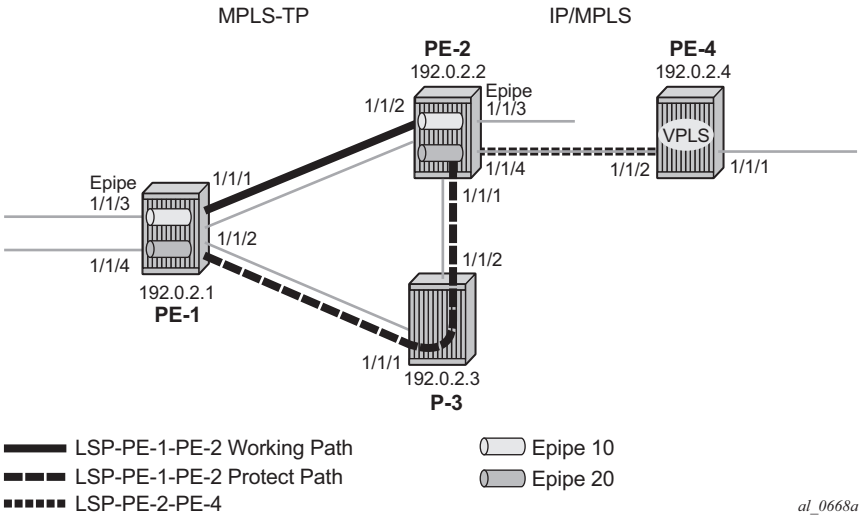

Figure 168 shows further details of the logical architecture of the services in the example network. The Epipe spoke-sdps use the static MPLS-TP transport LSP between PE-1 and PE-2, and the dynamically signaled RSVP-TE LSP between PE-2 and PE-4. The MPLS-TP LSP is protected using 1:1 linear protection, with a working path from PE-1 to PE-2, and a protect path from PE-1, through LSR P-3, to PE-2. The Ethernet PW for Epipe 10 connects an Ethernet SAP on port 1/1/3 on PE-1 to an Ethernet SAP on port 1/1/3 on PE-2. The PW for Epipe 20 connects an Ethernet SAP on port 1/1/4 on PE-1 to the VPLS on PE-4 and is switched between a static MPLS-TP segment and a dynamic targeted LDP (T-LDP) segment at PE-2. PE-2 thus acts as a gateway between the MPLS-TP domain and the IP/MPLS domain.

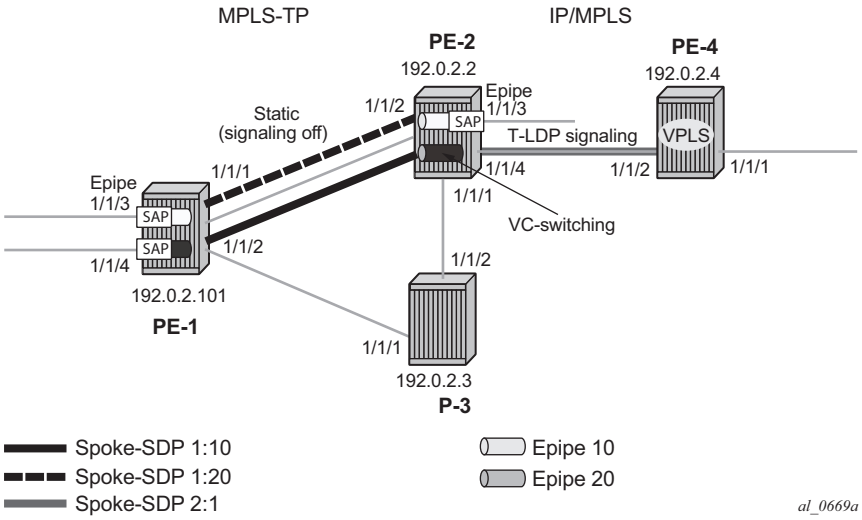
Figure 168 **MPLS-TP Example Network Showing Services Detail**



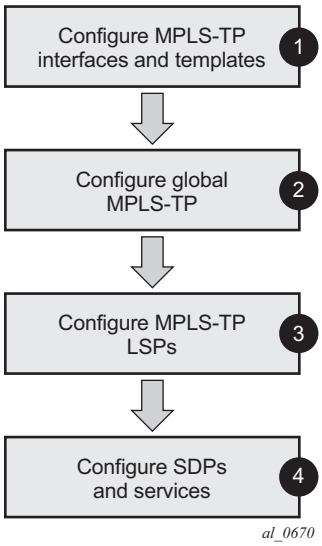


Figure 169 shows the configuration process to be followed when setting up MPLS-TP.

Figure 169 **MPLS-TP Configuration Steps**

Configure MPLS-TP Interfaces and Templates

MPLS-TP LSPs can use either numbered or unnumbered network IP interfaces, or unnumbered network interfaces that have been configured to operate without relying on IP routing. This non-IP interface type does not have an IP address associated with it and may be configured to have either a unicast, broadcast or multicast MAC address. The intent of using a broadcast or multicast MAC address is to enable a standard set of MAC addresses to be configured for a network without requiring any changes to the configuration of neighboring router interfaces each time an interface to which a router is connected is changed. If a broadcast or multicast MAC address is used, then the operator should take care that only a point-to-point link is connected to the Ethernet port used by the interface. Otherwise, MPLS-TP packets may be replicated to each remote port to which the link is connected.

The non-IP network interface type is known as an unnumbered-mpls-tp interface. Only MPLS-TP can use this interface type. That is, other IP protocols are blocked from using it. Furthermore, ARP is not used for next hop resolution. This example uses unnumbered-mpls-tp interfaces.

Unnumbered MPLS-TP interfaces are configured on each network-facing interface for the nodes in the MPLS-TP domain, as shown below. This is done using the **unnumbered-mpls-tp** keyword at create time. In addition, the **static-arp unnumbered** command is used to set the next-hop unicast, broadcast or multicast MAC address of the interface. The system interface should also be configured. Numbered IP Network interfaces, bound to port 1/1/4 of PE-2 and port 1/1/2 of PE-4 are used for the IP/MPLS portion of the network in Figure 167.

```
*A:PE-1# configure router
        interface "int-PE-1-P-3" unnumbered-mpls-tp
            port 1/1/2
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
        interface "int-PE-1-PE-2" unnumbered-mpls-tp
            port 1/1/1
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
        interface "system"
            address 192.0.2.1/32
        exit
        autonomous-system 64511

*A:PE-2# configure router
        interface "int-PE-2-P-3" unnumbered-mpls-tp
            port 1/1/1
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
```

```
        interface "int-PE-2-PE-1" unnumbered-mpls-tp
            port 1/1/2
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
        interface "int-PE-2-PE-4"
            address 192.168.24.1/30
            port 1/1/4
        exit
        interface "system"
            address 192.0.2.2/32
        exit
        autonomous-system 65535
        static-route-entry 192.0.2.4/32
            next-hop 192.168.24.2
                no shutdown
            exit
        exit

*A:P-3# configure router
        interface "int-P-3-PE-1" unnumbered-mpls-tp
            port 1/1/1
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
        interface "int-P-3-PE-2" unnumbered-mpls-tp
            port 1/1/2
            static-arp unnumbered 01:00:5e:90:00:00
            no shutdown
        exit
        interface "system"
            address 192.0.2.3/32
        exit
        autonomous-system 65535

*A:PE-4# configure router
        interface "int-PE-4-PE-2"
            address 192.168.24.2/30
            port 1/1/2
        exit
        interface "system"
            address 192.0.2.4/32
        exit
        autonomous-system 65535
        static-route-entry 192.0.2.2/32
            next-hop 192.168.24.1
                no shutdown
            exit
        exit
```

Next, MPLS should be configured on each of the interfaces to be used by MPLS-TP. As an example, only PE-1 configuration is shown although a similar configuration is provisioned on PE-2 and P-3.

```
*A:PE-1# configure router
        mpls
            mpls-tp
            exit
```

```
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-P-3"
            exit
            no shutdown
        exit
```

PE-4 is an IP/MPLS only node so there is no MPLS TP configuration

```
*A:PE-4# configure router
        mpls
            interface "int-PE-4-PE-2"
            exit
            no shutdown
        exit
```

The **mpls** context must be in the **no shutdown** state to enable MPLS-TP.

Static labels are used by MPLS-TP LSPs and PWs. By default, SR OS splits the full range in a static and a dynamic range,and these ranges are as follows:

```
*A:PE-1# show router mpls-labels label-range

===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          18431       -           18400       18400
Dynamic         18432       524287      0           505856      505856
    Seg-Route   0           0           -           0           505856
===============================================================================
*A:PE-1#
```

This can be modified by configuration. To reserve 2000 labels starting from label 32, the following command is launched:

```
*A:PE-1# configure router mpls-labels static-label-range 2000
```

As a result, the range from label 32 to 2031 is reserved for static labels.

```
*A:PE-1# show router mpls-labels label-range

===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          2031        -           2000        2000
Dynamic         2032        524287      0           522256      522256
    Seg-Route   0           0           -           0           522256
===============================================================================
*A:PE-1#
```

In this case, there is no need to modify the range for static labels. The labels that will be chosen are in the default range.

Next, one or more bidirectional forwarding detection (BFD) templates are configured on the LERs. These templates are used to define BFD state machine parameters used for BFD continuity check (CC) on an LSP, including the transmit and receive timer intervals (in milliseconds). CPM network processor BFD is required if timer intervals as short as 10ms are to be used, but depending on the platform, 100ms BFD may use CPU based BFD (as shown in the example here).

```
A:PE-1>config>router>bfd#
      abort           - Discard the changes that have been made to bfd template
                        during a session
      begin           - Switch to edit mode for bfd template - use commit to save
                        or abort to discard the changes made in a session
 [no] bfd-template    + Configure a bfd template
      commit          - Save the changes made to bfd template during a session

*A:PE-1# configure router bfd bfd-template
  - bfd-template <[32 chars max]>
  - no bfd-template <[32 chars max]>

 [no] echo-receive    - Configure echo receive interval
 [no] multiplier      - Configure multiplier
 [no] receive-interv* - Configure receive interval
 [no] transmit-inter* - Configure transmit interval
 [no] type            - Configure the bfd session endpoint type

*A:PE-1#
```

A subset of these parameters is used by MPLS-TP BFD sessions, as follows:

- **transmit-interval** *transmit-interval* and the **receive-interval** *receive-interval* — These are the transmit and receive timers for BFD packets. For MPLS-TP, these are the timers used by BFD CC packets. Values are in milliseconds: 10ms to 100,000ms, with 1ms granularity. Default 10ms for CPM3 or higher, 1 sec for other hardware. The minimum interval that can be supported is hardware dependent. For MPLS-TP BFD Connectivity Verification (CV) packets, a transmit interval of 1 sec is used.
- **multiplier** *multiplier* — Integer 3 – 20. Default: 3. The configured parameter is used for MPLS-TP CC BFD sessions. It is ignored for MPLS-TP combined CC/CV BFD sessions, and the default of 3 is used.
- **type cpm-np** — This selects the CPM network processor as the local termination point for the BFD session. This is used by default for MPLS-TP. Type CPM-NP is needed to configure a transmit interval down to 10ms.

The following CLI illustrates the BFD template configuration at PE-1. Since default parameters are sufficient, only the bfd-template name is configured. BFD templates use a begin/commit model for configuration. Create or modify a template with the **begin** statement. Changes to an existing template or the creation of a new template is not effected until the **commit** statement is entered.

```
*A:PE-1# configure router
        bfd
            begin
            bfd-template "tp-bfd"
            exit
            commit
        exit
```

The following **info detail** command shows the values that are assigned by default.

```
*A:PE-1>config>router>bfd# info detail
----------------------------------------------
            bfd-template "tp-bfd"
                no type
                transmit-interval 100
                receive-interval 100
                multiplier 3
                echo-receive 100
            exit
----------------------------------------------
```

Configure Global MPLS-TP Parameters

MPLS-TP global parameters are configured under **config>router>mpls>mpls-tp**. These include the MPLS-TP identifiers for the node and the range of tunnel identifiers that should be reserved for MPLS-TP LSPs.

Node identifiers include the global ID and the node ID. The node ID may be defined as an unsigned integer or use dotted quad notation (a.b.c.d), but the node ID does not have to be a routable IP address.

The CLI tree for configuring the MPLS-TP identifiers for a node is as follows:

```
*A:PE-1# configure router
        mpls
            mpls-tp
  - mpls-tp
  - no mpls-tp

 [no] global-id       - Global id for MPLS-TP
 [no] node-id         - Node id for MPLS-TP local router
 [no] oam-template    + Configure a MPLS-TP OAM Template
 [no] protection-tem* + Configure a MPLS-TP Protection Template
 [no] shutdown        - Administratively enable/disable the MPLS-TP
```

```
 [no] tp-tunnel-id-r* - Configure MPLS-TP tunnel id range on the ingress router
 [no] transit-path    + Configure a MPLS-TP Transit Path
```

The default value for the global-id is 0. This is used if the global-id is not configured. If an operator expects that inter-domain LSPs will be configured, then it is recommended to set the global ID to the local autonomous system number (ASN) of the node, as configured under **config>router**, to ensure that the combination of global-id and node-id is globally unique. If two-byte ASNs are used, then the two most significant bytes of the global-id are padded with zeros.

The default value of the **node-id** is the system interface IPv4 address. The MPLS-TP context cannot be administratively enabled unless at least a system interface IPv4 address is configured because MPLS requires that this value be configured.

In order to change the values, **config>router>mpls>mpls-tp** must be in the shutdown state. This will bring down all of the MPLS-TP LSPs on the node. New values are propagated to the system when a **no shutdown** is performed.

The following CLI shows the MPLS-TP node identifier configuration for PE-1. A similar configuration is implemented in all routers in this chapter, except that the node-ids must be different (PE-2 is 10.0.0. 2 and P-3 is 10.0.0. 3). In this example the global-id for PE-2 and P-3 equals 65535.

```
*A:PE-1# configure router
        mpls
            mpls-tp
                global-id 64511
                node-id 10.0.0.1
            exit

*A:PE-2# configure router
        mpls
            mpls-tp
                global-id 65535
                node-id 10.0.0.2
            exit
```

Next, protection and OAM templates should be configured at the MPLS-TP LERs. A protection template defines the parameters for the linear protection state coordination mechanism. MPLS-TP Linear Protection is specified in RFC6378. It provides protection for an LSP using a working and a protect path. A protection state coordination (PSC) protocol is used by the LERs at each end of the protected LSP to coordinate whether the working or protect path is used for forwarding. BFD is run on both the working and protect paths.

The linear protection parameters include revertive or non-revertive behavior, the wait-to-restore timer, the rapid-psc-timer and the slow-psc-timer. The wait-to-restore timer (in seconds) defines the time to wait before reverting to the working path if, on restoration of connectivity, the revertive behavior is selected.

The following CLI tree is used to configure the protection template:

```
*A:PE-1>config>router>mpls>tp$ protection-template
  - no protection-template <[32 chars max]>
  - protection-template <[32 chars max]>

     rapid-psc-timer - Configure the rapid Protection Switch Coordination (PSC) timer
 [no] revertive       - Enable/Disable the template's revertive mode
     slow-psc-timer  - Configure the slow Protection Switch Coordination (PSC) timer
 [no] wait-to-restore - Configure the WTR timer for the template
```

See the CLI command descriptions in the MPLS User Guide for further details of these commands.

The OAM template defines generic proactive OAM parameters, such as BFD hold down and hold up timer values (which can be used to introduce some hysteresis if BFD bounces) and the BFD template to use.

The following CLI tree is used to configure the OAM template:

```
*A:PE-1# configure router
        mpls
            mpls-tp
                oam-template
  - no oam-template <template-name>
  - oam-template <template-name>

 <template-name>      : [32 chars max]

 [no] bfd-template - Configure the Bidirectional Forwarding Detection (BFD) template
 [no] hold-time-down  - Configure hold-down dampening timer
 [no] hold-time-up    - Configure the hold-up dampening timer
```

See the CLI command descriptions in the MPLS User Guide for further details of these commands.

MPLS-TP requires the reservation of a tunnel ID range, dedicated for the use of MPLS-TP LSPs. This range is reserved using the following CLI tree:

```
*A:PE-1# configure router
        mpls
            mpls-tp
                tp-tunnel-id-range
  - tp-tunnel-id-range <min> <max>
  - no tp-tunnel-id-range

 <min>                : [1..61440]
 <max>                : [1..61440]
```

The default parameter values are used as shown below, where PE-1 and PE-2 have the same configuration:

```
*A:PE-1# configure router mpls
            mpls-tp
                tp-tunnel-id-range 100 1000
                protection-template "tp-protect"
                exit
                oam-template "tp-oam"
                    bfd-template "tp-bfd"
                exit
                no shutdown
            exit
```

Configure MPLS-TP LSPs

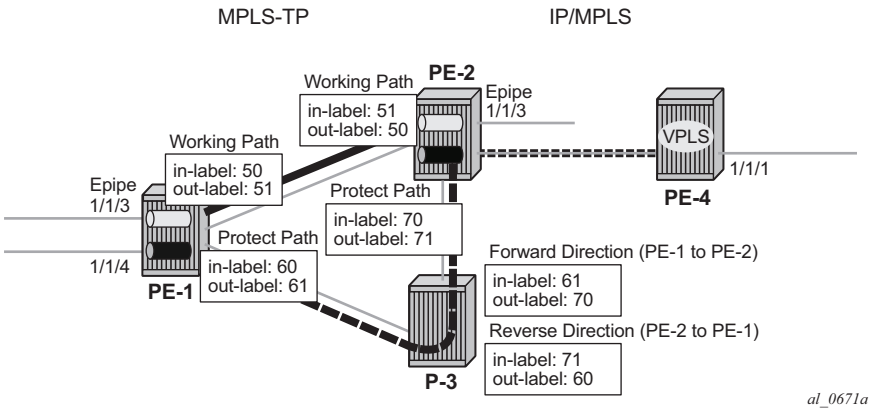
Once the global MPLS-TP parameters have been configured, the system is ready to configure MPLS-TP LSPs. An MPLS-TP LSP is configured under the **config>router>mpls>lsp** context.

Because LSP labels are statically configured, both ends of the LSP must be explicitly configured. The LSP paths must also be explicitly configured in the LSR nodes. MPLS-TP LSPs must use the mpls-tp keyword including a source tunnel number at creation time.

The following commands are used to configure an MPLS-TP LSP at an LER:

```
configure
   router
      mpls
         lsp <lsp-name> mpls-tp <src-tunnel-num>]
            to node-id {<a.b.c.d> | <1.. .4,294,967,295>}
            dest-global-id <global-id>
            dest-tunnel-number <tunnel-num>
            [no] working-tp-path
                lsp-num <lsp-num>
                in-label <in-label>
                out-label <out-label> out-link <if-name> [next-hop <ipv4-address>]
                [no] mep
                   [no] oam-template <name>
                   [no] bfd-enable [cc | cc-cv]
                   [no] shutdown
                   exit
                [no] shutdown
                exit
             [no] protect-tp-path
                lsp-num <lsp-num>
                in-label <in-label>
                out-label <out-label> out-link <if-name> [next-hop <ipv4-address> ]
                [no] mep
                   [no] protection-template <name>
                   [no] oam-template <name>
                   [no] bfd-enable [cc | cc-cv]
                   [no] shutdown
                   exit
                [no] shutdown
```

```
            exit
```



See the CLI command descriptions in the MPLS User Guide for further details of these commands.

A working path and a protect path for LSP LSP-PE-1-P-2 must be configured between PE-1 and PE-2. Each LSP is configured with the full set of MPLS-TP identifiers required to build the LSP ID. Each working path and protect path must have an incoming label, outgoing label and outgoing link configured.

Each working path and protect path also includes a maintenance entity group endpoint (MEP) configuration, under which the applicable OAM template is configured. BFD is also enabled under the MEP context for the path. In this example, BFD operating in CC mode is enabled on the working and protect paths. The protection template, containing parameters for linear protection, is only applied under the protect path context.

Figure 170 shows the LSP working and protect path label values configured at PE-1, PE-2 and P-3. At each node the outgoing label must match the incoming label on the next hop for a given direction. At the LERs (PE-1 and PE-2), the incoming and outgoing label values for each LSP path are configured together. At the LSR (P-3), the label values for the label mapping between ingress and egress for each direction of the path (that is, forward and reverse) are configured together.

Figure 170 **LSP Path Label Value Configurations**

The following shows the LER LSP configuration of PE-1 and PE-2.

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-2" mpls-tp 100
                to node-id 10.0.0.2
                dest-global-id 65535
                dest-tunnel-number 100
                working-tp-path
```

```
                        in-label 50
                        out-label 51 out-link "int-PE-1-PE-2"
                        mep
                            oam-template "tp-oam"
                            bfd-enable cc
                            no shutdown
                        exit
                        no shutdown
                    exit
                    protect-tp-path
                        in-label 60
                        out-label 61 out-link "int-PE-1-P-3"
                        mep
                            protection-template "tp-protect"
                            oam-template "tp-oam"
                            bfd-enable cc
                            no shutdown
                        exit
                        no shutdown
                    exit
                    no shutdown
                exit
                no shutdown
            exit

*A:PE-2# configure router
            mpls
               lsp "LSP-PE-1-PE-2" mpls-tp 100
                    to node-id 10.0.0.1
                    dest-global-id 64511
                    dest-tunnel-number 100
                    working-tp-path
                        in-label 51
                        out-label 50 out-link "int-PE-2-PE-1"
                        mep
                            oam-template "tp-oam"
                            bfd-enable cc
                            no shutdown
                        exit
                        no shutdown
                    exit
                    protect-tp-path
                        in-label 70
                        out-label 71 out-link "int-PE-2-P-3"
                        mep
                            protection-template "tp-protect"
                            oam-template "tp-oam"
                            bfd-enable cc
                            no shutdown
                        exit
                        no shutdown
                    exit
                    no shutdown
                exit
                no shutdown
            exit
```

Since this example requires a protect path to be switched via P-3, a transit path must be configured in P-3. The CLI tree for configuring MPLS-TP transit paths is as follows:

```
configure
   router
      mpls
         mpls-tp
            transit-path <path-name>
               [no] path-id {lsp-num <lsp-num>|working-path|protect-path

                  [src-global-id <global-id>]
                  src-node-id {<ipv4address> | <1.. .4,294,967,295>}
                  src-tunnel-num <tunnel-num>
                  [dest-global-id <global-id>]
                  dest-node-id {<ipv4address> | <1.. .4,294,967,295>}
                  [dest-tunnel-num <tunnel-num>]}
                  lsp-num <lsp-num>

               forward-path
                  in-label <in-label> out-label <out-label>
                  out-link <if-name> [next-hop <ipv4-next-hop>]
                  exit
               reverse-path
                  in-label <in-label> out-label <out-label>
                  [out-link <if-name> [next-hop <ipv4-next-hop>]]
                   exit
               [no] shutdown
```

See the CLI command descriptions in the MPLS User Guide for further details of these commands.

The CLI configuration for the forward and reverse directions of the transit path (that is, the protect path of the LSP) at P-3 is as follows:

```
*A:P-3# configure router
        mpls
            mpls-tp
                transit-path "LSP-PE-1-PE-2"
                    forward-path
                        in-label 61 out-label 70 out-link "int-P-3-PE-2"
                    exit
                    reverse-path
                        in-label 71 out-label 60 out-link "int-P-3-PE-1"
                    exit
                    path-id src-global-id 64511 src-node-id 10.0.0.1 src-tunnel-num
                            100 dest-global-id 65535 dest-node-id 10.0.0.2
                            dest-tunnel-num 100 lsp-num 2
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
```

The example also requires an LSP across the IP/MPLS network to backhaul traffic from PE-2 at the edge of the MPLS-TP network to the VPLS service hosted in PE-4. An RSVP LSP is configured at PE-2 for this purpose, as follows:

```
*A:PE-2# configure router
        mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-PE-2-PE-4"
                to 192.0.2.4
                primary "loose"
                exit
                no shutdown
            exit

*A:PE-2# configure router rsvp no shutdown
```

Create a T-LDP session toward PE-4. LDP over RSVP is preferred (prefer-tunnel-in-tunnel).

```
*A:PE-2# configure router
        ldp
            prefer-tunnel-in-tunnel
            interface-parameters
            exit
            targeted-session
                peer 192.0.2.4
                exit
            exit
        exit
```

A similar configuration is implemented in PE-4.

At this point in the configuration process, it is recommended to check the MPLS-TP LSP configuration and operation of BFD and linear protection.

First, check that the BFD sessions on both the working and protect paths are up:

```
*A:PE-1# show router bfd session

===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
===============================================================================
If/Lsp Name/Svc-Id/RSVP-sess  State                Tx Intvl  Rx Intvl  Multipl
  Rem Addr/Info/SdpId:VcId    Protocols            Tx Pkts   Rx Pkts   Type
   LAG port                      LAG ID
-------------------------------------------------------------------------------
wp::LSP-PE-1-PE-2             Up                   100       100       3
    65535::10.0.0.2           mplsTp               10566     10554     central
pp::LSP-PE-1-PE-2             Up                   100       100       3
    65535::10.0.0.2           mplsTp               7313      6938      central
-------------------------------------------------------------------------------
```

```
No. of BFD sessions: 2
===============================================================================
*A:PE-1#
```

Next, check the currently active path. This can be done using the oam lsp-trace command. The static option must be specified for MPLS-TP LSPs.

```
*A:PE-1# oam lsp-trace static "LSP-PE-1-PE-2"
lsp-trace to LSP-PE-1-PE-2: 0 hops min, 0 hops max, 100 byte packets
1  GlobalId 65535 NodeId 10.0.0.2
   rtt=0.564ms rc=3(EgressRtr)
*A:PE-1#
```

This shows that data packets currently follow the working path of the LSP (no transit node is shown).

In order to test the operation of linear protection, the port used by the working path can be shutdown, and the BFD session state checked again:

```
*A:PE-1# configure port 1/1/1 shutdown

*A:PE-1# show router bfd session

===============================================================================
Legend:  wp = Working path   pp = Protecting path
===============================================================================
BFD Session
===============================================================================
If/Lsp Name/Svc-Id/RSVP-sess  State                Tx Intvl  Rx Intvl  Multipl
  Rem Addr/Info/SdpId:VcId    Protocols            Tx Pkts   Rx Pkts   Type
   LAG port                      LAG ID
-------------------------------------------------------------------------------
wp::LSP-PE-1-PE-2             Down                 1000      100       3
    65535::10.0.0.2           mplsTp               12818     12806     central
pp::LSP-PE-1-PE-2             Up                   100       100       3
    65535::10.0.0.2           mplsTp               9565      9190      central
-------------------------------------------------------------------------------
No. of BFD sessions: 2
===============================================================================
*A:PE-1#
```

Execute LSP trace again to check that the LSP has failed over to use the protect path:

```
*A:PE-1# oam lsp-trace static  "LSP-PE-1-PE-2"
lsp-trace to LSP-PE-1-PE-2: 0 hops min, 0 hops max, 100 byte packets
1  GlobalId 65535 NodeId 10.0.0.3
   rtt=0.585ms rc=8(DSRtrMatchLabel)
2  GlobalId 65535 NodeId 10.0.0.2
   rtt=1.07ms rc=3(EgressRtr)
*A:PE-1#
```

This shows that packets are now forwarded via the protect path through P-3, which has node ID 10.0.0.3.

Finally bring the LSP back to the working path by bringing port 1/1/1 up, and either waiting for the LSP to revert to the working path or forcing it onto the working path and clearing the revert timer by executing a tools command as follows:

```
*A:PE-1# configure port 1/1/1 no shutdown

*A:PE-1# tools perform router mpls tp-tunnel force "LSP-PE-1-PE-2"

*A:PE-1# tools perform router mpls tp-tunnel clear "LSP-PE-1-PE-2"

*A:PE-1# oam lsp-trace static "LSP-PE-1-PE-2"
lsp-trace to LSP-PE-1-PE-2: 0 hops min, 0 hops max, 100 byte packets
1  GlobalId 65535 NodeId 10.0.0.2
   rtt=0.582ms rc=3(EgressRtr)
*A:PE-1#
```

Configure SDPs and Services

Services can be configured to use MPLS-TP LSPs once the LSP configuration is completed. SDPs and services are configured in a similar manner to those using static-labeled pseudowires without MPLS-TP.

Distributed services are configured to use MPLS-TP with the following steps:

- Configure an SDP with signaling off. With signaling off, the SDP far-end may then be configured as an MPLS-TP node-id or an IPv4 address. SDP keep-alive should be disabled.
- Configure the service, including the spoke-sdp using the SDP. To use MPLS-TP, the spoke-sdp must have statically assigned ingress and egress labels, the control-word must be enabled, and it must have an MPLS-TP identifier for the PW (the PW Path ID) configured. This is comprised of two parts, a Source Attachment Individual Identifier (SAII) and a Target Attachment Individual Identifier (TAII), both of which must be configured. Control channel status signaling may also be configured to support PW status signaling on the static MPLS-TP PW.

In this example, an SDP is configured to use the MPLS-TP LSP from PE-1 to PE-2, which will act as a transport for the static MPLS-TP PWs corresponding to Epipe 10 and Epipe 20. Another SDP is configured for the targeted LDP (T-LDP) PW segment corresponding to Epipe 20 between PE-2 and PE-4.

The following CLI shows the SDP between PE-1 and PE-2 and the SDP between PE-2 and PE-4:

```
*A:PE-1# configure service
        sdp 1 mpls create
            signaling off
```

```
            far-end node-id 10.0.0.2 global-id 65535
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit

*A:PE-2# configure service
        sdp 1 mpls create
            signaling off
            far-end node-id 10.0.0.1 global-id 64511
            lsp "LSP-PE-1-PE-2"
            no shutdown
        exit
        sdp 2 mpls create
            far-end 192.0.2.4
            lsp "LSP-PE-2-PE-4"
            no shutdown
        exit

*A:PE-4# configure service
        sdp 2 mpls create
            far-end 192.0.2.2
            lsp "LSP-PE-4-PE-2"
            no shutdown
        exit
```

Next, configure the services that will use the MPLS-TP LSPs.

The service configuration CLI tree for an Epipe service using MPLS-TP is as follows:

```
— configure
      service
        epipe
          [no] spoke-sdp sdp-id[:vc-id]
              [no] hash-label
              [no] standby-signaling-slave
          [no] spoke-sdp sdp-id[:vc-id] [vc-type {ether|vlan}]
             [create] [vc-switching] [no-endpoint | {endpoint [icb]}]
            egress
              vc-label <out-label>
            ingress
              vc-label <in-label>
—           [no] control-word
            [no] pw-path-id
              agi <agi>
              saii-type2 <global-id:node-id:ac-id>
              taii-type2 <global-id:node-id:ac-id>
              exit
            control-channel-status
              [no] acknowledgment
              [no] refresh-timer <value>
              [no] request-timer <value> retry-timer <value> [timeout-multiplier <value>]
              [no] shutdown
```

See the CLI command descriptions in the user guides for further details of these commands.

The following CLI examples show the Epipe service configuration at PE-1, PE-2, and the VPLS spoke-sdp termination point at PE-4.

Epipe 10 belongs to customer 1, and Epipe 20 belongs to customer 2 in this example.

```
*A:PE-1# configure service
        epipe 10 customer 1 create
            sap 1/1/3 create
            exit
            spoke-sdp 1:10 create
                ingress
                    vc-label 150
                exit
                egress
                    vc-label 151
                exit
                control-word
                pw-path-id
                    saii-type2 64511:10.0.0.1:1
                    taii-type2 65535:10.0.0.2:1
                exit
                control-channel-status
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
        epipe 20 customer 2 create
            sap 1/1/4 create
            exit
            spoke-sdp 1:20 create
                ingress
                    vc-label 200
                exit
                egress
                    vc-label 201
                exit
                control-word
                pw-path-id
                    saii-type2 64511:10.0.0.1:2
                    taii-type2 65535:10.0.0.2:2
                exit
                control-channel-status
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
```

At PE-2, Epipe 10 terminates on a SAP on port 1/1/3, while Epipe 20 is switched between a static MPLS-TP PW segment (spoke-sdp 1:20) and a T-LDP signaled PW segment (spoke-sdp 2:1) for backhaul to the remote PE-4 containing the VPLS service.

```
*A:PE-2# configure service
        epipe 10 customer 1 create
            sap 1/1/3 create
            exit
            spoke-sdp 1:10 create
                ingress
                    vc-label 151
                exit
                egress
                    vc-label 150
                exit
                control-word
                pw-path-id
                    saii-type2 65535:10.0.0.2:1
                    taii-type2 64511:10.0.0.1:1
                exit
                control-channel-status
                    no shutdown
                exit
                no shutdown
            exit
            no shutdown
        exit
        epipe 20 customer 2 vc-switching create
            spoke-sdp 1:20 create
                ingress
                    vc-label 201
                exit
                egress
                    vc-label 200
                exit
                control-word
                pw-path-id
                    saii-type2 65535:10.0.0.2:2
                    taii-type2 64511:10.0.0.1:2
                exit
                control-channel-status
                    no shutdown
                exit
                no shutdown
            exit
            spoke-sdp 2:1 create
                control-word
                no shutdown
            exit
            no shutdown
        exit
```

At PE-4, the T-LDP signaled PW segment for Epipe 20 is terminated on a VPLS service:

```
*A:PE-4# configure service
```

```
        vpls 1 customer 2 create
            sap 1/1/1 create
            exit
            spoke-sdp 2:1 create
                control-word
                no shutdown
            exit
            no shutdown
        exit
```

Epipe 10 uses a static MPLS-TP PW from end to end, which can be tested using the virtual circuit connectivity verification vccv-ping command at PE-1, as follows:

```
*A:PE-1# oam vccv-ping static 1:10
VCCV-PING 1:10 84 bytes MPLS payload
Seq=1, send from intf int-PE-1-PE-2
       send from lsp LSP-PE-1-PE-2
       reply via Control Channel
       src id tlv received: GlobalId 65535 NodeId 10.0.0.2
       cv-data-len=44 rtt=0.597ms rc=3 (EgressRtr)

---- VCCV PING 1:10 Statistics ----
1 packets sent, 1 packets received, 0.00% packet loss
round-trip min = 0.597ms, avg = 0.597ms, max = 0.597ms, stddev = 0.000ms
*A:PE-1#
```

The operation of control channel status signaling can also be tested for this Epipe, as follows:

Shutdown the port the SAP on PE-2 is using:

```
*A:PE-2# configure port 1/1/3 shutdown
```

The PW peer status bits for the spoke-sdp for Epipe 10, signaled using control channel status signaling, can be displayed at node PE-1 using the following command (some of the show command output has been removed for brevity). The peer PW status bits are shown in bold in the output below.

```
*A:PE-1# show service id 10 sdp detail

===============================================================================

```

Epipe 20 uses a static MPLS-TP PW from PE-1 to PE-2, identified by a static PW forwarding equivalence class (FEC), and a T-LDP segment with FEC128 from PE-2 to PE-4. Therefore the target FEC used for a vccv-ping command from PE-1 to PE-4 is different from the local FEC for the PW at PE-1. VCCV-trace provides a useful tool to test the resulting multi-segment PW (MS-PW). The same associated channel type must be used for both segments. This is the IPv4 channel.

```
*A:PE-1# oam vccv-trace static 1:20 assoc-channel ipv4 detail
VCCV-TRACE 1:20  with 116 bytes of MPLS payload
1  192.0.2.2 GlobalId 65535 NodeId 10.0.0.2
   rtt=0.599ms rc=8(DSRtrMatchLabel)
   Next segment: VcId=1 VcType=Ether Source=192.0.2.2 Remote=192.0.2.4
2  192.0.2.4  rtt=1.06ms rc=3(EgressRtr)

*A:PE-1#
```

The system supports the interworking of control channel status on a static MPLS-TP PW segment with T-LDP-signaled PW status on a T-LDP PW segment. This can be tested as follows.

Shut down the port the spoke SDP on PE-4 is using:

```
*A:PE-4# configure port 1/1/2 shutdown
```

The PW peer status bits for the spoke-sdp for Epipe 20 can then be displayed at node PE-1 using the following command (some of the show command output has been removed for brevity). The peer PW status bits are shown in bold in the output below.

```
*A:PE-1# show service id 20 sdp detail

Conclusion

Release 11.0.R4 of SR OS introduced extensive MPLS Transport Profile (MPLS-TP) capabilities. MPLS-TP is intended to allow MPLS to be operated in a manner similar to existing transport technologies, with proactive in-band and on-demand operations and maintenance (OAM), and protection mechanisms that do not rely on a control plane to operate. The 7x50 can operate both as an LER and LSR for MPLS-TP LSPs, and as a T-PE and S-PE for PWs with MPLS-TP OAM. The 7x50 can therefore act as a node within an MPLS-TP network, or as a gateway between MPLS-TP and IP/MPLS domains.

This example has illustrated a simple configuration, demonstrating the role of the 7x50 as an LER and LSR for MPLS-TP LSPs, and how its already extensive multi-service capabilities can be extended over an MPLS-TP network and between MPLS-TP and IP/MPLS networks.

Multicast Label Distribution Protocol

This chapter provides information about multicast label distribution protocol.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was initially written for release 13.0.R6. The CLI in this edition corresponds to release 14.0.R1. Chassis mode C or later must be used.

In this chapter, the emphasis is on IPv4. However, multicast label distribution protocol (mLDP) is also supported on IPv6 interfaces.

Overview

Multicast label distribution protocol provides extensions to LDP for the setup of point-to-multipoint (P2MP) label switched paths (LSPs) and multipoint-to-multipoint (MP2MP) LSPs in MPLS networks.

The protocol is described in RFC 6388 - Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths.

Multicast LSPs can be applied for IP multicast or support for multicast in BGP/MPLS Layer 3 virtual private networks (L3 VPNs).

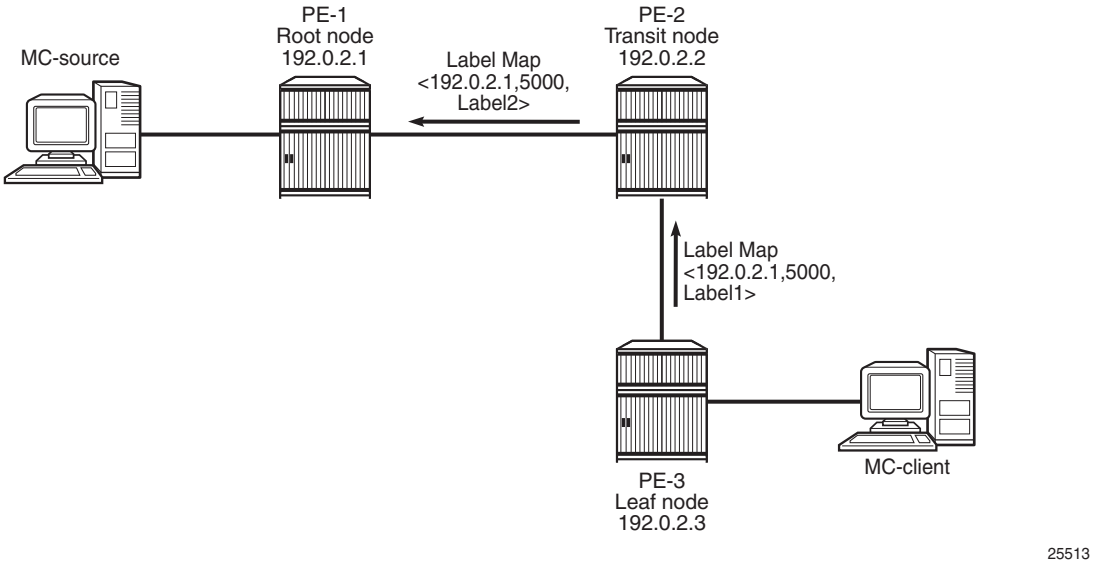
Compared to RSVP P2MP LSPs, mLDP P2MP LSPs are easier to configure and the setup direction is different. While the RSVP P2MP LSPs are set up from the root node toward the leaf nodes, mLDP P2MP LSPs are set up from the leaf nodes toward the root node.

P2MP Terminology

The following terminology will be used.

Table 15 **Terminology**

Node	Description
Ingress / Root	P2MP LSPs have just one ingress (root) node. The root node receives IP multicast traffic and maps the traffic to a P2MP LSP (push). The node might perform MPLS multicast replication.
Egress / Leaf	P2MP LSPs have multiple egress (leaf) nodes. A leaf node removes data packets from a P2MP LSP (pop) for further processing. The node might perform IP multicast replication.
Transit	A transit label switching router (LSR) can reach the root node via a directly connected upstream LSR. A transit LSR also has one or more directly connected downstream LSRs. The LSR swaps the MPLS label and might perform MPLS multicast replication.
Branch	A branch LSR is a transit LSR that has several directly connected LSRs. The LSR swaps the MPLS label and performs MPLS multicast replication.
Bud	A bud node is an egress node, but also a transit node. The node has directly connected receivers and also one or more directly connected downstream LSRs.



Setup of mLDP P2MP LSP

The setup of the P2MP LSP in the control plane is as follows.

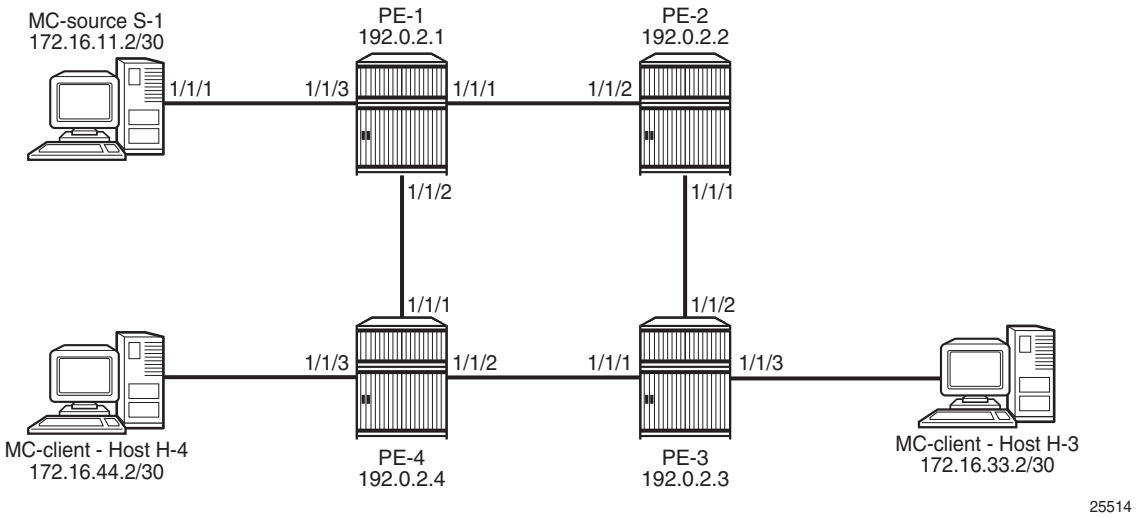
1. The leaf node initiates a tree setup according to what is configured. Mandatory parameters are the IP address of the root and an opaque value. The leaf node sends an LDP label map message to its upstream hop toward the root node of the tree.
2. Each transit node receives the LDP label map message and sends another LDP label map message to its upstream hop toward the root node of the tree. Each label can be different.
3. The root node receives the LDP label map message.

The label map message contains the root node address, an opaque value, and a label. In the example in Figure 1, the root node address is 192.0.2.1 and the opaque value is 5000.

Figure 171 **Setup of mLDP P2MP LSP**

After the LDP label map messages are sent in the control plane, the nodes program pop, swap, or push entries for the corresponding labels in the data plane.

1. The leaf node programs a pop entry for the label sent upstream.
2. The transit node programs a swap entry for the label it sent upstream with the next-hop address and the label it received from the downstream node.
3. The root node programs a push entry and a next-hop address for the label it received from the downstream node.



If multiple equal cost multi-path (ECMP) paths exist between two adjacent nodes, the upstream node of the multicast receiver must program all the entries in the forwarding plane. Only one entry must be active based on the ECMP hashing algorithm.

Configuration

The example setup shown in Figure 172 will be used. The multicast source S-1 is connected to root node PE-1. PE-2 or PE-4 will be the transit node for traffic destined to PE-3. There are two leaf nodes: PE-3 and PE-4. Multicast client H-3 is connected to PE-3, while multicast client H-4 is connected to PE-4.

Under normal circumstances, PE-2 is the transit node for traffic toward PE-3 and PE-4 is an egress node. If PE-4 is the transit node for traffic toward PE-3, while it also has a directly connected receiver, PE-4 is a bud node.

Figure 172 **Test Topology**

Configure LDP P2MP LSP

Initial Configuration

The PEs should have the following initial configuration:

- Chassis mode must be C or higher
- Cards, MDAs, ports
- Router interfaces
- IGP (OSPF or IS-IS)

As an example, the router interfaces and OSPF configuration on PE-1 are as follows:

```
*A:PE-1# configure router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/1
        exit
        interface "int-PE-1-PE-4"
            address 192.168.14.1/30
            port 1/1/2
```

```
        exit
        interface "int-PE-1-S-1"
            address 172.16.11.1/30
            port 1/1/3
        exit
        interface "system"
            address 192.0.2.1/32
        exit
    exit

*A:PE-1# configure router
        ospf
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-PE-4"
                    interface-type point-to-point
                exit
                interface "int-PE-1-S-1"
                    interface-type point-to-point
                exit
            exit
        exit
    exit
```

Enabling mLDP

When LDP is enabled, mLDP is enabled by default

- For releases earlier than 13.0.R1, mLDP had to be enabled with the command:

```
configure router ldp interface-parameters interface <ip-int-name> multicast-traffic
enable
```

- For release 13.0.R1 or later, the command is as follows:

```
configure router ldp interface-parameters interface <ip-int-name> ipv4 fec-type-
capability p2mp-ipv4 enable
```

Enable LDP (including mLDP) on PE-1, as follows:

```
*A:PE-1# configure router
        ldp
            interface-parameters
                interface "int-PE-1-PE-2"
                exit
                interface "int-PE-1-PE-4"
                exit
            exit
```

Verify that mLDP is enabled (P2MP: Enabled), as follows:

```
*A:PE-1# show router ldp status

*A:PE-1#
```

P2MP multicast forwarding can be disabled per LDP interface. Disabling P2MP multicast forwarding will not prevent LDP from exchanging P2MP FEC elements on that interface in the control plane. In the data plane, the forwarding plane is not programmed with the next hop on the outgoing interface that is P2MP disabled.

Configure Tunnel Interface on the Root and Leaf Nodes

Multicast LDP can be applied in different scenarios. In the following example, a tunnel interface is created on the root and leaf nodes. Other examples are multicast virtual private network (MVPN) with mLDP and dynamic PIM-mLDP mapping. In several ACG chapters on MVPN, mLDP is chosen; for example, in *Multicast VPN: Use of Wildcard Selective PMSI*.

A tunnel interface needs to be created on the root node, as follows:

```
*A:PE-1# configure router tunnel-interface ldp-p2mp 5000 sender 192.0.2.1 root-node
```

In this example, the tunnel interface gets interface index 73728, as follows:

```
*A:PE-1# show router tunnel-interface
===============================================================================
 P2MP-RSVP P2MP-LDP Tunnel-Interfaces
===============================================================================
LSP/LDP           Type        SenderAddr          IfIndex             RootNode
-------------------------------------------------------------------------------
5000              ldp         192.0.2.1           73728               Yes
-------------------------------------------------------------------------------
Interfaces : 1
===============================================================================
*A:PE-1#
```

A similar command will be launched on the leaf nodes, but without the keyword **root-node**, as follows:

```
*A:PE-3# configure router tunnel-interface ldp-p2mp 5000 sender 192.0.2.1
*A:PE-4# configure router tunnel-interface ldp-p2mp 5000 sender 192.0.2.1
*A:PE-3# show router tunnel-interface

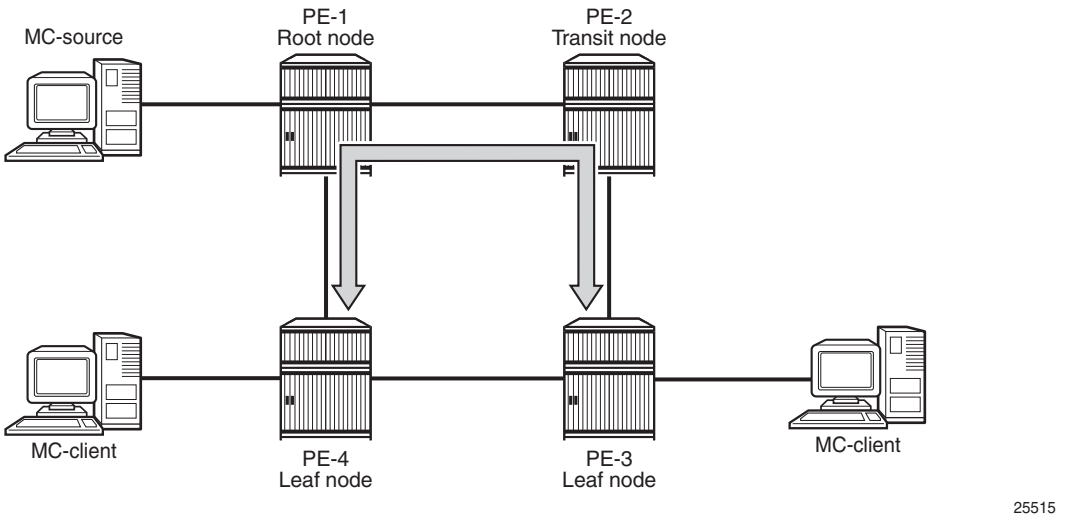
 <in|out>             : in|out - Default: out
 <fc-name>            : be|l2|af|l1|h2|ef|h1|nc - Default: be
 <octets>             : [1..9198] - Default: 1
 <label-ttl>          : [1..255] - Default: 255
 <timeout>            : [1..120] seconds - Default: 10
 <detail>             : keyword - displays detailed information
 <p2mp-identifier>    : [1..4294967295]
```

```
 <ldp-ssm>            : keyword
 <ip-address>         : ipv4-address    - a.b.c.d
                        ipv6-address    - x:x:x:x:x:x:x:x   (eight 16-bit pieces)
                                          x:x:x:x:x:x:d.d.d.d
                                          x - [0..FFFF]H
                                          d - [0..255]D
 <router-instance>    : <router-name>|<service-id>
                        router-name     - "Base"|"management"  Default - Base
                        service-id      - [1..2147483647]
 <service-name>       : [64 chars max]
*A:PE-1#
```

Verify the P2MP LSP with the following ping command:

```
*A:PE-1# oam p2mp-lsp-ping ldp 5000
P2MP identifier 5000: 88 bytes MPLS payload
Total Leafs responded = 2
          round-trip min/avg/max  = 0.898 / 1.01 / 1.12 ms
Responses based on return code:
        EgressRtr(3)=2
*A:PE-1#
```

Both leaf nodes have sent a reply. The return code 3 indicates that the replying router is an egress for the forwarding equivalence class (FEC).



For a detailed output per leaf, use the following command:

```
*A:PE-1# oam p2mp-lsp-ping ldp 5000 detail
P2MP identifier 5000: 88 bytes MPLS payload

```

Verify LDP P2MP Bindings

The example LDP P2MP LSP is shown in Figure 173. In this case, PE-4 is only an egress node and not a bud node.

Figure 173 **LDP P2MP LSP**

Verify the LDP P2MP bindings on the leaf node PE-4, as follows.

The leaf node programs a pop entry for the label sent upstream.

```
*A:PE-4# show router ldp bindings active p2mp

The egress next hop is PE-3.

On the root node PE-1, there is MPLS multicast replication. One traffic stream goes via transit node PE-2 toward leaf node PE-3 and the other traffic stream goes directly toward leaf node PE-4. There are two push entries with the corresponding next-hop address, as follows:

```
*A:PE-1# show router ldp bindings active p2mp

The output for leaf node PE-4 is similar.
```

Debug Commands

Debugging was enabled on the nodes when LDP was configured. To distinguish which messages are being logged for a debug command, the debug configuration is different for the nodes, as follows:

```
*A:PE-2# debug router ldp peer 192.0.2.1 event bindings
*A:PE-3# debug router ldp peer 192.0.2.2 packet label detail
*A:PE-4# debug router ldp peer 192.0.2.1 packet init detail
```

The following messages were logged. The first two messages correspond to the label mapping messages to establish LDP bindings. The first message is sent from transit node PE-2 to root node PE-1, while the second is sent by the leaf node PE-3 to the transit node PE-2.

```
*A:PE-2# debug router ldp peer 192.0.2.1 event bindings
```

```
---snip---
7 2016/03/25 14:05:27.21 UTC MINOR: DEBUG #2001 Base LDP

```

Configure Multicast LDP and Verify Traffic

Configure PIM and IGMP on the Root and Leaf Nodes

PIM needs to be enabled on the root node on the interface toward the multicast source S-1, as follows:

```
*A:PE-1# configure router pim interface "int-PE-1-S-1"
```

On the leaf nodes, PIM needs to be enabled (no shutdown), but no interfaces need to be assigned.

The IGMP configuration for root node PE-1 is needed to forward the incoming traffic for multicast group 232.1.1.1 from source 172.16.11.2 to the tunnel-interface. If IGMP is not configured, the incoming traffic on the interface toward the multicast source will be dropped, because no outgoing interface is defined.

```
*A:PE-1# configure router
        igmp
            tunnel-interface ldp-p2mp "5000" sender 192.0.2.1
                static
                    group 232.1.1.1
                        source 172.16.11.2
                    exit
                exit
            exit
        exit
```

The IGMP configuration for leaf node PE-3 is as follows:

```
*A:PE-3# configure router
        igmp
            interface "int-PE-3-H-3"
                static
                    group 232.1.1.1
                        source 172.16.11.2
                    exit
                exit
            exit
        exit
```

The incoming traffic from the tunnel interface will be forwarded to the outgoing interface toward the receiving multicast host H-3.

The IGMP configuration for leaf node PE-4 is similar.

At this point, the IGMP/PIM configuration on the root node is complete. This can be verified, as follows:

```
*A:PE-1# show router pim group

===============================================================================
*A:PE-1#
```

The incoming interface is the interface facing the multicast source S-1. The outgoing interface is a reference to the tunnel interface. The name for the outgoing interface (mpls-if-73728) contains the tunnel interface index 73728 as in previous CLI output. The multicast source S-1 is already sending traffic, but the receivers cannot receive it yet.

The configuration on the leaf nodes is still incomplete. A multicast policy needs to be configured and applied first.

Configure and Apply Multicast Policy on Leaf Nodes

The leaf nodes need to get multicast traffic off the LDP P2MP LSP. Therefore, a multicast policy needs to be created and applied. For leaf node PE-3, this is as follows:

```
*A:PE-3# configure mcast-management
        multicast-info-policy "p2mp-pol" create
            bundle "bundle1" create
                primary-tunnel-interface ldp-p2mp 5000 sender 192.0.2.1
                channel "232.1.1.1" create
                exit
```

```
            exit
         exit
*A:PE-3# configure router multicast-info-policy "p2mp-pol"
```

The configuration for leaf node PE-4 is identical.

Verify Multicast Traffic on Leaf Nodes

Verify the multicast traffic, as follows:

```
*A:PE-3# show router pim group
===============================================================================
Legend:  A = Active   S = Standby
===============================================================================
PIM Groups ipv4
===============================================================================

*A:PE-3#
```

The incoming interface is from the tunnel interface, while the outgoing interface is toward the receiving multicast host H-3.

mLDP Fast Upstream Switchover

mLDP fast upstream switchover allows a downstream node of an mLDP FEC to perform a fast switchover and source the traffic from another upstream node. This switchover is necessary when IGP and LDP are converging due to a failure of the upstream LSR, which is the primary next hop of the root LSR for the P2MP FEC. There will be traffic duplication toward the node that has the upstream alternate backup (in this case to PE-3), but only one stream will be accepted. The multicast stream will be sent to the primary next hop as well as to the loopfree alternate backup. As long as there is no failure, the primary next hop accepts the traffic and forwards it. The backup rejects the traffic. When a failure occurs and the primary LDP session goes down, the backup will start accepting packets.

mLDP fast upstream switchover provides an upstream Fast Reroute (FRR) node-protection capability for the mLDP FEC packets. This multicast upstream FRR node protection is at the expense of traffic duplication from two different upstream nodes into the node that performs the fast upstream switchover. This feature is described in *draft-pdutta-mpls-mldp-up-redundancy*.

Multicast upstream FRR can be configured for mLDP, as follows:

```
*A:PE-1# configure router ospf loopfree-alternate

*A:PE-1# configure router ldp mcast-upstream-frr
```

This configuration can be repeated on some or all of the nodes. In this example, it is configured on all nodes. FRR for unicast can be configured in combination with this, but that is not required. FRR for unicast can be enabled as follows:

```
*A:PE-1# configure router ldp fast-reroute
*A:PE-1# configure router ip-fast-reroute
```

In this example, it is assumed that unicast IP and unicast LDP prefixes do not need to be protected. Therefore, unicast FRR remains disabled.

FRR can be verified as disabled for unicast (FRR) and enabled for multicast (Mcast Upstream FRR), as follows:

```
*A:PE-1# show router ldp status

*A:PE-1#
```

Of the three nodes in the test topology that have upstream nodes, only PE-3 has an upstream alternate for FRR. PE-4 becomes a transit node for traffic destined to PE-3 (but PE-3 will drop it, until the primary LDP session fails). PE-3 sends a label mapping message to PE-4 for label 262138, as in the following trace message.

```
8 2016/03/25 14:10:34.07 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 63) to 192.0.2.4:0
Protocol version = 1
Label 262138 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 5000
"
```

PE-4 will have an additional LDP P2MP binding where the label is swapped, as follows:

```
*A:PE-4# show router ldp bindings active p2mp

Because LoopFree Alternate (LFA) and ECMP are mutually exclusive, LFA is only useful when ECMP is disabled. When both are enabled, ECMP will have preference.

mLDP fast upstream switchover relies on the fast detection of loss of the LDP session to the upstream peer to which the primary ingress label map (ILM) label had been advertised. As a result, Nokia recommends to perform the following:

1. Enable bidirectional forwarding detection (BFD) on all LDP interfaces to upstream LSR nodes. When BFD detects the loss of the last adjacency to the upstream LSR, BFD brings down the LDP session immediately. The backup ILM is activated.
2. If there is a concurrent T-LDP adjacency to the same LSR node, enable BFD on the T-LDP peer as well as on the interface.
3. Enable the ldp-sync-timer option on all interfaces to the upstream LSR nodes.

   If the LDP session for the primary ILM to the upstream LSR goes down for any other reason than a failure of the interface or of the upstream LSR, routing and LDP will go out of sync. The backup ILM will remain activated until the interior gateway protocol (IGP) seeks the next shortest path first (SPF). By enabling the ldp-sync-timer, this process is accelerated because the advertised link metric will get the maximum value as soon as the LDP session goes down. This triggers the IGP to calculate an SPF route.

The FRR configuration can be removed, as follows:

```
*A:PE-1# configure router ldp no mcast-upstream-frr
*A:PE-1# configure router ospf no loopfree-alternate
```

Multipoint Make-Before-Break (MP MBB)

Multipoint MBB is performed when the best path to the root changes, but the existing path can still be used, such as when a link comes up or when the routing metric changes. The goal of MBB is to establish a new P2MP LSP before the old P2MP is removed, in order to avoid traffic loss.

Leaf or transit nodes must allocate a new label and program the ILM with a duplicate set of existing next-hop label forwarding entries (NHLFEs) toward the upstream nodes. This may lead to traffic duplication for a short period of time.

Multipoint MBB is enabled by default, as follows:

```
*A:PE-3# show router ldp status

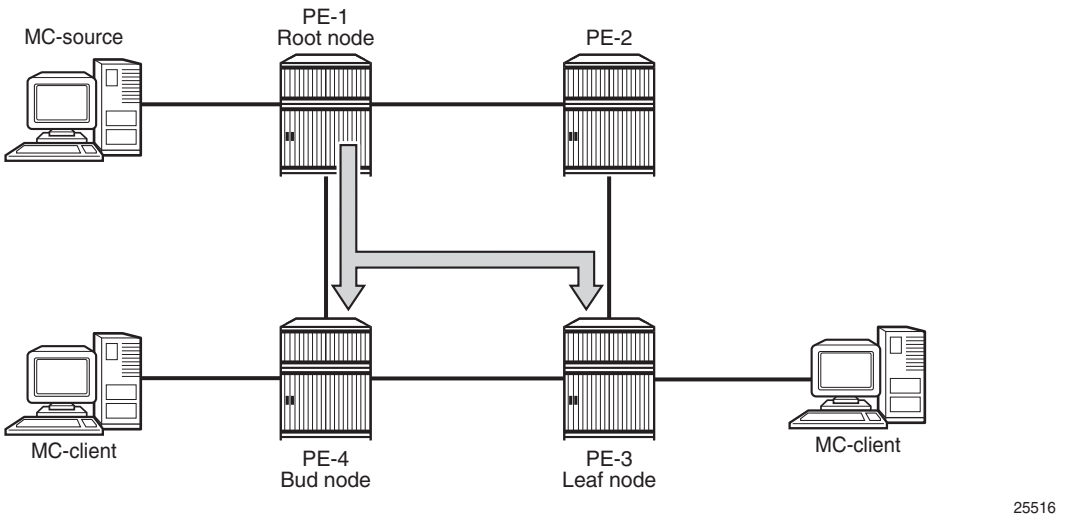
*A:PE-3#
```



When the metric is increased on the interface (int-PE-3-PE-2) toward the active upstream node, PE-3 sends out an OSPF link status update. Traffic still arrives at PE-3 using the original P2MP LSP. The MBB P2MP LSP is set up.

PE-3 sends a label mapping message toward PE-4, including an MP status TLV carrying an MBB status code indicating that MBB procedures apply to the LSP. PE-4 sends an LDP notification toward PE-3, including an MP status TLV indicating that PE-4 has a state for the existing P2MP LSP.

PE-3 sends an LDP withdrawal message to PE-2. PE-2 replies with an LDP release message.

The multicast traffic arrives at PE-3 using the new LDP P2MP LSP. This way, PE-4 becomes a bud node, and PE-2 is not used for transit anymore; see Figure 174.

Figure 174 **New LDP P2MP LSP after Metric Change**

Originally, leaf node PE-3 preferred the route via PE-2 toward root node PE-1, as follows:

```
*A:PE-3# show router route-table 192.0.2.1
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                                Type    Proto     Age        Pref
      Next Hop[Interface Name]                                        Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                      Remote  OSPF      00h00m52s  10
       192.168.23.1                                                    20
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-3#
```

Consequently, the label map messages were originally sent to PE-2, not to PE-4. PE-2 is the transit node for traffic destined to PE-3, as follows:

```
*A:PE-2# show router ldp bindings active p2mp
===============================================================================
LDP Bindings (IPv4 LSR ID 192.0.2.2)
             (IPv6 LSR ID ::)
===============================================================================

192.0.2.1                                Swap            262139    262139
192.168.23.2                             1/1/1

-------------------------------------------------------------------------------
No. of Generic IPv4 P2MP Active Bindings: 1
===============================================================================
---snip---
```

The metric is changed on the interface between PE-3 and PE-2, as follows:

```
*A:PE-3# configure router ospf area 0 interface "int-PE-3-PE-2" metric 1000
```

The preferred route from leaf node PE-3 to root node PE-1 is now via PE-4, as follows:

```
*A:PE-3# show router route-table 192.0.2.1
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                           Type    Proto     Age        Pref
      Next Hop[Interface Name]                                    Metric
-------------------------------------------------------------------------------
192.0.2.1/32                                 Remote  OSPF      00h13m02s  10
       192.168.34.2                                                 20
-------------------------------------------------------------------------------
No. of Routes: 1
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:PE-3#
```

The leaf node PE-3 will prefer to set up a path from PE-4 rather than PE-2. PE-3 will send label mapping messages to PE-4. The old P2MP LSP will be used until the new P2MP LSP is set up. There will be no traffic interruption.

PE-3 will send a label withdrawal message to PE-2 and PE-2 will no longer be a transit node, as follows:

```
*A:PE-2# show router ldp bindings active p2mp
===============================================================================
LDP Bindings (IPv4 LSR ID 192.0.2.2)
             (IPv6 LSR ID ::)

RootAddr                                    Op              IngLbl    EgrLbl
EgrNH                                       EgrIf/LspId
```

```
-------------------------------------------------------------------------------
5000                                        73728
192.0.2.1                                   Push              --      262139
192.168.14.2                                1/1/2

-------------------------------------------------------------------------------
No. of Generic IPv4 P2MP Active Bindings: 1
===============================================================================
---snip---
```

The switchover to this new P2MP LSP occurred without traffic loss.

The following debugging was enabled before the metric change:

```
*A:PE-3# debug router ldp peer 192.0.2.2 packet label detail
*A:PE-3# debug router ldp peer 192.0.2.4 packet label detail
*A:PE-3# debug router ldp peer 192.0.2.2 packet init detail
*A:PE-3# debug router ldp peer 192.0.2.4 packet init detail
```

The first trace message shows that label 262138 is advertised to PE-4. MBB is requested, as follows:

```
11 2016/03/25 14:12:16.89 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Mapping packet (msgId 76) to 192.0.2.4:0
Protocol version = 1
Label 262138 advertised for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 5000
MP Status MBB = REQ
"
```

The next message is a notification from PE-4 confirming that there is no fatal error and MBB can be applied, as follows:

```
12 2016/03/25 14:12:16.89 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Notification packet (msgId 76) from 192.0.2.4:0
Protocol version = 1
Status Code = MPStatus (0x00000040) Non-fatal
Causing message Id = 0
Causing message type = NULL
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 5000
MP Status MBB = ACK
"
```

The following message is a label withdraw message for label 262139 sent to PE-2:

```
13 2016/03/25 14:12:16.89 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Send Label Withdraw packet (msgId 76) to 192.0.2.2:0
Protocol version = 1
Label 262139 withdrawn for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 5000
"
```

The last message is a label release message for label 262139 received from PE-2, as follows. This message is only sent after the new P2MP LSP is set up.

```
14 2016/03/25 14:12:17.01 UTC MINOR: DEBUG #2001 Base LDP
"LDP: LDP
Recv Label Release packet (msgId 75) from 192.0.2.2:0
Protocol version = 1
Label 262139 released for the following FECs
P2MP: root = 192.0.2.1, T: 1, L: 4, TunnelId: 5000
"
```

Conclusion

Multicast LDP provides extensions to the LDP protocol for the setup of P2MP and MP2MP LSPs in MPLS networks. mLDP is simple to configure compared to RSVP. FRR and MBB are supported for mLDP.

RSVP Point-to-Point LSPs

This chapter provides information about point-to-point label switched paths (LSPs) established using resource reservation protocol (RSVP) with or without traffic engineering (TE).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was written for release 14.0.R1. There are no pre-requisites or conditions on the hardware for this configuration.

Overview

Due to the connectionless nature of the network layer protocol IP, packets travel through the network on a hop-by-hop basis with routing decisions made at each node. As a result, hyperaggregation of data on certain links may occur and it may impact the provider's ability to provide guaranteed service levels across the network end-to-end. To address these shortcomings, multiprotocol label switching (MPLS) was developed. The technology provides the capability to establish connection oriented paths, called label switched paths (LSPs), over a connectionless (IP) network. The LSP offers a mechanism to engineer network traffic independently from the underlying network routing protocol (mostly IP) to improve the network resiliency and recovery options and to permit delivery of new services that are not readily supported by conventional IP routing techniques, such as Layer 2 IP virtual private networks (VPNs). These benefits are essential for today's communication network explaining the wide deployment base of the MPLS technology.

RFC 3031, *Multiprotocol Label Switching Architecture*, specifies the MPLS architecture while this document describes the configuration and troubleshooting of RSVP point-to-point LSPs on SR OS. Besides RSVP P2P LSPs, there are also Static Point-to-Point LSPs, LDP Point-to-Point LSPs, and Segment Routing with IS-IS Control Plane.

Packet Forwarding

As a packet of a connectionless network layer protocol travels from one router to the next, each router in the network makes an independent forwarding decision by performing the following basic tasks: first analyzing the packet header, then referencing the local routing table to find the longest match based on the destination address in the IP header, and finally sending out the packet on the selected interface. In other words, the first function partitions the entire set of possible packets into a set of forwarding equivalence classes (FECs). All packets associated to a particular FEC will be forwarded along the same logical path to the same destination. The second function maps each FEC to a next hop destination router. Each router along the data path performs these actions.

On the other hand, in MPLS, the assignment of a particular packet to a particular FEC is done just once, as the packet enters the network. In turn, the FEC is mapped to an LSP, which is pre-signaled prior to any data flowing. An MPLS label, representing the FEC to which the packet is assigned, is attached to the packet (push operation) and once labeled, the packet is forwarded to the next hop router along that LSP path. At subsequent hops, there is no further analysis of the packet network layer header. Instead, the label is used as an index into a table which specifies the next hop and a new label. The old label is replaced with the new label (swap operation), and the packet is forwarded to its next hop. At the MPLS network egress, the label is removed from the packet (pop operation). If this router is the final destination (based on the remaining packet), the packet is handed to the receiving application (such as a virtual private LAN service (VPLS) domain). If this router is not the final destination of the packet, the packet will be sent into a new MPLS tunnel or forwarded by conventional IP forwarding towards the Layer 3 destination.

Terminology

Figure 175 **Generic MPLS Network, MPLS Label Operations**

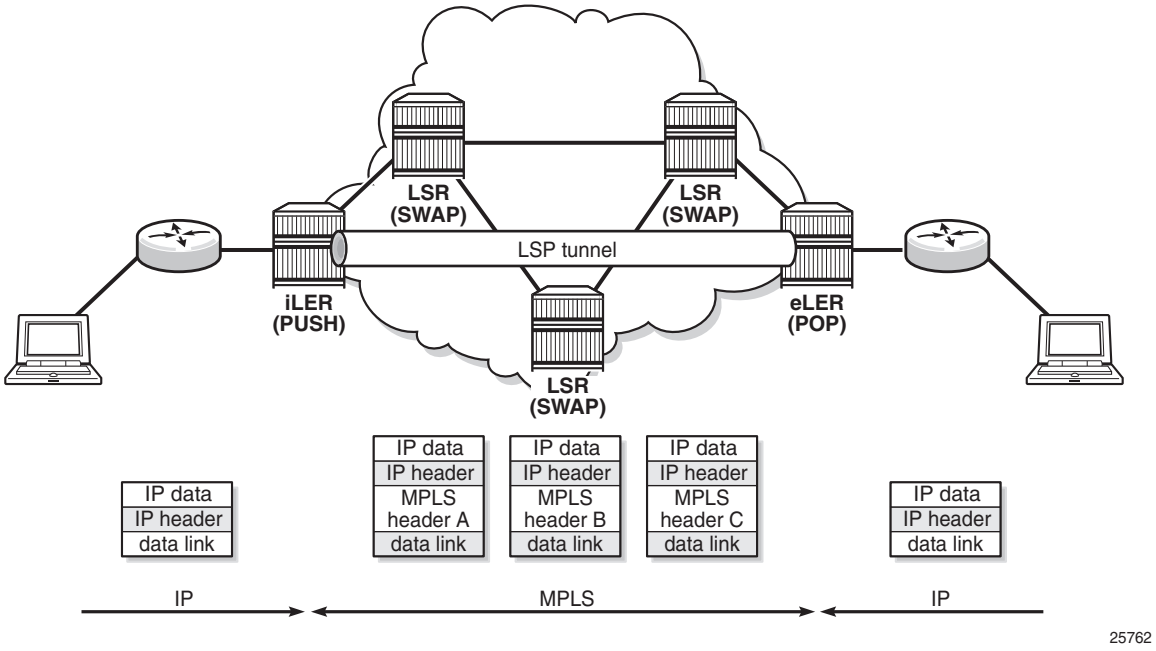

Figure 175 depicts a general network topology clarifying the MPLS-related terms. A label edge router (LER) is a device at the edge of an MPLS network, with at least one interface outside the MPLS domain. A router is usually defined as an LER based on its position relative to a particular LSP. The MPLS router at the head-end of an LSP is called the ingress label edge router (iLER). The MPLS router at the tail-end of an LSP is called the egress label edge router (eLER). The iLER receives unlabeled packets from outside the MPLS domain, then applies MPLS labels to the packets, and forwards the labeled packets into the MPLS domain. The eLER receives labeled packets from the MPLS domain, then removes the labels, and forwards unlabeled packets outside the MPLS domain. The eLER can signal an implicit-null label (numeric value 3). This informs the previous hop to send MPLS packets without an outer label and is known as penultimate hop popping (PHP).

A label switching router (LSR) is a device internal to an MPLS network, with all interfaces inside the MPLS domain. These devices switch labeled packets inside the MPLS domain. In the core of the network, LSR ignore the packet network layer (IP) header and simply forward the packet using the MPLS label swapping mechanism.

A single LSP is unidirectional. In common practice, because the bidirectional nature of most traffic flows is implied, the term LSP often is used to define the pair of LSPs that enable the bidirectional flow. For ease of terminology and discussion however, the LSP in this chapter is referred to as a single entity.

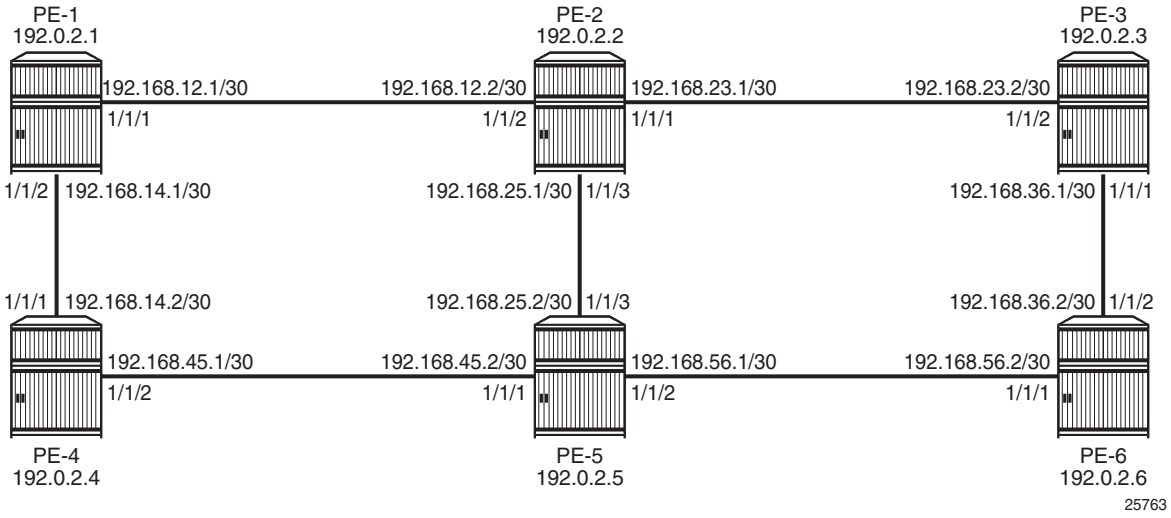
LSP Establishment

Prior to packet forwarding, the LSP must be established. In order to do so, labels need to be distributed for the path. Labels are usually distributed by a downstream router in the upstream direction (relative to the data flow). There are a number of ways used for label distribution: static, LDP, and RSVP. For static P2P LSPs, see chapter Static Point-to-Point LSPs; for LDP P2P LSPs, see chapter LDP Point-to-Point LSPs.

RSVP-TE (RFC 3209, *RSVP-TE: Extensions to RSVP for LSP Tunnels*) can be used to signal LSPs across the network. RSVP-TE is used for traffic engineering when the ingress router creates an LSP with specific constraints beyond the best route chosen by the IGP. RSVP-TE identifies the specific path desired for the LSP and may include resource requirements for the path.

The most important benefit of the label swapping mechanism RSVP-TE is its ability to map any type of user traffic to an LSP that has been specifically engineered to satisfy user traffic requirements. Customized LSPs may be created based on hop count, bandwidth requirements, administrative groups, or shared risk link groups (SRLGs). They can even be routed through a strict path with specific network links or nodes, as specified by the ingress node. This offers service providers precise control over the flow of traffic in their networks and results in a network that operates more efficiently and provides more predictable and scalable services. For information about SRLG, see chapter Shared Risk Link Groups for RSVP-Based LSP.

Fast reroute (FRR) allows to signal backup paths before a failure takes place. This allows traffic to flow almost continuously, without waiting for routing protocol convergence. There a two different methods for FRR for an RSVP-TE LSP: one-to-one and facility.



- FRR one-to-one defines detour tunnels toward the eLER for a particular LSP only. The advantage is that the detour tunnel is the best path to the eLER that avoids the node or link at the point of failure. The drawback is that when different LSPs would need the same detour, a dedicated RSVP-TE detour LSP needs to be signaled for each LSP.

- FRR facility defines local repair tunnels avoiding one particular node (the next hop in the data path) or one particular link (the next link in the data path), ignoring the eLER. These bypass tunnels originate in a point of local repair (PLR) and terminate in a merge point (MP) on the LSP. Bypass tunnels are shared between LSPs.

Example Topology

The example topology is displayed in Figure 176. The setup consists of six 7750 SR nodes located in a single autonomous system.

Figure 176 **MPLS Example Topology**

Configuration

In this chapter, RSVP LSPs are configured manually, but they can also be configured automatically using LSP templates; see chapter Automatic Creation of RSVP-TE LSPs.

As a general pre-requisite for the configuration of MPLS LSPs, a correctly working IGP is required. Open shortest path first (OSPF) or intermediate system to intermediate system (IS-IS) can be used as IGP.

RSVP-TE, an extension of the original RSVP protocol, has two major benefits adding to the basic MPLS functionality. The first benefit is traffic engineering, which allows the ingress router to create an LSP with specific constraints beyond the best route chosen by the IGP. The second benefit is improved network resiliency when a link or node fails in the network, using FRR and secondary paths. FRR is also supported for LDP, see chapter MPLS LDP FRR using ISIS as IGP.In this chapter, several RSVP-TE LSPs are configured:

- A simple LSP with a primary path that has strict hops and no specific TE constraints
- A simple LSP with a dynamic path without any configured hops is created. Initially, there are no constraints and the actual path is calculated based on the IGP best route.
- An LSP configured with constrained shortest path first (CSPF) that will use the TE metric, even though the IGP metric can also be used
- An LSP with fast reroute (FRR) one-to-one enabled
- An LSP with FRR facility enabled
- An LSP including an admin group "blue" and an LSP excluding admin group "red"
- An LSP with a hop limit configured

There is no configuration example with bandwidth constraints configured in this chapter. See chapter Automatic Bandwidth Adjustment in P2P LSPs for a configuration with bandwidth constraint with or without automatic adjustment.

Initially, no traffic engineering is enabled in the ISIS context, but it will be enabled when required. For RSVP LSPs, the MPLS instance needs to be enabled on each router and all network interfaces facing the MPLS domain. By default, the system interface is put automatically within the MPLS context. When adding interfaces to the MPLS instance, they are automatically added to the RSVP instance as well, but the instance itself is still in an administrative shutdown state. The next step is to enable the RSVP instance on all routers in the MPLS network. As a result, all interfaces facing the MPLS domain as well as the system interface are added to the MPLS and RSVP instance and both instances are in a no shutdown state. For PE-1, the following configuration is required:

```
*A:PE-1# configure router
        mpls
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-4"
            exit
            no shutdown
        exit
*A:PE-1# configure router rsvp no shutdown
```

Strict or Loose Path

On the iLER, first the definition of a path is required. A path is a sequence of MPLS routers (hops) through which the LSP using that path has to pass. It is not uniquely bound to a particular LSP; it can be used by any LSP originating in that node. A hop in a path can be strict or loose: strict or loose meaning that the LSP must take either a direct path from the previous hop router to this router (strict) or can traverse through other routers (loose). The hops not explicitly defined in the loose path definition are created by calculating the IGP shortest path. A third possibility is an empty path implying not a single node is required to be present in the LSP path and the shortest path from the IGP is used to define the LSP path. Other techniques, such as the use of admin groups or shared risk link groups, can also be used to influence the decision which hops to include in the path. Three paths will be configured, respectively:

1. Only strict hops
2. Mixed strict and loose hops
3. Empty path

To find a valid path, the last hop in the path sequence needs to be the system IP or an interface address of the terminating router (eLER). The IP addresses in the hop command can be the system IP addresses or the interface addresses of the node. However, it is recommended to use the system IP addresses with keyword **loose** as this allows more flexibility when finding new paths in failover scenarios (because the upstream node could use any of multiple paths to the system address, whereas specifying the interface address would restrict the upstream node to a single entry-point). The recommendation when using the keyword strict in the hop command context, is to use the physical link addresses. However, the last hop in the path should be a system address to make it appear in the list on the 5620 SAM (service-aware manager).

```
*A:PE-1# configure router
        mpls
            path "path-PE-1-PE-6-strict"
                hop 10 192.168.12.2 strict
                hop 20 192.168.25.2 strict
                hop 30 192.168.56.2 strict
                no shutdown
            exit
            path "path-PE-1-PE-6-semiLoose"
                hop 10 192.0.2.5 loose
                hop 20 192.168.56.2 strict
                no shutdown
            exit
            path "dyn"
                no shutdown
            exit
```

The paths can be checked with the **show router mpls path** command.

```
*A:PE-1# show router mpls path
===============================================================================
MPLS Path:
===============================================================================
Path Name                       Adm  Hop Index   IP Address       Strict/Loose

```

Simple RSVP LSP with Strict Primary Path

The configuration of a simple LSP using RSVP signaling contains at least on the iLER:

- System IP address of the terminating node (to)
- Path the LSP will take to the eLER (primary)
- Administratively enabled (no shutdown)

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-6"
                to 192.0.2.6
                primary "path-PE-1-PE-6-strict"
                exit
                secondary "dyn"
                exit
                no shutdown
            exit
```

All the hops in the strict path are already defined and there is no need to look up the IGP best route. The configuration of secondary paths is optional. In case the primary path fails, the secondary path can be signaled to take over the traffic. It can even be signaled as standby while the primary path is operational for a faster switchover when the keyword **standby** is added, which is not the case here. The secondary path has no hops defined. The hops will be calculated based on the IGP best route. The nodes through which the LSP will pass (LSRs and eLER) require no additional configuration: enabling MPLS and RSVP on their interfaces suffices.

An overview of all LSPs configured on a particular node is given by the **show router mpls lsp** command. More details about a particular LSP can be retrieved by adding the keyword **detail** to the previous command.

```
*A:PE-1# show router mpls lsp

LSP Attr Flags  : N/A
===============================================================================
*A:PE-1#
```

In the tunnel table, there is an RSVP LSP:

```
*A:PE-1# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.6/32      rsvp      MPLS  1         7        192.168.12.2   16777215
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

In order to signal PHP with RSVP, implicit-null must be configured on the eLER (RSVP must be shut down to perform this command).

```
*A:PE-6# configure router
        rsvp
            shutdown
            implicit-null-label
            no shutdown
            exit
```

The implicit-null is signaled after re-enabling RSVP and is shown on PE-5 as an egress label of 3. This label is not actually sent toward PE-6.

```
*A:PE-5# show router rsvp session detail
===============================================================================
RSVP Sessions (Detailed)
===============================================================================
-------------------------------------------------------------------------------
LSP : LSP-PE-1-PE-6::path-PE-1-PE-6-strict
-------------------------------------------------------------------------------
From            : 192.0.2.1             To              : 192.0.2.6
Tunnel ID       : 1                     LSP ID          : 41476
Style           : SE                    State           : Up
Session Type    : Transit
In Interface    : 1/1/3                 Out Interface   : 1/1/2
In Label        : 262143                Out Label       : 3
Previous Hop    : 192.168.25.1          Next Hop        : 192.168.56.2
---snip---
```

The use of implicit-null can also be enabled/disabled on a per interface basis (either RSVP, or the interface within RSVP, must be shut down to perform this change).

```
A:PE-6>config>router>rsvp# interface "int-PE-6-PE-5"
A:PE-6>config>router>rsvp>if# implicit-null-label
  - implicit-null-label {<enable|disable>}
  - no implicit-null-label
 <<enable|disable>>   : keyword
```

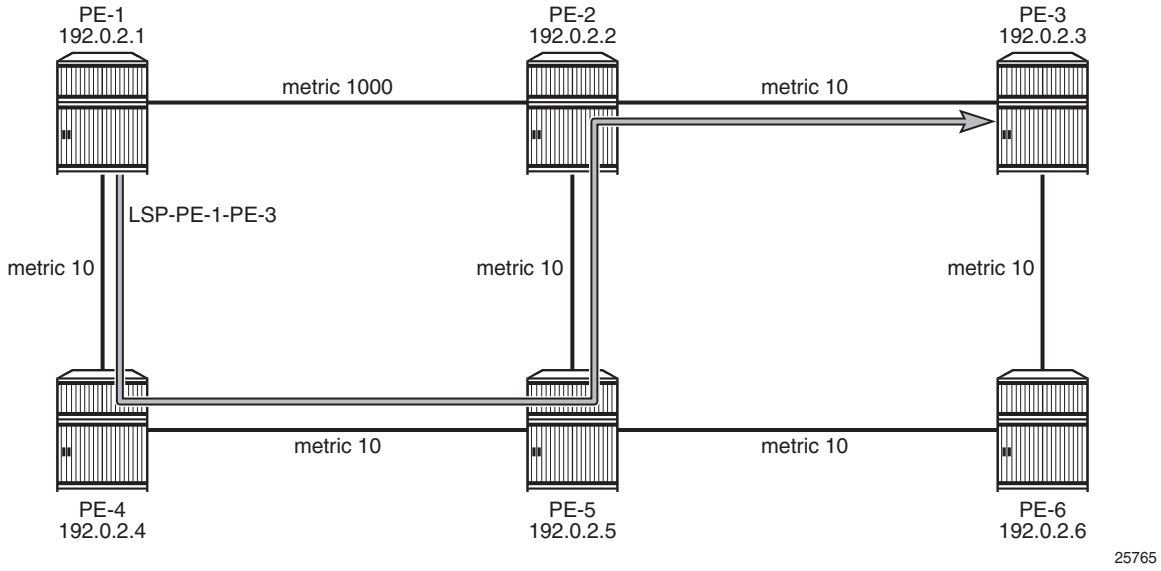
In the remainder of the chapter, LSPs with empty paths will be used. LSP "LSP-PE-1-PE-6" is shut down.

Simple RSVP LSP with Dynamic Path

In this section, an LSP is configured from PE-1 to PE-3 with a dynamic path that is empty. There is no secondary path. LSP "LSP-PE-1-PE-3" is configured as follows:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3"
                to 192.0.2.3
                primary "dyn"
                exit
                no shutdown
            exit
```

Interfaces with a lower metric will be preferred over links with a high metric. The default IGP metric in this example is 10. The metric is lower for higher speed links, but can be configured manually; as follows:



```
*A:PE-1# configure router isis interface "int-PE-1-PE-2" level 1 metric 1000
```

The link between PE-1 and PE-2 has a higher metric and will not be selected for forwarding traffic because the detour via PE-4 has a lower metric. The routing table shows that the route to prefix 192.0.2.3 has PE-4 as next hop instead of PE-2 and that the metric is 40:

```
*A:PE-1# show router route-table 192.0.2.3
===============================================================================
Route Table (Router: Base)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.2.3/32                                    Remote  ISIS      00h14m02s  15
       192.168.14.2                                                    40
-------------------------------------------------------------------------------
No. of Routes: 1
```

Figure 177 shows the path used by the LSP:

Figure 177 **LSP with Dynamic Path Takes IGP Best Route**

The actual hops can be verified in the following output. Since the path is dynamic, there are no explicit hops configured.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail
===============================================================================
MPLS LSP LSP-PE-1-PE-3 Path  (Detail)

```

```
---snip---
```

The tunnel table shows the RSVP LSP with PE-4 as the next hop and a metric of 40:

```
*A:PE-1# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.3/32      rsvp      MPLS  2         7        192.168.14.2   40
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

Another path with metric 40 is as follows: PE-1, PE-4, PE-5, PE-6, PE-3. This can equally well be selected.

RSVP-TE LSP with Dynamic Path

Traffic engineering is enabled in the ISIS context on all nodes; as follows:

```
*A:PE-1# configure router isis traffic-engineering
```

The LSP can be configured with constrained shortest path first (CSPF); as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" cspf
```

For this LSP, it will not make any difference. By default, the IGP metrics are used and the LSP path takes the IGP shortest path.

Besides IGP metrics, also TE metrics can be configured; as follows:

```
*A:PE-2# configure router
        mpls
            interface "int-PE-2-PE-1"
                te-metric 10
            exit
            interface "int-PE-2-PE-3"
                te-metric 500
            exit
            interface "int-PE-2-PE-5"
                te-metric 10
            exit
```

In this example, all interfaces on all PEs get a TE metric of 10, except for the interfaces between PE-2 and PE-3, which get a TE metric of 500. Even with these TE metrics configured, the LSP path will not change, because the IGP metric is used by default, as can be verified as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail
---snip---
-------------------------------------------------------------------------------
LSP LSP-PE-1-PE-3 Path dyn

---snip---
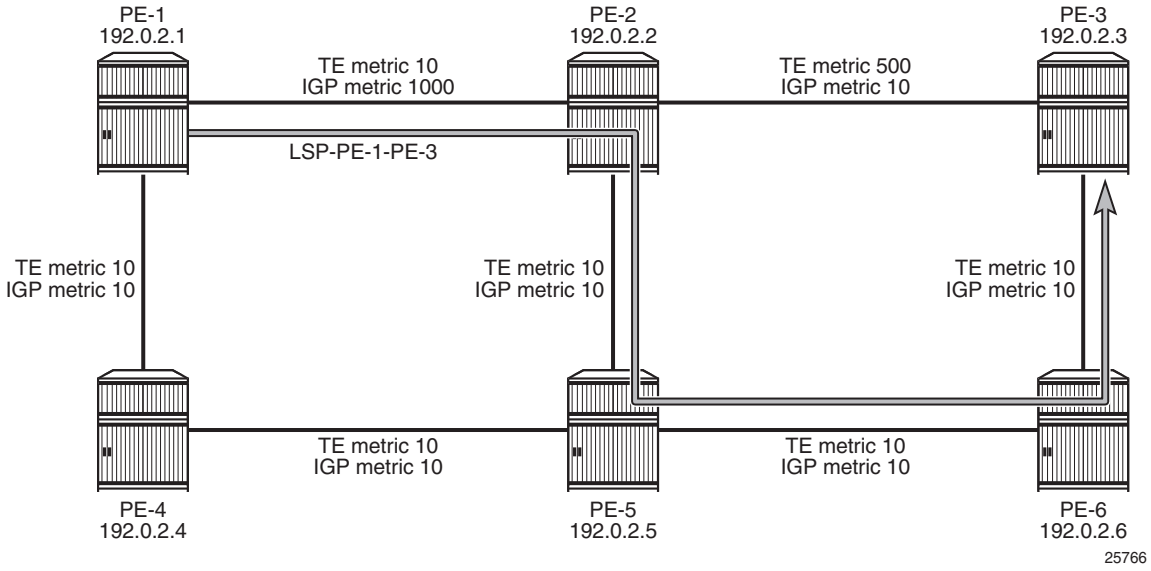
```

The RSVP LSP in the tunnel table has next hop PE-4 and a metric of 40:



```
*A:PE-1# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.3/32      rsvp      MPLS  2         7        192.168.14.2   40
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

To force the LSP to use the TE metric, the LSP is reconfigured as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" cspf use-te-metric
```

The LSP path is shown in Figure 178:

Figure 178 **RSVP-TE LSP with Dynamic Path Using TE Metric**

The LSP path goes from PE-1 to PE-2 and via PE-5 and PE-6 to PE-3, as can be seen in the following output. The CSPF metric is 40, which corresponds to the TE metric in this case:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail
---snip---

===============================================================================
*A:PE-1#
```

The tunnel table shows the RSVP LSP with next hop PE-2 and a metric of 16777215 (infinity) because the IGP metric is not used:

```
*A:PE-1# show router tunnel-table
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.3/32      rsvp      MPLS  2         7        192.168.12.2   16777215
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

The IGP metric values are restored to their default value as follows:

```
*A:PE-1# configure router isis interface "int-PE-1-PE-2" level 1 no metric
*A:PE-2# configure router isis interface "int-PE-2-PE-1" level 1 no metric
```

The TE metrics are configured with the same value for all interfaces; as follows:

```
*A:PE-2# configure router mpls interface "int-PE-2-PE-1" te-metric 10
*A:PE-3# configure router mpls interface "int-PE-3-PE-2" te-metric 10
```

Since all metrics have the same value, it does not matter whether CSPF uses the IGP or TE metric.

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" cspf
```

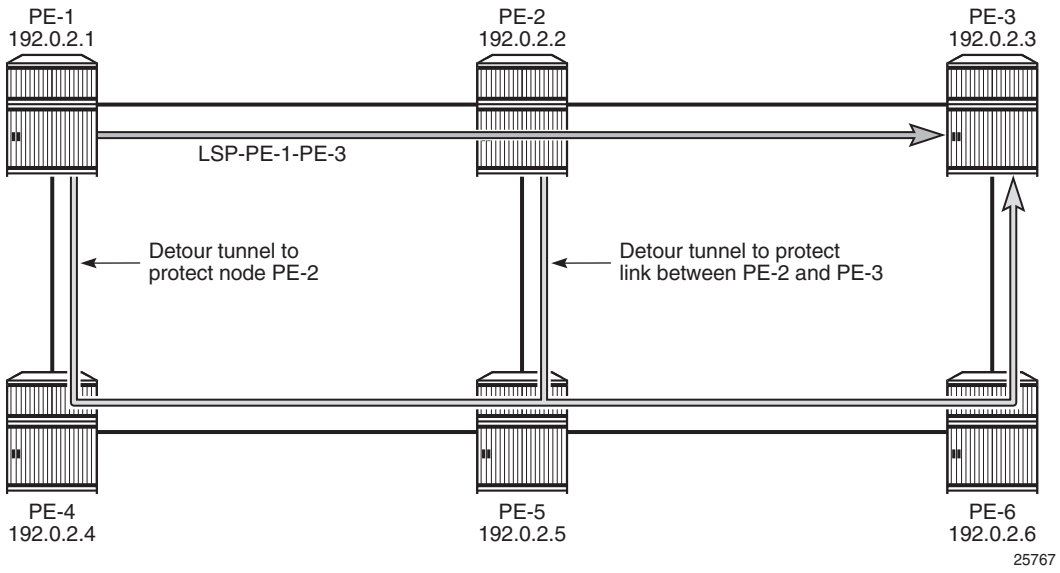
The primary path will go from PE-1 to PE-2 and then to PE-3 with a CSPF (IGP) metric of 20.

Fast Reroute for RSVP-TE LSPs

It is mandatory to have CSPF enabled for FRR.

Fast reroute can be configured on the RSVP LSP in two ways:

1. One-to-one: for each potential point of failure, the best detour tunnel to the eLER is signaled. This detour tunnel is signaled for this particular LSP only and cannot be shared among LSPs
2. Facility: local bypass tunnels are signaled from each point of local repair avoiding the next link or the next node. The bypass tunnels can be shared among LSPs.



FRR One-to-One

The LSP "LSP-PE-1-PE-3" is configured with FRR one-to-one; as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" fast-reroute one-to-one
```

The preferred path from PE-1 to PE-3 is via PE-2. There will be two detour tunnels: one originating in PE-1 to protect node PE-2, and a second detour tunnel originating in PE-2 to protect the link between PE-2 and PE-3. Both detour tunnels use the same path from PE-5 to PE-3 and there is no need to signal this path twice. One detour tunnel terminates in PE-5, and the diverted traffic in this tunnel will be sent to PE-6 and PE-3 via the established detour tunnel. Depending on which detour tunnel is established first, the other detour tunnel terminates in PE-5. The preferred tunnel and the detour tunnels are shown in Figure 179:

Figure 179 **Fast Reroute One-to-One Detour Tunnels**

The protection can be seen in the list of actual hops in the path. In PE-1, a detour tunnel for node protection originates (indicated by @ n; see legend) and in PE-2 a detour tunnel for link protection (indicated by @):

---snip---
```

PE-5 is a transit node for the detour tunnel with previous hop PE-4 and a terminating node for the detour tunnel with previous hop PE-2. In both cases, the next hop is PE-6.

FRR Facility

The drawback of FRR one-to-one is that each LSP requires its own detour tunnels to be signaled. FRR facility does not have this issue, because it offers local repair for the next node or the next link that uses bypass tunnels that can be shared by LSPs. FRR facility bypass tunnels terminate in the merge point (MP), which is a hop in the primary path. FRR facility bypass tunnels for link protection terminate in the next hop in the primary path and FRR facility bypass tunnels for node protection terminate in the next hop of that next hop. FRR bypass tunnels are unaware of the final destination of the LSP and need not terminate in the final destination, but in this case they do, because the number of hops in the primary path is limited. Figure 180 shows the FRR facility bypass tunnels for LSP "LSP-PE-1-PE-3":

Figure 180 **Fast-Reroute Facility Bypass Tunnels**

Fast reroute facility is enabled on LSP "LSP-PE-1-PE-3" as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" fast-reroute facility
```

The LSP path detail output shows that there is a bypass tunnel available in PE-1 that offers node protection for the next node in the primary path: PE-2. In PE-2, there is a bypass tunnel offering link protection for the next link, which is the link between PE-2 and PE-3; as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail

===============================================================================
*A:PE-1#
```

This is the bypass tunnel that originates in PE-1 to protect (avoid) PE-2. In this example, there is only one LSP protected by this bypass tunnel, but the list of protected LSPs can be longer. The same command can be launched on PE-2, where a bypass tunnel originates that protects the link between PE-2 and PE-3.

The RSVP sessions can be displayed as follows:

```
*A:PE-3# show router rsvp session
===============================================================================
RSVP Sessions
===============================================================================
From            To              Tunnel LSP   Name                          State
                                ID     ID
-------------------------------------------------------------------------------
192.0.2.1       192.0.2.3       2      55820 LSP-PE-1-PE-3::dyn            Up
192.0.2.2       192.168.36.1    61442  4     bypass-link192.168.23.2-614*  Up
192.0.2.1       192.168.36.1    61442  4     bypass-node192.0.2.2-61442    Up
-------------------------------------------------------------------------------
Sessions : 3
```

In PE-3, there is an RSVP session for the regular LSP and two bypass tunnels. In this case, the bypass tunnels all go to PE-3, which is the terminating node for the LSP, but that need not be the case. All bypass tunnels are signaled from the point of local repair to the merge point on the LSP path.

To force a FRR facility switchover to a bypass tunnel, a failure is simulated as follows:

```
*A:PE-2# configure port 1/1/1 shutdown
```

The detailed output for the LSP path on PE-1 shows that the tunnel is locally repaired.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail

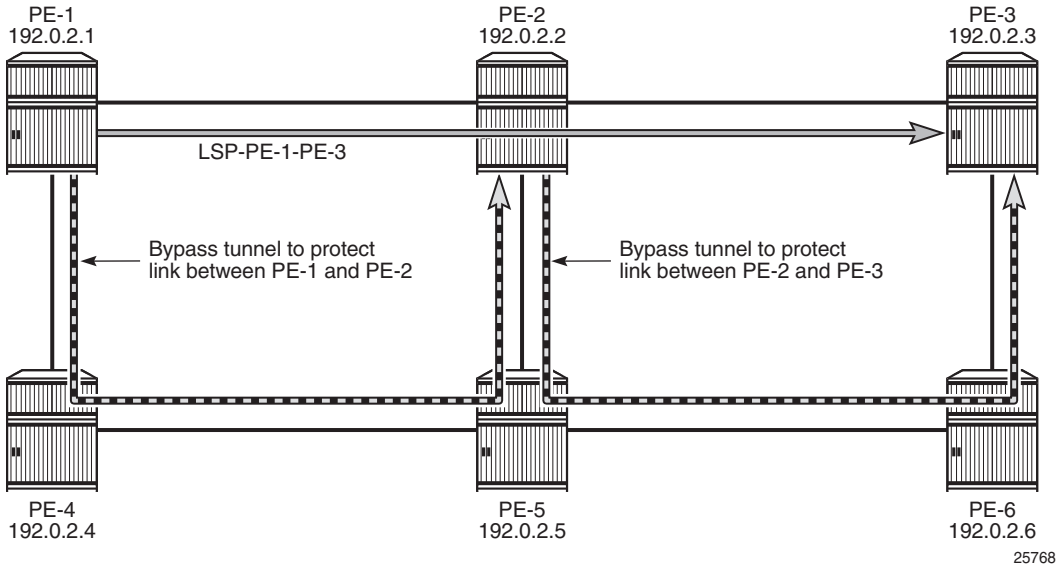
    192.168.12.1 (192.0.2.1) @ n                Record Label        : N/A
 -> 192.168.12.2 (192.0.2.2) @ #                Record Label        : 262141
 -> 192.168.23.2 (192.0.2.3)                    Record Label        : 262141
---snip---
```

The failure code is tunnelLocallyRepaired and next to the actual hop 192.168.12.2 (PE-2), the symbol # indicates that the detour is in use.



FRR Facility without Node Protection

Node protection is by default enabled, but can be disabled as follows:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-3"
                fast-reroute facility
                    no node-protect
                exit
```

As a result, there is only link protection. The bypass tunnels from PE-1 and PE-2 terminate in the next hop in the primary path, as shown in Figure 181:

Figure 181 **FRR Facility without Node Protection**

The LSP path detail output shows that there is no node protection (@):

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3" path detail

===============================================================================
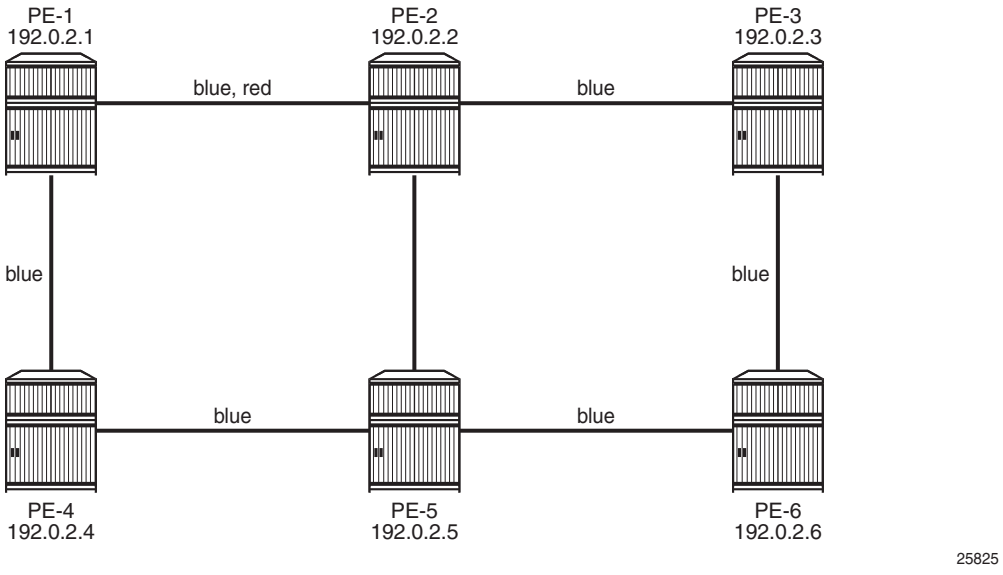
*A:PE-1#
```

In the remainder of this chapter, this LSP is no longer used. Therefore, the LSP is shut down:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-3" shutdown
```

Administrative Groups for RSVP-TE LSPs



Administrative groups (link-coloring) can be used to calculate a path with the restriction to only include links of a particular admin group (color) or to exclude links of a particular admin group. Paths can be disjointed from each other, without the need for an explicit hops list.

Two admin groups are configured on all nodes; as follows:

```
*A:PE-1# configure router if-attribute admin-group "red" value 0
*A:PE-1# configure router if-attribute admin-group "blue" value 1
```

Admin group "blue" is assigned to all MPLS interfaces, except for the link between PE-2 and PE-5 while admin group "red" is only assigned to the link between PE-1 and PE-2; see Figure 182:

Figure 182 **Admin Groups 'Blue' and 'Red'**

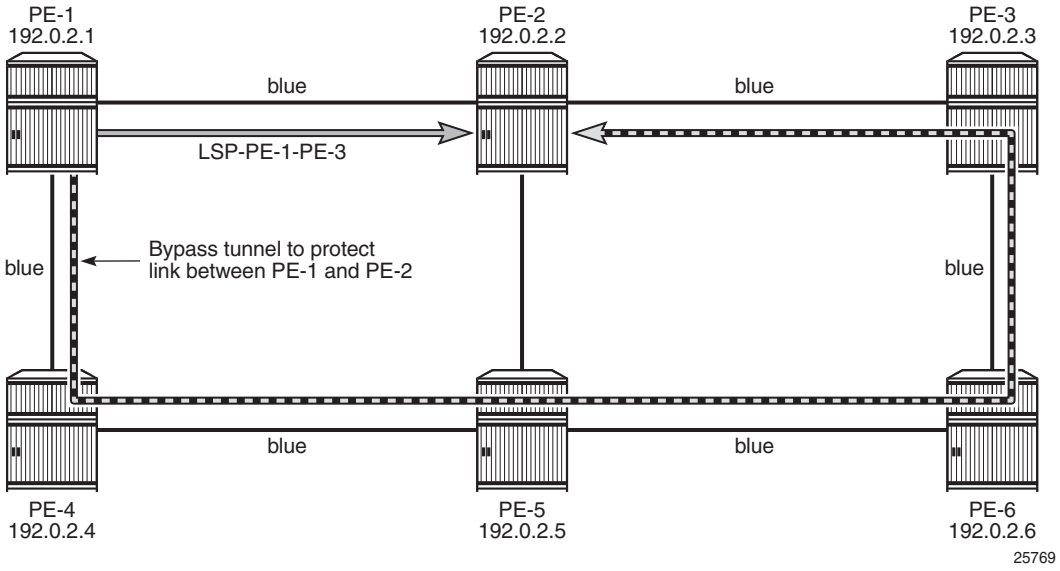
The admin groups are assigned to the MPLS interfaces as follows:

```
*A:PE-1# configure router
        mpls
            interface "int-PE-1-PE-2"
                admin-group "blue"
                admin-group "red"
            exit
            interface "int-PE-1-PE-4"
                admin-group "blue"
            exit
```

The configuration on the other nodes is similar.

To ensure that FRR bypass tunnels will adhere to the same admin group constraints as defined in the LSP, the following is configured on all nodes. It is required on all points of local repair (PLRs):

```
*A:PE-1# configure router mpls admin-group-frr
```



LSP Includes Admin Group 'blue'

LSP "LSP-PE-1-PE-2" is created on PE-1 with a dynamic primary path. FRR facility is enabled. The LSP includes admin group blue and both the primary path as the bypass tunnel must use links in admin group "blue" (propagate-admin-group). Admin-group-frr is enabled in the MPLS context, to ensure that the admin group restriction is respected for FRR.

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-2"
                to 192.0.2.2
                cspf
                include "blue"
                propagate-admin-group
                fast-reroute facility
                    propagate-admin-group
                exit
                primary "dyn"
                exit
                no shutdown
            exit
```

The bypass tunnel cannot include the link between PE-2 and PE-5, since that link does not belong to admin group "blue". The LSP and its bypass tunnel are shown in Figure 183:

Figure 183 **LSP and Bypass within Admin Group 'Blue'**

The LSP path detailed information is as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" path detail

===============================================================================
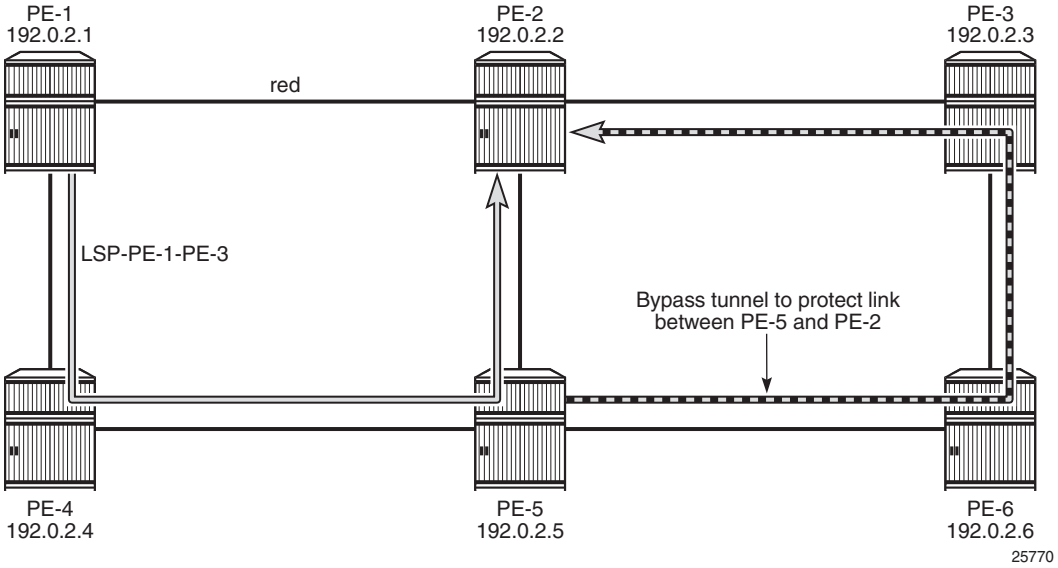
*A:PE-1#
```

All egress links are in admin group blue on the originating and transit nodes.

LSP Excludes Admin Group 'red'



The LSP is reconfigured: instead of including admin group 'blue', it will exclude admin group 'red'. Nothing is changed to the configuration of FRR.

The MPLS configuration is modified as follows:

```
*A:PE-1# configure router
        mpls
            lsp "LSP-PE-1-PE-2"
                no include "blue"
                exclude "red"
            exit
```

The LSP cannot use the red link between PE-1 and PE-2. The path that avoids the red link, is from PE-1 via PE-4 and PE-5 to PE-2. On all PLRs, admin-group-frr is configured, which implies that the originating FRR bypass tunnels need to respect the admin-group constraint of the LSP. There can be no node protection for PE-4 or PE-5 without using the red link between PE-1 and PE-2. The only link that can be protected without using the red link between PE-1 and PE-2, is the link between PE-5 and PE-2. The LSP and the FRR bypass tunnel are shown in Figure 184:

Figure 184 **LSP and FRR Bypass Tunnel Excluding Admin Group 'Red'**

The LSP path can be verified as follows:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" path detail
---snip---
-------------------------------------------------------------------------------
LSP LSP-PE-1-PE-2 Path dyn
```

```
-------------------------------------------------------------------------------
LSP Name         : LSP-PE-1-PE-2
Path LSP ID      : 25610

```

```
===============================================================================
*A:PE-5#
```

This configuration is preserved for the following example.

Hop Limit for RSVP-TE LSPs

Another constraint to influence the path selection, is hop limit. This can be configured on the LSP, on a secondary path, or on FRR in case the path should not contain too many hops. In this example, it will be configured on the LSP and later also for FRR on that LSP. By default, the LSP hop limit is 255, but it can be configured as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" hop-limit 5
```

This hop limit of 5 is enough for the path via PE-4 and PE-5, but it will not be sufficient when the link between PE-2 and PE-5 is down:

```
*A:PE-5# configure port 1/1/3 shutdown
```

In this case, the only possible path that excludes the 'red' link between PE-1 and PE-2, has to go to PE-2 via PE-4, PE-5, PE-6, and PE-3. There are too many hops. The FRR bypass tunnel can do a local repair, but no new LSP path can be signaled, with failure code: noCspfRouteToDestination:

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-2" path detail
---snip---

===============================================================================
* indicates that the corresponding row element may have been truncated.
*A:PE-1#
```

FRR tunnels also have a hop limit. The FRR hop limit is by default 16, but can be configured as follows:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" fast-reroute hop-limit 3
```

When the LSP is recalculated, it is impossible to establish the primary path with a hop limit of 5 and it is also impossible to establish a bypass tunnel protecting the link between PE-5 and PE-2 when the FRR hop limit is 3. The LSP will remain operationally down with failure code: noCspfRouteToDestination:

```

```

For the remainder of the examples, FRR is disabled and the hop limit is restored to the default value, which is 255:

```
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" no fast-reroute
*A:PE-1# configure router mpls lsp "LSP-PE-1-PE-2" no hop-limit
```

The port is put in a no shutdown state:

```
*A:PE-5# configure port 1/1/3 no shutdown
```

Manual Resignal

Instead of waiting for the resignal timer to expire, one can manually trigger the resignal process.

The command to resignal the path "dyn" of LSP "LSP-PE-1-PE-2":

```
*A:PE-1# tools perform router mpls resignal lsp "LSP-PE-1-PE-2" path "dyn"
```

The command to resignal all RSVP LSPs originating at node PE-1:

*A:PE-1# tools perform router mpls resignal delay 0This command can only be launched after the resignal timer is configured.

```
*A:PE-1# configure router mpls resignal-timer
  - no resignal-timer
  - resignal-timer <minutes>
 <minutes>            : [30..10080]
```

The configuration timer is configured to 30 minutes as follows:

```
*A:PE-1# configure router mpls resignal-timer 30
```

Whenever an LSP is resignaled, the resignal timer is restarted.

LSP OAM

The LSP diagnostics are modeled after ICMP echo request/reply which provides a mechanism to detect data plane failures in MPLS LSPs. For a given FEC, LSP ping verifies whether the packet reaches the egress label edge router (LER).

```
*A:PE-1# oam lsp-ping "LSP-PE-1-PE-2"
LSP-PING LSP-PE-1-PE-2: 92 bytes MPLS payload
Seq=1, send from intf int-PE-1-PE-4, reply from 192.0.2.2
       udp-data-len=32 ttl=255 rtt=1.09ms rc=3 (EgressRtr)
---- LSP LSP-PE-1-PE-2 PING Statistics ----
1 packets sent, 1 packets received, 0.00% packet loss
round-trip min = 1.09ms, avg = 1.09ms, max = 1.09ms, stddev = 0.000ms
*A:PE-1#
```

In LSP traceroute mode, the packet is sent to the control plane of each transit label switched router (LSR) which performs various checks to see if it is actually a transit LSR for the path.

```
*A:PE-1# oam lsp-trace "LSP-PE-1-PE-2"
lsp-trace to LSP-PE-1-PE-2: 0 hops min, 0 hops max, 116 byte packets
1  192.0.2.4  rtt=0.679ms rc=8(DSRtrMatchLabel) rsc=1

3  192.0.2.2  rtt=1.84ms rc=3(EgressRtr) rsc=1
*A:PE-1#
```

RSVP LSP Statistics

Statistics can be collected for RSVP LSPs. For each accounting record, a file ID is configured; as follows:

```
*A:PE-1# configure log
        file-id 2
            location cf1:
            rollover 5 retention 1
        exit
```

An accounting policy is configured for each record type; as follows:

```
*A:PE-1# configure log
```

```
        accounting-policy 2
            record combined-mpls-lsp-ingress
            to file 2
            no shutdown
        exit
```

The collection of statistics is enabled in the MPLS context as follows:

```
*A:PE-1# configure router
        mpls
            ingress-statistics
                lsp "LSP-PE-1-PE-2" sender 192.0.2.1
                    no shutdown
                    collect-stats
                    accounting-policy 2
                exit
            exit
```

To display the statistics, the following options are available for lsp-ingress-stats:

```
*A:PE-1# show router mpls lsp-ingress-stats
  - - lsp-ingress-stats [type <lsp-type>] [active] [template-
match <SessionNameString> [sender
    <ip-address>]]
  -  - lsp-ingress-stats lsp <lsp-name> sender <ip-address>
 <lsp-name>           : max 64 chars
 <ip-address>         : a.b.c.d
 <lsp-type>           : p2p|p2mp
 <active>             : match on all stats enabled lsp
 <template-match>     : match on p2p/p2mp stats template
 <SessionNameString>  : [Max 64 chars]
```

The following command retrieves the LSP ingress statistics for LSP "LPS-PE-1-PE-2" with sender 192.0.2.1:

```
*A:PE-1# show router mpls lsp-ingress-stats lsp "LSP-PE-1-PE-2" sender 192.0.2.1

*A:PE-1#
```

Statistics can be cleared as follows:

```
*A:PE-1# clear router mpls lsp-ingress-stats 192.0.2.1 lsp "LSP-PE-1-PE-2"
```

Debug Tools

A wide range of debug tools are available which can be tuned to the specific information of importance for a certain troubleshooting task. In the **debug router mpls** context, the LSP object to trace or monitor can be selected by the following parameters:

- LSP name
- Source address of the LSP (the from parameter in the LSP definition)
- Termination point of the LSP (the to parameter in the LSP definition)
- Tunnel ID of the LSP
- LSP ID

```
A:PE-1# debug router rsvp
  - no rsvp
  - rsvp [lsp <lsp-name>] [sender <sender-address>] [endpoint <endpoint-address>]
         [tunnel-id <tunnel-id>] [lsp-id <lsp-id>] [interface <ip-int-name>]
 <lsp-name>           : [80 chars max]
 <sender-address>     : a.b.c.d
 <endpoint-address>   : a.b.c.d
 <tunnel-id>          : [0..4294967295]
 <lsp-id>             : [1..65535]
 <ip-int-name>        : [32 chars max]
 [no] event           + Enable/disable debugging for specific RSVP events
 [no] packet          + Enable/disable debugging for specific RSVP packets
A:PE-1# debug router mpls
  - mpls [lsp <lsp-name>] [sender <source-address>] [endpoint <endpoint-address>]
[tunnel-id <tunnel-id>] [lsp-id <lsp-id>]
  - no mpls
 <lsp-name>           : [80 chars max]
 <source-address>     : a.b.c.d
```

```
 <endpoint-address>   : a.b.c.d
 <tunnel-id>          : [0..4294967295]
 <lsp-id>             : [1..65535]
 [no] event           + Enable/disable debugging for specific MPLS events
```

In the **debug** command tree, the MPLS event type can be selected (tracing must be enabled):

```
*A:PE-1# debug router mpls lsp "LSP-PE-1-PE-2" event
  - event
  - no event
 [no] all             -  Enable/disable debugging for MPLS all
 [no] frr             -  Enable/disable debugging for MPLS frr
 [no] iom             -  Enable/disable debugging for MPLS iom
 [no] lsp-setup       -  Enable/disable debugging for MPLS lsp setup
 [no] mbb             -  Enable/disable debugging for MPLS mbb
 [no] misc            -  Enable/disable debugging for MPLS misc
 [no] pcc             -  Enable/disable debugging for MPLS PCC
 [no] xc              -  Enable/disable debugging for MPLS xc
```

As an example, the **all** keyword is entered, logging all MPLS events related to the selected LSP:

```
*A:PE-1# debug router mpls lsp "LSP-PE-1-PE-2" event all
```

The last step is to create a log container which will gather all MPLS debugging information according to the criteria set in the debug context. The **from debug-trace** parameter must be configured but there are several options where the different captured entries will be stored: console, a syslog server, SNMP, local file on the compact flash card, a temporary circular memory buffer, or the telnet/SSH session from which you are logged into the node.

The ID of the log container is a local number without any other significance.

```
A:PE-1# configure log log-id 2
A:PE-1>config>log>log-id# from debug-trace
A:PE-1>config>log>log-id# to
  - to console
  - to file <log-file-id>
  - to memory [<size>]
  - to session
  - to snmp [<size>]
  - to syslog <syslog-id>
 <console>            : keyword - specifies console as destination
 <syslog-id>          : [1..10]
 <snmp>               : keyword - specifies SNMP as destination
 <log-file-id>        : [1..99]
 <memory>             : keyword - specifies memory as destination
 <size>               : [50..3000]
 <session>            : keyword - specifies telnet session as destination
```

For this example, the temporary buffer (with adjustable size) is chosen and the log container is enabled (no shutdown).

```
A:PE-1>config>log>log-id# to memory
A:PE-1>config>log>log-id# no shutdown
```

All MPLS events related to the selected LSP are stored in the location (memory) specified. The content of this log container can be viewed through the **show log log-id 2** command. After disabling port 1/1/3 on PE-5, the LSP goes down and a new path needs to be calculated and signaled. FRR is disabled.

```
*A:PE-1# clear log 2
*A:PE-1# show log log-id 2

```

Conclusion

MPLS provides the capability to establish connection oriented paths over a connectionless network. The LSP offers a mechanism to engineer network traffic on constraint-based paths rather than the IGP shortest path. This can greatly improve network resiliency. In this chapter, the configuration of several RSVP LSP features is given together with the associated show output which can be used to verify and troubleshoot.

RSVP Signaled Point-to-Multipoint LSPs

This chapter provides information about RSVP signaled point-to-multipoint LSPs.

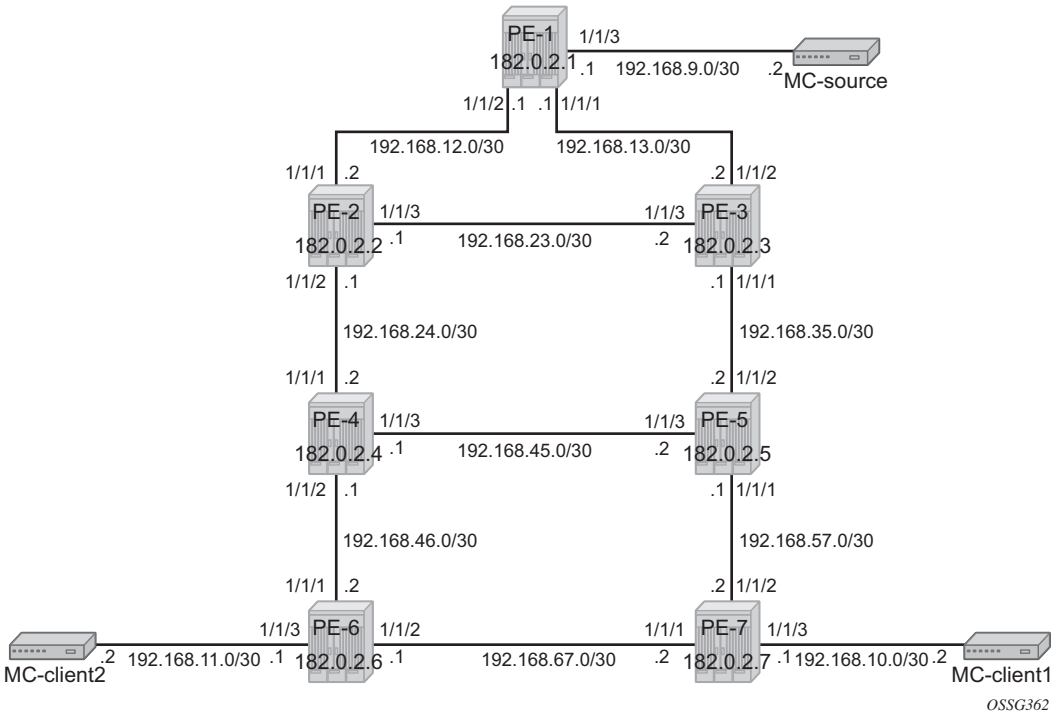
Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This feature is applicable to SR OS. This chapter was originally written for and tested on release7.0.R5, but the CLI in this edition corresponds to 14.0.R1. On all nodes involved with the LSP, at least chassis mode C is required. This means that modular systems should be equipped with IOM-2 line cards or higher.

Overview



Point-to-MultiPoint (P2MP) MPLS label switched paths (LSP) allow the source of multicast traffic to forward packets to one or many multicast receivers over a network without requiring a multicast protocol, such as protocol independent multicast (PIM), to be configured in the network. A P2MP LSP tree is established in the control plane, and the path consists of a head-end node, one or many branch and bud nodes, and the leaf nodes. A bud node combines the roles of branch node and leaf node (for different source-to-leaf LSPs). Packets injected by the head-end node are replicated in the data plane at the branching nodes before they are delivered to the leaf nodes.

Similar to point-to-point (P2P) LSPs, also P2MP LSPs are unidirectional, originating on a head-end node (the ingress LER) and terminating on one or more leaf node(s) (the egress LER(s)). RSVP is used as signaling protocol. A P2MP LSP is modeled as a set of root-to-leaf sub LSPs (Source-to-Leaf: S2L). Each S2L is modeled as a point-to-point LSP in the control plane. This means that each S2L has its own PATH/RESV messages. This is called the de-aggregated method.

The forwarding of multicast packets to the LSP tree is based on static multicast routes initially, and will evolve to BGP based VPN routes in the future. Forwarding multicast packets is done over P2MP RSVP LSPs in the base router instance, but will evolve to VPRNs.

RSVP signaled P2MP LSPs can have fast reroute (FRR) enabled, the facility method (one-to-many) with link protection is supported.

Figure 185 **P2MP Network Topology**

Configuration

The following sections describe the tasks which must be performed to configure RSVP signaled point-to-multipoint LSPs.

Configuring the IP/MPLS Network

After configuring the cards and MDAs, the correct chassis-mode must be set (C or higher) on all MPLS nodes along the P2MP LSP.

```
A:PE-1# configure system chassis-mode

  - chassis-mode <chassis-mode> [force]
 <chassis-mode>       : a|b|c|d
                        Chassis Mode corresponds to scaling and feature sets associated
                        with a card.
                        mode 'a' corresponds to the iom-20g.
                        mode 'b' corresponds to the iom-20g-b.
                        mode 'c' corresponds to the iom2-20g.
                        mode 'd' corresponds to the iom3-xp.
 <force>             : keyword - forces an upgrade from a lesser scaling and feature
                        set to a greater one.
A:PE-1#

A:PE-1# configure system chassis-mode c

*A:PE-1# show chassis | match "chassis mode"
    Admin chassis mode            : c
    Oper chassis mode             : c
```

The system addresses and Layer 3 interface addresses are configured according to Figure 185. An interior gateway protocol (IGP) is needed to distribute routing information to all PEs. In this case, the IGP is OSPF using the backbone area 0.0.0.0. A configuration example is shown for PE-1. A similar configuration is needed on all PEs.

```
*A:PE-1# configure router
        interface "int-PE-1-PE-2"
            address 192.168.12.1/30
            port 1/1/2
        exit
        interface "int-PE-1-PE-3"
            address 192.168.13.1/30
            port 1/1/1
        exit
        interface "system"
            address 192.0.2.1/32
        exit

*A:PE-1# configure router
        ospf
            traffic-engineering
            area 0.0.0.0
                interface "system"
                exit
                interface "int-PE-1-PE-2"
                    interface-type point-to-point
                exit
                interface "int-PE-1-PE-3"
                    interface-type point-to-point
                exit
            exit
        exit
```

Since fast reroute (FRR) is enabled for the P2MP LSP, traffic engineering (TE) is needed on the IGP. By doing this, OSPF will generate opaque LSAs which are collected in a traffic engineering database (TED), separate from the traditional OSPF topology database. OSPF interfaces are set up as type *'point-to-point'* to improve convergence, no designated router/backup designated router (DR/BDR) election process is done. However, convergence is out of the scope of this chapter.

To verify that OSPF neighbors are up (state **Full**), **show router ospf neighbor** is performed. To check if Layer 3 interface addresses/subnets are known on all PEs, **show router route-table** or **show router fib** *iom-card-slot* will display the content of the forwarding information base (FIB).

```

*A:PE-1#
```

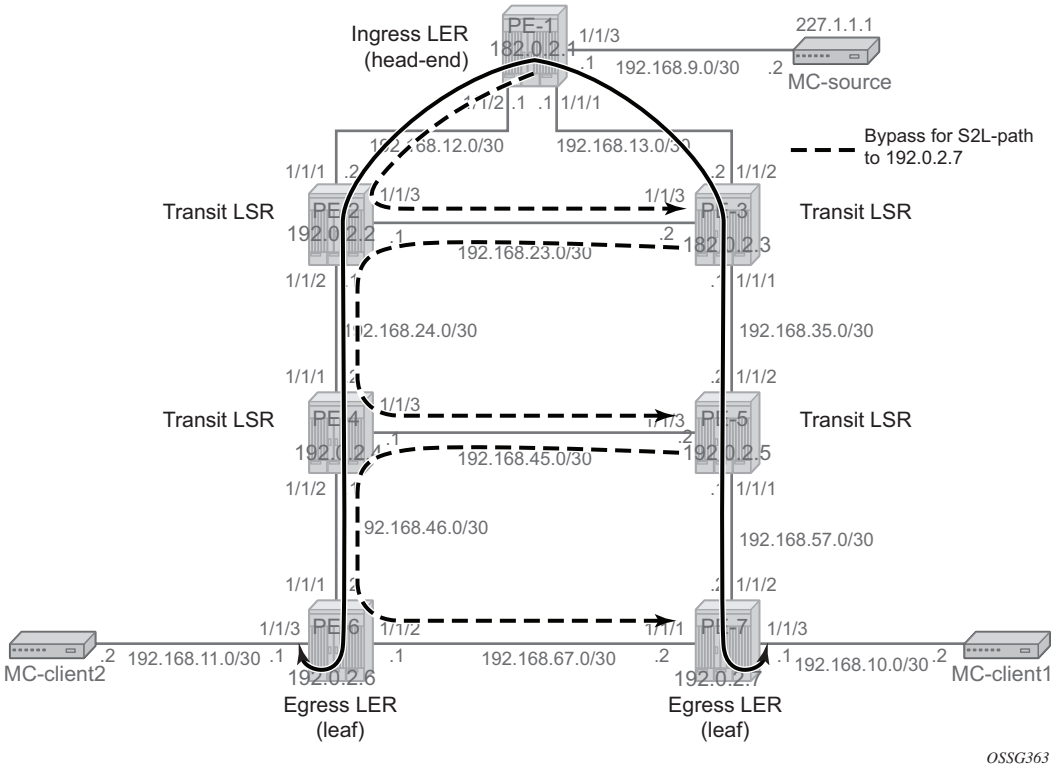
On PE-1, the interface toward the multicast source is configured in an IES service. This could have been on a router interface instead.

```
*A:PE-1# configure service
        ies 1 customer 1 create
            interface "int-PE-1-MC-source" create
                address 192.168.9.1/30
                sap 1/1/3 create
                exit
            exit
            no shutdown
        exit
```

Similar IES services are configured on PE-7 and PE-6 for multicast client 1 and multicast client 2.

```
*A:PE-7# configure service
        ies 1 customer 1 create
            interface "int-PE-7-MC-client1" create
                address 192.168.10.1/30
                sap 1/1/3 create
                exit
            exit
            no shutdown
        exit



*A:PE-6# configure service
        ies 1 customer 1 create
            interface "int-PE-6-MC-client2" create
                address 192.168.11.1/30
                sap 1/1/3 create
                exit
            exit
            no shutdown
        exit
```

The next step in the process of setting up a P2MP LSP, is enabling the L3 interfaces in the MPLS and RSVP context on all involved PE nodes (from PE-1 to PE-7). By default, the system interface is put automatically within the MPLS/RSVP context. When an interface is put in the MPLS context, 7x50 copies it also in the RSVP context. Explicit enabling of MPLS and RSVP context is done by the **no shutdown** command. The MPLS/RSVP configuration for PE-1 is as follows:

```
*A:PE-1# configure router mpls no shutdown
*A:PE-1# configure router rsvp no shutdown
*A:PE-1#
```

```
*A:PE-1# configure router mpls
            interface "system"
            exit
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-3"
            exit
```

Figure 186 **P2MP LSP LSP-p2mp-1**

Configuring P2MP RSVP LSP

See Figure 186 for P2MP LSP LSP-p2mp-1 with facility backup.

A P2MP LSP (LSP-p2mp-1) will be set up from PE-1 acting as head-end node and PE-6 and PE-7 acting as leaf nodes. Because FRR is enabled, constrained shortest path first (CSPF) is enabled to do route calculations on the traffic engineering database (TED). FRR method **facility** is used without node protection, **facility** stands for one-to-many, meaning that one bypass tunnel can protect a set of primary LSPs with similar backup constraints. When a link failure occurs on one of the active S2L paths, the point of local repair (PLR) node will push an additional MPLS label on the incoming MPLS packet before sending it into the bypass tunnel downstream toward the merge point (MP) node.

In the first example, the IGP OSPF will do the path calculation to the two destinations PE-6 and PE-7. The intermediate hops of the LSP are dynamically assigned by OSPF best route selection, thus the S2L paths follow the IGP least cost path. Therefore, an MPLS path called “**loose”** is configured without specifying any hops.

```
*A:PE-1# configure router mpls
            path "loose"
                no shutdown
            exit
```

Creation of the P2MP LSP itself is done on the ingress LER or head-end node (PE-1 in the example) and can be seen in following CLI output. The name of the P2MP LSP is “**LSP-p2mp-1”**. A create time keyword **p2mp-lsp** is added in addition to the P2MP name to make a distinction in configuration between normal point-to-point LSPs and point-to-multipoint LSPs. A primary P2MP instance is initiated using the **primary-p2mp-instance** keyword accompanied with the P2MP instance name “p-LSP-p2mp-1”. Within this primary P2MP instance, the different S2Ls are defined using the **s2l-path** keyword. Be aware that the same MPLS path name can be used for different S2Ls as long as the destination is different (**to** command).

```
*A:PE-1# configure router mpls
            lsp "LSP-p2mp-1" p2mp-lsp
                cspf
                fast-reroute facility
                    no node-protect
                exit
                primary-p2mp-instance "p-LSP-p2mp-1"
                    s2l-path "loose" to 192.0.2.6
                    exit
                    s2l-path "loose" to 192.0.2.7
                    exit
                exit
                no shutdown
            exit
```

On the head-end LER node of the P2MP LSP, several show commands can be used. A first set of show commands is used to verify the administrative and operational state of the P2MP LSP and its different S2L paths (including FRR bypass information). In this example, ”LSP-p2mp-1” P2MP LSP has two active S2L paths: one toward leaf node PE-6 and one to leaf node PE-7.

```

Mapping Multicast Traffic

To map multicast traffic into the LSP tree from the head-end node until leaf node, PIM and internet group management protocol (IGMP) configurations are needed on the head-end node (PE-1) and leaf nodes (PE-6 and PE-7) of the P2MP RSVP LSP. The intermediate nodes (transit LSR or branch LSR) do not need any explicit configuration for that.

Head-end Node (Ingress LER)

PIM must be enabled on the interface toward the MC source and PIM must be enabled on the tunnel interface. A tunnel interface should be seen as an internal representation of a specific P2MP LSP. Creation is done within the PIM context using the **tunnel-interface rsvp-p2mp** command followed by the P2MP LSP name. This is configured as follows:

```
*A:PE-1# configure router pim
            interface "int-PE-1-MC-source"
            exit
            tunnel-interface rsvp-p2mp "LSP-p2mp-1"
```

For multicast packets received on an interface to pass through the data plane, a successful reverse path forwarding (RPF) check must be done on the source address otherwise the packet will be dropped.

Besides enabling PIM on the tunnel interface, also IGMP is enabled to do a static <S,G> or <*,G> join of a multicast group address (227.1.1.1 in the example) to the tunnel interface/P2MP LSP. Be aware that there is always a one-to-one mapping between <S,G> or <*,G> and a tunnel interface/P2MP LSP. In the example a < S,G > will be configured. A <*,G> join scenario is included in Additional Topics.

```
*A:PE-1# configure router igmp        …
            tunnel-interface rsvp-p2mp "LSP-p2mp-1"
                static
                    group 227.1.1.1
                        source 192.168.9.2
                    exit
                exit
            exit
            no shutdown
```

The **show router pim tunnel-interface** command shows you the admin state of the tunnel interface and an association to an internal local ifindex (**73728** in the example).

```
*A:PE-1# show router pim tunnel-interface

*A:PE-1#
```

Leaf Node (Egress LER)

In the PIM context, the same tunnel interface must be created as the head-end node. An explicit reference to the head-end system address, using the **sender** *systemIP_head-end_node* parameter is needed.

```
*A:PE-7# configure router pim
           tunnel-interface rsvp-p2mp LSP-p2mp-1 sender 192.0.2.1
```

The **show router pim tunnel-interface** command provides the admin state of the tunnel interface and an association to an internal local ifindex (73728 in this example, by coincidence the same ifindex as the one on the head-end node/PE-1).

```
*A:PE-7# show router pim tunnel-interface

===============================================================================
*A:PE-7#
```

The main goal on the leaf node(s) is to get traffic off the P2MP LSP/tunnel interface. This is done using a multicast information policy (*multicast-info-policy*). Inside this MC policy, a range of multicast group addresses must be defined under a bundle context *(bundle1*) in order to see traffic *(channel*). Also inside the bundle context, the P2MP LSP is presented by the tunnel interface *(primary-tunnel-interface*). This is configured as follows:

```
*A:PE-7# configure mcast-management
```

```
multicast-info-policy "p2mp-pol" create
    bundle "bundle1" create
        primary-tunnel-interface rsvp-p2mp LSP-p2mp-1 sender 192.0.2.1
        channel "227.1.1.1" "227.1.1.1" create
        exit
    exit
    bundle "default" create
    exit
exit
```

Note: The **channel** command must be seen as a range command with a start-mc-group-address and an end-mc-group-address. In this example, only one MC group address, 227.1.1.1 is seen.

The configured multicast information policy must be applied to the base router instance.

```
*A:PE-7# configure router multicast-info-policy "p2mp-pol"
```

On the leaf node (PE-7/PE-6), MC clients are connected. IGMP is enabled on those MC clients with a static <S,G> join to redirect MC traffic downstream to the MC client. This is configured as follows:

```
*A:PE-7# configure router igmp
            interface "int-PE-7-MC-client1"
                static
                    group 227.1.1.1
                        source 192.168.9.2
                    exit
                exit
            exit
```

The **show router igmp group** provides the configured <S,G> entry and outgoing interface “int-PE-7-MC-client1”.

```
*A:PE-7# show router igmp group 227.1.1.1

OAM Tools

P2P LSP operation and maintenance (OAM) commands (**oam lsp-ping** and **oam lsp-trace**) are extended for P2MP LSP. The user can instruct the head-end node to generate an P2MP LSP ping or a P2MP LSP trace by entering the command **oam p2mp-lsp-ping** or **oam p2mp-lsp-trace**. The P2MP OAM extensions are defined in **draft-ietf-mpls-p2mp-lsp-ping**.

For P2MP LSP ping, the echo request is sent on the active P2MP instance and replicated in the data path over all branches of the P2MP LSP instance. By default, all egress LER nodes which are leaves of the P2MP LSP instance will reply. Echo reply messages can be reduced by configuring the **s2l-dest-address** (a maximum of up to five egress nodes in a single run of the OAM command). Replies are sent by IP.

```
*A:PE-1# oam p2mp-lsp-ping
  - p2mp-lsp-ping {<lsp-name> [p2mp-instance <instance-name> [s2l-dest-address
                  <ipv4-  address> [... up to 5]]] [ttl <label-ttl>]}
  - p2mp-lsp-ping {ldp <p2mp-identifier> [sender-addr <ipv4-address>] [leaf-addr
                  <ipv4-address> [... up to 5]]}
  - p2mp-lsp-ping {ldp-ssm source <ip-address> group <ip-address> [router
                  <router-instance>|service-name <service-name>][sender-addr
                  <ipv4-address>] [leaf-addr <ipv4-address> [... up to 5]]}
  - options common to all p2mp-lsp-ping cases:  [fc <fc-name> [profile {in|out}]]

===============================================================================
S2L Information
===============================================================================
From             RTT                  Return Code
-------------------------------------------------------------------------------
192.0.2.6        =5.91ms              EgressRtr(3)
192.0.2.7        =6.07ms              EgressRtr(3)
===============================================================================

Total S2L configured/up/responded = 2/2/2,
          round-trip min/avg/max  = 5.91 / 5.99 / 6.07 ms
```

```
Responses based on return code:
        EgressRtr(3)=2

*A:PE-1#
```

Return codes are based on RFC4379. Value 3 means the replying router is an egress for the FEC at stack-depth.

P2MP LSP trace allows the user to trace the path of a single S2L path of a P2MP LSP from head-end node to leaf node. Using the downstream mapping TLV, each node along the S2L path can fill in the appropriate flags: B or E flag. The B-flag is set when the responding node is a branch LSR and the E-flag is set when the responding node is an egress LER.

```
*A:PE-1# oam p2mp-lsp-trace
  - p2mp-lsp-trace <lsp-name> p2mp-instance <instance-name> s2l-dest-address

 <interval>           : [1..10] seconds - Default: 1

*A:PE-1#

*A:PE-1# oam p2mp-lsp-trace "LSP-p2mp-1" p2mp-instance "p-LSP-p2mp-1" s2l-dest-
address 192.0.2.7 detail
P2MP LSP LSP-p2mp-1: 132 bytes MPLS payload
P2MP Instance p-LSP-p2mp-1, S2L Egress 192.0.2.7

  1  192.0.2.3  rtt=2.10 ms rc=8(DSRtrMatchLabel)
     DS 1: ipaddr=192.168.35.2 ifaddr=192.168.35.2 iftype=ipv4Numbered MRU=1564
     label=262143 proto=4(RSVP-TE) B/E flags:0/0
  2  192.0.2.5  rtt=3.32 ms rc=8(DSRtrMatchLabel)
     DS 1: ipaddr=192.168.57.2 ifaddr=192.168.57.2 iftype=ipv4Numbered MRU=1564
     label=262143 proto=4(RSVP-TE) B/E flags:0/0
  3  192.0.2.7  rtt=4.55 ms rc=3(EgressRtr)

*A:PE-1#
```

Return codes are based on RFC4279. Value 8 means that the label is switched at stack-depth. This is the case for a transit LSR doing MPLS label swapping. No B or E flag is set.

Additional Topics

<*,G> IGMP join instead of <S,G> IGMP join

In the Head-end Node (Ingress LER) and Leaf Node (Egress LER) steps, a source specific IGMP join (<S,G> join) was used at the head-end node and leaf nodes. Another possibility is to use a source unknown or starg IGMP join (<*,G> join). When doing the latter, a rendezvous point (RP) must be defined in the PIM network. The RP allows multicast data flows between sources and receivers to meet at a predefined network location (in this example, the loopback address of node PE-1). It must be seen as an intermediate device to establish a multicast flow.

The RP can be defined in a dynamic way (BSR protocol) or a static way. In this example the static way is chosen meaning that on all involved PIM nodes, the RP address will be statically configured. The following configuration is needed on head-end and leaf nodes.

```
*A:PE-1/PE-6/PE-7# configure router pim
            rp
                static
                    address 192.0.2.1
                        group-prefix 227.1.1.1/32
                    exit
                exit
```

The **group-prefix** is a mandatory keyword. It references a group address or group address range for which this rendezvous point will be used.

```
*A:PE-1/PE-6/PE_7# show router pim rp
===============================================================================
PIM RP Set ipv4

-------------------------------------------------------------------------------
Group Prefixes : 1
===============================================================================
*A:PE-1#
```

As previously mentioned, the configuration of the <*,G> IGMP join is done on the head-end node (PE-1) and leaf nodes (PE-6 and PE-7)

```
*A:PE-1# configure router igmp
            tunnel-interface rsvp-p2mp "LSP-p2mp-1"
                no shutdown
                static
```

```
                    group 227.1.1.1
                        starg
                    exit
                exit
            exit

*A:PE-6# configure router igmp
            interface "int-PE-6-MC-client2"
                static
                    group 227.1.1.1
                        starg
                    exit
                exit
            exit

*A:PE-7# configure router igmp
            interface "int-PE-7-MC-client1"
                static
                    group 227.1.1.1
                        starg
                    exit
                exit
            exit
```

The same previous **show** command can be used to verify the multicast traffic on head-end node and leaf nodes, **show router igmp group 227.1.1.1** and **show router pim group 227.1.1.1 detail**.

```

*A:PE-3# configure router ospf area 0 interface "int-PE-3-PE-2" metric 10000

*A:PE-4# configure router ospf area 0 interface "int-PE-4-PE-2" metric 10000

*A:PE-5# configure router ospf area 0 interface "int-PE-5-PE-7" metric 10000

*A:PE-7# configure router ospf area 0 interface "int-PE-7-PE-5" metric 10000
```

The existing P2MP LSP *LSP-p2mp-1* will not take into account these new constraints. The two S2L paths (one *loose* toward PE-6 and another one *loose* toward PE-7) are calculated using the default OSPF metric. To trigger MPLS to re-compute the S2L paths, configure a p2mp-resignal-timer on the head-end node inside the global MPLS context. Each time this timer expires (in the example, every 60 minutes), MPLS will trigger CSPF to re-compute the whole set of S2L paths of all active P2MP instances. MPLS performs a global make-before-break (MBB) and moves each S2L sub-LSP in the instance into its new path using a new P2MP LSP ID if the global MBB is successful. **show router mpls status** gives an indication when the P2MP resignal timer will expire and which types of LSPs are set up on the node.

```
*A:PE-1# configure router mpls p2mp-resignal-timer 60

*A:PE-1# show router mpls status

```

As an alternative the user can also perform a manual resignal of a P2MP instance on the head-end node using a tools command.

```
*A:PE-1# tools perform router mpls resignal p2mp-lsp "LSP-p2mp-1" p2mp-instance"p-LSP-
p2mp-1"

*A:PE-1# tools perform router mpls resignal p2mp-delay 0
```

Figure 187 **P2MP LSP p-to-mp-1 with Metric Change**

After an instantaneous tools resignal command which is executed with no delay (p2mp-delay 0), the S2L paths can be verified, also check Figure 187. Node PE-6 is now a bud LSR node (instead of egress LER before).

```

*A:PE-1#
```

Inthenext step, the S2L path toward PE-7 is changed from **loose** to a **strict** direct MPLS path (*strict-to-PE-7)*. In that way, OSPF is not calculating anymore the shortest path to the leaf node.

```
*A:PE-1# configure router mpls
            path "path-strict-to-PE-7"
                hop 10 192.168.13.2 strict
                hop 20 192.168.35.2 strict
                hop 30 192.168.57.2 strict
                no shutdown
            exit
```

Before applying this new S2L path to the existing P2MP LSP (*LSP-p2mp-1*), the existing S2L path toward PE-7 must be removed.

```
*A:PE-1# configure router mpls lsp "LSP-p2mp-1" primary-p2mp-instance "p-LSP-p2mp-1"
                    s2l-path "loose" to 192.0.2.7 shutdown
                    no s2l-path "loose" to 192.0.2.7
                    s2l-path"path-strict-to-PE-7" to 192.0.2.7
                    exit
                exit
```

Figure 188 **P2MP LSP LSP-p2mp-1 with Strict S2L Path toward PE-7**

As a consequence of this, only the **S2l Grp Id** has changed while **S2L LSP ID** remains the same as before. Now, S2L paths can be verified according to Figure 188. PE-5 is now a branch LSR node (instead of a transit LSR before).

```

Intelligent Re-merge

Intelligent re-merge protects users from receiving duplicate multicast traffic during convergence. It also protects against duplicate traffic in case of badly designed S2L paths. Three cases are described for which intelligent re-merge is implemented.

Case 1

When the paths of two different S2Ls of the same P2MP LSP instance have ingress label maps (ILMs) on different ports but go out on the same next-hop label forwarding entry (NHLFE).

Figure 189 **Intelligent Remerge, Case 1**

On the head-end node (PE-1), a new P2MP LSP *('LSP-p2mp-2'*) will be created with two strict direct MPLS paths *('strict-to-PE-7'* and *'strict-to-PE-6'*). See Figure 190 for detailed address information. Intelligent re-merge is performed at node PE-5.

```
*A:PE-1# configure router mpls
            path "path-strict-to-PE-7"
                hop 10 192.168.13.2 strict
                hop 20 192.168.35.2 strict
                hop 30 192.168.57.2 strict
                no shutdown
```

```
            exit
            path "path-strict-to-PE-6"
                hop 10 192.168.12.2 strict
                hop 20 192.168.24.2 strict
                hop 30 192.168.45.2 strict
                hop 40 192.168.57.2 strict
                hop 50 192.168.67.1 strict
                no shutdown
            exit

*A:PE-1#
```

To verify that node PE-5 is not sending duplicate multicast traffic downstream toward PE-7 while it receives two incoming multicast streams, a new tunnel interface and a new static <S,G> IGMP join will be configured on head-end node (PE-1) and leaf nodes (PE-6 and PE-7). Also on the leaf nodes, an extension to the existing multicast information policy is needed. This is configured as follows:

```
*A:PE-1# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-2"
```

```
*A:PE-1# configure router igmp
            tunnel-interface rsvp-p2mp "LSP-p2mp-2"
                static
                    group 227.2.2.2
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-6# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-2" sender 192.0.2.1

*A:PE-6# configure router igmp
            interface "int-PE-6-MC-client2"
                static
                    group 227.2.2.2
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-6# configure mcast-management
        multicast-info-policy "p2mp-pol" create
            bundle "bundle2" create
                primary-tunnel-interface rsvp-p2mp "LSP-p2mp-2" sender 192.0.2.1
                    channel 227.2.2.2 create
                    exit
                exit
            exit

*A:PE-7# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-2" sender 192.0.2.1

*A:PE-7# configure router igmp
            interface "int-PE-7-MC-client1"
                static
                    group 227.2.2.2
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-7# configure mcast-management
        multicast-info-policy "p2mp-pol" create
            bundle "bundle2" create
                primary-tunnel-interface rsvp-p2mp "LSP-p2mp-2" sender 192.0.2.1
                    channel 227.2.2.2 create
                    exit
                exit
            exit
```

For verification of incoming/outgoing multicast traffic at node PE-5, the **monitor** command is used.

```
*A:PE-5# monitor port 1/1/1 1/1/2 1/1/3 rate interval 3 repeat 100

Two incoming multicast streams are seen at PE-5 node (**port 1/1/2** and **port 1/1/3**) and only one outgoing multicast stream (**port 1/1/1**) is sent. No traffic duplication is seen.

Case 2

When two paths of the same S2L have ILMs on different incoming ports and go out on the same NHLFE. This is the case when we perform make-before-break (MBB) on an S2L path due to graceful shutdown or global revertive. This is only a temporary situation since the original path will be torn down.

Figure 190 **Intelligent Re-merge, Case 2**

For this test, only one MC-client will be looked at (the one connected to leaf node PE-7). On nodes PE-4 and PE-7, the port to PE-6 will be shut down to isolate PE-6. On the head-end node PE-1, a new P2MP LSP “LSP-p2mp-3” will be created with one loose MPLS path “loose” and keyword **cspf use-te-metric** to ensure that CSPF will use the TE metric instead of the IGP metric. In this case, the TE metric has the same value on all MPLS interfaces and the path has the hops PE-1, PE-3, PE-5, and PE-7. See Figure 190 for detailed address information. Also in this case, intelligent re-merge is performed at node PE-5.

```
*A:PE-1# configure router mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-p2mp-3" p2mp-lsp
                cspf use-te-metric
                primary-p2mp-instance "p-LSP-p2mp-3"
                    s2l-path "loose" to 192.0.2.7
                    exit
                exit
                no shutdown
            exit
            no shutdown

*A:PE-1# show router mpls p2mp-lsp "LSP-p2mp-3" p2mp-instance "p-LSP-p2mp-3" s2l loose
```

*A:PE-1#
```

In a normal situation, the P2MP LSP would follow the nodes PE-1, PE-3, PE-5, and PE-7. This can be verified with MC traffic. Therefore, a new tunnel interface and a new static <S,G> IGMP join will be configured on head-end node PE-1 and leaf node PE-7. On the leaf node, an extension to the existing multicast information policy is needed. This is configured as follows:

```
*A:PE-1# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-3"

*A:PE-1# configure router igmp
            tunnel-interface rsvp-p2mp "LSP-p2mp-3"
                static
                    group 227.3.3.3
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-7# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-3" sender 192.0.2.1
```

```
*A:PE-7# configure router igmp
            interface "int-PE-7-MC-client1"
                static
                    group 227.3.3.3
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-7# configure mcast-management
        multicast-info-policy "p2mp-pol" create
            bundle "bundle3" create
                primary-tunnel-interface rsvp-p2mp LSP-p2mp-3 sender 192.0.2.1
                channel 227.3.3.3 create
                exit
            exit
        exit
```

Monitor the traffic on PE-5. Under normal circumstances, the ingress port is 1/1/2 and the egress port is 1/1/1.

```
*A:PE-5# monitor port 1/1/1 1/1/2 1/1/3 rate interval 3 repeat 999

```

An RSVP graceful shutdown is performed on node PE-3, as follows:

```
*A:PE-3# configure router rsvp graceful-shutdown
```

Global revertive is triggered on head-end node PE-1. A new MPLS path will be calculated (see the dotted line in Figure 190). For a few seconds or even less than a second, the old path and new path are active (two incoming MC streams on node PE-5). Node PE-5 is doing intelligent re-merge, not sending duplicate multicast traffic downstream toward PE-7:

```
*A:PE-5# monitor port 1/1/1 1/1/2 1/1/3 rate interval 3 repeat 100
===============================================================================
Monitor statistics for Ports

-------------------------------------------------------------------------------
```

The granularity of the monitoring command is 3 seconds. The graceful shutdown takes less than 3 seconds. However, we can clearly see that the number of outgoing packets on port 1/1/1 equals the number of incoming packets on port 1/1/2. A number of these incoming packets also arrived on port 1/1/3, but no duplicate packets were sent on the outgoing port. No traffic duplication is seen.

Case 3

When a bypass is active on the S2L path and the new global revertive path of the same S2L arrives on the same incoming interface as the original path (interface flapped) at the FRR merge point node, the node will do intelligent re-merge. The implementation recognizes this specific case and will signal a different label from the original S2L path coming on that same interface.

Figure 191 **Intelligent Re-merge, Case 3**

For this test, all the non-default OSPF metrics are removed from the interfaces. Only one MC-client will be looked at (the one connected to leaf node PE-7). On nodes PE-4 and PE-7, the port toward PE-6 will be shut down to isolate PE-6. On the head-end node PE-1, a new P2MP LSP “LSP-p2mp-4” will be created with one loose MPLS path “loose” and FRR enabled. See Figure 191 for detailed address information. Also in this case, intelligent re-merge is performed at node PE-5.

```
*A:PE-1# configure router mpls
            path "loose"
                no shutdown
            exit
            lsp "LSP-p2mp-4" p2mp-lsp
                cspf
                fast-reroute facility
                    no node-protect
                exit
                primary-p2mp-instance "p-LSP-p2mp-4"
```

```
                    s2l-path "loose" to 192.0.2.7
                    exit
                exit
                no shutdown
            exit
            no shutdown

*A:PE-1#
```

In the normal situation, the P2MP LSP follows the nodes PE-1, PE-3, PE-5 and PE-7. This can be verified with MC traffic. Therefore, a new tunnel interface and a new static <S,G> IGMP join will be configured on head-end node PE-1 and leaf node PE-7. On the leaf node, an extension to the existing multicast information policy is needed. This is configured as follows:

```
*A:PE-1# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-4"

*A:PE-1# configure router igmp
            tunnel-interface rsvp-p2mp LSP-p2mp-4
                static
                    group 227.4.4.4
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-7# configure router pim tunnel-interface rsvp-p2mp "LSP-p2mp-4" sender 192.0.2.1

*A:PE-7# configure router igmp
            interface "int-PE-7-MC-client1"
                static
                    group 227.4.4.4
                        source 192.168.9.2
                    exit
                exit
            exit

*A:PE-7# configure mcast-management
        multicast-info-policy "p2mp-pol" create
            bundle "bundle4" create
                primary-tunnel-interface rsvp-p2mp LSP-p2mp-4 sender 192.0.2.1
                channel 227.4.4.4 create
                exit
            exit
        exit

*A:PE-1#
```

For a short time, PE-5 will receive two incoming MC streams (both arriving on port 1/1/3). One from ‘bypass’ path (PE-3 => PE-2 => PE-4 => PE-5) and one from new MPLS path (PE-1 => PE-2 => PE-4 => PE-5 => PE-7). Port 1/1/1 on PE-5 performs intelligent remerge, only one MC stream is sent downstream toward leaf node PE-7.

Conclusion

From a configuration point of view, a P2MP LSP is only configured on the head-end node of that P2MP LSP; no explicit configuration is needed on the transit LSRs, branch LSRs, bud LSRs, and egress LERs/leaf nodes.

Since the PIM protocol is only needed on the head-end node and the leaf nodes, we can work in a PIM-free core network. Although convergence is not covered in this chapter, failures in the core will be resolved by MPLS (in case of FRR, traffic loss for less than 50ms is expected). This is a major improvement compared to PIM convergence.

Seamless MPLS: Isolated IGP/LDP Domains and Labeled BGP

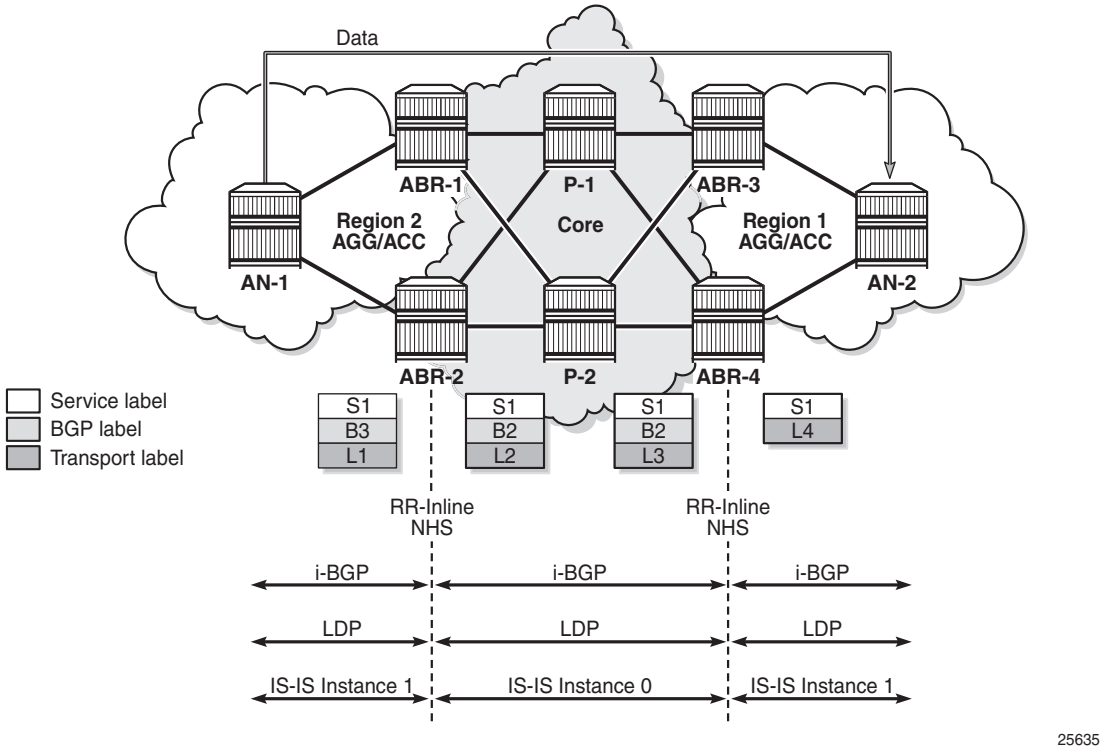
This chapter provides information about Seamless MPLS: Isolated IGP/LDP domains and Labeled BGP.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS routers and was initially written for release 13.0.R7. The CLI in this edition is based on release 14.0.R1.



Overview

Seamless multiprotocol label switching (MPLS) is a network architecture that extends MPLS networks to integrate access and aggregation networks into a single MPLS domain, to solve the scaling problems in flat MPLS-based deployments. The Seamless MPLS transport concept described in this chapter partitions the core, aggregation, and access networks into isolated IGP/LDP domains. Seamless MPLS does not define any new protocols or technologies and is based on existing and well-known ones. Seamless MPLS provides end-to-end service-independent transport, separating the service and transport plane. Therefore, it removes the need for service-specific configurations in network transport nodes. Service provisioning is restricted only at the points of the network where it is required.

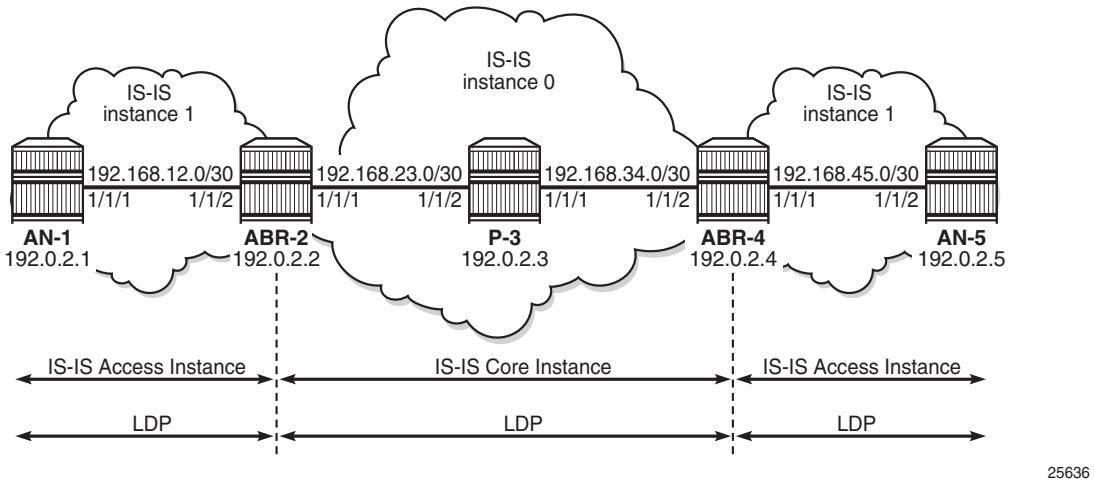
When BGP is used to distribute a route, it can also distribute an MPLS label that is mapped to that route. The label mapping information is appended to the BGP update message that is used to distribute the route. This is described in RFC 3701, *Carrying Label Information in BGPv4*.

Figure 192 shows a network with a core area and regional areas. Figure 1 also shows the control plane used in this Seamless MPLS implementation. For simplification, the control plane is displayed from right to left and the data plane from left to right. In this example, LDP will be used as the underlying transport inside each IGP domain. Alternatively, RSVP-TE could be used.

Figure 192 **Seamless MPLS - Network Topology, control and data plane**

In typical Seamless MPLS solutions, multiple ABRs are in place that result in some specific BGP configurations to send/receive multiple paths, such as the add-path feature. Due to this, ANs and ABRs will have several next hops for the same prefix, allowing the use of redundancy mechanisms such as BGP prefix independent convergence (PIC) edge, also known as BGP fast reroute (FRR). These mechanisms are beyond the scope of this chapter.

AN routers in a regional area learn the reachability of AN routers in other regional areas through BGP labeled routes redistributed by the local ABRs (RFC 3107).



The label stack contains three labels for packets sent in a VPN service between the access nodes:

- The ANs push a service label to the packets sent in the VPN service. The service label remains unchanged end-to-end between ANs. The service label is popped by the remote AN and is the inner label of the label stack.
- The BGP label is the middle label of the label stack and should be regarded as a transport label. The transport label stack is increased to two labels: BGP and LDP transport labels. The BGP label is pushed by the iLER AN and is swapped at the BGP next hop, which can be one of the two local ABRs. Both ABRs are configured with next-hop-self. The BGP label is popped by the remote ABR.
- The iLER AN pushes an LDP transport label to the packets sent to the remote AN to reach the BGP next hop. At the local ABR, the LDP transport label is popped and a new LDP transport label is pushed to reach the BGP next hop (remote ABR). The LDP transport label is swapped in every label switching router (LSR) and popped by the ABR nearest to the remote AN. That ABR pops the BGP label and the LDP transport label, and pushes an LDP transport label to reach the remote eLER AN.

Configuration

Figure 193 shows the example topology that is used in this chapter. An Epipe and VPRN will be established between the access nodes AN-1 and AN-5. In the regional areas, and in the core area, IS-IS L2 capability is used.

Figure 193 **Seamless MPLS - IGP/LDP domains**

Initial Configuration

All nodes have the following initial configuration:

- Cards, media dependent adapters (MDAs), ports
  - Router interfaces:

```
*A:ABR-2# configure router
        interface "int-ABR-2-AN-1"
            address 192.168.12.2/30
            port 1/1/2
        exit
        interface "int-ABR-2-P-3"
            address 192.168.23.1/30
            port 1/1/1
        exit
        interface "system"
            address 192.0.2.2/32
        exit
```

- IS-IS (alternatively, OSPF could be used). Core area and regional areas run an isolated IS-IS instance. ABRs run two IS-IS instances: instance 0 belongs to the core and instance 1 belongs to the access network.
  - **Core instance**. All ABRs and Ps have level 2 (L2) capability, as follows:

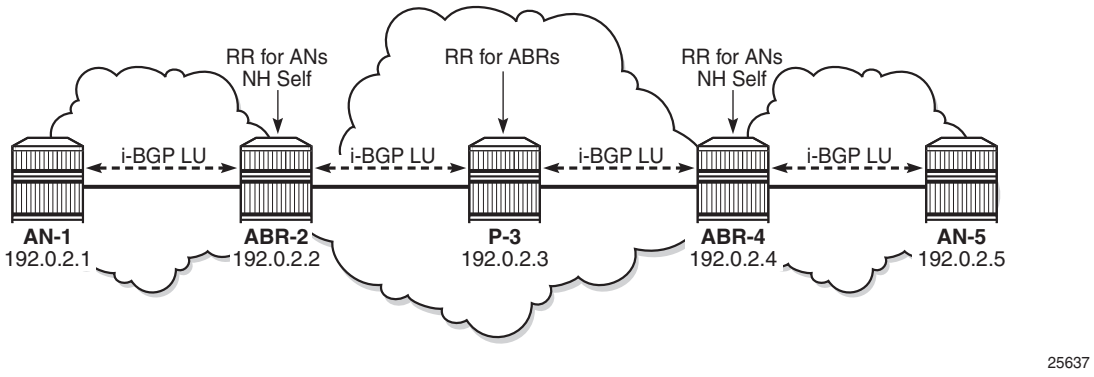
```
*A:ABR-2# configure router
        isis 0
            level-capability level-2
            area-id 49.0001
            interface "system"
            exit
            interface "int-ABR-2-P-3"
                interface-type point-to-point
            exit
        exit
```

  - **Access instance**. All ABRs and ANs have L2 capability, as follows:

```
*A:ABR-2# configure router
        isis 1
            level-capability level-2
            interface "system"
            exit
            interface "int-ABR-2-AN-1"
                interface-type point-to-point
            exit
        exit
```

- LDP

  Link LDP is enabled on all router interfaces on all nodes, as follows:



```
*A:ABR-2# configure router
        ldp
            interface-parameters
```

```
            interface "int-ABR-2-AN-1"
            exit
            interface "int-ABR-2-P-3"
            exit
        exit
    exit
```

Configure BGP

BGP is configured on all ABRs and all ANs. P-3 acts as a core route reflector (RR). To allow for separation of core/access IGP domains, the ABRs become RRs inline and implement next-hop-self on labeled IPv4 BGP prefixes. Figure 194 shows the exchange of iBGP labeled unicast (LU) routes.

Figure 194 **Seamless MPLS - BGP**

BGP configuration on ABRs

There are two groups. One group toward the core RR and another group toward the AN, as follows:

```
*A:ABR-2# configure router
        autonomous-system 64496
        bgp
            group "core"
                family ipv4 vpn-ipv4
                peer-as 64496
                advertise-inactive
                neighbor 192.0.2.3
                    description "coreRR_P-3"
                    next-hop-self
                    advertise-label ipv4
                exit
            exit
```

```
            no shutdown
        exit
```

Advertise-inactive must be enabled on the BGP group toward the core. The /32 system IP addresses, learned in labeled BGP, will also be learned in IS-IS. Because IS-IS has a lower preference compared to iBGP, the IS-IS routes will be installed in the routing table. BGP default behavior only advertises those prefixes that were elected by RTM and used. The VPNv4 address family is also included, along with labeled IPv4, to allow setting up L3 VPN services, as shown in next sections. The next-hop attribute of VPNv4 prefixes remains unchanged.

```
*A:ABR-2# configure router
        bgp
            group "ANs_Label_IPv4+VPNv4"
                family ipv4 vpn-ipv4
                cluster 2.2.2.2
                peer-as 64496
                neighbor 192.0.2.1
                    description "AN-1"
                    next-hop-self
                    advertise-label ipv4
                exit
            exit
            no shutdown
        exit
```

BGP configuration on the core RR

```
*A:P-3# configure router
        autonomous-system 64496
        bgp
            cluster 3.3.3.3
            group "core"
                family ipv4 vpn-ipv4
                peer-as 64496
                advertise-inactive
                neighbor 192.0.2.2
                    description "ABR-2"
                    advertise-label ipv4
                exit
                neighbor 192.0.2.4
                    description "ABR-4"
                    advertise-label ipv4
                exit
            exit
            no shutdown
        exit
```

BGP configuration on ANs toward ABRs

```
*A:AN-1# configure router
        autonomous-system 64496
        bgp
            group "ABRs_Label_IPv4+VPNv4"
                family ipv4 vpn-ipv4
                peer-as 64496
                neighbor 192.0.2.2
                    advertise-label ipv4
                exit
            exit
            no shutdown
        exit
```

Configuring **advertise-label ipv4** implies that all IPv4 prefixes advertised will be sent to the remote BGP peer as an RFC 3107 formatted label. The next-hop-self command only applies to IPv4 prefixes.

The BGP sessions can be shown with the following command:

```

Export Policies for BGP

A policy is required on the ANs to advertise the system IP address in labeled BGP toward the ABRs. The same policy is required on the ABRs to advertise their system IP address in labeled BGP toward the core and the AN.

Policy configuration on ANs and ABRs

```
configure
    router
        policy-options
            begin
            prefix-list "system"
                prefix 192.0.2.1/32 exact
            exit
            policy-statement "export-system"
                entry 10
                    from
                        protocol direct
                        prefix-list "system"
                    exit
                    action accept
                    exit
                exit
            exit
            commit
        exit
```

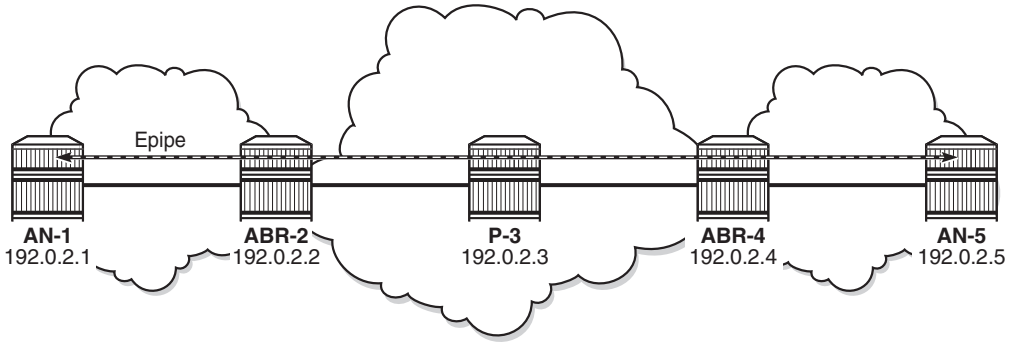
This export policy must be applied in the BGP context on AN-1: either in the general settings or per group or per neighbor, as follows:

```
*A:AN-1# configure router
```

```
        bgp
            group "ABRs_Label_IPv4+VPNv4"
                export "export-system"
            exit
        exit
```

This export policy is applied in the group "core" on the ABRs, as follows:

```
*A:ABR-2# configure router
        bgp
            group "core"
                export "export-system"
            exit
        exit
```



The prefix of the remote AN is added to the routing table in AN-1 and services can be configured in the ANs. No service configuration is required in the transit nodes.

```
*A:AN-1# show router route-table

```

Configure SDP and Epipe

An end-to-end Epipe service is established between AN-1 and AN-5, as shown in Figure 195.

Figure 195 **End-to-End Epipe Service**

The SDP is configured on AN-1 and AN-5, as follows:

```
*A:AN-1# configure service
        sdp 15 mpls create
            far-end 192.0.2.5
            bgp-tunnel
            no shutdown
        exit

*A:AN-5# configure service
        sdp 51 mpls create
            far-end 192.0.2.1
            bgp-tunnel
            no shutdown
        exit
```

Epipe 1 is configured on AN-1 and AN-5, as follows:

```
*A:AN-1# configure service
        epipe 1 customer 1 create
            sap 1/1/3:1 create
            exit
            spoke-sdp 15:1 create
                no shutdown
            exit
            no shutdown
        exit

*A:AN-5# configure service
        epipe 1 customer 1 create
            sap 1/1/3:1 create
            exit
            spoke-sdp 51:1 create
                no shutdown
            exit
            no shutdown
        exit
```

The state of the SDP and of the Epipe service can be verified on AN-1, as follows:

```
*A:AN-1# show service sdp
===============================================================================

Configure VPRN

An L3 VPN service is established on AN-1 and AN-5, as shown in Figure 196.

Figure 196 **L3 VPN service**

The VPRN service is configured on AN-1 and AN-5, as follows. For simplicity, no CEs are attached to the ANs and only one loopback is created for verification.

```
*A:AN-1# configure service
        vprn 2 customer 1 create
            route-distinguisher 64496:2
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:2
            interface "loopback" create
                address 192.0.1.1/32
                loopback
            exit
            no shutdown
        exit

*A:AN-5#  configure service
        vprn 2 customer 1 create
            route-distinguisher 64496:2
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:2
            interface "loopback" create
                address 192.0.1.5/32
                loopback
            exit
            no shutdown
        exit
```

The routing table for VPRN 2 contains the local and the remote loopback addresses. On AN-1, this can be verified as follows:

```
*A:AN-1# show router 2 route-table
===============================================================================
Route Table (Service: 2)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                     Metric
-------------------------------------------------------------------------------
192.0.1.1/32                                    Local   Local     00h04m28s  0
       loopback                                                       0
192.0.1.5/32                                    Remote  BGP VPN   00h03m05s  170
       192.0.2.5 (tunneled:BGP)                                       0
-------------------------------------------------------------------------------
No. of Routes: 2
Flags: n = Number of times nexthop is repeated
       B = BGP backup route available
       L = LFA nexthop available
       S = Sticky ECMP requested
===============================================================================
*A:AN-1#
```

On AN-5, this can be verified as follows:

```
*A:AN-5# show router 2 route-table
===============================================================================
Route Table (Service: 2)
===============================================================================
Dest Prefix[Flags]                              Type    Proto     Age        Pref
      Next Hop[Interface Name]                                      Metric
-------------------------------------------------------------------------------
192.0.1.1/32                                    Remote  BGP VPN   00h00m49s  170

```

Data Plane Overview

Figure 197 shows the label stacks used for traffic from AN-1 to AN-5. As an example, an Epipe service is used.

Figure 197 **Label Stacks for Traffic from AN-1 to AN-5**

1. The service label added for Epipe 1 on AN-1 for egress traffic to AN-5 is 262138. Ingress traffic on AN-1 has service label 262138. This can be shown as follows:

```
*A:AN-1# show service id 1 labels
===============================================================================
Martini Service Labels
===============================================================================
Svc Id     Sdp Binding        Type  I.Lbl                E.Lbl
-------------------------------------------------------------------------------
1          15:1               Spok  262138               262138
-------------------------------------------------------------------------------
Number of Bound SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
*A:AN-1#
```

   This service label remains unchanged end-to-end.

   On AN-1, the (middle) BGP label for traffic with destination AN-5 is 262138, as follows:

```
*A:AN-1# show router bgp routes 192.0.2.5
===============================================================================
 BGP Router ID:192.0.2.1        AS:64496       Local AS:64496
===============================================================================

EgrNextHop                              EgrIf/LspId
-------------------------------------------------------------------------------
192.0.2.5/32                            Pop             262143      --
  --                                      --

-------------------------------------------------------------------------------
No. of IPv4 Prefix Active Bindings: 1
===============================================================================
*A:AN-5#
```

Then, the ingress service label 262138 is popped, as follows:

```
*A:AN-5# show service id 1 labels
===============================================================================
Martini Service Labels
===============================================================================
Svc Id     Sdp Binding        Type  I.Lbl                E.Lbl
-------------------------------------------------------------------------------
1          51:1               Spok  262138               262138
-------------------------------------------------------------------------------
Number of Bound SDPs : 1
-------------------------------------------------------------------------------
===============================================================================
*A:AN-5#
```

OAM

The following operations, administration, and maintenance (OAM) commands can be launched to validate reachability between regions using BGP IPv4 labeled routes.

```
*A:AN-1# oam lsp-ping bgp-label prefix 192.0.2.5/32
LSP-PING 192.0.2.5/32: 80 bytes MPLS payload
Seq=1, send from intf int-AN-1-ABR-2, reply from 192.0.2.5
       udp-data-len=32 ttl=255 rtt=2.11ms rc=3 (EgressRtr)
---- LSP 192.0.2.5/32 PING Statistics ----
1 packets sent, 1 packets received, 0.00% packet loss
round-trip min = 2.11ms, avg = 2.11ms, max = 2.11ms, stddev = 0.000ms
```

```
*A:AN-1#

*A:AN-5# oam lsp-ping bgp-label prefix 192.0.2.1/32
LSP-PING 192.0.2.1/32: 80 bytes MPLS payload
Seq=1, send from intf int-AN-5-ABR-4, reply from 192.0.2.1
       udp-data-len=32 ttl=255 rtt=2.21ms rc=3 (EgressRtr)
---- LSP 192.0.2.1/32 PING Statistics ----
1 packets sent, 1 packets received, 0.00% packet loss
round-trip min = 2.21ms, avg = 2.21ms, max = 2.21ms, stddev = 0.000ms
*A:AN-5#
```

In a similar way, LSP trace can validate the reachability of the remote AN, as follows:

```
*A:AN-1# oam lsp-trace bgp-label prefix 192.0.2.5/32
lsp-trace to 192.0.2.5/32: 0 hops min, 0 hops max, 104 byte packets
1  192.0.2.2  rtt=0.666ms rc=8(DSRtrMatchLabel) rsc=1
2  192.0.2.4  rtt=1.78ms rc=8(DSRtrMatchLabel)
3  192.0.2.5  rtt=2.09ms rc=3(EgressRtr) rsc=1
*A:AN-1#

*A:AN-5# oam lsp-trace bgp-label prefix 192.0.2.1/32
lsp-trace to 192.0.2.1/32: 0 hops min, 0 hops max, 104 byte packets
1  192.0.2.4  rtt=0.631ms rc=8(DSRtrMatchLabel) rsc=1
2  192.0.2.2  rtt=1.48ms rc=8(DSRtrMatchLabel)
3  192.0.2.1  rtt=2.06ms rc=3(EgressRtr) rsc=1
*A:AN-5#
```

Conclusion

Seamless MPLS helps to solve the scalability problems of large networks. Seamless MPLS partitions the core, aggregation, and access networks into isolated IGP/LDP domains, which helps to maintain IGP databases small and controlled. Label BGP allows the establishment of hierarchical LSPs for end-to-end service set up.

Segment Routing with IS-IS Control Plane

This chapter provides information about segment routing (SR) with intermediate system to intermediate system (IS-IS) control plane.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

Segment routing is supported in SR OS release 13.0, and later. This chapter was originally written for SR OS release 13.0.R3, but the CLI in this edition corresponds to release 14.0.R1.

Overview

Segment routing (SR) is a technology for IP/multiprotocol label switching (MPLS) networks that enables source routing. With source routing, operators can specify a forwarding path, from ingress to egress, that is independent of the shortest path determined by the interior gateway protocol (IGP).

The main benefit of segment routing compared to other source routing protocols (such as resource reservation protocol with traffic engineering (RSVP-TE)) is that, from a control plane perspective, no signaling protocol is required. Segment routing provides a path or tunnel, encoded as a sequential list of sub-paths or segments that are advertised within the segment routing domain, using extensions to well-known link state routing protocols, such as IS-IS or open shortest path first (OSPF).

Implementation

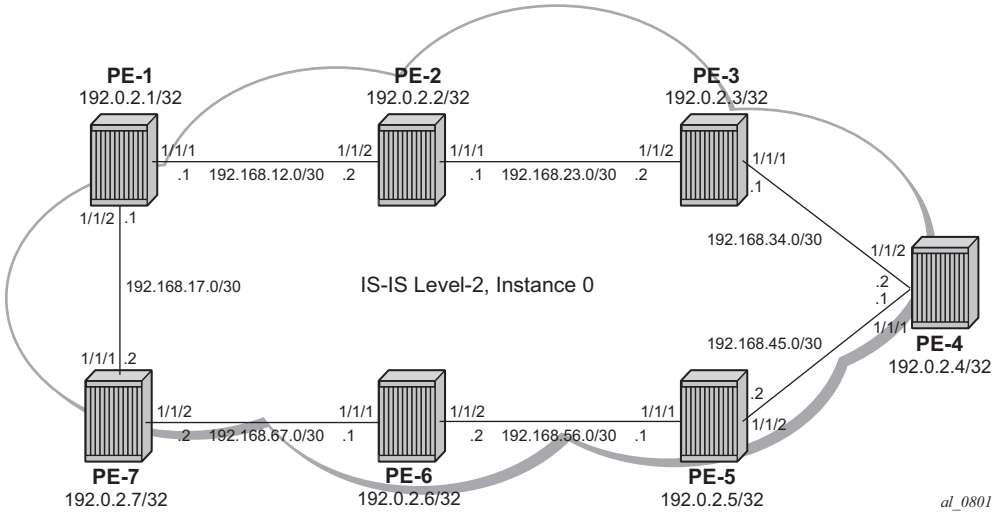
A segment routing tunnel can contain a single segment that represents the destination node, or it can contain a list of segments that the tunnel must traverse. The tunnel can be established over an IPv4/IPv6 MPLS or IPv6 data plane, encoded as a stack of MPLS labels or as a number of IPv6 addresses contained in an IPv6 extension header.

Network elements are modeled as segments. For each segment, IGP advertises an identifier referred to as a segment ID (SID).

The two segment types are:

- Prefix segment — Globally unique and allocated from a segment routing global block (SRGB), typically multi-hop and signaled by the IGP. It is the equal cost multi-path ECMP-aware shortest path IGP route to a related prefix. A typical example of a prefix segment is a node SID. Within the SR OS implementation, the node SID is either the system address or another interface address in the global routing table (GRT) of type loopback. Node SIDs are advertised in IS-IS using a prefix SID sub-TLV (type length value).
- Adjacency segment — Locally unique and allocated from the (local) dynamic label space, so that other routers in the SR domain can use the same label space. Adjacency segments are signaled by the IGP. Within the SR OS implementation, Adjacency SIDs are automatically assigned and advertised when the SR context within the IGP instance is set in no shutdown. Adjacency SIDs are advertised in IS-IS using an adjacency SID sub-TLV.

To make prefix segments globally unique within the segment routing domain, an indexing mechanism is required, because production networks consist of multiple vendors and multiple products. As a result, it is often difficult to agree on a common SRGB for the prefix SIDs.



All routers within the SR domain are expected to configure and advertise the same Prefix SID index range for an IGP instance. The label value used by each router to represent a prefix can be local to that router by the use of an offset label, referred to as a start label:

Local label (for a prefix) = (local) start label + {Prefix SID index}

Within the SR OS implementation, prefix loop-free alternate (LFA) is supported for segment routing to improve the fast reroute (FRR) coverage. Remote LFA (RLFA) is also supported. With RLFA, segment routing shortest path tunnels are used as a virtual LFA or repair tunnel toward the PQ node.

The following example uses IS-IS as an IGP protocol, with an MPLS data plane and services enabled using LFA and RLFA.

Figure 198 **Network Topology**

Configuration

Step 1. Configure an IP/MPLS network according to Figure 198.

- The system and IP interface addresses are configured according to Figure 1.
- IS-IS level 2 is selected as the IGP to distribute routing information between all PEs. All IS-IS interfaces are of type point-to-point to avoid running the DR/BDR (Designated Router/Backup Designated Router) election process.

Step 2. Configure segment routing.

Before enabling segment routing on a router, define a dedicated SRGB. This SRGB is required on each individual router part of the SR domain and is used to allocate the Prefix SIDs.

By default, an SRGB is not instantiated and, when configured by the operator, it is taken from the system dynamic label range. Translated into a show command:

```
*A:PE-1# show router mpls-labels label-range
===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          18431       -           18400       18400
Dynamic         18432       524287      0           505856      505856
    Seg-Route   0           0           -           0           505856
===============================================================================
```

```
*A:PE-1#
```

For simplicity, the same SRGB is used in this example for all SR domain routers. Within the command, a start value and end value defines the size of the SRGB. Translated into configuration commands for an SRGB of 100 MPLS labels, this becomes:

```
*A:PE-1# configure router mpls-labels sr-labels start 20000 end 20099

*A:PE-1# show router mpls-labels label-range
===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          18431       -           18400       18400
Dynamic         18432       524287      0           505756      505856
    Seg-Route   20000       20099       -           0           100
===============================================================================
*A:PE-1#
```

This command is repeated for all other nodes. The allocated MPLS labels are only for the prefix SIDs. The adjacency SIDs, which are only locally unique, are taken from the dynamic range; in this example, between 18432 and 524287.

1. Enable router capability in the IGP instance.

   It is mandatory to enable the router-capability parameter inside the IS-IS instance, to advertise SR support among the IS-IS adjacencies. By configuring this command within the IGP instance, the SR capability sub-TLV is propagated and is used to indicate the index range and the start label. The SR algorithm sub-TLV is also used to advertise the algorithm used for path calculations. Only shortest path first (SPF) (value 0) is defined. This is configured as follows:

```
<all-nodes-within-SR-domain># configure router isis advertise-router-capability area
```

   The flooding parameter is a mandatory parameter in this CLI command. The keyword area or as indicates that the router capabilities label switched path (LSP) should be advertised throughout the same level or throughout the whole autonomous system (AS). In the preceding example, all routers belong to the same level, so the area argument is sufficient. When the SR context within the IGP instance is set in no shutdown, both IS-IS sub-TLVs are flooded.

2. Define the Prefix SID index range.

The SR OS implementation for SR provides two mutually exclusive modes of operation to define the Prefix SID index range: global mode and per-instance mode. Per-instance mode is useful in a seamless MPLS environment when multiple IGP instances are used. The main difference between the modes is the way that the start label and index range are calculated.

A comparison of the modes is shown in following table:

Table 16 **Mode Comparison**

Global	Per Instance
Applicable for all IGP instances on that node	Applicable for one dedicated IGP instance
Start label is first label of SRGB	Start label is configurable (but part of SRGB range); use of non-overlapping sub-ranges of SRGB
Prefix SID index range is “size” of SRGB	Prefix SID index-range is configurable
If SRGB needs to change, shutdown SR and delete prefix-SID-ranges in all IGP instances	If prefix SID index and/or label range needs to change, shut down SR in that specific IGP instance
SW checks whether any allocated SID index/label goes out of range. SW checks also for overlaps of the resulting net label value range across IGP instances.	

For simplicity, global mode is used for this example, as follows:

```
<all-nodes-within-SR-domain># configure router isis segment-routing prefix-sid-range
global
```

3. Assign a Prefix SID index or label to the prefix representing a node.

   To be able to set up SR shortest path tunnels to all routers of the SR domain, each router needs to be uniquely defined within the SR domain. Therefore, the system address or other loopback interface in the GRT will be assigned an ipv4-node-sid index or label value that is unique within the SR domain.

   Translated into configuration commands, this becomes:

```
*A:PE-1# configure router isis interface "system" ipv4-node-sid index 1
*A:PE-2# configure router isis interface "system" ipv4-node-sid index 2
*A:PE-3# configure router isis interface "system" ipv4-node-sid index 3
*A:PE-4# configure router isis interface "system" ipv4-node-sid index 4
*A:PE-5# configure router isis interface "system" ipv4-node-sid index 5
*A:PE-6# configure router isis interface "system" ipv4-node-sid index 6
*A:PE-7# configure router isis interface "system" ipv4-node-sid index 7
```

Because the SRGB is the same on all nodes, each node in the network can be reached using the same MPLS label. For example, the node SID for PE-5 on all nodes has a start label (first label of the SRGB (= 20000) + ipv4-node-sid index on node PE-5 (= 5)) of 20005.

When there is one consistent SRGB for the SR domain, the SR OS CLI allows the use of absolute MPLS label values instead of index values. For example, on PE-1, an operator can use an explicit MPLS label value:

```
*A:PE-1# configure router isis interface "system" ipv4-node-sid label 20001
```

Internally, this explicit value is translated into an index value (index-value 1) before advertising it toward its neighbors, taking into account the prefix SID index-range mode (global or per-instance) and the SRGB.

4. Enable SR context within the IGP instance, as follows:

```
<all-nodes-within-SR-domain># configure router isis segment-routing no shutdown
```

After enabling the SR context within an IGP instance, the SR Capability sub-TLV, and the SR Algorithm sub-TLV between all routers within the SR domain, are flooded. A show command is available to display the SR related router capability information. For example, on PE-1, this becomes:

```
*A:PE-1# show router isis capabilities level 2
===============================================================================
Rtr Base ISIS Instance 0 Capabilities

===============================================================================
*A:PE-1#
```

A similar output occurs for each router in the SR domain.

After enabling the SR context within the IGP instance, the assigned index for each locally configured Prefix SID is advertised. After the advertisement of prefix SIDs, MPLS data plane ingress label mapping (ILM) is programmed with a pop operation. In this context, a show command can be used to display the prefix SIDs, in order, within the SR domain. As an example, on PE-1, this becomes:

```
*A:PE-1# show router isis prefix-sids
===============================================================================
Rtr Base ISIS Instance 0 Prefix/SID Table
===============================================================================
Prefix                          SID        Lvl/Typ    SRMS   AdvRtr

                                                         0      NnP
192.0.2.6/32                    6          2/Int.     N      PE-6
                                                         0      NnP
192.0.2.7/32                    7          2/Int.     N      PE-7
                                                         0      NnP
-------------------------------------------------------------------------------
No. of Prefix/SIDs: 7
Flags: R  = Re-advertisement
       N  = Node-SID
```

```
       nP = no penultimate hop POP
       E  = Explicit-Null
       V  = Prefix-SID carries a value
       L  = value/index has local significance
===============================================================================
*A:PE-1#
```

The SR OS implementation, by default, sets the node SID (or N–flag) and noPenultimate hop PoP (or nP–flag) inside the prefix SID TLV. Another useful flag that can be set is the re-advertisement (or R-flag). The R-flag is set when a prefix SID is propagated between levels or areas, or redistribution is in place (from another protocol).

Prefix SID information can also be viewed within the IGP database attached to (extended) IP prefix reachability TLVs. For example, on PE-1, this becomes:

```
*A:PE-1# show router isis database level 2 PE-1.00-00 detail
===============================================================================
Rtr Base ISIS Instance 0 Database (detail)
===============================================================================
Displaying Level 2 database

```

After enabling the SR context within the IGP instance, adjacency SIDs are also automatically assigned and advertised for each formed adjacency over an IP interface. From a data plane perspective, one local adjacency SID consumes one ILM entry, programming a pop operation.

Similar to prefix SIDs, adjacency SID information can be viewed within the IGP database attached to IS neighbor TLVs. Translated into the previous show command on PE-1, this becomes:

```
*A:PE-1# show router isis database level 2 PE-1.00-00 detail
===============================================================================
Rtr Base ISIS Instance 0 Database (detail)
===============================================================================
Displaying Level 2 database

    Nbr IP    : 192.168.17.2
    Adj-SID: Flags:v4VL Weight:0 Label:262142
  ---snip---
```

The SR OS implementation, by default, sets the value (or V–flag), meaning that the adjacency SID carries a value (as opposed to an index). Also, the local (or L-flag) is set by default, meaning that the adjacency SID has only local significance. The v4-flag set to 0 means that the adjacency SID references to an adjacency with outgoing IPv4 encapsulation.

Another way to display adjacency SID information is using the show router isis adjacency detail command.

```
*A:PE-1# show router isis adjacency "int-PE-1-PE-2" detail
===============================================================================

===============================================================================
*A:PE-1#
```

Finally, when enabling the SR context within the IGP instance, the SR module resolves received prefixes with prefix SID sub-TLVs present. As a result, MPLS data plane resources are consumed. The ILM is programmed with a swap operation and the label-to-next-hop-label-forwarding-entry (LTN) with a push operation, both pointing to the primary and/or LFA next-hop label forwarding entry (NHLFE). Also, an SR tunnel is added in the tunnel table manager (TTM). As a result, an SR shortest path tunnel is set up to each other router that is part of the SR domain. Now, SR shortest path tunnels can be used for all users of TTM.

Example 1: VPRN service with LFA and RLFA enabled

In the network topology of Figure 198, no LDP and RSVP-TE signaling protocols are enabled. Each router of the SR domain has a full mesh of SR shortest path tunnels to the other routers, and no LDP and RSVP-TE LSPs are present. For example, on PE-1, the TTM looks like:

```
*A:PE-1# show router tunnel-table
===============================================================================

-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-1#
```

The objective is to configure a VPRN between PE-1 and PE-7, using SR shortest path tunnels as transport tunnel. The configuration is as follows:

```
*A:PE-1# configure service vprn 100 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:10001
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:100
            interface "loopback" create
                address 192.0.1.1/32
                loopback
            exit
            no shutdown

*A:PE-7# configure service vprn 100 customer 1 create
            autonomous-system 64496
            route-distinguisher 64496:10007
            auto-bind-tunnel
                resolution any
            exit
            vrf-target target:64496:100
            interface "loopback" create
                address 192.0.1.7/32
                loopback
            exit
            no shutdown
```

Within the VPRN service configuration, a loopback interface is created on both PEs to verify the transport mechanism. Tunnel information displaying the MPLS label value is retrieved using the show router fp-tunnel-table <slot number> command, as follows:

```
*A:PE-1# show router fp-tunnel-table 1 192.0.2.7/32
===============================================================================
Tunnel Table Display
Legend:
B - FRR Backup
===============================================================================
Destination                                             Protocol   Tunnel-ID
    Lbl                 NextHop           Intf/Tunnel
-------------------------------------------------------------------------------
192.0.2.7/32                                            SR-ISIS-0   -
  20007                 192.168.17.2        1/1/2
-------------------------------------------------------------------------------
Total Entries : 1
-------------------------------------------------------------------------------
===============================================================================
*A:PE-1#
```

This means that, when traffic arrives on PE-1, the MPLS label 20007 is pushed to reach destination PE-7. Because, in this example, the prefix SID index range global mode is used, the value 20007 comes from the start label on PE-7 (first label of the SRGB, which is 20000, plus the configured index value of node SID PE-7 (7)), so 20007.

Enabling prefix LFA within the IS-IS context on PE-1 will enable LFA/FRR protection. Next-hop LFA protection is present for node PE-4, node PE-5, and the link between PE-4 and PE-5. Translated into CLI and show commands, this becomes:

```
*A:PE-1# configure router isis loopfree-alternate
*A:PE-1# show router isis lfa-coverage
===============================================================================

When a failure occurs on the primary SR path (only applicable for prefix PE-4/PE-5 and the link between PE-4 and PE-5), the traffic takes the LFA backup SR path to the destination using the same MPLS label value.

To extend the LFA/FRR coverage, for example, to find an LFA protection for node PE-7, which is one of the VPRN service endpoints, RLFA can be enabled. RLFA creates a virtual LFA by using a repair tunnel to carry packets to a point in the network from where they will not be looped back to the source, but forwarded (SPF-based) toward the destination prefix.

The RLFA implementation uses the PQ algorithm. The node where RLFA is configured (PE-1 in this example) computes an extended P-space and a Q-space. The intersection of both spaces is called the PQ-node. This PQ node is the destination node of the repair tunnel using an SR shortest path tunnel. To compute both spaces, SPF is used.

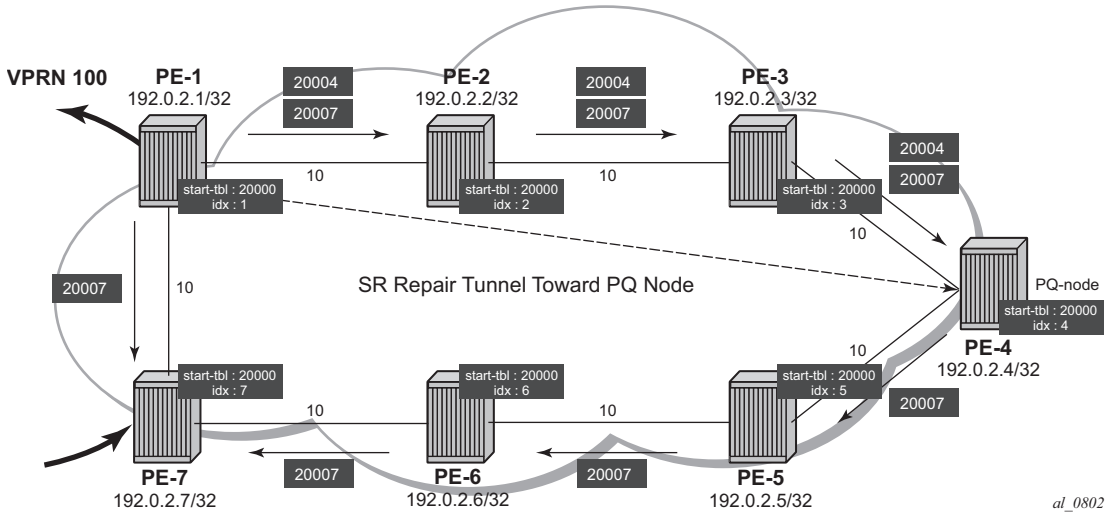
In this example, IS-IS is used as the IGP, using a default metric value of 10 for all links. With the assumption that the link between PE-1and PE-7 is broken, the calculation of both the extended P-space and the Q-space at PE-1 is as follows:

- extended P-space — An SPF computed from node PE-1 and rooted at PE-2. It is used to calculate the set of routers that are reachable without any path transiting the protected link between PE-1 and PE-7. The following nodes belong to the extended P-space: PE-2, PE-3, PE-4, and PE-5.
- Q-space — A reverse SPF computed from PE-1 and rooted from PE-7 (acting as destination proxy). It is used to calculate the set of routers that can reach PE-7 without transiting the protected link between PE-1 and PE-7. The nodes PE-4, PE-5, and PE-6 belong to the Q-space.

Possible PQ-nodes are PE-4 or PE-5, because they are in the intersection of both spaces.

RLFA is configured as follows:

```
*A:PE-1# configure router isis loopfree-alternate remote-lfa



The nodes PE-2, PE-3, PE-6, and PE-7 now have RLFA protection, while PE-4 and PE-5have
LFA protection.
*A:PE-1# show router fp-tunnel-table 1

192.0.2.6/32                                                  SR-ISIS-0    -
  20006                 192.168.17.2        1/1/2
  20006/20004           192.168.12.2(B)     1/1/1
192.0.2.7/32                                                  SR-ISIS-0    -
  20007                 192.168.17.2        1/1/2
  20007/20004           192.168.12.2(B)     1/1/1
---snip---
```

The main difference between normal prefix LFA and RLFA is that for RLFA a two-MPLS label stack is pushed by the head-end node (PE-1). The top label is the SR-label to reach the PQ node (for example, 20004 for PE-4) and the bottom label is the SR-label to reach the destination node (for example,20007 for PE-7). The notation inside the show command is bottom-label/top-label.

Figure 199 illustrates the RLFA traffic path protecting the link between PE-1 and PE-7:

Figure 199 **RLFA Traffic Path During Protection**

Inside the TTM, a tunnel-flag, has-lfa exclude-for-igpshortcuts, is set for all destination nodes that have LFA protection available:

```
*A:PE-1# show router tunnel-table detail

```

Example 2: TTM preference with VPRN service

The following example is a variant on the previous example. The difference in this example is that, in addition to SR, LDP and RSVP-TE are also enabled between PE-1 and PE-7. A single RSVP LSP is configured originating at PE-1 and terminating at PE-7.

The objective of this example is to show the difference in protocol preference within TTM and how to influence the default behavior. This can be useful in case of migration scenarios from a non-SR environment toward a hybrid environment having LDP/RSVP and SR enabled.

In the following example, LFA/RLFA is no longer configured on the PE-1 node.

Translated into configuration commands, this becomes:

```
*A:PE-1# configure router isis no loopfree-alternate
*A:PE-1# configure router ldp interface-parameters interface "int-PE-1-PE-7"
*A:PE-1# configure router mpls interface "int-PE-1-PE-7"
*A:PE-1# configure router mpls no shutdown
*A:PE-1# configure router rsvp no shutdown
*A:PE-1# configure router mpls
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-7"
                to 192.0.2.7
                primary "dyn"
                exit
                no shutdown
            exit
            no shutdown

*A:PE-7# configure router ldp interface-parameters interface "int-PE-7-PE-1"
*A:PE-7# configure router mpls no shutdown
*A:PE-7# configure router rsvp no shutdown
```

By enabling LDP and RSVP between PE-1 and PE-7, the TTM on both nodes changed. With the VPRN service between PE-1 and PE-7 of example 1, only those two specific service endpoints are displayed:

```
*A:PE-1# show router tunnel-table 192.0.2.7
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================

192.0.2.1/32      isis (0)  MPLS  524294    11       192.168.17.1   10
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-7#
```

On node PE-1, an RSVP LSP, an LDP LSP, and an SR shortest path tunnel (using IS-IS) are present. Because the VPRN service has auto-bind-tunnel resolution any enabled, the protocol type with the highest TTM preference (meaning the lowest absolute preference value in TTM) is taken; in this case, the RSVP LSP. This can be verified for the configured loopback address within the VPRN service context, as follows:

```
*A:PE-1# show router 100 route-table 192.0.1.7/32 extensive
===============================================================================
Route Table (Service: 100)
===============================================================================
Dest Prefix             : 192.0.1.7/32
  Protocol              : BGP_VPN
  Age                   : 00h00m48s
  Preference            : 170
  Indirect Next-Hop     : 192.0.2.7
    Label               : 262141
    QoS                 : Priority=n/c, FC=n/c
    Source-Class        : 0
    Dest-Class          : 0
    ECMP-Weight         : N/A
```

```
    Resolving Next-Hop  : 192.0.2.7 (RSVP tunnel:1)
      Metric            : 10
      ECMP-Weight       : N/A
-------------------------------------------------------------------------------
No. of Destinations: 1
===============================================================================
*A:PE-1#
```

On node PE-7, only an LDP LSP and an SR shortest path tunnel (using IS-IS) are present. Because the VPRN service has auto-bind-tunnel resolution any enabled, the protocol type with highest TTM preference (meaning the lowest absolute preference value in TTM) is taken; in this case, the LDP LSP. This can be verified for the configured loopback address within the VPRN service context, as follows:

```
*A:PE-7# show router 100 route-table 192.0.1.1/32 extensive
===============================================================================
Route Table (Service: 100)
===============================================================================
Dest Prefix             : 192.0.1.1/32
  Protocol              : BGP_VPN
  Age                   : 00h01m03s
  Preference            : 170
  Indirect Next-Hop     : 192.0.2.1
    Label               : 262141
    QoS                 : Priority=n/c, FC=n/c
    Source-Class        : 0
    Dest-Class          : 0
    ECMP-Weight         : N/A
    Resolving Next-Hop  : 192.0.2.1 (LDP tunnel)
      Metric            : 10
      ECMP-Weight       : N/A
-------------------------------------------------------------------------------
No. of Destinations: 1
===============================================================================
*A:PE-7#
```

Some configuration changes are possible to change this default behavior:

- It is possible to change the auto-bind-tunnel resolution any command into auto-bind-tunnel resolution filter. Because this is a service-specific parameter, the operator has the choice to only configure this on one specific service endpoint. From a migration point of view, a smooth and easy SR migration is possible, having no affect on other deployed services on this node.
- It is possible to change the SR tunnel-table protocol preference on a node. From a migration point of view, this affects all services initiating on this node.

Using the current example, PE-1 implements the auto-bind-tunnel change (option 1), while PE-7 implements the TTM preference change (option 2).

First, a resolution-filter CLI context within VPRN service 100 on node PE-1 must be created. The example uses a resolution-filter context, which uses a filter to only allow SR shortest path tunnels (IS-IS based). Translated into configuration commands, this becomes:

```
*A:PE-1# configure service vprn 100 auto-bind-tunnel resolution-filter sr-isis
```

Then, change the auto-bind-tunnel resolution any command into resolution filter on PE-1. Translated into a configuration command, this becomes:

```
*A:PE-1# configure service vprn 100 auto-bind-tunnel resolution filter
```

As a result, the RSVP LSP is no longer used. Instead, the SR shortest path tunnel is used for the traffic from PE-1 to PE-7:

```
*A:PE-1# show router 100 route-table 192.0.1.7/32 extensive
===============================================================================
Route Table (Service: 100)
===============================================================================
Dest Prefix             : 192.0.1.7/32
  Protocol              : BGP_VPN
  Age                   : 00h00m12s
  Preference            : 170
  Indirect Next-Hop     : 192.0.2.7
    Label               : 262141
    QoS                 : Priority=n/c, FC=n/c
    Source-Class        : 0
    Dest-Class          : 0
    ECMP-Weight         : N/A
    Resolving Next-Hop  : 192.0.2.7 (SR-ISIS:0 tunnel)
      Metric            : 10
      ECMP-Weight       : N/A
-------------------------------------------------------------------------------
No. of Destinations: 1
===============================================================================
*A:PE-1#
```

The VPRN service on node PE-7 is still using the LDP LSP as transport mechanism to reach node PE-1 at this point. Because the previous CLI change is only done within the VPRN service context 100 on PE-1, only the direction from PE-1 to PE-7 is affected.

Another way to influence the default TTM preference is shown as follows on the PE-7 node. Using the default behavior, the LDP LSP is used, because of the preference value of 9. If the SR tunnel table preference value is lowered to a value smaller than LDP, for instance 4, the SR shortest path tunnels originating on this node will always have preference compared to LDP LSP. Translated into a configuration command, this becomes:

```
*A:PE-7# configure router isis segment-routing tunnel-table-pref 4
```

```
*A:PE-7# show router tunnel-table 192.0.2.1
===============================================================================
IPv4 Tunnel Table (Router: Base)
===============================================================================
Destination       Owner     Encap TunnelId  Pref     Nexthop        Metric
-------------------------------------------------------------------------------
192.0.2.1/32      isis (0)  MPLS  524294    4        192.168.17.1   10
192.0.2.1/32      ldp       MPLS  65537     9        192.168.17.1   10
-------------------------------------------------------------------------------
Flags: B = BGP backup route available
       E = inactive best-external BGP route
===============================================================================
*A:PE-7#
```

As a result, the LDP LSP is no longer used and the SR shortest path tunnel is the preferred transport tunnel:

```
*A:PE-7# show router 100 route-table 192.0.1.1/32 extensive
===============================================================================
Route Table (Service: 100)
===============================================================================
Dest Prefix             : 192.0.1.1/32
  Protocol              : BGP_VPN
  Age                   : 00h00m25s
  Preference            : 170
  Indirect Next-Hop     : 192.0.2.1
    Label               : 262141
    QoS                 : Priority=n/c, FC=n/c
    Source-Class        : 0
    Dest-Class          : 0
    ECMP-Weight         : N/A
    Resolving Next-Hop  : 192.0.2.1 (SR-ISIS:0 tunnel)
      Metric            : 10
      ECMP-Weight       : N/A
-------------------------------------------------------------------------------
No. of Destinations: 1
===============================================================================
*A:PE-7#
```

At this point, within the VPRN service, the SR shortest path tunnels are used bidirectionally between PE-1 and PE-7.

If, for example, an operator configures explicit SDP binding within the same VPRN service on both endpoints, the explicit SDPs will always have preference. In this example, manual SDPs are configured on nodes PE-1 and PE-7, both using LDP. Translated into configuration commands, this becomes:

```
*A:PE-1# configure service sdp 17 mpls create
           far-end 192.0.2.7
           ldp
           no shutdown

*A:PE-1# configure service vprn 100 spoke-sdp 17 create

*A:PE-7# configure service sdp 71 mpls create
```

```
            far-end 192.0.2.1
            ldp
            no shutdown

*A:PE-7# configure service vprn 100 spoke-sdp 71 create
```

As a result, SR shortest path tunnels are no longer used, but rather LDP-based SDPs are used instead:

```
*A:PE-1# show router 100 route-table 192.0.1.7/32 extensive
===============================================================================
Route Table (Service: 100)
===============================================================================
Dest Prefix             : 192.0.1.7/32

```

Conclusion

Segment Routing is a technique using extensions of the existing link state protocols, and using existing MPLS or IPv6 infrastructure as the data plane. It is a source routing technique similar to RSVP-TE, but without the need to run an extra signaling protocol. SR also avoids other scaling restrictions of associated RSVP-TE, such as midpoint state. SR is simple to control and operate because the intelligence and state are part of the packet, not held by the network. Other benefits are that SR can be introduced in an incremental way using different migration scenarios to assure a smooth transition.

Shared Risk Link Groups for RSVP-Based LSP

This chapter provides information about Shared Risk Link Groups for RSVP-Based LSPs.

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This feature is applicable to SR OS. See the release notes for a full and up to date list of supported hardware.

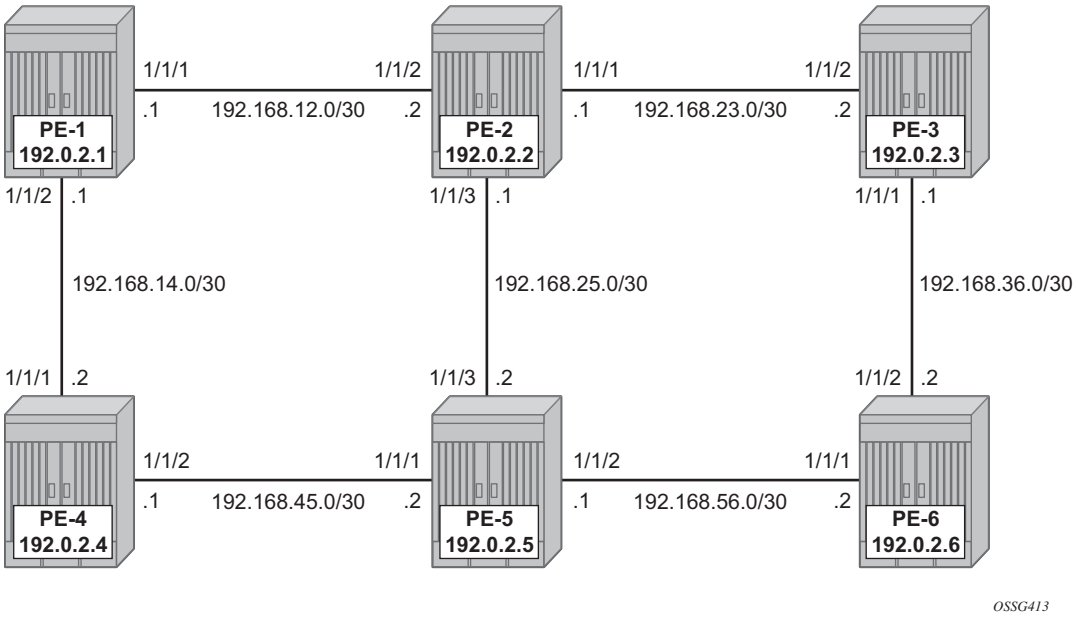
Originally, this chapter was written for release 7.0. The CLI in this edition corresponds to release 14.0.R1. No prerequisites are needed.

Overview

Introduction

Shared risk link group (SRLG) is a feature which allows the user to establish a backup secondary label switched path (LSP) path or a fast-reroute (FRR) LSP path which is disjoint from the path of the primary LSP. Links which are members of the same SRLG represent resources which share the same risk. For example, fiber links sharing the same conduit or multiple wavelengths sharing the same fiber.

A typical application of the SRLG feature is to provide an automatic placement of secondary backup LSPs or FRR bypass/detour LSPs that minimizes the probability of fate sharing with the path of the primary LSP.



SRLG groups are used to determine which links belong to the same SRLG. The mechanism is similar to multiprotocol label switching (MPLS) admin groups. To advertise SRLG, the information is part of the IGP TE parameters in an opaque link state advertisement (LSA). The SRLG is advertised in a new Shared Risk Link Group TLV (type 138) in IS-IS (RFC 4205, *Intermediate System to Intermediate System (IS-IS) Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*). It is advertised in a new SRLG sub-TLV (type 16) of the existing Link TLV in OSPF (RFC 4203, *OSPF Extensions in Support of Generalized Multi-Protocol Label Switching (GMPLS)*.

For FRR, a choice can be made on what to do when no FRR tunnel can be found with the SRLG constraints. No FRR tunnel might be signaled or a FRR tunnel might be signaled not taking the SRLG constraints into account.

SRLG

Figure 200 displays the example topology for this chapter.

Figure 200 **Example Topology**

A single IGP area (IS-IS in this case) with traffic engineering (TE) enabled is required for the SRLG feature to work properly.

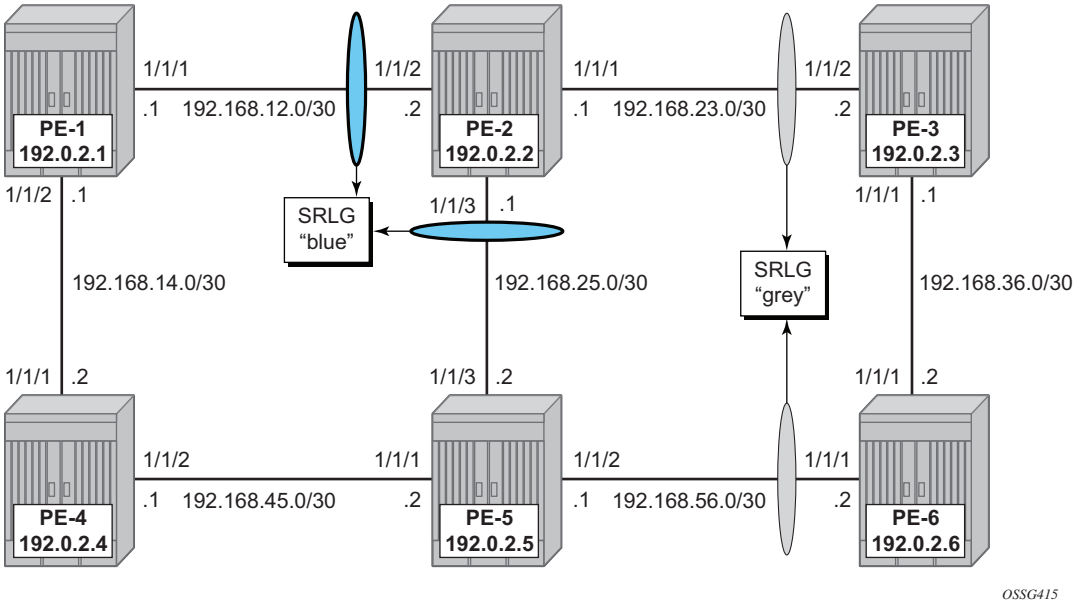
When OSPF is used as the IGP, the functionality is similar.

Configuration

Configuring the IP/MPLS network

IS-IS, MPLS, and RSVP are configured on all interfaces. TE is enabled in IS-IS. Optionally, admin groups “green” and “red” are configured on all nodes. The “green” links are the following: the link between PE-1 and PE-2, the link between PE-2 and PE-3, and the link between PE-3 and PE-6. The “red” links are: the link between PE-1 and PE-4, the link between PE-4 and PE-5, and the link between PE-5 and PE-6. The remaining link is the link between PE-2 and PE-5, which does not belong to an admin group. For more information about admin groups, see chapter RSVP Point-to-Point LSPs.

In addition, ECMP is set to 2, instead of the default value 1 in order to highlight the application of SRLG in the final example: SRLG database.



```
*A:PE-1# configure router ecmp 2
```

Define SRLG groups

Define the SRLG groups, and link them to the related MPLS interfaces.

Two SRLG groups are defined, named blue and gray. On following drawing the related IP/MPLS interfaces are indicated.

Figure 201 **SRLG Topology**

The configuration of the blue SRLG group is only mandatory on PE-1, PE2 and PE-5, while the gray SRLG group is only mandatory on PE-2, PE-3, PE-5 and PE6. However, it is good practice to configure both SRLG groups on all nodes, for example as follows on PE-1.

```
*A:PE-1# configure router if-attribute srlg-group blue value 1
*A:PE-1# configure router if-attribute srlg-group gray value 2
```

The IP/MPLS interfaces need to be linked to the related SRLG group, which is a uni-directional indicator, applying only to the egress direction; therefore, it needs to be configured on both sides of the IP/MPLS interface. For example on PE-1, the interface to PE-2 is part of **srlg-group "blue"**. An interface can be part of multiple SRLG groups similar to the admin-group functionality.

```
*A:PE-1>config>router>mpls# info
----------------------------------------------
            entropy-label rsvp-te enable
            interface "system"
                no shutdown
            exit
            interface "int-PE-1-PE-2"
                admin-group "green"
                no shutdown
            exit
            interface "int-PE-1-PE-4"
                admin-group "red"
                no shutdown
            exit
            no shutdown
```

```
*A:PE-1>config>router>mpls# interface "int-PE-1-PE-2"
*A:PE-1>config>router>mpls>if# srlg-group "blue"
```

The same must be done on PE-2, PE-3, PE-5 and PE-6. Afterwards, verify the MPLS configuration for example on PE-2, where the SRLG groups are linked to the interfaces. Admin-groups are configured in parallel to indicate that both can be configured and will work independently.

```
*A:PE-2>config>router>mpls# info
----------------------------------------------
        entropy-label rsvp-te enable
        interface "system"
            no shutdown
        exit
        interface "int-PE-2-PE-1"
            admin-group "green"
            srlg-group "blue"
            no shutdown
        exit
        interface "int-PE-2-PE-3"
            admin-group "green"
            srlg-group "gray"
            no shutdown
        exit
        interface "int-PE-2-PE-5"
            srlg-group "blue"
            no shutdown
        exit
        no shutdown
```

The SRLG configuration can be verified using the following show commands.

To show all SRLG groups on the node:

```
*A:PE-2# show router if-attribute srlg-group
===============================================================================
Interface Srlg Groups
===============================================================================
Group Name                      Group Value      Penalty Weight
-------------------------------------------------------------------------------
blue                            1                0
gray                            2                0
-------------------------------------------------------------------------------
No. of Groups: 2
===============================================================================
*A:PE-2#
```

In the list of MPLS interfaces, admin groups and SRLG groups are indicated.

```
A:PE-2# show router mpls interface
===============================================================================
MPLS Interfaces
===============================================================================

  Admin Groups                         None
  SRLG Groups                          blue
-------------------------------------------------------------------------------
Interfaces : 4
===============================================================================
A:PE-2#
```

To verify the SRLG groups in the IGP TE database, the following command can be used. The output can be extensive, but searching on the SRLG group name will lead to the correct interfaces.

The following output shows the link-state advertisements of PE-2 on PE-1 in this case. The SRLG information is linked to the IP interfaces in a dedicated TE-TLV.

```

On-Line Verification

An on-line verification can be done by a **tools perform** command. This will trigger a constrained shortest path first (CSPF) call to the interior gateway protocol (IGP) TE database, and the result will be an explicit route object (ERO) object which can potentially be used to set up a CSPF-based LSP.

The following shows the command syntax.

```
*A:PE-1# tools perform router mpls cspf
  - cspf to <ip-addr> [from <ip-addr>] [bandwidth <bandwidth>] [include-bitmap
<bitmap>] [exclude-bitmap <bitmap>] [hop-limit <limit>] [exclude-address <excl-addr>
[<excl-addr>...(upto 8 max)]] [use-te-metric] [strict-srlg] [srlg-group <grp-
id>...(upto 8 max)] [exclude-node <excl-node-id> [<excl-node-id>..(upto 8 max)]]
[skip-interface <interface-name>] [ds-class-type <class-type>] [cspf-reqtype <req-
type>] [least-fill-min-thd <thd>] [setup-priority <val>] [hold-priority <val>]

 <ip-addr>            : a.b.c.d
 <bandwidth>          : [1..100000] in Mbps
 <bitmap>             : [0..4294967295] - accepted in decimal, hex(0x) or binary(0b)
 <limit>              : [2..255]
 <excl-addr>          : a.b.c.d (outbound interface)
 <use-te-metric>      : keyword
 <strict-srlg>        : keyword
 <grp-id>             : [0..4294967295]
 <excl-node-id>       : [a.b.c.d] (outbound interface)
 <interface-name>     : [max 32 chars]
 <class-type>         : [0..7]
 <req-type>           : all|random|least-fill : keywords
 <thd>                : [1..100]
 <priority>           : [0..7]
```

Where the relevant parameters are:

- **to** — Defines the far-end address of the LSP. This is the system-address of the destination LER
- **srlg-group** — Specifies which SRLG groups should be avoided while building the path to the destination (ERO object)

- **strict-srlg** — Indicates whether the SRLG group is a strict requirement or not. When this parameter is given, only paths without traversing the SRLG will be displayed.

Example:

On PE-1, a CSPF calculation is made with PE-3 as destination, without any SRLG restrictions, as follows:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/(no Diffserv) class: 0 , setup Priority 7, Hold
Priority 0 TE Class: 7

CSPF Path
To        : 192.0.2.3
Path 1    : (cost 20)
    Src:   192.0.2.1   (= Rtr)
   Egr:  192.168.12.1      -> Ingr:  192.168.12.2       Rtr:  192.0.2.2     (met 10)
   Egr:  192.168.23.1      -> Ingr:  192.168.23.2       Rtr:  192.0.2.3     (met 10)
    Dst:   192.0.2.3   (= Rtr)

*A:PE-1#
```

Given a restriction on **srlg-group “blue”** (grp-id =1), the result is as follows:

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 srlg-group 1
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/(no Diffserv) class: 0 , setup Priority 7, Hold
Priority 0 TE Class: 7

CSPF Path
To        : 192.0.2.3
Path 1    : (cost 40)
    Src:   192.0.2.1   (= Rtr)
   Egr:  192.168.14.1       -> Ingr:  192.168.14.2      Rtr:  192.0.2.4     (met 10)
   Egr:  192.168.45.1       -> Ingr:  192.168.45.2      Rtr:  192.0.2.5     (met 10)
   Egr:  192.168.56.1       -> Ingr:  192.168.56.2      Rtr:  192.0.2.6     (met 10)
      1 SRLGs:  2
   Egr:  192.168.36.2       -> Ingr:  192.168.36.1      Rtr:  192.0.2.3     (met 10)
    Dst:   192.0.2.3   (= Rtr)

*A:PE-1#
```

The path will be through PE-4, PE-5 and PE-6.

When a strict restriction is requested on **srlg-group “gray**”, no valid CSPF path toward the destination can be found.

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 srlg-group 2 strict-srlg
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/(no Diffserv) class: 0 , setup Priority 7, Hold
Priority 0 TE Class: 7

MINOR: CLI No CSPF path to "192.0.2.3" with specified constraints.
```

```
*A:PE-1#
```

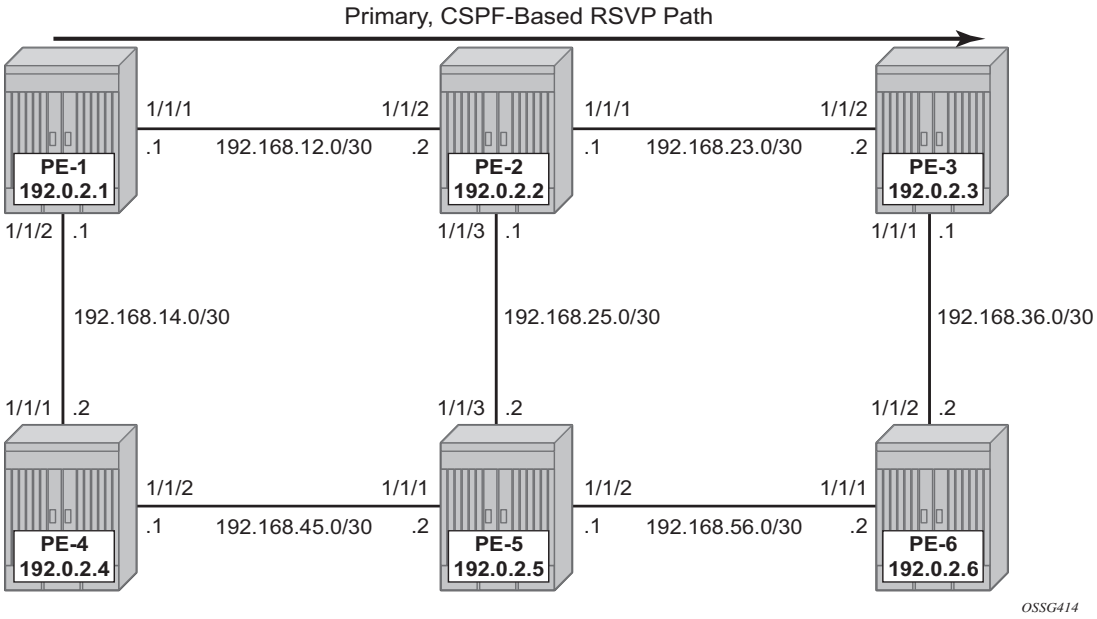
Removing the **strict** restriction results in a successful return of CSPF, indicating that the CSPF path is not SRLG disjoint.

```
*A:PE-1# tools perform router mpls cspf to 192.0.2.3 srlg-group 2
Req CSPF for all ECMP paths
    from: this node to: 192.0.2.3 w/(no Diffserv) class: 0 , setup Priority 7, Hold
Priority 0 TE Class: 7

CSPF Path
To        : 192.0.2.3 (NOT SRLG DISJOINT)
Path 1    : (cost 20)
    Src:   192.0.2.1   (= Rtr)
   Egr:  192.168.12.1       -> Ingr:  192.168.12.2       Rtr:  192.0.2.2    (met 10)
      1 SRLGs:  1
   Egr:  192.168.23.1       -> Ingr:  192.168.23.2       Rtr:  192.0.2.3    (met 10)
      1 SRLGs:  2
    Dst:   192.0.2.3   (= Rtr)

*A:PE-1#
```

The best practice for debugging is to enable debug-tracing on the CSPF process, with following command:



```
*A:PE-1# debug router isis cspf
```

SRLG for FRR

The fast-reroute mechanism used here is facility link-protection. The SRLG feature is independent of the FRR type and works for all combinations (facility versus one-to-one, link versus node protection).

Configure an LSP from PE-1 to PE-3, and enable CSPF.

Figure 202 **Path Primary RSVP_TE LSP**

The configuration of the LSP"LSP-PE-1-PE-3_FRR_facility-link" is based on an empty path, with FRR facility link protection enabled.

```
*A:PE-1# configure router
        mpls
            path "dyn"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-3_FRR_facility-link"
                to 192.0.2.3
                cspf
                fast-reroute facility
                    no node-protect
                exit
                primary "dyn"
                exit
                no shutdown
            exit
```

To verify the primary path, **oam lsp-trace** command can be used, checking the intermediate nodes.

```
*A:PE-1# oam lsp-trace "LSP-PE-1-PE-3_FRR_facility-link" detail
lsp-trace to LSP-PE-1-PE-3_FRR_facility-
link: 0 hops min, 0 hops max, 116 byte packets
1  192.0.2.2  rtt=0.670ms rc=8(DSRtrMatchLabel) rsc=1
     DS 1: ipaddr=192.168.23.2 ifaddr=192.168.23.2 iftype=ipv4Numbered MRU=1564
           label[1]=262143 protocol=4(RSVP-TE)
2  192.0.2.3  rtt=1.13ms rc=3(EgressRtr) rsc=1
*A:PE-1#
```

To check if the bypass tunnels are up and running, an indication (@)can be found in the detail output of **show router mpls ls <x> path detail** as seen in the following output.

```
*A:PE-1# show router mpls lsp "LSP-PE-1-PE-3_FRR_facility-link" path detail

* indicates that the corresponding row element may have been truncated.

*A:PE-1#
```

Two links are protected: one bypass tunnel originates in PE-1 protecting the link between PE-1 and PE-2. Another bypass tunnel originates in PE-2 protecting the link between PE-2 and PE-3. The focus is on the bypass tunnel originating in PE-1. When SRLG is enabled, the bypass tunnel originating in PE-1 will have different hops. The expected paths followed by the bypass tunnels originating in PE-1 with and without SRLG are shown in Figure 203.

Figure 203 **FRR Bypass Tunnels Originating in PE-1 With and Without SRLG**

To verify the bypass data path on the point of local repair (PLR) PE-1, the following command can be used.

```
*A:PE-1# show router mpls bypass-tunnel detail

===============================================================================
*A:PE-1#
```

The SRLG restriction is not taken into account at this moment at PLR PE-1. The actual hops are PE-4, PE-5 and PE-2 visualized by the path with the long dashes in Figure 203.

To take the SRLG restrictions into account, additional configuration is needed for MPLS.

```
*A:PE-1>config>router>mpls# srlg-
srlg-database  srlg-frr

*A:PE-1>config>router>mpls# srlg-frr
  - no srlg-frr
  - srlg-frr [strict]

 <strict>             : keyword

*A:PE-1# configure router mpls srlg-frr strict
```

The option **strict** should only be used if the logical topology allows this. In other words, one must be sure that an alternative path is possible which avoids SRLG-groups.

Note: Enabling or disabling SRLG for FRR is a system-wide configuration and requires the MPLS routing instance to be manually set to shutdown and then to no shutdown to activate the change. This may cause service outage. Nokia recommends that the operator incorporates the SRLG into the initial network design and implementation to minimize the traffic loss.

```
*A:PE-1# configure router rsvp shutdown
*A:PE-1# configure router rsvp no shutdown
```

The bypass tunnel originating in PLR PE-1can be verified with a previously used command.

```
*A:PE-1# show router mpls bypass-tunnel detail

===============================================================================
*A:PE-1#
```

This path taking the SRLG constraints into account is represented by the line with the short dashes in Figure 203 .

SRLG for Standby Path

Where SRLG groups can be constraints for bypass tunnels, they can also be a constraint to set up a secondary path. Looking at the following picture, the secondary path is expected to follow the dotted-line instead of passing over the direct link between PE-5 and PE-2.

Figure 204 **SRLG for Secondary Path**

An LSP is configured with a primary and a secondary path, which have no hops defined. The configuration of the LSP will need a specific indication at the level of the secondary path to enable the restriction on the srlg-groups.

```
*A:PE-1# configure router
        mpls
            path "prim"
                no shutdown
            exit
            path "secon"
                no shutdown
            exit
            lsp "LSP-PE-1-PE-2-srlg"
                to 192.0.2.2
                cspf
                primary "prim"
                exit
                secondary "secon"
                    standby
                    srlg
                exit
                no shutdown
            exit
```

Where both paths are empty paths, the ERO object creation solely relies on CPSF without any specific hop.

To verify the data path, the detailed output of the **show router mpls** lsp <..> path command can be used, as well as the **lsp-trace** OAM command. This output shows both ERO objects of the primary and secondary path.

```

SRLG Database

In case not all IP/MPLS routers in the area support SRLG, a static SRLG database can be created on the systems which will be used as an additional constraint when performing the CSPF calculation to define the path.

An example can be seen in Figure 205 where an additional SRLG group “red” is defined on PE-1, with information related to the interface between PE-4 and PE-5.

Figure 205 **SRLG Database Example**

```
*A:PE-1# configure router if-attribute srlg-group "red" value 3

*A:PE-1# configure router
        mpls
            interface "int-PE-1-PE-4"
                srlg-group "red"
            exit
            srlg-database
                router-id 192.0.2.4
                    interface 192.168.45.1 srlg-group "red"
                    no shutdown
                exit
                router-id 192.0.2.5
                    interface 192.168.45.2 srlg-group "red"
                    no shutdown
                exit
            exit
```

This information is local to PE-1 and will only have effect on CSPF calculations on PE-1, not on the other nodes.

When a CSPF calculation is done for a path from PE-1 to PE-5, the result will be two equal-cost paths, because ECMP equals 2. When adding the **srlg-group “red”** as a restriction, only a single path will be found, passing PE-2.

Conclusion

Interpreting the SRLG information into the TE database makes it possible to protect an LSP even when multiple IP/MPLS interfaces fail as a result of an underlying transmission failure. Transmission failures can occur quite often since not all transmission links are one to one protected.

SRLG groups in MPLS provide a very dynamic and simple way to assure LSP FRR path protection on every PLR throughout the followed LSP path. The SRLG groups are also taken into account when defining the ERO for secondary paths, at least if the configured secondary path is empty.

For interoperability reasons, the SRLG-database is available, because systems can link interfaces to an SRLG with interconnecting systems that do not support the SRLG feature; therefore they cannot advertise the SRLG information through the IGP.

The creation and maintenance of an SRLG database requires operational effort and systems that do not support SRLG will never take any SRLG information into account during CSPF calculation for the creation of FRR bypass or detour tunnels.

Static Point-to-Point LSPs

This chapter provides information about static point-to-point label switched paths (LSPs).

Topics in this chapter include:

- Applicability
- Overview
- Configuration
- Conclusion

Applicability

This chapter is applicable to SR OS and was originally written for release 7.0.R5. The output in this edition corresponds to release 14.0.R1. There are no pre-requisites or conditions on the hardware for this configuration.

Overview

Due to the connectionless nature of the network layer protocol IP, packets travel through the network on a hop-by-hop basis with routing decisions made at each node. As a result, hyperaggregation of data on certain links may occur and it may impact the provider's ability to provide guaranteed service levels across the network end-to-end. To address these shortcomings, multiprotocol label switching (MPLS) was developed. The technology provides the capability to establish connection oriented paths, called label switched paths (LSPs), over a connectionless (IP) network. The LSP offers a mechanism to engineer network traffic independently from the underlying network routing protocol (mostly IP) to improve the network resiliency and recovery options and to permit delivery of new services that are not readily supported by conventional IP routing techniques (Layer 2 IP virtual private networks (VPNs)). These benefits are essential for today's communication network explaining the wide deployment base of the MPLS technology.

RFC 3031, *Multiprotocol Label Switching Architecture,* specifies the MPLS architecture while this document describes the configuration and troubleshooting of static point-to-point LSPs on SR OS. Point-to-point LSPs can also be dynamically established using a label signaling protocol, such as label distribution protocol (LDP) or resource reservation protocol (RSVP). See chapters LDP Point-to-Point LSPs and RSVP Point-to-Point LSPs.

Packet Forwarding

As a packet of a connectionless network layer protocol travels from one router to the next, each router in the network makes an independent forwarding decision by performing the following basic tasks: first analyzing the packet's header, then referencing the local routing table to find the longest match based on the destination address in the IP header, and finally sending out the packet on the selected interface. In other terms, the first function partitions the entire set of possible packets into a set of forwarding equivalence classes (FECs). All packets associated to a particular FEC will be forwarded along the same logical path to the same destination. The second function maps each FEC to a next hop destination router. Each router along the path performs these actions.

On the other hand, in MPLS, the assignment of a particular packet to a particular FEC is done just once, as the packet enters the network. In turn, the FEC is mapped to an LSP, which is established prior to any data flowing. An MPLS label, representing the FEC to which the packet is assigned, is attached to the packet (push operation) and once labeled, the packet is forwarded to the next hop router along that LSP path. At subsequent hops, there is no further analysis of the network layer header of the packet. Instead, the label is used as an index into a table which specifies the next hop and a new label. The old label is replaced with the new label (swap operation), and the packet is forwarded to its next hop. At the MPLS network egress, the label is removed from the packet (pop operation). If this router is the final destination (based on the remaining packet), the packet is handed to the receiving application (such as a virtual private LAN service (VPLS) domain). If this router is not the final destination of the packet, the packet will be sent into a new MPLS tunnel or forwarded by conventional IP forwarding towards the layer 3 destination.

Terminology

Figure 206 **Generic MPLS Network, MPLS Label Operations**

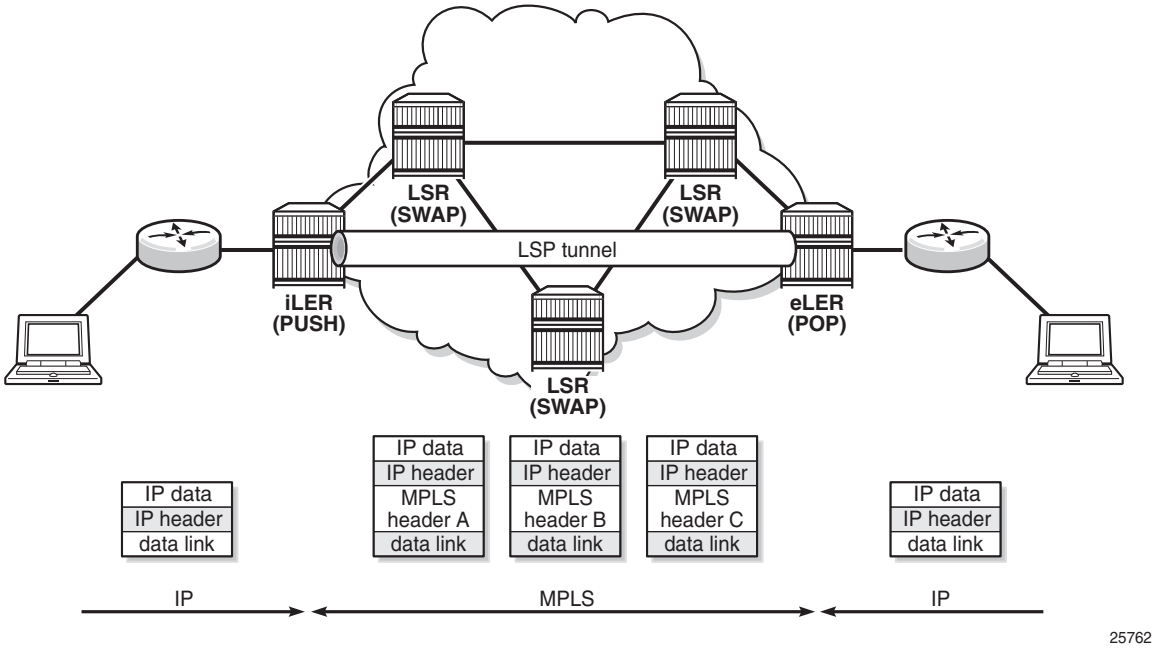

Figure 206depicts a general network topology clarifying the MPLS-related terms. A label edge router (LER) is a device at the edge of an MPLS network, with at least one interface outside the MPLS domain. A router is usually defined as an LER based on its position relative to a particular LSP. The MPLS router at the head-end of an LSP is called the ingress label edge router (iLER). The MPLS router at the tail-end of an LSP is called the egress label edge router (eLER). The iLER receives unlabeled packets from outside the MPLS domain, then applies MPLS labels to the packets, and forwards the labeled packets into the MPLS domain. The eLER receives labeled packets from the MPLS domain, then removes the labels, and forwards unlabeled packets outside the MPLS domain. The last LSR before the eLER can be configured with an implicit-null label (numeric value 3). This LSR will pop the outer label and send MPLS packets without an outer label to the eLER. This is known as penultimate hop popping (PHP). A label switching router (LSR) is a device internal to an MPLS network, with all interfaces inside the MPLS domain. These devices switch labeled packets inside the MPLS domain. In the core of the network, LSRs ignore the network layer (IP) header of the packet and simply forward the packet using the MPLS label swapping mechanism.

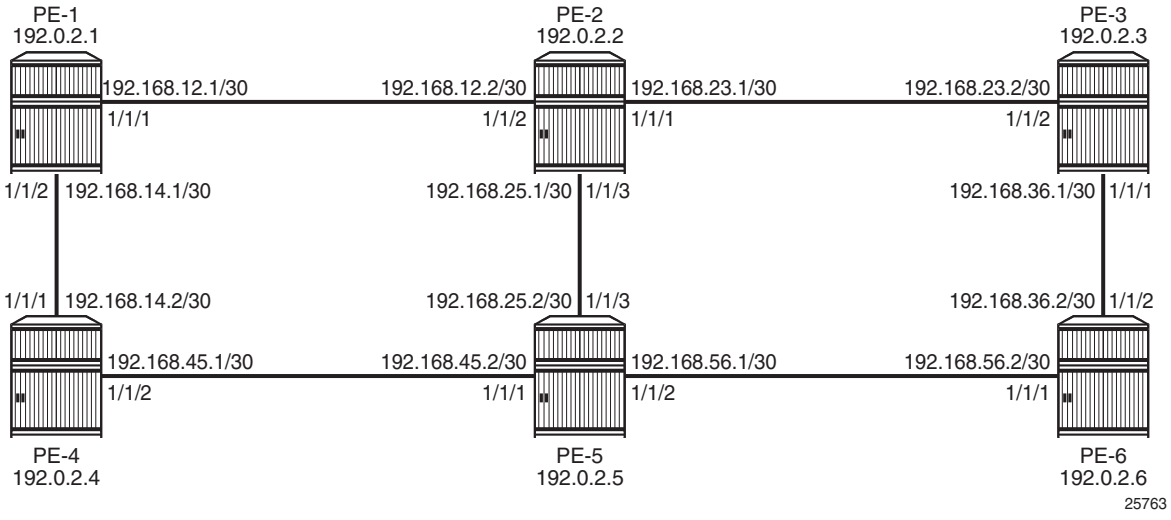
A single LSP is unidirectional. In common practice, because the bidirectional nature of most traffic flows is implied, the term LSP often is used to define the pair of LSPs that enable the bidirectional flow. For ease of terminology and discussion however, the LSP in this chapter is referred to as a single entity.



LSP Establishment

Prior to packet forwarding, the LSP must be established. In order to do so, labels need to be distributed for the path. For static LSPs, the label distribution is done manually by the network administrator. Although a high control level of the labels in use is achieved, the LSP cannot enjoy the resilience and recovery functionality the dynamic label signaling protocols can offer.

Example Topology

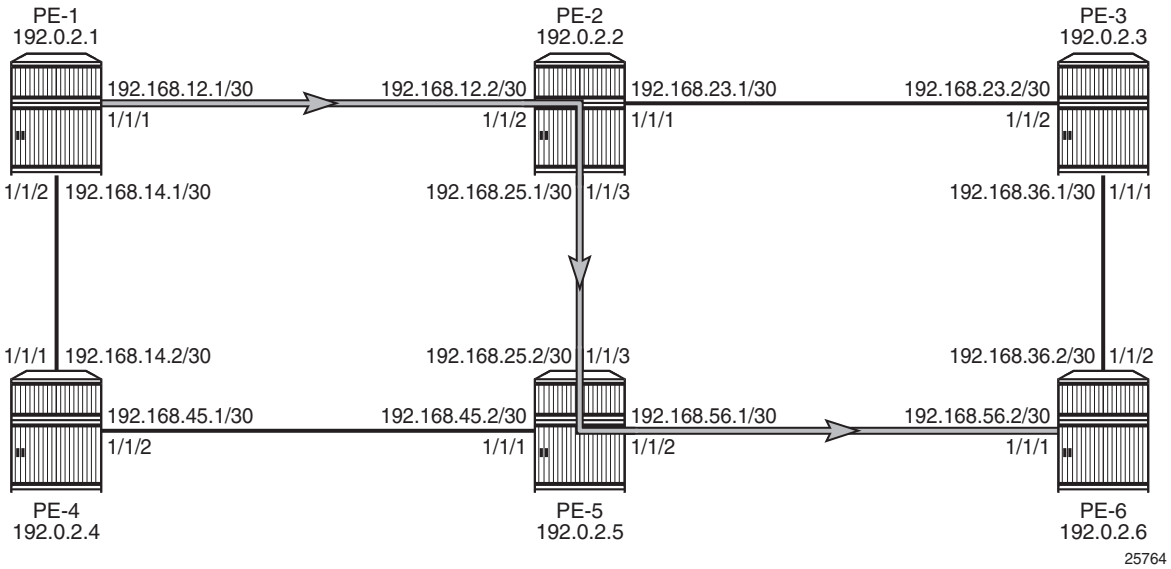
The example topology is displayed in Figure 207. The setup consists of six 7750 SR nodes located in a single autonomous system.

Figure 207 **MPLS Example Topology**

Configuration

For static LPSs, there is no need for an IGP.

For LSPs that are set up manually, the first step is to enable MPLS on:



- All network interfaces that will be used to carry LSPs
- System IP address

For manually configured LSPs, any interface used by the static LSP must be added into the MPLS protocol instance, even though RSVP is not actually used to signal labels. For router PE-1, this results in the following configuration:

```
*A:PE-1# configure router
        mpls
            interface "system"
            exit
            interface "int-PE-1-PE-2"
            exit
            interface "int-PE-1-PE-4"
            exit
            no shutdown
```

As an example, a static LSP will be created starting from PE-1, running over PE-2 and PE-5, then terminating on PE-6 as shown in Figure 208.

Figure 208 **Static LSP Running over PE-1, PE-2, PE-5, PE-6**

Verify the acceptable label range for use with static configurations for each node; as follows:

```
*A:PE-1# show router mpls-labels label-range
===============================================================================
Label Ranges
===============================================================================
Label Type      Start Label End Label   Aging       Available   Total
-------------------------------------------------------------------------------
Static          32          18431       -           18400       18400
Dynamic         18432       524287      0           505856      505856
    Seg-Route   0           0           -           0           505856
===============================================================================
*A:PE-1#
```

The label range for static LSPs extends from the value 32 to 18431. To ensure the labels have not yet been allocated to another configuration, use the command:

```
*A:PE-1# show router mpls-labels label 32 18431 in-use
===================================================================
MPLS Labels from 32 to 18431 (In-use)
===================================================================
Label               Label Type          Label Owner
-------------------------------------------------------------------
-------------------------------------------------------------------
In-use labels (Owner: All) in specified range   : 0
In-use labels in entire range                   : 0
===================================================================
*A:PE-1#
```

This command shows the number of incoming labels in use. At the iLER, the number of labels in use will remain 0 even after the static LSP has been configured where the iLER has a push operation for a label. The reason is that the labels shown are relevant to the labels that the router is generating, as for label swap or pop operations. There is no information shown about labels that other routers are advertising. For the push operation, any label can be used, even if it is not within the label range of the router pushing the label. For the originating router PE-1, the label 100 will be used for the push operation on the interface towards PE-2.

Static LSPs are configured within the MPLS configuration context, but do not rely on dynamic label signaling.

The configuration of the MPLS static LSP head-end PE-1 contains:

- The system IP address of the destination router PE-6 (to).
- A push operation of the label 100.
- The interface address facing the current node of the next hop along the static path, which is PE-2 (nexthop).

```
*A:PE-1# configure router
        mpls
            static-lsp "LSP-PE-1-PE-6-static"
```

```
                to 192.0.2.6
                push 100 nexthop 192.168.12.2
                no shutdown
            exit
```

The transit LSRs (PE-2 and PE-5) perform swap operations and forward the packet to the manually defined next-hop. On the LSR under the context of the interface on which the incoming LSP arrives, the correct label is selected (label-map) and in this context a swap operation with a new label and the new next hop (nexthop) is entered.

```
*A:PE-2# configure router
        mpls
            interface "int-PE-2-PE-1"
                label-map 100
                    swap 150 nexthop 192.168.25.2
                    no shutdown
                exit
                no shutdown
            exit
*A:PE-5# configure router
        mpls
            interface "int-PE-5-PE-2"
                label-map 150
                    swap 200 nexthop 192.168.56.2
                    no shutdown
                exit
```

The terminating router PE-6 performs a pop operation and forwards the now unlabeled packets external to the MPLS domain.

```
*A:PE-6# configure router
        mpls
            interface "int-PE-6-PE-5"
                label-map 200
                    pop
                    no shutdown
                exit
```

To verify the operational status of the static LSP configuration, the **show router mpls static-lsp** command is used on the iLER. A static LSP is considered to be operationally up when its next-hop is reachable. Since there is no check whether the end-to-end LSP path is up (the LSP connectivity to the eLER is never verified), it can be that the static LSP path is broken while the iLER displays an operational enabled LSP.

```
*A:PE-1# show router mpls static-lsp
