1 Versatile Service Module

1.1 In This Guide

This guide describes Versatile Service Module (VSM) functionality provided and presents examples to configure and implement various protocols and services.

This guide is organized into functional chapters and provides concepts and descriptions of the implementation flow, as well as Command Line Interface (CLI) syntax and command usage.

The topics and commands described in this document apply to the:

- 7450 ESS
- 7750 SR

Table 1 lists the available chassis types for each SR OS router.

Table 1 Supported SR OS Router Chassis Types

7450 ESS	7750 SR
7450 ESS-6/6v 7450 ESS-7/12 running in standard mode (not mixed-mode)	 7450 ESS-7/12 running in mixed-mode (not standard mode) 7750 SR-a4/a8 7750 SR-c4/c12 7750 SR-1e/2e/3e 7750 SR-7/12 7750 SR-12e

For a list of unsupported features by platform and chassis, refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000*x* TQZZA.

Command outputs shown in this guide are examples only; actual displays may differ depending on supported functionality and user configuration.

Note: This guide generically covers Release 14.0 content and may contain some content that will be released in later maintenance loads. Please refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000*x* TQZZA, for information on features supported in each load of the Release 14.0 software.

1.1.1 In This Chapter

This chapter provides information about configuring Versatile Service Module (VSM) parameters.

Topics in this chapter include:

- VSM Overview
 - Multiple System Solution
 - Hybrid Service Solution
 - Single System Multiple Interface Solution
 - Full Feature Internal Service Cross Connect Solution
- Functional Components
 - Service Cross Connect Adapter (CCA)
 - Internal Service CCAG
 - Internal Service Cross Connect Identifier (CCID)
 - CCAG SAP QoS
 - VSM-CCA-XP
- CCAG Bandwidth and Resiliency
- Configuration Process Overview
- Configuration Notes

1.2 VSM Overview

In many instances, it is desirable to process a stream of packets from one or more subscribers through multiple features that, for one reason or another, are mutually exclusive in the 7750 SR and the 7450 ESS forwarding planes. For example, multiple subscriber sites could be bridged together through a VPLS instance while requiring in-service high speed Internet access (IES). Functionality of this type can be handled several ways:

- Multiple System Solution
- Hybrid Service Solution
- Single System Multiple Interface Solution
- Full Feature Internal Service Cross Connect Solution

For the purpose exploring each of these solutions, the VPLS and IES service interconnection scenario is examined.

1.2.1 Multiple System Solution

The multiple system (meaning multiple boxes) solution splits the functionality between two distinct nodes. The first node performs the VPLS bridging functions while maintaining per site QoS and accounting functions. The second node connects to the first node as a destination in the VPLS service. This connection could be configured as a SAP to SAP or a pseudo-wire spoke connection.

1.2.2 Hybrid Service Solution

The hybrid solution merges the two services into a single, common service. This can be accomplished for our example service interconnect by either supporting a virtual IP interface in the context of a VPLS service or providing an IP-only solution that provides for multiple SAPs on a single IES IP interface.

The hybrid solution does not provide for separate accounting and QoS for packets forwarded (or routed) between the subscriber sites and the packets routed to next-hops outside the subscriber domain.

1.2.3 Single System Multiple Interface Solution

The single system solution retains the same SLA enforcement and accounting capabilities as the multiple system solution but with the advantage of only requiring a single chassis. This is accomplished by defining the VPLS and IES services on different physical interfaces of the same type. Both interfaces are defined as access types and use the same encapsulation type (i.e., Dot1q). The services are configured with the same encapsulation values and the physical interfaces are interconnected using an external jumper cable. To avoid single point of failure issues, Link Aggregation Groups (LAG) can be used to provide an N-to-1 redundancy mechanism (as well as adding more interconnect bandwidth).

1.2.4 Full Feature Internal Service Cross Connect Solution

The internal service cross connect solution provides similar functionality as the single system multiple interface solution while attempting to minimize the cost, density and provisioning issues inherent to the external port jumper method. The internal service cross connection feature uses new service provisioning objects and a new type of hardware adapter to manage internal service cross connections. The remainder of this document describes the internal service cross connection feature.

1.3 Functional Components

The internal service cross connection feature uses an adapter designed to fit within an IOM (Input Output Module) MDA (Media Dependant Adapter) slot. There are two types of adapters the VSM-CCA and the new VSM-CCA-XP which supports all of the features of the VSM-CCA but allows for a new higher capacity mode. One or more adapters are placed into a cross connect aggregation group (CCAG). To cross connect two services, each service is bound to the same cross connect aggregation group using the same cross connection identifier. This section introduces each object and gives a brief explanation of its function.

1.3.1 Service Cross Connect Adapter (CCA)

The VSM Cross Connect Adapter (CCA) is a type of MDA for the 7750 SR and 7450 ESS platforms designed to provide an egress to ingress forwarding plane interconnection. When a CCA is installed in an MDA slot, a set of virtual ports is available to the system providing the ability to extend packet processing through an extra set of egress and ingress forwarding paths that CCA interfaces.

Unlike external port connections which utilize two TX-RX paths, a CCA interconnects the egress forwarding path on the IOM directly to the ingress forwarding path. This eliminates the need for the physical port MAC, PHY, cable and other MDA-specific components producing a less costly and more reliable adapter. The complete 10G+forwarding path is available allowing single conversations up to 10G.

Bandwidth is utilized more efficiently than with externally cabled ports. Typically, the offered load presented to each side of the cross-connect port-pair is asymmetric in nature. When physical ports are used to cross connect services, each service is egress bandwidth-limited to the link speed of the TX-RX path.

If one TX-RX path is under-utilized, egress services on the other path cannot make use of the available bandwidth. Since the CCA is forwarding all services over the same path, all the available bandwidth can be used.

The forwarding plane that the CCA interconnects maintains the complete egress and ingress features of the services it is interconnecting. This includes the ability to remap QoS, enforce policing and shaping, and provide ingress and egress accounting for each service.

1.3.2 Internal Service CCAG

VSM CCAs are placed in a CCAG. A CCAG provides a mechanism to aggregate multiple CCAs into a single forwarding group. The CCAG uses conversation hashing to dynamically distribute cross-connect traffic to the active CCAs in the aggregation group. In the event that an active CCA fails or is removed from the group, the conversation hashing function redistributes the traffic over the remaining active CCAs within the group.

The conversation hashing mechanism performed for a CCAG is identical to the hashing functions performed for Ethernet LAGs (Link Aggregation Groups).

1.3.3 Internal Service Cross Connect Identifier (CCID)

Services and IP interfaces are bound to a CCAG through a CCID (Cross Connect Identifier). When two services or a service and an IP interface are assigned the same CCID the CCAG attempts to provide a cross connection path between the objects. The CCID enables multiple pairs of cross connected services to share the same CCAG.

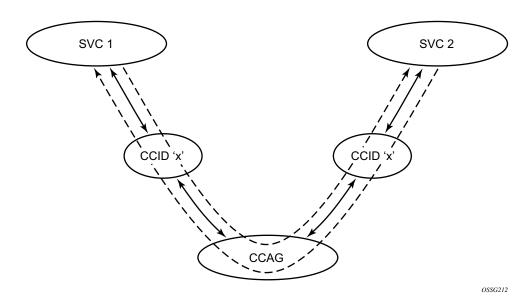

Figure 1 Internal Service Interconnection Using CCID

From a service perspective, a CCID is an object that not only binds two services together, but also provides the attachment point for the ingress and egress QoS, filtering, and accounting parameters. When considered in conjunction with the CCAG, it allows the actual cross connection path (through the CCAs) to be indirectly associated with the services using the CCAG and maintains a simplified provisioning model over port level cross connected services.

1.4 CCAG Bandwidth and Resiliency

A CCAG is an intermediate object between cross-connected objects (SAPs and network IP interfaces) and the CCAs. A CCAG is similar to a Link Aggregation Group (LAG) of Ethernet ports and uses the same underlying mechanisms to distribute conversations over multiple CCAs and converge when a CCA becomes active or inactive in the group.

When a CCAG is created, the system allocates six Ethernet LAGs for the virtual ports on the CCAs placed into the group. Each virtual port is placed into a respective LAG. For instance, each time a CCA is placed into the CCAG, virtual port 1 on that CCA is placed into the first LAG allocated to that CCAG. Virtual port 2 is placed into the second LAG on the CCAG. Virtual ports 3 through 6 are placed into their respective LAGs as well.

Using the set of LAGs provides a mechanism for conversation hashing or service mapping over all member CCAs in the CCAG. In the unlikely event that a CCA fails or is removed from the CCAG, the system will automatically modify the conversation hashing or service mapping on the CCAG to represent the available active CCAs.

1.4.1 CCAG LAG Attributes

Unlike user provisioned LAGs, the internal LAGs do not use a primary member to control the typical port level configuration parameters. Instead, the parameters usually found at the port level are implemented directly on the CCAG internal LAG representative objects (**sap-sap**, **sap-net** and **net-sap**) for each path. These commands perform functions such as MTU definition and locally administering the MAC address.

The default unique MAC addresses used in each internal LAG within the CCAG are automatically assigned from the chassis MAC pool. These MAC addresses are assigned from the pool based on an offset relative to the CCAG-ID. The same set of default MAC addresses are assigned each time a specific CCAG-ID is created.

Although a CCAG uses internal LAG mechanisms, the LACP protocol is not supported or required. LAG resources used for CCAG purposes are not exposed to the user.

1.4.2 CCAG Traffic Distribution

A CCAG uses both direct object mapping and conversation hashing to distribute traffic over multiple CCAs. To understand how each object type's ingress traffic is distributed over the active CCAs in a CCAG, refer to the LAG and ECMP Hashing section of the *Interface Configuration Guide*.

1.4.3 CCAG SAP QoS

When a SAP is created on a CCAG, the service queues defined by the ingress and egress QoS policy are created on each CCA member in the CCAG. Packets are forwarded to the egress queues based on the hashing or service mapping enforced by the LAG functions internal to the system. Packets are received on a CCA ingress queue based on which CCA handled the egress processing. Each ingress and egress hardware queue buffering and rate parameters are managed by the system based on one of two models governed by the state of the LAG QoS adaptation setting. The adaptation state also governs the application of hierarchical virtual schedulers associated with the SAP queues.

1.4.3.1 Link Level CCAG SAP QoS Adaptation

Link level QoS adaptation is set when the CCA access QoS adaptation flag is set to **link**. Link-level distribution informs the system that a service queue's buffering and rate parameters should be applied directly to each hardware queue representing the service queue. For example, when a service queue is configured with a rate equal to 10Mbps, each corresponding CCA hardware queue will be configured with a rate of 10Mbps. Given many flows conversation hashing to different CCAs, the maximum forwarded rate will be the 10Mbps multiplied by the number of active CCAs.

When a link-level adaptation service queue is a child to a parent virtual scheduler, the parent scheduler and the rest of the scheduler hierarchy is implemented per CCA. An instance of the scheduler policy is maintained per CCA.

When a CCAG SAP is a member of a Multi-Service Site (MSS), all SAPs in the MSS must be CCAG SAPs created on the same CCAG-ID.

1.4.3.2 Distributed CCAG SAP QoS Adaptation

Distributed QoS adaptation is set when the CCA access QoS adaptation flag is set to distribute. The distributed QoS parameter setting informs the system that a service queue's buffering and rate parameters should be distributed between the active CCAs in the CCAG. For example, when a service queue is configured with a rate equal to 10Mbps and two CCAs are active in the CCAG, each corresponding CCA hardware queue will be configured with a rate of 5Mbps (1/2 of the provisioned service queue parameters). Given many flows conversation hashing to different CCAs, the maximum forwarded rate will be limited to 10Mbps.

When a distributed adaptation service queue is a child to a parent virtual scheduler, the parent scheduler and the rest of the scheduler hierarchy is implemented on each IOM with an active member CCA from the CCAG. The scheduler parameters are divided amongst the IOMs with active CCAs based on the total number of active CCAs. If there are three active CCAs in the CCAG, each CCA represents 1/3 of the rate and CIR defined for each scheduler in the policy. If two of the active CCAs are on one IOM and one active CCA is on a second IOM, the first IOM would receive 2/3 of the rate and CIR for each scheduler and the second IOM would receive 1/3. The overall distribution is based on the following equation:

IOM Scheduler Rate = Policy Scheduler Rate * (Number Active CCAs on IOM / Total Active CCAs)

IOM Scheduler CIR = Policy Scheduler CIR * (Number Active CCAs on IOM / Total Active CCAs)

When a CCAG SAP is a member of a multi-service site, all SAPs in the multi-service site must be CCAG SAPs created on the same CCAG-ID.

1.4.4 VSM-CCA-XP

In addition to supporting all the features of the existing VSM-CCA, the new VSM-CCA-XP MDA offers a new hybrid mode for simplified provisioning and a higher capacity VSM when inserted on IOM3 cards. As with the VSM-CCA MDA the complete forwarding path bandwidth (in this case 25G) is available allowing single conversations up to 25G on a single MDA.

The uses cases for VSM-CCA-XP are nearly identical to the VSM-CCA. When configured as a VSM-CCA-XP port x/x1 and port x/x/2 are internally connected. Therefore configuration is very similar to a physical loop back port using Ethernet with dot1Q encapsulation. The use of hybrid port removes the requirement to configure net and sap parameters and simplifies provisioning. The use of the Ethernet VLAN Tag is used to connect the SAPs.

VSM-CCA-XP Exceptions:

- While LAG is available LACP is not allowed.
- Ethernet CFM is only available when Eth-Rings are configured on the VSM (Ethernet rings use Ethernet MEPS for Control)

The new VSM-CCA-XP can be configured as a VSM-CCA MDA to support CCA functions on IOM1, IOM2 and IOM3. On IOM3 the VSM-CCA MDA supports a loop back mode that uses LAG and 2 ports using Ethernet as the internal connection. The LAG feature also conversations hashing just as the original VSM-CCA. The hybrid port mode eliminates the need to specify network or access modes.

The following is a sample configuration for an MDA. Normally when a VSM-CCA-XP MDA is inserted it may be configured as a VSM-CCA or a VSM-CCA-XP.

```
______
MDA Summarv
______
Slot Mda Provisioned Equipped Mda-type Mda-type
                     Admin Operational
                        State
 1 vsm-cca
              vsm-cca-xp
                         up
  2 vsm-cca-xp
              vsm-cca-xp
                         up
                              up
______
 card 1
     mda-type vsm-cca-xp
     no shutdown
   exit
 exit
```

The following is a sample VSM-CCM-XP configuration for ports:

```
port 1/2/1
ethernet
exit
no shutdown
exit
port 1/2/2
ethernet
exit
no shutdown
exit
```

Port and Ethernet QoS parameters may be configured as with physical port. The Ethernet on VSM-CCA-XP has a reduced set of features. For example dot1Q is the only supported encapsulation. LACP cannot be configured on LAGs using the port.

The ports may be used directly by service SAP in the case of a single loop back. If resiliency desired, or more capacity is needed, a LAG can be configured.

The following is a sample configuration for LAG on a single VSM-CCA-XP MDA:

```
lag 1
   mode hybrid
   encap-type dot1q
   port 1/2/1 // VSM-CCA-XP
   no shutdown
exit
```

```
lag 2
   mode hybrid
   encap-type dot1q
   port 1/2/2 // VSM-CCA-XP
   no shutdown
exit
```

The following is a sample for an VPLS service equivalent using the LAG port.

```
vpls 121 customer 1 create
   stp
        shutdown
   exit
   sap lag-1:1001 create // Connect using VLAN Tag 1001
   exit
   no shutdown
   ...
exit
```

The following is a sample for an IES service equivalent to the configuration.

```
ies 122 customer 1 create
interface "Loopback" create
address 8.1.1.1/24
sap lag-2:1001 create
ingress
qos 3
exit
egress
qos 1010
exit
exit
exit
...
no shutdown
exit
```

A VSM-CCA-XP may be configured as either a VSM-CCA MDA or a VSM-CCA-XP MDA. When configured as a VSM-CCA-XP it is not a member of a CCA Group (ref VSM-CCA-XP).

1.5 Configuration Process Overview

Figure 2 shows the process to provision VSM parameters on the 7750 SR.

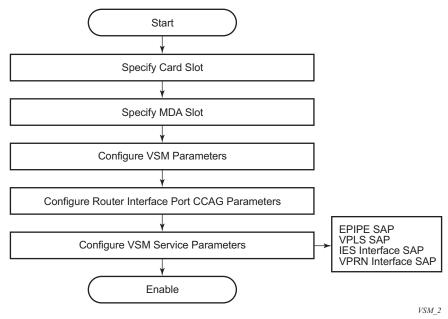

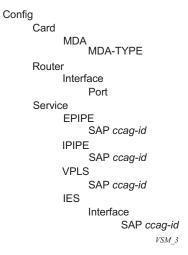

Figure 2 7750 SR VSM/CCAG Configuration and Implementation Flow

Figure 3 shows the basic components to configure card, router interface, and service CCAG components for the 7450 ESS.

Figure 3 7450 ESS VSM/CCAG Configuration Components

1.6 Configuration Notes

The following information describes provisioning caveats:

- Services can only be provisioned on Ethernet SAPs.
- The cross connections supported are:
 - IP to all Layer 2 SAPs
 - SAP to SAP of all types with the exception of:
 - A cross connection within the same service.
 - An IES service to another IES service.

1.7 Configuring VSM and CCAG with CLI

This section provides information to configure cards, MDAs, and ports.

Topics in this section include:

- Basic Configuration
- Common Configuration Tasks
- Service Management Tasks

1.8 Basic Configuration

The following fields require specific input (there are no defaults) to configure VSM:

- CCAG ID
- For a local service, two SAPs must be configured specifying the source and destination nodes and ports
- For a distributed service, one SAP and one SDP must be specified

The following example shows VSM defaults when a *ccag-id* is created.

```
A:ALA-48>config>vsm# info detail

                        exit
                    exit
                exit
            exit
            no shutdown
        exit
    exit
A:ALA-48>config>vsm#
```

1.9 Common Configuration Tasks

This section provides a brief overview of the tasks that should be performed to configure VSM on an MDA, router, router interface, and services.

- Provision one or more CCA as MDAs in the system
- Create VSM CCAGs on the system
- Provision CCAG path bandwidth, path weighting, and overall bandwidth parameters.
- Provision member CCAs into a CCAG
- Provision service SAPs using a CCAG, path, and CCID for cross connect purposes
- Bind routed network IP interfaces to a CCAG, path, and CCID for cross connect purposes

1.9.1 Configure VSM CCAG Components

Use the CLI syntax shown below to configure the following entities:

- Provision VSM on an MDA
- Cross Connecting Network IP Interfaces
- Provision CCAG Parameters
- Configure Path Components
- Cross Connecting Services

1.9.1.1 Provision VSM on an MDA

Before a CCA module may be utilized in the system, the CCA must be provisioned into an MDA slot. The MDA provisioning command must be modified to support provisioning a CCA adapter type. Up to 8 member CCAs can be configured per CCAG.

```
CLI Syntax: config>card# mda mda-number mda-type {other-MDA-
type|cca}
```

The following example shows the command usage to provision CCA on an MDA:

```
Example: config# card 10 config>card# mda 1 config>card>mda# mda-type vsm-cca config>card>mda# exit config>card#
```

The following output shows the configuration:

1.9.1.2 Provision CCAG Parameters

Once a CCA is provisioned into the system, it must be placed in a Cross Connect Aggregation Group (CCAG) to be used by cross connect objects. Besides CCA membership, the CCAG also supports bandwidth control parameters (see Configure Path Components) used to manipulate forwarding distribution between objects in the alpha and beta path groups and the aggregate rate allowed on the CCA.

Use the following CLI syntax to provision CCAG components.

The following example shows the command usage to provision CCAG components:

The following example shows the configuration:

```
A:ALA-48>config>vsm# info

ccag 1 create
description "VSM test"
cca-rate 1000000
member-cca 10/1
exit
...

A:ALA-48>config>vsm#
```

1.9.1.3 Configure Path Components

Each CCA is divided into two distinct paths for bandwidth management purposes. One path is identified as alpha (a) and the other beta (b). The significance of each path for bandwidth distribution is dependent on the relative path weights each path is given in relationship to the other. A maximum path rate may also be defined allowing the provisioning of a maximum cap on the aggregate bandwidth allowed to the SAP or IP interface queues associated with the path.

Each path is separated into three other contexts; SAP-2-SAP (sap-sap), SAP-2-Net (sap-net) and Net-2-SAP (net-sap). Each path context allows for the definition of the features that are usually associated with physical ports on other MDAs in the system. These include buffer pool management, ingress network queue definitions and accounting policy control.

Use the following CLI syntax to provision path components.

- Net SAP
- SAP net
- SAP SAP

Use the following CLI syntax to provision CCAG path components.

```
CLI Syntax:
            config>vsm>ccag#
            path {a|b}
                 net-sap
                      accounting-policy policy-id
                      collect-stats
                      egress
                           pool
                                resv-cbs percent-or-default
                                slope-policy slope-policy-name
                      mac ieee-address
                      mtu mtu-bvtes
                      queue-policy queue-policy-name
                 rate kilo-bits-per-second [aggregate | cca]
                 sap-net
                      egress
                           pool
                                resv-cbs percent-or-default
                                slope-policy slope-policy-name
                      ingress
                           pool
                                resv-cbs percent-or-default
                                slope-policy slope-policy-name
                      mac ieee-address
                      mtu mtu-bytes
                 sap-sap
                      egress
                           pool
                                resv-cbs percent-or-default
                                slope-policy slope-policy-name
                      ingress
                           pool
                                resv-cbs percent-or-default
                                slope-policy slope-policy-name
                      mac ieee-address
```

```
mtu mtu-bytes
weight path-weight
```

The following example shows a CCAG path configuration example:

```
A:ALA-48>config>vsm# info
_____
     ccag 1 create
        description "VSM test"
        member-cca 10/1
        path a
           weight 100
        exit
        path b
           weight 100
           rate 99999999
        exit
        no shutdown
     exit
_____
A:ALA-48>config>vsm#
```

1.9.1.4 Cross Connecting Network IP Interfaces

To support cross connection between services and network IP interfaces, the network interface port command has been augmented to allow the binding of the IP interface to a **ccag** *cc-id*. Similar to service CCAG SAPs, the network IP interface port binding command must reference the ccag-id, the CCA path (.a or .b) and the *cc-id* used by the service CCAG SAP on the other CCA path.

Use the following CLI syntax to configure CCAG a network IP interface.

```
CLI Syntax: config# router [router-name]
    interface interface-name
        port ccag-ccag-id.{a|b}[.net-sap]:cc-id
        address {ip-address/mask | ip-address netmask}
        [broadcast all-ones|host-ones]
        mac ieee-address
```

The following shows CCAG network IP interface configuration examples:

```
A:ALA-48>config>router# info
#------
echo "IP Configuration"
#-----
...
interface "ccanet"
address 2.1.1.1/24
port ccag-1.a.net-sap:200
```

1.9.1.5 Cross Connecting Services

Services are provisioned onto a CCAG using a special CCAG SAP definition. CCAG SAPs must reference a *ccag-id*, a CCA path (a or b), a pairing type (sap-sap or sapnet) and a unique *cc-id*. The *ccag-id* identifies the group of CCAs that will be used for forwarding packets associated with the SAP. The path identifies the bandwidth control grouping used to manage CCA egress bandwidth. The pairing type helps the system identify which buffering resources will be used to manage egress queuing of packets. Finally, the *cc-id* is used to explicitly cross connect the SAP to another SAP or network IP interface configured with the same *cc-id*.

- Epipe
- VPLS
- IES
- VPRN

1.9.1.6 **Epipe**

The following example shows an Epipe SAP configuration referencing a ccag-id:

```
A:ALA-48>config>service# info
....

epipe 103 customer 6 vpn 103 create
sap 3/1/1.1.1 create
exit
sap ccag-1.a:100 create
exit
no shutdown
exit.
```

```
A:ALA-48>config>service#
```

1.9.1.7 VPLS

The following example shows a VPLS SAP configuration referencing a ccag-id:

```
A:ALA-48>config>service# info
       vpls 740 customer 1 vpn 740 create
           stp
               shutdown
           sap 1/1/19:1 create
           exit
           sap 1/1/19:2 create
               ingress
                 qos 3
               exit
           exit
           sap ccag-1.a:456 create
               ingress
                   qos 3
               exit
               egress
                   qos 1010
               exit
           exit
           no shutdown
       exit
A:ALA-48>config>service#
```

1.9.1.8 IES

```
CLI Syntax: config>service#
    ies service-id [customer customer-id]
        interface ip-interface-name
        sap ccag-ccag-id.{a|b}[.sap-net|.sap-sap]:cc-id
        [create]
```

The following example shows an IES SAP configuration referencing a ccag-id:

```
A:ALA-48>config>service# info
       ies 200 customer 1 create
           interface "ccaiesif" create
               address 8.1.1.1/24
               sap ccag-1.b:456 create
                   ingress
                       qos 3
                    exit
                   egress
                       qos 1010
                    exit
               exit
            exit
            no shutdown
       exit
A:ALA-48>config>service#
```

1.9.1.9 VPRN

config>service>vprn>if>sap\$ no shutdown

config>service>vprn>if>sap# exit
config>service>vprn>if# exit
config>service>vprn# no shutdown

The following example shows the configuration:

1.10 Service Management Tasks

This section discusses the following service management tasks:

- Modifying or Deleting a VSM MDA
- Modifying CCAG Parameters on a Network IP Interface
- Modifying CCAG Parameters
- Modifying Path Parameters
- Modifying Service Parameters

1.10.1 Modifying or Deleting a VSM MDA

To change or delete a VSM MDA already provisioned for a specific slot, first you must shut down and remove all service SAP and router interface associations to delete the VSM MDA from the configuration.

```
CLI Syntax: config> card slot-number
[no] mda mda-number
[no] mda-type mda-type
shutdown
```

Example: config# card 10config>card# mda 1config>card>mda# mdatype vsm-cca

config>card>mda# shutdownconfig>card>mda# exit
config>card# no mda 1

The following example shows the configuration:

1.10.2 Modifying CCAG Parameters on a Network IP Interface

CLI Syntax: config# router [router-name]

The following example shows the command usage:

```
Example:
            config>router# interface ccanet
            config>router>if# address 3.1.1.1/24
            config>router>if# exit
A:ALA-48>config>router# info
#-----
echo "IP Configuration"
      interface "ccanet"
         address 3.1.1.1/24
         port ccag-1.a.net-sap:200
         mac 00:00:00:00:00:ff
      interface "ccanet2"
         address 4.1.1.1/24
         port ccag-1.b.net-sap:300
         static-arp 4.1.1.2 00:00:00:00:00:aa
#-----
A:ALA-48>config>router#
```

1.10.3 Modifying CCAG Parameters

```
CLI Syntax: config>vsm#
    ccag ccag-id [create]
    no ccag ccag-id [force]
    access
        adapt-qos {link | distribute | port-fair}
    cca-rate kilobits-per-second
    no cca-rate
    description description-string
    no description
    [no] member-cca card-slot/mda-number
    path {a|b}
    no shutdown
```

The following example shows the command usage to provision CCAG components:

```
Example: config>vsm# ccag 1 config>vsm>ccag# access
```

```
config>vsm>ccag>access#
config>vsm>ccag>access# adapt-qos distribute
config>vsm>ccag>access# exit
config>vsm>ccag# member-cca 10/2
config>vsm>ccag# exit
```

The following example shows the configuration:

```
A:ALA-48>config>vsm# info

ccag 1 create
    description "VSM test"
    member-cca 10/1
    member-cca 10/2
    path a
        weight 100
    exit
    path b
        weight 100
        rate 9999999
    exit
    no shutdown
    exit

...

A:ALA-48>config>vsm# ccag 1
```

1.10.4 Modifying Path Parameters

The following example shows the command usage to provision CCAG path parameters:

```
Example:
            config>vsm# ccag 1
            config>vsm>ccag# path a
            config>vsm>ccag>path# no weight
            config>vsm>ccag>path# net-sap
            config>vsm>ccag>path>net-sap# queue-policy nq1
            config>vsm>ccag>path>net-sap# egress
            config>vsm>ccag>path>net-sap>egr# pool
            config>vsm>ccag>path>net-sap>egr>pool# slope-policy A
            config>vsm>ccag>path>net-sap>egr>pool# exit
            config>vsm>ccag>path>net-sap>egr# exit
            config>vsm>ccag>path>net-sap# exit
            config>vsm>ccag>path# exit
            config>vsm>ccag# path b
            config>vsm>ccag>path# no rate
            config>vsm>ccag>path# sap-sap
            config>vsm>ccag>path>sap-sap# egress
```

```
config>vsm>ccag>path>sap-sap>egr# pool
config>vsm>ccag>path>sap-sap>egr>pool#
config>vsm>ccag>path>sap-sap>egr>pool# slope-policy B
config>vsm>ccag>path>sap-sap>egr>pool# exit
config>vsm>ccag>path>sap-sap>egr# exit
config>vsm>ccag>path>sap-sap# exit
config>vsm>ccag>path>sap-sap# exit
config>vsm>ccag>path>sap-sap# exit
config>vsm>ccag>path# exit
```

The following example shows the configuration:

```
A:ALA-48>config>vsm# info
      ccag 1 create
         description "VSM test"
          member-cca 10/1
          member-cca 10/2
          path a
             net-sap
                queue-policy "nq1"
                 egress
                       slope-policy "A"
                    exit
                 exit
             exit
          exit
          path b
             weight 100
             sap-sap
                egress
                    pool
                       slope-policy "B"
                    exit
                 exit
             exit
          exit
          no shutdown
      exit
_____
A:ALA-48>config>vsm#
```

1.10.5 Modifying Service Parameters

- Epipe
- VPLS
- IES
- VPRN

1.10.5.1 Epipe

The following service examples show the command usage to provision CCAG.

The following output shows the configuration:

```
A:ALA-48>config>service>epipe# info

sap 3/1/1.1.1 create
exit
sap ccag-1.b:200 create
exit
no shutdown

A:ALA-48>config>service>epipe#
```

1.10.5.2 VPLS

```
CLI Syntax: config>service#
    vpls service-id [customer customer-id]
        sap ccag-ccag-id.{a|b}[.sap-net|.sap-sap]:cc-id
        no sap sap-id
        shutdown
Example: config>service>vpls# sap ccag-1.a:456
```

```
config>service>vpls>sap# shutdown
config>service>vpls>sap# exit
config>service>vpls# no sap ccag-1.a:456
config>service>vpls# sap ccag-1.b:100 create
config>service>vpls>sap$ no shutdown
config>service>vpls>sap$ exit
```

```
config>service>vpls# sap ccag-1.a:100
config>service>vpls>sap# ingress
config>service>vpls>sap>ingress# qos 3
config>service>vpls>sap>ingress# exit
config>service>vpls>sap# egress
config>service>vpls>sap>egress# qos 1010
config>service>vpls>sap>egress# exit
config>service>vpls>sap>egress# exit
```

The following output shows the configuration:

1.10.5.3 IES

```
config>service# ies 200
config>service>ies# interface "ccanet6"
config>service>ies>if# sap ccag-1.a:101 create
config>service>ies>if>sap# ingress
config>service>ies>if>sap>ingress# qos 3
config>service>ies>if>sap>ingress# exit
config>service>ies>if>sap egress
config>service>ies>if>sap>egress# qos 1010
config>service>ies>if>sap>egress# exit
config>service>ies>if>sap>egress# exit
config>service>ies>if>sap egress# exit
config>service>ies>if>sap# no shutdown
config>service>ies>if>sap# exit
```

config>service>ies>if#

The following output shows the configuration:

```
A:ALA-48>config>service>ies# info
           interface "ccaiesif" create
               address 8.1.1.1/24
               sap ccag-1.b:456 create
                   ingress
                       gos 3
                   exit
                   egress
                       qos 1010
                   exit
               exit
           exit
            interface "ccanet6" create
               address 7.1.1.1/24
               sap ccaq-1.a:101 create
                   ingress
                       qos 3
                   exit
                   egress
                     qos 1010
                   exit
               exit
           exit
           no shutdown
A:ALA-48>config>service>ies#
```

1.10.5.4 VPRN

The following output shows the configuration:

1.11 VSM Command Reference

1.11.1 Command Hierarchies

- VSM Configuration Commands
- Related Commands

1.11.1.1 VSM Configuration Commands

```
config
    — vsm
           — ccag ccag-id [create]
           - no ccag ccag-id [force]

1.11.2.1 Generic Commands

shutdown

Syntax [no] shutdown

Context config>vsm>ccag

Description

This command controls the administrative state of the *ccag-id* the command is executed under. Upon creation, the default state of a CCAG is to be administratively up which corresponds to the no shutdown form of the command. If the CCAG must be forced to be operationally down, the **shutdown** command will place the CCAG into an administratively down state causing the operational state to also be down.

When a CCAG is shutdown, all SAPs associated with the CCAG will be operationally down. An operationally down SAP cannot be used for forwarding packets. If the SAP is part of the VPLS service, all MAC entries associated with the SAP will be removed from the VPLS FDB and the SAP will be removed from the flooding domain of the VPLS. If the SAP is part of an IES service, the associated IP interface will be set to an operationally down state. Network IP interfaces bound to a shutdown CCAG will be operationally down as well.

Executing the no shutdown command sets the CCAG to the default up administrative state. As long as at least one member CCA in the CCAG is active, all SAPs and network IP interfaces associated with the CCAG will be allowed to enter the operationally up state.

Default no shutdown

description

Syntax description description-string

no description

Context config>vsm

Description This command defines an informational string associated with the CCAG. The description

string may be up to 80 characters long and contain only printable ASCII characters. Each time this command is successfully executed, any previous description string will be overwritten. If the command fails due to improper string definition, a previously successful description string

will remain.

The **no** form of the command removes any current description string from the CCAG.

Default None (A description string must be explicitly defined)

Parameters description-string — Defines the string of printable ASCII characters, up to 80 characters

that will be stored and displayed as a description for the *ccag-id* that the **description** command is executed under. The string must be entered in double quotation marks

if the string contains spaces.

1.11.2.2 VSM CLI Tree Node Commands

vsm

Syntax [no] vsm

Context config

Description This command changes the current CLI context to the CCA nodal context. The CCA nodal

context is where CCAGs are created and maintained.

The CCA nodal context always exists and cannot be removed.

ccag

Syntax ccag ccag-id [create]

no ccag ccag-id [force]

Context

config>vsm

Description

This command creates a Cross Connect Aggregation Group (CCAG). A CCAG represents a group of CCAs as a common forwarding entity. Objects requiring a CCA cross connect function are mapped to a CCAG, not the individual CCAs within the CCAG. The CCAG treats each active member CCA as a possible destination when forwarding packets between the cross connected objects mapped to the CCAG. The system uses both conversation hashing functions and direct service mappings to determine the load sharing distribution between the active CCAs. All packets for a given conversation flow through the same CCA to preserve packet order. Packet ordering may be momentarily affected during convergence events when CCAs are dynamically added or removed from the active list.

The CCAG context is used to manage the following functions per CCAG instance:

- Informational description of the CCAG
- · Administrative state of the CCAG
- Alpha path bandwidth and weight parameters
- Beta path bandwidth and weight parameters
- · CCA total bandwidth limit
- CCA membership in the CCAG

The **no** form of the command removes an existing *ccag-id* from the system. Once the specified *ccag-id* is removed from the system, it may not be referenced by any cross connect objects. If the **force** keyword is not specified, the **no ccag** *ccag-id* command will fail if the specified *ccag-id* has one or more *cc-ids* associated with it. In the event that the specified *ccag-id* does not exist, the **no ccag** *ccag-id* command will return to the current CLI context without any change to the system.

Default

None (each CCAG context must be explicitly created to be used)

Parameters

ccag-id — Identifies the CCAG instance that the system is creating or editing. Up to eight CCAGs may be created within the system. A ccag-id must be created on the system prior to creating cross connect object associations.

After a *ccag-id* is created, a CCAG SAP may be created with an association with the *ccag-id*. A CCAG SAP is identified by a concatenation of an existing *ccag-id* and a *cc-id*. The *cc-id* must match the *cc-id* of the other object the CCAG SAP is paired with on the *ccag-id*. The created *ccag-id* may also be associated with a network IP interface. A network IP interface is bound to the *ccag-id* through the port command in the config router interface ip-interface context and references the *ccag-id* and a *cc-id*. Again, the *cc-id* must match the other object the IP interface is paired with on the *ccag-id*.

Once created, the **ccag** *ccag-id* command may be executed to enter the *ccag-id* instance for the purpose of editing the CCAG parameters or operational state.

Values 1 through 8

create — The **create** keyword explicitly indicates that the specified *ccag-id* is being created. Handling the inclusion or exclusion state of the create keyword is dependent on the system environment variable create.

When the system environment variable create is enabled, the system requires the explicit use of the create keyword when creating objects such as a CCAG. If the keyword is not included and the *ccag-id* has not already been created, an error will occur and the CLI will remain at the current CLI context. This is designed to prevent the inadvertent creation of a CCAG instance in the event where the wrong *ccag-id* is specified during an attempt to edit an existing CCAG instance. If the create keyword is specified, the *ccag-id* will be created given the *ccag-id* is within the proper range for CCAG identifiers.

When the system environment variable create is disabled (using the no create command), the system will not require the create keyword when creating a CCAG instance. In the event that the ccag command is issued with a *ccag-id* that previously had not been created, that *ccag-id* will be considered available for cross connect associations and bindings.

Once a *ccag-id* has been created, the create keyword is ignored when a ccag command is executed with that *ccag-id*. The **ccag** *ccag-id* create command will only result in a CLI context change to the specified CCAG instance for a pre-existing *ccag-id*.

force — The force keyword removes the specified ccag-id regardless of the presence of one or more cc-id. If a SAP exists on the ccag-id, the force keyword will cause the SAP to be removed from the configuration. If a network IP interface is bound to the ccag-id, the interface will be silently unbound from the ccag-id. The force keyword is intended as a time saving feature, preventing the need to first remove all service and network associations with the ccag-id.

It is not required to first remove all CCAs from the CCAG prior to deleting the CCAG from the system. When the CCAG is removed, association with all member CCAs is automatically removed.

access

Syntax access

Context config>vsm>ccag

Description This command changes the current CLI context to the CCAG access nodal context. The access nodal context contains the gos adaptation command used to control the SAP QoS

distribution across the active member CCAs within the CCAG.

The CCAG access nodal context always exists and cannot be removed.

adapt-qos

Syntax adapt-qos {link | distribute | port-fair}

no adapt-qos

Context config>vsm>ccag>access

Description This command controls how the CCAG SAP queue and virtual scheduler buffering and rate

parameters are adapted over multiple active CCAs. Two adaptation modes are supported;

link and distributed.

The no form of the command returns the CCAG access QoS adaptation rule to the default

setting of distribute.

Default distribute

Parameters link — The link keyword is mutually exclusive with the distribute and port-fair

keywords. When **link** is specified, the CCAG will create the SAP queues and virtual schedulers on each CCA with the actual parameters defined in the QoS and scheduler policies. This mode is useful when conversation hashing places all or most

traffic over a single CCA.

distribute — The distribute keyword is mutually exclusive with the link and port-fair keywords. When distribute is specified, the CCAG SAP queues and schedulers on each CCA will receive a portion of the defined parameters in the QoS and scheduler policies. The portion is decided on an IOM basis with the ratio determined by the number of active CCA members on the IOM relative to the total number of active members within the CCAG. The following equation may be used to determine the actual ratio:

IOM-parameter-value = (IOM-active-CCA / total-active-CCA) * policy-parameter-value

port-fair — The port-fair keyword is mutually exclusive with the link and distribute keywords. When port-fair is specified, the CCAG SAP queues and schedulers on each CCA will receive a portion of the defined parameters in the QoS and scheduler policies. The portion is per-port basis and equals the value configured divided by the total number of active members within the CCAG. The following equation may be used to determine the actual ratio:

Per-port-parameter-value = (1 / total-active-CCA) * policy-parameter-value

cca-rate

Syntax cca-rate kilobits-per-second

no cca-rate

Context config>vsm>ccag

Description

This command defines a maximum forwarding rate for each CCA member within the CCAG. Support of setting a maximum CCA forwarding rate is provided to prevent overrunning the ingress forwarding plane when sub-line rate ingress features are enabled. The primary ingress feature requiring this support is dual ingress access queuing. When dual ingress queuing is enabled on cross connect SAPs, the CCA forwarding rate should be limited to a rate that prevents packet loss due to ingress forwarding congestion. The specified limit is applied to the aggregate alpha and beta path bandwidth.

The **no** form of the command removes CCA bandwidth rate limiting.

Parameters

kilobits-per-second — Defines the maximum CCA rate in kilobits per second. The actual Kilobits per second rate is rounded up to the nearest 50Mbps increment.

Values 0 to 100000000, max

Default max

member-cca

Syntax [no] member-cca card-slot/mda-number

Context config>vsm>ccag

Description

This command adds and deletes provisioned CCAs from the CCAG. The only requirement to defining a CCA member is that the defined MDA position be provisioned as type cca. A CCA does not need to be populated in the defined MDA position prior to membership definition. A non-populated CCA member is considered inactive from a CCAG perspective. A populated CCA member will become active once it has been initialized by the system. A CCA member may be removed from the CCAG or depopulated from MDA slot at any time. At least one member CCA must be active on the CCAG for the CCAG to be placed in the operational state. Up to 8 member CCAs can be configured per CCAG.

The **no** form of the command removes a CCA member from the CCAG. If the CCA does not exist or is not currently a member of the CCAG, no error is returned. Once removed from the CCAG, all forwarding through the specified CCA stops.

Parameters

card-slot/mda-number — Identifies the system MDA slot that is will be added as a member CCA for the CCAG. The specified MDA slot must have been pre-provisioned as type cca for the membership command to be successful.

card-slot — Defines the IOM slot the provisioned CCA is or will be populated. It is separated from the following mda-position portion of the parameter by a forward slash (/).

Values 1 through 10 (chassis type dependent)

mda-position — The mda-position portion of the parameter defines the MDA slot number on the IOM the CCA is or will be populated. It must be separated from the preceding card-slot portion of the parameter by a forward slash (/).

Values 1 or 2 (IOM type dependent)

1.11.2.3 VSM Path Commands

path

Syntax path {a | b}

Context config>vsm>ccag

Description

This command changes the current CLI context to the path nodal context. The CCA path nodal context is where CCA path bandwidth, buffer and accounting parameters are maintained. The path context command must be specified with either the a or b keyword specifying the CCA path context to be entered.

Each CCA is divided into two distinct paths for bandwidth management purposes. One path is identified as alpha (a) and the other beta (b). The significance of each path for bandwidth distribution is dependent on the relative path weights each path is given in relationship to the other. A maximum path rate may also be defined allowing the provisioning of a maximum cap on the aggregate bandwidth allowed to the SAP or IP interface queues associated with the path. Each path is separated into three other contexts; SAP-2-SAP (sap-sap), SAP-2-Net (sap-net) and Net-2-SAP (net-sap). Each path context allows for the definition of the features that are usually associated with physical ports on other MDAs in the system. These include buffer pool management, ingress network queue definitions and accounting policy control.

The CCA path nodal contexts always exist and cannot be removed.

Parameters

- a The a keyword is mutually exclusive to the b keyword and defines the CLI CCA path context to be the alpha path. Either the a or b path must be specified. If the a or b keyword is not present, the path command will fail without changing the current CLI context.
- b The b keyword is mutually exclusive to the a keyword and defines the CLI CCA path context to be the beta path. Either the a or b path must be specified. If the a or b keyword is not present, the path command will fail without changing the current CLI context.

rate

Syntax rate kilobits-per-second [aggregate | cca]

no rate

Context config>vsm>ccag>path {a | b}

Description This cor

This command defines a specific bandwidth rate limitation for the alpha or beta paths on each member CCA in the CCAG. Use of the rate command is optional. When the rate command is not executed or the no rate command is executed, bandwidth allocated to the path is not limited to a specific rate.

Path limiting on a CCA prevents the aggregate bandwidth for the path from exceeding a certain rate. If the rate is exceeded, the CCA will backpressure all active egress queues sending on that path. Access to the available bandwidth is dependent on the various parameters associated with each object egress queue.

The specified rate may be defined as an aggregate path rate for all CCAs in the CCAG or it may be defined as a per CCA path rate.

The **no** form of the command removes path rate limiting from all CCAs in the CCAG membership list for the path.

Default None (rate limiting the alpha path must be explicitly defined)

Parameters

kilobits-per-second — Defines the path rate in kilobits per second. The aggregate and cca keywords specify how the defined rate is applied on a per CCA basis. The actual rate at each CCA is rounded up to the nearest 50Mbps.

Values 0 to 100000000, max

Default max

aggregate — The aggregate keyword is optional and mutually exclusive to the cca keyword. When aggregate is specified, the defined rate is divided among the CCAs in the CCAG member list based on the number of active CCAs. If three CCAs are active, the rate is divided by three and the result is applied to each active CCA. If a fourth CCA becomes active on the CCAG, the defined rate is then divided by four with the result applied to each CCA member on the CCAG. The actual rate at each CCA is implemented in 50Mbps increments. The system will adapt the specified rate to the best rate available per CCA.

Default When the kilobits-per-second parameter is specified, the default keyword is aggregate.

cca — The cca keyword is optional and mutually exclusive to the aggregate keyword. When cca is specified, the defined rate is applied to all CCAs in the CCAG member list. The actual rate at each CCA is implemented in 50Mbps increments. The system will adapt the specified rate to the best rate available per CCA.

weight

Syntax weight path-weight

no weight

Context config cca>ccag>path {a | b}

Description This command defines a scheduling we

This command defines a scheduling weight to the aggregate output of the alpha and beta paths. The specified weight is used to calculate a scheduling percentage for each path. The percentage for each path is based on:

Alpha scheduling percentage = alpha-path-weight / (alpha-path-weight + beta-path-weight)
Beta scheduling percentage = blue-path-weight / (alpha-path-weight + beta-path-weight)

Based on the above calculation, the sum of the alpha and beta scheduling percentage always equals 100 percent. When one path is not using all of its available scheduling bandwidth, the other path may use the remainder.

The **no** form of the command returns the path-weight for the path to the default value of 50.

Parameters

path-weight — The path-weight parameter is required and is used by the system to determine the scheduling percentage for both paths. Changing the path-weight for one path affects both paths scheduling percentage. The resulting scheduling percentage changes are applied to all CCAs in the CCAG membership list.

Values 1 to 100

Default 50

sap-sap

Syntax sap-sap

Context config>vsm>ccag>path {a | b}

Description

This command changes the current CLI context to the path SAP-SAP nodal context. This context contains the ingress and egress buffer pool configuration commands. The sapsap>path context is associated with all SAPs defined on the CCAG path (alpha or beta depending on the path context) that cross connect to a SAP on the other path.

The CCA path SAP-SAP nodal context always exists and cannot be removed.

mac

Syntax [no] mac mac-address

Context config>vsm>ccag>path {a | b}>sap-net

 $\label{lem:config} $$ config>vsm>ccag>path {a \mid b}>net-sap $$ config>vsm>ccag>path {a \mid b}>sap-sap $$$

Description This command overrides the default MAC address for the path's context.

The **no** form of the command returns the in-use MAC address for the path's context to the

default MAC from the chassis MAC pool.

Parameters mac-address — Defines the IEEE MAC address that is to be associated with the path's

context.

Values Any valid IEEE MAC source MAC address

(6 byte address expressed in hexadecimal notation with

each byte separated by a dash (-)).

Default The path's default sap-sap MAC address is derived from the

chassis MAC address pool.

mtu

Syntax mtu mtu-size

no mtu

Context config>vsm>ccag>path {a | b}>sap-sap

config>vsm>ccag>path {a | b}>sap-net config>vsm>ccag>path {a | b}>net-sap

Description This command overrides the default port level MTU for the path's context.

The **no** form of the command returns the MTU for the path's sap-sap, sap-net or net-sap

context to the default MTU.

Parameters mtu-size — Defines the Ethernet MTU that is to be associated with the path's context.

Default

1518 sap-sap1518 sap-net9212 net-sap

Values 512 to 9212 bytes

egress

Syntax egress

Context config>vsm>ccag>path {a | b}>sap-sap

config>vsm>ccag>path {a | b}>sap-net config>vsm>ccag>path {a | b}>net-sap

Description This command changes the current CLI context to the path's context. This context contains

the egress buffer pool configuration commands.

The CCA path's egress nodal context always exists and cannot be removed.

pool

Syntax pool

Context config>vsm>ccag>path {a | b}>sap-sap>egress

config>vsm>ccag>path {a | b}>sap-sap>ingress config>vsm>ccag>path {a | b}>sap-net>egress config>vsm>ccag>path {a | b}>sap-net>ingress config>vsm>ccag>path {a | b}>net-sap>egress

Description

This command changes the current CLI context to the path's nodal context. This context contains the egress buffer pool configuration commands. The CCA path's egress or ingress pool nodal context always exists and cannot be removed.

resv-cbs

Syntax [no] resv-cbs percentage-of-pool

Context config>vsm>ccag>path {a | b}>sap-sap>egress>pool

config>vsm>ccag>path {a | b}>sap-sap>ingress>pool config>vsm>ccag>path {a | b}>sap-net>egress>pool config>vsm>ccag>path {a | b}>sap-net>ingress>pool config>vsm>ccag>path {a | b}>net-sap>egress>pool config>vsm>ccag>path {a | b}>net-sap>egress>pool

Description This command defines the percentage of the buffer pool that is considered reserved for the

CBS buffer allocation for queues created in the path's pool context.

The **no** form of the command returns the reserved portion of the buffer pool to the default

percentage.

Parameters

percentage-of-pool — The percentage-of-pool parameter defines the percentage of the buffer pool that is not considered shared. The shared portion of the pool is used by queues that have crossed their CBS buffer threshold and is subject to the WRED slope functions. The reserved portion of the pool is used by queues that have not crossed their CBS threshold. The aggregate CBS on the queues associated with the pool may oversubscribe the resv-cbs percentage. If the reserved portion is oversubscribed and the in-use reserved buffers exceed the defined percentage, buffers are removed from the shared portion of the pool.

Values 1 to 100 (percent)

Default 30

ingress

Syntax ingress

Context config>vsm>ccag>path {a | b}>sap-sap

config>vsm>ccag>path {a | b}>sap-net

Description This command changes the current CLI context to the path's context. This context contains

the ingress buffer pool configuration commands.

The CCA path's ingress nodal context always exists and cannot be removed.

sap-net

Syntax sap-net

Context config>vsm>ccag>path {a | b}

Description This command changes the current CLI context to the path sap-net nodal context. This

context contains the ingress and egress buffer pool configuration commands. The sapnet>path context is associated with all SAPs defined on the CCAG path (alpha or beta depending on the path context) that cross connect to a network IP interface on the other path.

The CCA path sap-net nodal context always exists and cannot be removed.

slope-policy

Syntax slope-policy slope-policy-name

no slope-policy

Context config>vsm>ccag>path {a | b}>sap-net>ingress>pool

Description This command defines the slope policy used to mange the shared portion of the buffer pools

WRED slopes. The commands in the policy control the administrative state of the slopes, the start and knee points of each slope and the time-average-factor for the weighted average

buffer utilization calculation.

The **no** form of the command configures the default slope policy as the managing policy for

the buffer pool.

Parameters slope-policy-name — The slope-policy-name parameter defines the name of the WRED

slope policy used to manage the WRED slopes in the shared portion of the buffer

pool.

Values Any existing slope policy name.

net-sap

Syntax net-sap

Context config>vsm>ccag>path {a | b}>net-sap

Description This command changes the current CLI context to the path net-sap nodal context. The net-

sap nodal context contains the network accounting and queue policies and the egress buffer pool configuration commands. The net-sap path context is associated with all network IP interfaces bound to the CCAG path (alpha or beta depending on the path context) that cross

connects to a SAP on the other path.

The CCA path net-sap nodal context always exists and cannot be removed.

accounting-policy

Syntax accounting-policy accounting-policy

no accounting-policy

Context config>vsm>ccag>path {a | b}>net-sap

Description This command defines the network accounting policy that will be used to define which

statistics will be collected when the collect-stats command is enabled in the path's net-sap

context.

The **no** form of the command reverts the path's net-sap context statistics billing collection to

the statistics defined in the default network accounting policy.

Parameters accounting-policy — The accounting-policy parameter is required and identifies which

set of statistics will be collected for billing output.

Values Any existing network accounting policy in the system.

Default The default network accounting policy

collect-stats

Syntax [no] collect-stats

Context config>vsm>ccag>path {a | b}>net-sap

Description This command enables collecting stats on the path's net-sap context. When enabled the

statistics defined in the accounting-policy accounting-policy command will be collected

according to the specifications in the policy.

The no form of the command disables network billing statistics collection on the net-sap

context.

Default Network statistics are not collected by default on the net-sap context.

queue-policy

Syntax queue-policy queue-policy-name

no queue-policy

Context config>vsm>ccag>path {a | b}>net-sap

Description This command defines the egress network queues used by IP interfaces bound to the path's

net-sap context. The specified *queue-policy-name* defines the number of queues, the rate and buffering parameters for the queues and the forwarding class mappings to the queues.

The no form of the command reverts the path's net-sap network IP interface queues to the

systems default queue policy.

Parameters queue-policy-name — Specifies which existing Queue Policy will define the queuing

structure for network IP interfaces bound to the path's net-sap context.

Values Any existing queue policy on the system.

Default The default queue policy is used when another is not

specified.

egress

Syntax egress

Context config>vsm>ccag>path {a | b}>net-sap

Description This command changes the current CLI context to the path>net-sap>egress nodal context.

This context contains the egress buffer pool configuration commands.

The CCA path net-sap egress nodal context always exists and cannot be removed.

pool

Syntax pool

Context config>vsm>ccag>path {a | b}>net-sap>egress

Description This command changes the current CLI context to the path>net-sap>egress pool>nodal

context. This context contains the egress buffer pool configuration commands.

The CCA path net-sap egress pool nodal context always exists and cannot be removed.

1.11.2.4 Related Commands

Refer to the 7450 ESS, 7750 SR, and 7950 XRS Interface Configuration Guide for more card, MDA, and port command information or for details about configuring specific service parameters.

mda

Syntax mda mda-slot

no mda mda-slot

Context config>card

Description

This command provisions an adapter into an MDA position on an IOM slot. The provisioned MDA may or may not exist in the system at the time of provisioning. If the provisioned MDA does not currently exist in the specified MDA position number, it is considered to be a 'ghost' MDA. Ports and other resources on a ghost MDA may be configured once the MDA is provisioned. When a proper MDA matching the provisioned MDA type is inserted into the IOM MDA position, forwarding though the MDA based on configured services or network interface will be available once the MDA has been properly initialized.

A Versatile Service Module (VSM) is provisioned into the system in the same manner as all other adapters using MDA slots. Once a VSM is provisioned, independent of it actually existing in the system on the specified slot and MDA position, the VSM may be defined as a member of a CCAG (Cross Connect Adapter Group). A VSM inserted into the system prior to provisioning is not available for CCAG membership and will be treated as an unprovisioned MDA.

Once a VSM is provisioned and populated in the system, it cannot be used until it has been defined membership into a CCAG. When the CCAG membership has been defined for the VSM, the various internal resources of the VSM will be configured according to the CCAG bandwidth control parameters. This includes the alpha and beta path weights, the alpha and beta path maximum rates and the aggregate alpha and beta maximum rate. A VSM-CCA-XP may be configured as either a VSM-CCA MDA or a VSM-CCA-XP MDA. When configured as a VSM-CCA-XP it is not a member of a CCA Group (ref VSM-CCA-XP).

The **no** form of the command unprovisions an MDA from the system. For a VSM to be unprovisioned, the VSM must not be a member of a CCAG. If the VSM is a member of a CCAG, the **no cca** *slot-number/mda-number* command must be used in the CCAG member-list context. Once a CCA is unprovisioned from the system; it cannot be made a member of a CCAG until it has been reprovisioned.

Default

None (An MDA position number must be explicitly specified.)

Parameters

mda-slot — Defines the position on the card slot-number the CCA will be populated into.
On the iom-20g IOM module, two MDA positions are available. Future IOMs will support a different number of MDA positions.

Values 1 or 2

port

Syntax port ccag-ccag-id.{a | b}[.net-sap]:cc-id

no port

Context config>router>interface

Description This command cross connects a network IP interface to a CCAG SAP using the referenced

ccag-id. A CCAG network IP interface binding is identified by four items; the *ccag-id*, the CCAG path, the pairing type and the *cc-id.* A network IP interface CCAG port binding supports all the available features as port binding using a Dot1Q virtual interface.

To support cross connection between services and network IP interfaces, the network interface port command allows the binding of the IP interface to a *ccag cc-id*. Similar to service CCAG SAPs, the network IP interface port binding command must reference the *ccag-id*, the CCA path (.a or .b) and the *cc-id* used by the service CCAG SAP on the other CCA path. The pairing type is optional as only *.net-sap* is supported.

The **no** form of the command removes the CCAG binding from the network IP interface.

Parameters

ccag — The ccag portion of the port binding is required and specifies that the network IP interface is binding to a **ccag** *cc-id*.

ccag-id — The ccag-id portion of the port binding is required and specifies which ccag-id the network IP interface must be bound to. The specified ccag-id must exist on the system or the port binding will fail. The leading dash must be included as a separator between ccag and the ccag-id.

Values -1 (dash 1) to -8 (dash 8)

Default None

.a | .b — The .a and .b portion of the port binding is required and is used to define the CCA bandwidth path the network IP interface will be associated with. The path association must be specified and .a and .b are mutually exclusive. The .a designation identifies the network IP interface as being on the Alpha path and the .b designation identifies the network IP interface as being on the Beta path. The paired SAP using the same cc-id as the bound network IP interface must be associated with the opposite path. The leading period must be included as a separator between the ccag-id and the path designator.

Values .a or .b

Default None

.net-sap — The .net-sap portion of the network IP interface CCAG binding is optional and is used to explicitly define the pairing type as Net-2-SAP. A cross connection between two network IP interfaces is not currently allowed. The .net-sap pairing type is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Default .net-sap

:cc-id — The :cc-id portion of the port binding is required and specifies the unique cc-id in use by the CCAG network IP interface port binding and the cross connect SAP on the other path.

Values 1 to 4094

1.11.2.5 Services Commands

- sap (Epipe)
- sap (VPLS)

- sap (IES)
- sap (VPRN)

1.11.2.5.1 Service CCAG SAP Provisioning

Services are provisioned onto a CCAG using a special CCAG SAP definition. CCAG SAPs must reference a *ccag-id*, a CCA path (a or b), a pairing type (sap-sap or sapnet) and a unique *cc-id*. The *ccag-id* identifies the group of CCAs that will be used for forwarding packets associated with the SAP. The path identifies the bandwidth control grouping used to manage CCA egress bandwidth. The pairing type helps the system identify which buffering resources will be used to manage egress queuing of packets. Finally, the *cc-id* is used to explicitly cross connect the SAP to another SAP or network IP interface configured with the same *cc-id*.

sap (Epipe)

Syntax sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id [create] no sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id

Context config>service>epipe

Description

This command creates a cross connect SAP on the *ccag-id* referenced in the Epipe service. A CCAG SAP is identified by four items; the *ccag-id*, the CCAG path, the pairing type and the *cc-id*. An Epipe CCAG SAP supports all the available QoS, filtering and accounting features as an Epipe Dot1Q SAP.

The **no** form of the command removes a SAP from a service context. Once removed, all information and resources concerning the SAP is deleted from the system including the CCAG *cc-id* in use on the CCA path.

Parameters

ccag — The ccag portion of the SAP identifier is required and specifies that the Epipe SAP is of the CCAG type.

-ccag-id — The ccag-id portion of the SAP identifier is required and specifies which ccag-id on which the SAP must be created. The specified ccag-id must exist on the system or the SAP creation will fail. The leading dash must be included as a separator between ccag and the ccag-id.

Values -1 (dash 1) to -8 (dash 8)

Default None

.a | .b — The .a and .b portion of the CCAG SAP identifier is required and is used to define the CCA bandwidth path which will be associated with the SAP. The path association must be specified and .a and .b are mutually exclusive. The .a designation identifies the SAP as being on the Alpha path and the .b designation identifies the SAP as being on the Beta path. The paired SAP or network IP interface using the same cc-id as the SAP must be associated with the opposite path. The leading period must be included as a separator between the ccag-id and the path designator.

Values .a or .b

Default None

.sap-net — The .sap-net portion of the CCAG SAP identifier specifies that the SAP is of the SAP-2-Net pairing type and is required when the cc-id is paired with a network IP interface. The pairing type .sap-net is mutually exclusive with pairing type .sap-sap. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

.sap-sap — The .sap-sap portion of the CCAG SAP identifier is mutually exclusive to .sap-sap and is used to define the pairing type as SAP-2-SAP. The .sap-sap pairing type is only used when the cross connect object sharing the same cc-id on the opposite path is a CCAG SAP. If the other cross connect object is a network IP interface, the pairing type must be defined as .sap-net. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

:cc-id — The :cc-id portion of the CCAG SAP identifier is required and specifies the unique cc-id in use by the CCAG SAP and the cross connect object on the other path.

Values 0 to 4094

Default None

create — Explicitly indicates that the specified CCAG SAP is being created by the sap command. Handling the inclusion or exclusion state of the create keyword is dependent on the system environment variable create. When the system environment variable create is enabled, the system requires the explicit use of the **create** keyword when creating objects such as SAPs. If the keyword is not included and the specified CCAG SAP has not already been created, an error will occur and the CLI will not change context to the specified CCAG SAP instance. This is designed to prevent the inadvertent creation of a CCAG SAP in the event where the wrong CCAG SAP identifier is specified during an attempt to edit an existing CCAG SAP. If the **create** keyword is specified, the CCAG SAP will be created if it does not already exist or if it does exist, the CLI context will change to the specified CCAG SAP.

When the system environment variable create is disabled (using the **no create** command), the system will not require the **create** keyword when creating a CCAG SAP. In the event that the **sap** command is issued with a CCAG SAP identifier that previously had not been created, that CCAG SAP will be created.

Once a CCAG SAP has been created, the **create** keyword is ignored when a **sap** command is executed with that CCAG SAP identifier and the CLI context will change to the specified CCAG SAP.

vsm-cca-xp — In addition to supporting all the features of the existing VSM-CCA, the new VSM-CCA-XP MDA offers a new hybrid mode for simplified provisioning and a higher capacity VSM when inserted on IOM3-XP cards. As with the CSM-CCA MDA, the complete forwarding path bandwidth (in this case 25G) is available allowing single conservations up to 25G on a single MDA.

The use cases for VSM-CCA-XP are nearly identical to the VSM-CCA. When configured as a VSM-CCA-XP port x/x1 and port x/x/2 are internally connected. Therefore, configuration is very similar to a physical loop back port using Ethernet with dot1Q encapsulation. The use of hybrid port removes the requirement to configure net and sap parameters and simplifies provisioning. The use of the Ethernet VLAN tag is used to connect the SAPs.

VSM-CCA-XP exceptions:

- While LAG is available, LACP is not allowed.
- Ethernet CFM is only available when Eth-Rings are configured on the VSM (Ethernet rings use Ethernet MEPS for control).

The new VSM-CCA-XP can be configured as a VSM-CCA MDA to support CCA functions on IOM1, IOM2 and IOM3. On IOM3, the VSM-CCA MDA supports a loop back mode that uses LAG and two ports using Ethernet as the internal connection. The LAG feature also conversations hashing just as the original VSM-CCA. The hybrid port mode eliminates the need to specify network or access modes.

sap (VPLS)

Syntax sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id [create]

no sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id

Context config>service>vpls

Description

This command creates a cross connect SAP on the *ccag-id* referenced in the VPLS service. A CCAG SAP is identified by four items; the *ccag-id*, the CCAG path, the pairing type and the *cc-id*. A VPLS CCAG SAP supports all the available QoS, filtering and accounting features as a VPLS Dot1Q SAP.

The **no** form of the command removes a SAP from a service context. Once removed, all information and resources concerning the SAP is deleted from the system including the CCAG *cc-id* in use on the CCA path.

Parameters

- ccag The ccag portion of the SAP identifier is required and specifies that the vpls SAP is of the CCAG type.
- -ccag-id Specifies which ccag-id on which the SAP must be created. The specified ccag-id must exist on the system or the SAP creation will fail. The leading dash must be included as a separator between ccag and the ccag-id.

Values -1 (dash 1) to -8 (dash 8)

Default None

.a | .b — The .a and .b portion of the CCAG SAP identifier is required and is used to define the CCA bandwidth path which will be associated with the SAP. The path association must be specified and .a and .b are mutually exclusive. The .a designation identifies the SAP as being on the Alpha path and the .b designation identifies the SAP as being on the Beta path. The paired SAP or network IP interface using the same cc-id as the SAP must be associated with the opposite path. The leading period must be included as a separator between the ccag-id and the path designator.

Values .a or .b

Default None

.sap-net — The .sap-net portion of the CCAG SAP identifier specifies that the SAP is of the SAP-2-Net pairing type and is required when the cc-id is paired with a network IP interface. The pairing type .sap-net is mutually exclusive with pairing type .sap-sap. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

.sap-sap — The .sap-sap portion of the CCAG SAP identifier is mutually exclusive to .sap-sap and is used to define the pairing type as SAP-2-SAP. The .sap-sap pairing type is only used when the cross connect object sharing the same cc-id on the opposite path is a CCAG SAP. If the other cross connect object is a network IP interface, the pairing type must be defined as .sap-net. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

:cc-id — The :cc-id portion of the CCAG SAP identifier is required and specifies the unique cc-id in use by the CCAG SAP and the cross connect object on the other path.

Values 0 to 4094

Default None

create — Explicitly indicates that the specified CCAG SAP is being created by the sap command. Handling the inclusion or exclusion state of the create keyword is dependent on the system environment variable create.

When the system environment variable create is enabled, the system requires the explicit use of the **create** keyword when creating objects such as SAPs. If the keyword is not included and the specified CCAG SAP has not already been created, an error will occur and the CLI will not change context to the specified CCAG SAP instance. This is designed to prevent the inadvertent creation of a CCAG SAP in the event where the wrong CCAG SAP identifier is specified during an attempt to edit an existing CCAG SAP. If the **create** keyword is specified, the CCAG SAP will be created if it does not already exist or if it does exist, the CLI context will change to the specified CCAG SAP.

When the system environment variable create is disabled (using the **no create** command), the system will not require the **create** keyword when creating a CCAG SAP. In the event that the **sap** command is issued with a CCAG SAP identifier that previously had not been created, that CCAG SAP will be created.

Once a CCAG SAP has been created, the **create** keyword is ignored when a **sap** command is executed with that CCAG SAP identifier and the CLI context will change to the specified CCAG SAP.

sap (IES)

Syntax sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id [create]

no sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id

Context config>service>ies>interface

Description This command creates a cross connect SAP on the *ccag-id* referenced in the IES service. A

CCAG SAP is identified by four items; the *ccag-id*, the CCAG path, the pairing type and the *cc-id*. A CCAG SAP on an IES IP interface supports all the available QoS, filtering and

accounting features as an IES IP interface Dot1Q SAP.

The **no** form of the command removes a SAP from the IES service IP interface context. Once removed, all information and resources concerning the SAP is deleted from the system

including the CCAG cc-id in use on the CCA path.

Parameters ccag — The ccag portion of the SAP identifier is required and specifies that the ies SAP

is of the CCAG type.

ccag-id — The ccag-id portion of the SAP identifier is required and specifies which ccag-id on which the SAP must be created. The specified ccag-id must exist on the system or the SAP creation will fail. The leading dash must be included as a separator between ccag and the ccag-id.

Values -1 (dash 1) to -8 (dash 8)

Default None

.a | .b — The .a and .b portion of the CCAG SAP identifier is required and is used to define the CCA bandwidth path which will be associated with the SAP. The path association must be specified and .a and .b are mutually exclusive. The .a designation identifies the SAP as being on the Alpha path and the .b designation identifies the SAP as being on the Beta path. The paired SAP or network IP interface using the same cc-id as the SAP must be associated with the opposite path. The leading period must be included as a separator between the ccag-id and the path designator.

Values .a or .b

Default None

.sap-sap — The .sap-sap portion of the CCAG SAP identifier is optional and is used to explicitly define the pairing type as SAP-2-SAP. The .sap-sap pairing type is only used when the cross connect object sharing the same cc-id on the opposite path is a CCAG SAP. A cross connection between an IES CCAG SAP and a network IP interface is not currently allowed. If .sap-sap is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Default .sap-sap

:cc-id — The :cc-id portion of the CCAG SAP identifier is required and specifies the unique cc-id in use by the CCAG SAP and the cross connect object on the other path.

Values 0 to 4094

Default None

create — Explicitly indicates that the specified CCAG SAP is being created by the sap command. Handling the inclusion or exclusion state of the create keyword is dependent on the system environment variable create.

When the system environment variable create is enabled, the system requires the explicit use of the **create** keyword when creating objects such as SAPs. If the keyword is not included and the specified CCAG SAP has not already been created, an error will occur and the CLI will not change context to the specified CCAG SAP instance. This is designed to prevent the inadvertent creation of a CCAG SAP in the event where the wrong CCAG SAP identifier is specified during an attempt to edit an existing CCAG SAP. If the **create** keyword is specified, the CCAG SAP will be created if it does not already exist or if it does exist, the CLI context will change to the specified CCAG SAP.

When the system environment variable create is disabled (using the **no create** command), the system will not require the **create** keyword when creating a CCAG SAP. In the event that the **sap** command is issued with a CCAG SAP identifier that previously had not been created, that CCAG SAP will be created.

Once a CCAG SAP has been created, the **create** keyword is ignored when a **sap** command is executed with that CCAG SAP identifier and the CLI context will change to the specified CCAG SAP.

sap (VPRN)

Syntax sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id [create]

no sap ccag-ccag-id.{a | b}[.sap-net | .sap-sap]:cc-id

Context config>service>vprn>interface

Description

This command applies to the 7750 SR and creates a cross connect SAP on the *ccag-id* referenced in the VPRN service. A CCAG SAP is identified by four items; the *ccag-id*, the CCAG path, the pairing type and the *cc-id*. A CCAG SAP on a VPRN IP interface supports all the available QoS, filtering and accounting features as a VPRN IP interface Dot1Q SAP.

The **no** form of the command removes a SAP from the VPRN service IP interface context. Once removed, all information and resources concerning the SAP is deleted from the system including the CCAG *cc-id* in use on the CCA path.

Parameters

ccag — The ccag portion of the SAP identifier is required and specifies that the vprn SAP is of the CCAG type.

-ccag-id — Specifies which ccag-id on which the SAP must be created. The specified ccag-id must exist on the system or the SAP creation will fail. The leading dash must be included as a separator between ccaq and the ccaq-id.

Values -1 (dash 1) to -8 (dash 8)

Default None

.a | .b — The .a and .b portion of the CCAG SAP identifier is required and is used to define the CCA bandwidth path which will be associated with the SAP. The path association must be specified and .a and .b are mutually exclusive. The .a designation identifies the SAP as being on the alpha path and the .b designation identifies the SAP as being on the beta path. The paired SAP or network IP interface using the same cc-id as the SAP must be associated with the opposite path. The leading period must be included as a separator between the ccag-id and the path designator.

Values .a or .b

Default None

.sap-net — Specifies that the SAP is of the SAP-2-Net pairing type and is required when the cc-id is paired with a network IP interface. The pairing type .sap-net is mutually exclusive with pairing type .sap-sap. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

.sap-sap — The .sap-sap portion of the CCAG SAP identifier is mutually exclusive to .sap-net and is used to define the pairing type as SAP-2-SAP. The .sap-sap pairing type is only used when the cross connect object sharing the same cc-id on the opposite path is a CCAG SAP. If the other cross connect object is a network IP interface, the pairing type must be defined as .sap-net. If .sap-net is not specified, .sap-sap is assumed and does not need to be included in the SAP identification. When specified, the leading period must be used as a separator between the path designator and the pairing type.

Values .sap-net or .sap-sap

Default .sap-sap

:cc-id — The :cc-id portion of the CCAG SAP identifier is required and specifies the unique cc-id in use by the CCAG SAP and the cross connect object on the other path.

Values 0 to 4094

Default None

create — Explicitly indicates that the specified CCAG SAP is being created by the sap command. Handling the inclusion or exclusion state of the create keyword is dependent on the system environment variable create.

When the system environment variable create is enabled, the system requires the explicit use of the **create** keyword when creating objects such as SAPs. If the keyword is not included and the specified CCAG SAP has not already been created, an error will occur and the CLI will not change context to the specified CCAG SAP instance. This is designed to prevent the inadvertent creation of a CCAG SAP in the event where the wrong CCAG SAP identifier is specified during an attempt to edit an existing CCAG SAP. If the create keyword is specified, the CCAG SAP will be created if it does not already exist or if it does exist, the CLI context will change to the specified CCAG SAP.

When the system environment variable create is disabled (using the no create command), the system will not require the create keyword when creating a CCAG SAP. In the event that the sap command is issued with a CCAG SAP identifier that previously had not been created, that CCAG SAP will be created.

Once a CCAG SAP has been created, the **create** keyword is ignored when a **sap** command is executed with that CCAG SAP identifier and the CLI context will change to the specified CCAG SAP.

RFC 6425, Detecting Data Plane Failures in Point-to-Multipoint Multiprotocol Label Switching (MPLS) - Extensions to LSP Ping

SFLOW-MIB, sFlow MIB Version 1.3 (Draft 5)

MPLS — General

RFC 3031, Multiprotocol Label Switching Architecture

RFC 3032, MPLS Label Stack Encoding

RFC 3443, Time To Live (TTL) Processing in Multi-Protocol Label Switching (MPLS)
Networks

RFC 4023, Encapsulating MPLS in IP or Generic Routing Encapsulation (GRE)

RFC 4182, Removing a Restriction on the use of MPLS Explicit NULL

RFC 5332, MPLS Multicast Encapsulations

RFC 6790, The Use of Entropy Labels in MPLS Forwarding

MPLS — GMPLS

- draft-ietf-ccamp-rsvp-te-srlg-collect-04, RSVP-TE Extensions for Collecting SRLG Information
- RFC 3471, Generalized Multi-Protocol Label Switching (GMPLS) Signaling Functional Description
- RFC 3473, Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions
- RFC 4204, Link Management Protocol (LMP)
- RFC 4208, Generalized Multiprotocol Label Switching (GMPLS) User-Network Interface (UNI): Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Support for the Overlay Model
- RFC 4872, RSVP-TE Extensions in Support of End-to-End Generalized Multi-Protocol Label Switching (GMPLS) Recovery

MPLS — LDP

draft-ietf-mpls-ldp-ip-pw-capability-09, Controlling State Advertisements Of Nonnegotiated LDP Applications

draft-ietf-mpls-ldp-ipv6-15, Updates to LDP for IPv6

draft-pdutta-mpls-ldp-adj-capability-00, LDP Adjacency Capabilities

draft-pdutta-mpls-ldp-v2-00, LDP Version 2

draft-pdutta-mpls-multi-ldp-instance-00, Multiple LDP Instances

draft-pdutta-mpls-tldp-hello-reduce-04, Targeted LDP Hello Reduction

RFC 3037, LDP Applicability

RFC 3478, Graceful Restart Mechanism for Label Distribution Protocol (Helper Mode)

RFC 5036, LDP Specification

RFC 5283, LDP Extension for Inter-Area Label Switched Paths (LSPs)

RFC 5443, LDP IGP Synchronization

RFC 5561, LDP Capabilities

RFC 5919, Signaling LDP Label Advertisement Completion

RFC 6388, Label Distribution Protocol Extensions for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths

RFC 6826, Multipoint LDP in-band signaling for Point-to-Multipoint and Multipoint-to-Multipoint Label Switched Paths

MPLS — MPLS-TP

RFC 5586, MPLS Generic Associated Channel

RFC 5921, A Framework for MPLS in Transport Networks

RFC 5960, MPLS Transport Profile Data Plane Architecture

RFC 6370, MPLS Transport Profile (MPLS-TP) Identifiers

RFC 6378, MPLS Transport Profile (MPLS-TP) Linear Protection

RFC 6426, MPLS On-Demand Connectivity and Route Tracing

RFC 6427, MPLS Fault Management Operations, Administration, and Maintenance (OAM)

RFC 6428, Proactive Connectivity Verification, Continuity Check and Remote Defect indication for MPLS Transport Profile

RFC 6478, Pseudowire Status for Static Pseudowires

RFC 7213, MPLS Transport Profile (MPLS-TP) Next-Hop Ethernet Addressing

MPLS — RSVP-TE

draft-newton-mpls-te-dynamic-overbooking-00, A Diffserv-TE Implementation Model to dynamically change booking factors during failure events

RFC 2702, Requirements for Traffic Engineering over MPLS

RFC 2747, RSVP Cryptographic Authentication

RFC 2961, RSVP Refresh Overhead Reduction Extensions

RFC 3097, RSVP Cryptographic Authentication -- Updated Message Type Value

RFC 3209. RSVP-TE: Extensions to RSVP for LSP Tunnels

- RFC 3473, Generalized Multi-Protocol Label Switching (GMPLS) Signaling Resource ReserVation Protocol-Traffic Engineering (RSVP-TE) Extensions (IF_ID RSVP_HOP Object With Unnumbered Interfaces and RSVP-TE Graceful Restart Helper Procedures)
- RFC 3477, Signalling Unnumbered Links in Resource ReSerVation Protocol Traffic Engineering (RSVP-TE)
- RFC 3564, Requirements for Support of Differentiated Services-aware MPLS Traffic Engineering
- RFC 3906, Calculating Interior Gateway Protocol (IGP) Routes Over Traffic Engineering Tunnels
