| <b>Description</b> | <p>This indicates the time in seconds to wait before a SAP that has been disabled after exceeding the maximum relearn rate is re-enabled.</p> <p>It is recommended that the retry-timeout value is larger or equal to 5s * cumulative factor of the highest priority port so that the sequential order of port blocking will not be disturbed by re-initializing lower priority ports.</p> <p>A zero value indicates that the SAP will not be automatically re-enabled after being disabled. If, after the SAP is re-enabled it is disabled again, the retry timeout is increased with the provisioned retry timeout in order to avoid thrashing. For example, when retry-timeout is set to 15, it increments (15,30,45,60...).</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |

| <b>Syntax</b>      | <b>renotify</b> <i>value</i><br><b>no renotify</b>                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vpls>mac-notification                                                                                                                                                                                                             |
| <b>Description</b> | This command controls the periodic interval at which sets of MAC notification messages are sent. At each expiration of the renotify timer, a new burst of notification messages is sent, specifically <count> frames at <interval> deci-seconds. |
| <b>Default</b>     | no renotify                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>value</i> — Specifies the time interval between re-notification, in seconds<br><b>Values</b> 240 to 840                                                                                                                                       |

| <b>Description</b> | <p>This command specifies the number of bits to be considered when performing MAC learning (MAC source) and MAC switching (MAC destination). Specifically, this value identifies how many bits, starting from the beginning of the MAC address are used. For example, if the mask-value of 28 is used, MAC learning will only do a lookup for the first 28 bits of the source MAC address when comparing with existing FDB entries. Then, it will install the first 28 bits in the FDB while zeroing out the last 20 bits of the MAC address. When performing switching in the reverse direction, only the first 28 bits of the destination MAC address will be used to perform a FDB lookup to determine the next hop.</p> <p>The <b>no</b> form of this command switches back to full MAC lookup.</p> |
| <b>Parameters</b>  | <i>subnet-length</i> — Specifies the number of bits to be considered when performing MAC learning or MAC switching                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Values</b>      | 24 to 48                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command specifies the forwarding scope used for IPv6 multicast traffic when PIM snooping for IPv6 is enabled.</p> <p>By default, the scope is <b>mac-based</b>; IPv6 snooped multicast traffic is forwarded is based on the low-order 32 bits of the destination IPv6 address.</p> |

When the scope is configured as **sg-based**, the IPv6 snooped multicast traffic is forwarded based on both its full source (if specified in the join) and destination IPv6 address. SG-based forwarding is only supported on FP3- (or higher) based line cards.

PIM snooping for IPv6 must be disabled to change the forwarding mode within a VPLS service between **mac-based** and **sg-based**.

| <b>Context</b>     | config>service>vpls<br>config>service>vpls>mesh-sdp<br>config>service>vpls>sap<br>config>service>vpls>spoke-sdp |
| <b>Description</b> | This command configures Multiple Registration Protocol (MRP) parameters.                                        |

## mmrp

|                    |                                          |
|--------------------|------------------------------------------|
| <b>Syntax</b>      | <b>mvrp</b>                              |
| <b>Context</b>     | config>service>vpls>mrp                  |
| <b>Description</b> | This command configures MMRP parameters. |

## mvrp

|                |                         |
|----------------|-------------------------|
| <b>Syntax</b>  | <b>mvrp</b>             |
| <b>Context</b> | config>service>vpls>mrp |

---

**Description** This command configures MVRP parameters.

## attribute-table-high-wmark

**Syntax** [no] **attribute-table-high-wmark** *high-water-mark*

**Context** config>service>vpls>mrp>mmrp  
config>service>vpls>mrp>mvrp

**Description** This command specifies the percentage filling level of the MMRP attribute table where logs and traps are sent.

**Default** attribute-table-high-wmark 95

**Parameters** *high-water-mark* — Specifies the utilization of the MRP attribute table of this service at which a table full alarm will be raised by the agent

**Values** 1% to 100%

## attribute-table-low-wmark

**Syntax** [no] **attribute-table-low-wmark** *low-water-mark*

**Context** config>service>vpls>mrp>mmrp  
config>service>vpls>mrp>mvrp

**Description** This command specifies the MMRP attribute table low watermark as a percentage. When the percentage filling level of the MMRP attribute table drops below the configured value, the corresponding trap is cleared and/or a log entry is added.

**Default** attribute-table-low-wmark 90

**Parameters** *low-water-mark* — Specifies utilization of the MRP attribute table of this service at which a table full alarm will be cleared by the agent

**Values** 1% to 100%

## attribute-table-size

**Syntax** [no] **attribute-table-size** *value*

**Context** config>service>vpls>mrp>mmrp  
config>service>vpls>mrp>mvrp

**Description** This command controls the number of attributes accepted on a per BVPLS basis. When the limit is reached, no new attributes will be registered.

If a new lower limit (smaller than the current number of attributes) from a local or dynamic IVPLS is being provisioned, a CLI warning will be issued stating that the system is currently beyond the new limit. The value will be accepted, but any creation of new attributes will be blocked under the attribute count drops below the new limit; the software will then start enforcing the new limit.

|                   |                                                                                 |
|-------------------|---------------------------------------------------------------------------------|
| <b>Default</b>    | maximum number of attributes                                                    |
| <b>Parameters</b> | <i>value</i> — Specifies the number of attributes accepted on a per BVPLS basis |
| <b>Values</b>     | 1 to 4095 for MVRP                                                              |
| <b>Values</b>     | ESS-7/12: 1 to 2047                                                             |
| <b>Values</b>     | SR-7/SR-12: 1 to 2047                                                           |

## end-station-only

|                    |                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] end-station-only</b>                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>mrp>mmrp                                                                                                                                                             |
| <b>Description</b> | This command configures the end-station-only. This option prevents MMRP messages from being generated or processed. It is useful in case all the MMRP entries for the B-VPLS are static. |

## flood-time

|                    |                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>flood-time</b> <i>flood-time</i><br><b>no flood-time</b>                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpls>>mrp>mmrp                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures the amount of time, in seconds, after a status change in the VPLS service during which traffic is flooded. Once that time expires, traffic will be delivered according to the MMRP registrations that exist in the VPLS. |
| <b>Default</b>     | 3 seconds                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>flood-time</i> — Specifies the MRP flood time, in seconds                                                                                                                                                                                     |

| <b>Description</b> | <p>This command enables the dampening timer and applies to both types of provisioned SAPs – end-station and UNI. When a value is configured for the timer, it controls the delay between detecting that the last provisioned SAP in VPLS goes down and reporting it to the MVRP module. The CPM will wait for the time specified in the value parameter before reporting it to the MVRP module. If the SAP comes up before the hold-timer expires, the event will not be reported to MVRP module.</p> <p>The non-zero hold-time does not apply for SAP transition from down to up. This kind of transition is reported immediately to MVRP module without waiting for hold-time expiration. Also this parameter applies only to the provisioned SAPs. It does not apply to the SAPs configured with the <b>vpls-sap-template</b> command. Also when end-station QinQ SAPs are present only the “no hold-time” configuration is allowed.</p> <p>The <b>no</b> form of this command disables tracking of the operational status for the last active SAP in the VPLS. MVRP will stop declaring the VLAN only when the last provisioned customer (UNI) SAP associated locally with the service is deleted. Also MVRP will declare the associated VLAN attribute as soon as the first provisioned SAP is created in the associated VPLS instance, regardless of the operational state of the SAP.</p> |
| <b>Default</b>     | no hold-time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command configures the duration that allows the PIM-snooping switch to snoop all the PIM states in the VPLS. During this duration, multicast traffic is flooded in the VPLS. At the end of this duration, multicast traffic is forwarded using the snooped states.</p> <p>When PIM snooping is enabled in VPLS, there is a period of time when the PIM snooping switch may not have built complete snooping state. The switch cannot build states until the routers connected to the VPLS refresh their PIM messages.</p> <p>This parameter is applicable only if PIM snooping is enabled.</p> |               |          |                |    |

| <b>Description</b> | <p>Specifies the aging time for remotely learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance. In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.</p> <p>Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The <b>remote-age</b> timer specifies the aging time for remote learned MAC addresses. To reduce the amount of signaling required between switches configure this timer larger than the <b>local-age</b> timer.</p> <p>The <b>no</b> form of this command returns the remote aging timer to the default value.</p> |
| <b>Default</b>     | remote age 900 — Remote MACs aged after 900 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the aging time for remote MACs expressed in seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Values</b>      | 60 to 86400                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## selective-learned-fdb

|                |                                   |
|----------------|-----------------------------------|
| <b>Syntax</b>  | <b>[no] selective-learned-fdb</b> |
| <b>Context</b> | config>service>vpls               |

**Description** This command determines which line cards FDB entries are allocated on for MAC addresses in the VPLS service in which the command is configured.

By default, FDB entries for MAC addresses in VPLS services are allocated on all line cards in the system. Enabling **selective-learned-fdb** causes FDB entries to be allocated only on the line cards on which the service has a configured object, which includes all line cards:

- on which a SAP is configured
- which have ports configured in a LAG SAP
- which have ports configured in an Ethernet tunnel SAP
- which have ports configured on a network interface (which also may be on a LAG) when the service has a mesh or spoke-SDP, VXLAN or EVPN-MPLS configured

Only MAC addresses with a type “L” or “Evpn” in the **show** output displaying the FDB can be allocated selectively, unless a MAC address configured as a conditional static MAC address is learned dynamically on an object other than its monitored object; this can be displayed with type “L” or “Evpn” but is allocated as global because of the conditional static MAC configuration.

The **no** form of this command returns the FDB MAC address entry allocation mode to its default where FDB entries for MAC addresses are allocated on all line cards in the system.

**Default** no selective-learned-fdb

## send-flush-on-failure

**Syntax** [no] send-flush-on-failure

**Context** config>service>vpls

**Description** This command enables sending out flush-all-from-me messages to all LDP peers included in affected VPLS, in the event of physical port failures or “operationally down” events of individual SAPs. This feature provides an LDP-based mechanism for recovering a physical link failure in a dual-homed connection to a VPLS service. This method provides an alternative to RSTP solutions where dual homing redundancy and recovery, in the case of link failure, is resolved by RSTP running between a PE router and CE devices. If the endpoint is configured within the VPLS and send-flush-on-failure is enabled, flush-all-from-me messages will be sent out only when all spoke-SDPs associated with the endpoint go down.

This feature cannot be enabled on management VPLS.

**Default** no send-flush-on-failure

## propagate-mac-flush

**Syntax** [no] propagate-mac-flush

---

|                    |                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command enabled propagation of mac-flush messages received from the specified T-LDP on all spoke and mesh-SDPs within the context of the VPLS service. The propagation will follow split-horizon principles and any data-path blocking in order to avoid looping of these messages. |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                 |

## service-mtu

|                    |                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>service-mtu</b> <i>octets</i><br><b>no service-mtu</b>                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpls<br>config>service>template>vpls-template                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the service payload (Maximum Transmission Unit – MTU), in bytes, for the service. This MTU value overrides the service-type default MTU. The <b>service-mtu</b> defines the payload capabilities of the service. It is used by the system to validate the SAP and SDP binding's operational state within the service. |

The service MTU and a SAP's service delineation encapsulation overhead (4 bytes for a dot1q tag) is used to derive the required MTU of the physical port or channel on which the SAP was created. If the required payload is larger than the port or channel MTU, then the SAP will be placed in an inoperative state. If the required MTU is equal to or less than the port or channel MTU, the SAP will be able to transition to the operative state.

When binding an SDP to a service, the service MTU is compared to the path MTU associated with the SDP. The path MTU can be administratively defined in the context of the SDP. The default or administrative path MTU can be dynamically reduced due to the MTU capabilities discovered by the tunneling mechanism of the SDP or the egress interface MTU capabilities based on the next hop in the tunnel path. If the service MTU is larger than the path MTU, the SDP binding for the service will be placed in an inoperative state. If the service MTU is equal to or less than the path MTU, then the SDP binding will be placed in an operational state.

If a service MTU, port or channel MTU, or path MTU is dynamically or administratively modified, then all associated SAP and SDP binding operational states are automatically re-evaluated.

For i-VPLS and Epipes bound to a b-VPLS, the service-mtu must be at least 18 bytes smaller than the b-VPLS service MTU to accommodate the PBB header.

The **no** form of this command returns the default **service-mtu** for the indicated service type to the default value.

|                    |                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>site                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command configures for how long the service manger waits after a node reboot before running the DF election algorithm. The boot-timer value should be configured to allow for the BGP sessions to come up and for the NLRI information to be refreshed/exchanged.</p> <p>The <b>no</b> form of the command reverts the default.</p> |
| <b>Default</b>     | 10                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the site boot-timer in seconds                                                                                                                                                                                                                                                                                   |
| <b>Values</b>      | 0 to 100                                                                                                                                                                                                                                                                                                                                    |

**failed-threshold**

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>failed-threshold</b> [1 to 1000]<br><b>failed-threshold all</b>                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>site                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command defines the number of objects should be down for the site to be declared down. Both administrative and operational status must be evaluated and if at least one is down, the related object is declared down.</p> |
| <b>Default</b>     | failed-threshold all                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>1 to 1000</i> — Specifies the threshold for the site to be declared down                                                                                                                                                       |

| <b>Description</b> | <p>This command configures the BGP multi-homing site minimum down time. When set to a non-zero value, if the site goes operationally down it will remain operationally down for at least the length of time configured for the <b>site-min-down-timer</b>, regardless of whether other state changes would have caused it to go operationally up. This timer is restarted every time that the site transitions from up to down. Setting this parameter to zero allows the minimum down timer to be disabled for this service.</p> <p>The above operation is optimized in the following circumstances:</p> <ul style="list-style-type: none"><li>• If the site goes down on the designated forwarder but there are no BGP multi-homing peers with the same site in an UP state, then the <b>site-min-down-timer</b> is not started and is not used.</li><li>• If the site goes down on the designated forwarder but there are no active BGP multi-homing peers, then the <b>site-min-down-timer</b> is not started and is not used.</li><li>• If the <b>site-min-down-timer</b> is active and a BGP multi-homing update is received from the designated forwarder indicating its site has gone down, the <b>site-min-down-timer</b> is immediately terminated and this PE becomes the designated forwarder if the BGP multi-homing algorithm determines it should be the designated forwarder.</li></ul> <p>The <b>no</b> form of this command reverts to the default value.</p> |
| <b>Default</b>     | Taken from the value of <b>site-min-down-timer</b> configured for Multi-Chassis BGP multi-homing under the <b>config&gt;redundancy&gt;bgp-multi-homing</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | This command binds a service to an existing Service Distribution Point (SDP).<br><br>The <b>no</b> form of the command removes the parameter from the configuration.             |
| <b>Parameters</b>  | <i>sdp-id</i> — Specifies the SDP identifier<br><br><b>Values</b> 1 to 17407<br><br><i>vc-id</i> — Specifies the virtual circuit identifier.<br><br><b>Values</b> 1 to 429496729 |

## spb

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>spb</b> [ <i>isis-instance</i> ] [ <b>fid</b> <i>fid</i> ] [ <b>create</b> ]<br><b>no spb</b> |
| <b>Context</b>     | config>service>vpls<br>config>service>vpls>sap<br>config>service>vpls>spoke-sdp                  |
| <b>Description</b> | This command configures Shortest Path Bridging.                                                  |
| <b>Parameters</b>  | <i>isis-instance</i> — Specifies the ISIS instance<br><br><b>Values</b> 1024 to 2047             |

*fid* — Specifies the FID

**Values** 1 to 4095

**create** — This keyword is mandatory when creating an SPB instance

## level

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>level</b> [1 to 1]                                                                       |
| <b>Context</b>     | config>service>vpls>spb<br>config>service>vpls>sap>spb<br>config>service>vpls>spoke-sdp>spb |
| <b>Description</b> | This command enters the context to configure SPB level information.                         |

## bridge-priority

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bridge-priority</b> <i>bridge-priority</i><br><b>no bridge-priority</b>                                                             |
| <b>Context</b>     | config>service>vpls>spb>level                                                                                                          |
| <b>Description</b> | This command configures the level 1 four bit bridge priority associated with this Shortest Path Bridging context in this VPLS service. |
| <b>Default</b>     | bridge-priority 8                                                                                                                      |
| <b>Parameters</b>  | <i>bridge-priority</i> — Specifies the bridge priority<br><b>Values</b> 0 to 15                                                        |

## ect-algorithm

|                    |                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ect-algorithm</b> <i>fid-range</i> <i>fid-range</i> { <b>low-path-id</b>   <b>high-path-id</b> }<br><b>no ect-algorithm</b> <i>fid-range</i> <i>fid-range</i>                                                                                                                        |
| <b>Context</b>     | config>service>vpls>spb>level                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command configures the ECT algorithm of forwarding range.                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>fid-range</i> — Specifies the FID range in the form <i>start-end</i> ; for example, 50-120<br><b>Values</b> <i>start</i> — 1 to 4095<br><i>end</i> — 1 to 4095<br><b>low-path-id</b> — Keyword specifies the low path ID<br><b>high-path-id</b> — Keyword specifies the high path ID |

## forwarding-tree-topology

|                    |                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>forwarding-tree-topology unicast {spf   st}</b>                                                                                                                          |
| <b>Context</b>     | config>service>vpls>spb>level                                                                                                                                               |
| <b>Description</b> | This command specifies level 1 unicast forwarding to follow the shortest path tree or to follow a single tree for this Shortest Path Bridging context in this VPLS service. |
| <b>Default</b>     | forwarding-tree-topology unicast spf                                                                                                                                        |
| <b>Parameters</b>  | <b>spf</b> — Follows the shortest path tree.<br><b>st</b> — Follows a single tree.                                                                                          |

## lsp-lifetime

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the LSP refresh timer interval. When configuring the LSP refresh interval, the value that is specified for <b>lsp-lifetime</b> must also be considered. The LSP refresh interval cannot be greater than 90% of the LSP lifetime.</p> <p>The no form of the command reverts to the default (600 seconds), unless this value is greater than 90% of the LSP lifetime. For example, if the LSP lifetime is 400, then the <b>no lsp-refresh-interval</b> command will be rejected.</p> |
| <b>Default</b>     | lsp-refresh-interval 600 half-lifetime enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><b>seconds</b> — Specifies the refresh interval.</p> <p><b>Values</b> 150 to 65535</p> <p><b>half-lifetime</b> — Sets the refresh interval to always be half the <b>lsp-lifetime</b> value. When this parameter is set to <b>enable</b>, the configured refresh interval is ignored.</p> <p><b>Values</b> enable, disable</p>                                                                                                                                                                              |

| <b>Description</b> | <p>This command administratively sets the router to operate in the overload state for a specific time period, in seconds, or indefinitely.</p> <p>During normal operation, the router may be forced to enter an overload state due to a lack of resources. When in the overload state, the router is only used if the destination is reachable by the router and will not be used for other transit traffic.</p> <p>If a time period is specified, the overload state persists for the configured length of time. If no time is specified, the overload state operation is maintained indefinitely.</p> <p>The <b>overload</b> command can be useful in circumstances where the router is overloaded or used prior to executing a <b>shutdown</b> command to divert traffic around the router.</p> <p>The <b>no</b> form of the command causes the router to exit the overload state.</p> |
| <b>Default</b>     | no overload                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>When the router is in an overload state, the router is used only if there is no other router to reach the destination. This command configures the IGP upon bootup in the overload state until one of the following events occur:</p> <ol style="list-style-type: none"> <li>1. The timeout timer expires.</li> <li>2. A manual override of the current overload state is entered with the <b>config&gt;router&gt;isis&gt;no overload</b> command.</li> </ol> <p>The <b>no overload</b> command does not affect the <b>overload-on-boot</b> function.</p> <p>If no timeout is specified, IS-IS will go into overload indefinitely after a reboot. After the reboot, the IS-IS status will display a permanent overload state:</p> <ul style="list-style-type: none"> <li>• L1 LSDB Overload : Manual on boot (Indefinitely in overload)</li> <li>• L2 LSDB Overload : Manual on boot (Indefinitely in overload)</li> </ul> <p>This state can be cleared with the <b>config&gt;router&gt;isis&gt;no overload</b> command.</p> <p>When specifying a timeout value, IS-IS will go into overload for the configured timeout after a reboot. After the reboot, the IS-IS status will display the remaining time the system stays in overload:</p> <ul style="list-style-type: none"> <li>• L1 LSDB Overload : Manual on boot (Overload Time Left : 17)</li> <li>• L2 LSDB Overload : Manual on boot (Overload Time Left : 17)</li> </ul> <p>The overload state can be cleared before the timeout expires with the <b>config&gt;router&gt;isis&gt;no overload</b> command.</p> <p>The <b>no</b> form of the command removes the overload-on-boot functionality from the configuration.</p> |
| <b>Default</b>     | no overload-on-boot                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## lsp-wait

|                    |                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b><i>lsp-wait</i> <i>lsp-wait</i> [<i>lsp-initial-wait</i> <i>lsp-initial-wait</i>] [<i>lsp-second-wait</i> <i>lsp-second-wait</i>]</b><br><b>no <i>lsp-wait</i></b>                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>spb>timers                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command is used to customize LSP generation throttling. Timers that determine when to generate the first, second and subsequent LSPs can be controlled with this command. Subsequent LSPs are generated at increasing intervals of the second <b><i>lsp-wait</i></b> timer until a maximum value is reached. |

**Note:** The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>lsp-wait</i> — Specifies the maximum interval in milliseconds between two consecutive occurrences of an LSP being generated.<br><b>Values</b> 10 to 120000<br><b>Default</b> 5000<br><i>initial-wait</i> — Specifies the initial LSP generation delay in milliseconds. Values < 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.<br><b>Values</b> 10 to 100000<br><b>Default</b> 10<br><i>second-wait</i> — Specifies the hold time in milliseconds between the first and second LSP generation.<br><b>Values</b> 10 to 100000<br><b>Default</b> 1000 |

| <b>Description</b>                                                                | <p>This command defines the maximum interval between two consecutive SPF calculations in milliseconds. Timers that determine when to initiate the first, second and subsequent SPF calculations after a topology change occurs can be controlled with this command.</p> <p>Subsequent SPF runs (if required) will occur at exponentially increasing intervals of the <i>spf-second-wait</i> interval. For example, if the <i>spf-second-wait</i> interval is 1000, then the next SPF will run after 2000 milliseconds, and then next SPF will run after 4000 milliseconds, and so on, until it reaches the <i>spf-wait</i> value. The SPF interval will stay at <i>spf-wait</i> value until there are no more SPF runs scheduled in that interval. After a full interval without any SPF runs, the SPF interval will drop back to <i>spf-initial-wait</i>.</p> |
|  | <p><b>Note:</b> The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command creates a new split horizon group for the VPLS instance. Traffic arriving on a SAP or spoke-SDP within this split horizon group will not be copied to other SAPs or spoke-SDPs in the same split horizon group.</p> <p>A split horizon group must be created before SAPs and spoke-SDPs can be assigned to the group.</p> <p>The split horizon group is defined within the context of a single VPLS. The same group-name can be re-used in different VPLS instances.</p> <p>Up to 30 split horizon groups can be defined per VPLS instance. Half are supported in i-VPLS.</p> <p>The <b>no</b> form of the command removes the group name from the configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>     | A split horizon group is by default not created as a residential-group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>group-name</i> — Specifies the name of the split horizon group to which the SDP belongs</p> <p><i>residential-group</i> — Defines a split horizon group as a residential split horizon group (RSHG). Doing so entails that:</p> <ul style="list-style-type: none"> <li>a) SAPs which are members of this Residential Split Horizon Group will have: <ul style="list-style-type: none"> <li>• Double-pass queuing at ingress as default setting (can be disabled)</li> <li>• STP disabled (cannot be enabled)</li> <li>• ARP reply agent enabled per default (can be disabled)</li> <li>• MAC pinning enabled per default (can be disabled)</li> <li>• Downstream broadcast packets are discarded thus also blocking the unknown, flooded traffic</li> <li>• Downstream multicast packets are allowed when IGMP snooping is enabled</li> </ul> </li> <li>b) Spoke SDPs which are members of this Residential Split Horizon Group will have: <ul style="list-style-type: none"> <li>• Downstream multicast traffic supported</li> <li>• Double-pass queuing is not applicable</li> <li>• STP is disabled (can be enabled)</li> <li>• ARP reply agent is not applicable (dhcp-lease-states are not supported on spoke-SDPs)</li> <li>• MAC pinning enabled per default (can be disabled)</li> </ul> </li> </ul> |

|----------------|------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>lag-link-map-profile</b> <i>link-map-profile-id</i><br><b>no lag-link-map-profile</b> |
| <b>Context</b> | config>service>vpls>sap                                                                  |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command assigns a pre-configured lag link map profile to a SAP/network interface configured on a LAG or a PW port that exists on a LAG. Once assigned/unassigned, the SAP/network interface egress traffic will be re-hashed over LAG as required by the new configuration.</p> <p>The <b>no</b> form of this command reverts the SAP/network interface to use per-flow, service or link hash as configured for the service/LAG.</p> |
| <b>Default</b>     | no lag-link-map-profile                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>link-map-profile-id</i> — An integer from 1 to 64 that defines a unique lag link map profile on which the LAG the SAP/network interface exist.                                                                                                                                                                                                                                                                                            |

## lag-per-link-hash

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lag-per-link-hash class {1   2   3} weight [weight]</b><br><b>no lag-per-link-hash</b>                                                                                                                |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                  |
| <b>Description</b> | <p>This command configures weight and class to this SAP to be used on LAG egress when the LAG uses weighted per-link-hash.</p> <p>The <b>no</b> form of this command restores default configuration.</p> |
| <b>Default</b>     | no lag-per-link-hash (equivalent to weight 1 class 1)                                                                                                                                                    |

## l2pt-termination

|                    |                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | This command enters the context to configure the default gateway information when using Dual Homing in L2-TPSDA. The IP and MAC address of the default gateway used for subscribers on an L2 MC-Ring are configured in this context. After a ring heals or fails, the system will send out a gratuitous ARP on an active ring SAP in order to attract traffic from subscribers on the ring with connectivity to that SAP. |

| <b>Syntax</b>      | <b>dist-cpu-protection</b> <i>policy-name</i><br><b>no dist-cpu-protection</b>                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command assigns a Distributed CPU Protection (DCP) policy to the SAP. Only a valid existing DCP policy can be assigned to a SAP or a network interface (this rule does not apply to templates, such as an msap-policy template).</p>                          |
| <b>Default</b>     | <p>If no dist-cpu-protection policy is assigned to a SAP, then the default access DCP policy (_default-access-policy) is used.</p> <p>If no DCP functionality is required on the SAP, then an empty DCP policy can be created and explicitly assigned to the SAP.</p> |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the name of the DCP policy up to 32 characters in length                                                                                                                                                                               |

| <b>Description</b> | <p>This command assigns a conditional static MAC address entry to an SPBM B-VPLS SAP/spoke-SDP allowing external MACs for single and multi-homed operation.</p> <p>For the 7450 ESS or 7750 SR, this command also assigns a conditional static MAC address entry to an EVPN VPLS SAP/spoke-SDP.</p> <p>Static MACs are used for PBB Epipe and I-VPLS services that may terminate external to SPBM. If this is configured under a Control B-VPLS the interface referenced will not use IS-IS for this neighbor. This may also be configured under a User B-VPLS where the corresponding interface is not supported under the Control B-VPLS.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>ieee-address</i> — Specifies the static MAC address to an SPBM/sdp-binding interface</p> <p><b>Values</b> 6-byte mac-address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx) Cannot be all zeros.</p> <p><i>sap-id</i> — Specifies the SAP identifier</p>                                                                                                                                                                                                                                                                                                                                                                                        |

*sdp-id* — Specifies the SDP identifier

**Values** 1 to 17407

*vc-id* — Specifies the virtual circuit identifier

**Values** 1 to 4294967295

**create** — This keyword is mandatory while creating a static MAC

**fwd-status** — Specifies that this static mac is based on the forwarding status of the SAP or spoke-SDP for multi-homed operation.

**black-hole** — Specifies for TLS FDB entries defined on a local SAP the value 'sap', remote entries defined on an SDP have the value 'sdp'.

## use-def-mcast

**Syntax** [no] **use-def-mcast**

**Context** config>service>vpls>isid-policy>entry

**Description** The **use-def-mcast** option prevents local installation of the ISIDs in the range in the MFIB and uses the default multicast tree instead for a B-VPLS. In a node that does not have I-VPLS or static-isids, this command prevents the building of an MFIB entry for this ISID when received in a SPBM TLV and allows the broadcast of ISID based traffic on the default multicast tree. If an **isid-policy** exists, the core nodes can have this policy to prevent connectivity problems when some nodes are advertising an ISID and others are not. In a I-VPLS service if the customer MAC (C-MAC) is unknown, a frame will have the Multicast DA for an ISID (PBB-OUI + ISID) flooded on the default multicast tree and not pruned.

**Default** no use-def-mcast

## lsp-pacing-interval

**Syntax** **lsp-pacing-interval** *milli-seconds*  
**no lsp-pacing-interval**

**Context** config>service>vpls>sap>spb  
config>service>vpls>spoke-sdp>spb

**Description** This command configures the interval during which LSPs are sent from the interface.

To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent during an interval. LSPs may be sent in bursts during the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface.

The **no** form of the command reverts to the default value.

**Note:** The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

|                   |                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | <code>lsp-pacing-interval 100</code>                                                                                                               |
| <b>Parameters</b> | <i>milli-seconds</i> — Specifies the interval, in milliseconds, during which IS-IS LSPs are sent from the interface expressed as a decimal integer |
| <b>Values</b>     | 0 to 65535                                                                                                                                         |

## retransmit-interval

|                    |                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <code>retransmit-interval seconds</code><br><code>no retransmit-interval</code>                                                                                                |
| <b>Context</b>     | <code>config&gt;service&gt;vpls&gt;sap&gt;spb</code><br><code>config&gt;service&gt;vpls&gt;spoke-sdp&gt;spb</code>                                                             |
| <b>Description</b> | This command configures the minimum time between LSP PDU retransmissions on a point-to-point interface.<br><br>The <b>no</b> form of the command reverts to the default value. |
| <b>Default</b>     | <code>retransmit-interval 100</code>                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the interval in seconds that IS-IS LSPs can be sent on the interface                                                                                |
| <b>Values</b>      | 1 to 65535                                                                                                                                                                     |

## process-cpm-traffic-on-sap-down

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | <code>config&gt;service&gt;vpls&gt;sap</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command is applicable to simple SAPs configured on LAGs that are not part of any “endpoint” configurations or complicated resiliency schemes like MC-LAG with inter-chassis-backup (ICB) configurations. When configured, a simple LAG SAP will not be removed from the forwarding plane and flooded traffic (unknown unicast, broadcast and multicast) will be dropped on egress. This allows applicable control traffic that is extracted at the egress interface to be processed by the CPM. This command will not prevent a VPLS service from entering an Operational Down state if it is the last active connection to enter a non-operational state. By default, without this command, when a SAP on a LAG enters a non-operational state it is removed from the forwarding plane and no forwarding occurs to the egress. |

The **no** form of the command means a SAP over a LAG that is not operational will be removed from the forwarding process.

**Default** no process-cpm-traffic-on-sap-down

## pppoe-policy

**Syntax** **pppoe-policy** *pppoe-policy-name*  
**no pppoe-policy**

**Context** config>service>vpls>sap

**Description** For the 7450 ESS or 7750 SR, this command specifies an existing PPPoE policy. These policies are referenced from interfaces configured for PPPoE. Multiple PPPoE policies may be configured.

**Default** none

**Parameters** *pppoe-policy-name* — Specifies an existing PPPoE policy name up to 32 characters in length

## auto-learn-mac-protect

**Syntax** [**no**] **auto-learn-mac-protect**

**Context** config>service>vpls>sap  
config>service>vpls>spoke-sdp  
config>service>vpls>mesh-sdp  
config>service>vpls>split-horizon-group  
config>service>vpls>endpoint  
config>service>pw-template  
config>service>pw-template>split-horizon-group

**Description** This command enables the automatic protection of source MAC addresses learned on the associated object. MAC protection is used in conjunction with **restrict-protected-src**, **restrict-unprotected-dst** and **mac-protect**. When this command is applied or removed, the MAC addresses are cleared from the related object.

When the **auto-learn-mac-protect** is enabled on an SHG the action only applies to the associated SAPs (no action is taken by default for spoke-SDPs in the SHG). To enable this function for spoke-SDPs within a SHG, the **auto-learn-mac-protect** must be enabled explicitly under the spoke-SDP. If required, **auto-learn-mac-protect** can also be enabled explicitly under specific SAPs within the SHG.

**Default** no auto-learn-mac-protect

## restrict-unprotected-dst

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command indicates how the system will forward packets destined for an unprotected MAC address, either manually added using the <b>mac-protect</b> command or automatically added using the <b>auto-learn-mac-protect</b> command. While enabled all packets entering the configured SAP or SAPs within a split horizon group (but not spoke or mesh-SDPs) will be verified to contain a protected destination MAC address. If the packet is found to contain a non-protected destination MAC, it will be discarded. Detecting a non-protected destination MAC on the SAP will not cause the SAP to be placed in the operationally down state. No alarms are generated.</p> <p>If the destination MAC address is unknown, even if the packet is entering a restricted SAP, with restrict-unprotected-dst enabled, it will be flooded.</p> |
| <b>Default</b>     | no restrict-unprotected-dst                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | This command defines a vpls-group index. Multiple vpls-group commands can be specified to allow the use of different VPLS and SAP templates for different ranges of service ids. A vpls-group can be deleted only in shutdown state. Multiple commands under different vpls-group ids can be issued and can be in progress at the same time. |
| <b>Default</b>     | no vpls-group                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>vpls-group-id</i> — Specifies the ID associated with the VPLS group<br><b>Values</b> 1 to 4094                                                                                                                                                                                                                                            |

## mvrp-control

|                |                                |
|----------------|--------------------------------|
| <b>Syntax</b>  | [no] <b>mvrp-control</b>       |
| <b>Context</b> | config>service>vpls>vpls-group |

**Description** This command enables MVRP control in the VPLS instances instantiated using the templates for the specified vpls-group. That means the flooding FDB will be created empty and will be populated with endpoints whenever MVRP receives a declaration and a registration on a specific endpoint. Also the VLAN ID associated by the control VPLS with the instantiated VPLS will be declared on service activation by MVRP on all virtual MVRP ports in the control VPLS. Service activation takes place when at least one other SAP is provisioned and brought up under the data VPLS. This is usually a customer facing SAP or a SAP leading outside of the MVRP controlled domain.

The **no** form of this command disallows MVRP control over this VPLS. The VPLS will be created with a regular FDB and will become as a result active upon creation time. Command change is allowed only when the related vpls-group is in shutdown state.

**Default** no mvrp-control

## sap-template-binding

**Syntax** **sap-template-binding** *name/id*  
**no sap-template-binding**

**Context** config>service>vpls>vpls-group

**Description** This command configures the binding to a SAP template to be used to instantiate SAPs in the data VPLS using as input variables the VLAN IDs generated by the vid-range command.

The **no** form of this command removes the binding and deletes the related SAP instances. The command will fail if any of the affected VPLS instances have either a provisioned SAP or an active MVRP declaration/registration or if the related vpls-group is in no shutdown state. Any changes to the **sap-template-binding** require the **vpls-group** to be in **shutdown** state. New control SAP additions to the management VPLS are allowed as long as data VPLS instantiations/removals for vpls-groups are not in progress. Control SAPs can be removed at any time generating the removal of related data SAPs from the data VPLS. The **shutdown** or **no shutdown** state for the control SAPs does not have any effect on data SAPs instantiated with this command.

**Default** no sap-template-binding

**Parameters** *name* — Specifies the name of the VPLS template

**Values** ASCII character string

*id* — Specifies the ID of the VPLS template

**Values** 1 to 8196

## service-range

**Syntax** **service-range** *startid-endid* [*start-vlan-id startvid*]  
**no service-range**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>vpls>vpls-group                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command configures the service ID and implicitly the VLAN ID ranges to be used as input variables for related VPLS and SAP templates to pre-provision “data” VPLS instances and related SAPs using the service ID specified in the command. If the <b>start-vlan-id</b> is not specified then the service-range values are used for vlan-ids. The data SAPs will be instantiated on all the ports used to specify SAP instances under the related control VPLS.</p> <p>Modifications of the service id and vlan ranges are allowed with the following restrictions.</p> <ul style="list-style-type: none"> <li>• service-range increase can be achieved in two ways: <ul style="list-style-type: none"> <li>– Allowed when vpls-group is in shutdown state</li> <li>– By creating a new vpls-group</li> </ul> </li> <li>• service-range decrease can be achieved in two ways: <ul style="list-style-type: none"> <li>– Allowed when vpls-group is in shutdown state; when <b>shutdown</b> command is executed the associated service instances are deleted.</li> <li>– Allowed when vpls-group is in no shutdown state and has completed successfully instantiating services.</li> <li>– In both cases, only the services that do not have user configured SAPs will be deleted. Otherwise the above commands are rejected. Existing declarations or registrations do not prevent service deletion.</li> </ul> </li> <li>• start-vlan-id change can be achieved in two ways: <ul style="list-style-type: none"> <li>– Allowed when vpls-group is in shutdown state</li> <li>– At the time of range decrease by increasing the start-vlan-id which can be done when vpls-group is in no shutdown state and has completed successfully instantiating services</li> </ul> </li> </ul> <p>The <b>no</b> form of this command removes the specified ranges and deletes the pre-provisioned VPLS instances and related SAPs. The command will fail if any of the VPLS instances in the affected ranges have a provisioned SAP.</p> |
| <b>Default</b>     | no service-range                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>startid-endid</i> — Specifies the range of service IDs</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>startvid</i> — Specifies the starting VLAN ID; it provides a way to set aside a service ID range that is not the same as the VLAN range and allows for multiple MVRP control-VPLSs to control same VLAN range on different ports.</p> <p><b>Values</b> 1 to 4094</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command configures the binding to a VPLS template to be used to instantiate pre-provisioned data VPLS using as input variables the service IDs generated by the vid-range command.</p> <p>The <b>no</b> form of this command removes the binding and deletes the related VPLS instances. The command will fail if any of the affected VPLS instances have either a provisioned SAP or an active MVRP declaration/registration or if the related vpls-group id is in no shutdown state. Any changes to the vpls-template-binding require the vpls-group to be in shutdown state.</p> |
| <b>Default</b>     | no vpls-template-binding                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>name/id</i> — Specifies the name or the ID of the VPLS template                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command specifies the range of VLAN IDs that are controlled by MVRP on the port associated with the parent SAP. When the command is present under a certain SAP, the MVRP will treat the associated virtual port as an end-station.</p> <p>MVRP endstation behavior means that configuration of a new data SAP with the outer tag in the configured endstation-vid-group will generate down that virtual port a MVRP declaration for the new [outer] VLAN attribute. Also registration received for the VLAN attribute in the range will be accepted but not propagated in the rest of MVRP context.</p> <p>VPLS-groups are not allowed under the associated Management VPLS (M-VPLS) when the endstation is configured under one SAP. VPLS-groups can be supported in the chassis using a different M-VPLS.</p> |

The **no** form of the command removes the specified group id.

|                   |                                                                                |
|-------------------|--------------------------------------------------------------------------------|
| <b>Default</b>    | no endstation-vid-group                                                        |
| <b>Parameters</b> | <i>id</i> — Specifies the range index                                          |
| <b>Values</b>     | 1 to 4094                                                                      |
|                   | <i>startvid-endvid</i> — Specifies the range of VLANs to be controlled by MVRP |
| <b>Values</b>     | 1 to 4094                                                                      |

## static-host

|                    |                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | This command configures a static host on this SAP.                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IPv4 unicast address<br><i>ieee-address</i> — Specify this optional parameter when defining a static host. Every static host definition must have at least one address defined, IP or MAC.<br><b>force</b> — Specifies the forced removal of the static host addresses.<br><b>create</b> — This keyword is mandatory while configuring a static host. |

## ancp-string

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp-string</b> <i>ancp-string</i><br><b>no ancp-string</b>               |
| <b>Context</b>     | config>service>vpls>sap>static-host                                          |
| <b>Description</b> | This command specifies the ANCP string associated to this SAP host.          |
| <b>Parameters</b>  | <i>ancp-string</i> — Specifies the ANCP string up to 63 characters in length |

## app-profile

|               |                                                                     |
|---------------|---------------------------------------------------------------------|
| <b>Syntax</b> | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b> |
|---------------|---------------------------------------------------------------------|

---

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>sap>static-host                                                            |
| <b>Description</b> | This command specifies an application profile name.                                            |
| <b>Parameters</b>  | <i>app-profile-name</i> — Specifies the application profile name up to 32 characters in length |

## inter-dest-id

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inter-dest-id</b> <i>intermediate-destination-id</i><br><b>no inter-dest-id</b>                    |
| <b>Context</b>     | config>service>vpls>sap>static-host                                                                   |
| <b>Description</b> | Specifies to which intermediate destination (for example a DSLAM) this host belongs.                  |
| <b>Parameters</b>  | <i>intermediate-destination-id</i> — Specifies the intermediate destination ID. 32 characters maximum |

## sla-profile

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sla-profile</b> <i>sla-profile-name</i><br><b>no sla-profile</b>                                                                                                                             |
| <b>Context</b>     | config>service>vpls>sap>static-host                                                                                                                                                             |
| <b>Description</b> | This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |
| <b>Parameters</b>  | <i>sla-profile-name</i> — Specifies the SLA profile name                                                                                                                                        |

## sub-profile

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sub-profile</b> <i>sub-profile-name</i><br><b>no sub-profile</b>                                          |
| <b>Context</b>     | config>service>vpls>sap>static-host                                                                          |
| <b>Description</b> | This command specifies an existing subscriber profile name to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-profile-name</i> — Specifies the sub-profile name                                                     |

## subscriber

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>subscriber</b> <i>sub-ident</i><br><b>no subscriber</b>                                                             |
| <b>Context</b>     | config>service>vpls>sap>static-host                                                                                    |
| <b>Description</b> | This command specifies an existing subscriber identification profile to be associated with the static subscriber host. |
| <b>Parameters</b>  | <i>sub-ident</i> — Specifies the subscriber identification                                                             |

## subscriber-sap-id

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Description</b> | This command enables triggering packet to initiate RADIUS authentication that provides a service context. The authentication, together with the service context for this request, creates a managed SAP. The VLAN is the same as the triggering packet. This SAP behaves as a regular SAP but the configuration is not user-editable and not maintained in the configuration file. The managed SAP remains active as long as the session is active.                                                                                                                                                                                                                                                                                     |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <b>dhcp</b> — Specifies whether the receipt of DHCP trigger packets on this VPLS SAP when the keyword <b>capture-sap</b> is specified in the <b>sap</b> command creation string, will result in a RADIUS authentication that will provide a service context and the creation of a SAP with a value of <b>managed</b><br><br><b>pppoe</b> — Specifies whether the receipt of PPPoE trigger packets on this VPLS SAP when the keyword <b>capture-sap</b> is specified in the <b>sap</b> command creation string, will result in a RADIUS authentication that will provide a service context and the creation of a SAP with a value of <b>managed</b><br><br><b>arp</b> — Indicates that ARP is the type of trigger packets for this entry |

**dhcp6** — Indicates that DHCP6 is the type of trigger packets for this entry

**ppp** — Indicates that PPP is the type of trigger packets for this entry

**data** — Indicates that subscriber data packets are the type of trigger packets for this entry

## vsd-domain

**Syntax** **vsd-domain** *name*  
**no vsd-domain**

**Context** config>service>vpls  
config>service>vprn

**Description** This command associates a previously configured vsd-domain to an existing VPRN or VPLS service. The vsd-domain is a tag used between the VSD and the 7750 SR, 7450 ESS, or 7950 XRS to correlate configuration parameters to a service.

**Parameters** *name* — Specifies the vsd-domain name.

## vxlan

**Syntax** **vxlan vni** *vni-id* [**create**] [**instance** *instance-id*]  
**no vxlan vni** *vni-id* [**instance** *instance-id*]

**Context** config>service>vpls

**Description** This command enables the use of vxlan in the VPLS service.

**Default** none

**Parameters** *vni-id* — Specifies the vxlan network identifier (VNI) configured in the VPLS service. All EVPN advertisements (mac routes and inclusive multicast routes) for this services will encode the configured VNI in the Ethernet Tag field of the NLRI.

**Values** 1 to 16777215

**create** — This keyword is mandatory when creating a vxlan instance

## assisted-replication

**Syntax** **assisted-replication** {**replicator** | **leaf**} [**replicator-activation-time** *seconds*]  
**no assisted-replication**

**Context** config>service>vpls>vxlan

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command enables the Assisted Replication (AR) function for VXLAN tunnels in the service. The execution of this command triggers the BGP EVPN to send an update containing the inclusive multicast route for the service and the AR type=AR Replicator (AR-R) or AR Leaf (AR-L).</p> <p>The Replicators switch the VXLAN traffic back to VXLAN destinations when the IP destination address matches their own AR-IP address. Leaf nodes select a Replicator node and send all the Broadcast or Multicast frames to it so that the Replicator can replicate the traffic on their behalf.</p> <p>Enabling or disabling the AR function, or changing the role between the replicator and leaf requires the BGP EVPN MPLS to be shutdown.</p> <p>If the <b>leaf</b> parameter is configured, the system creates a Broadcast or Multicast (BM) destination to the selected AR-R and Unknown Unicast (U) destinations to the rest of the VTEPs. If no replicator exists, the leaf creates BUM bindings to all the VTEPs.</p> <p>If the <b>replicator</b> parameter is configured, the system will create BUM destinations to the remote leafs, Regular Network Virtualization Edge routers (RNVE), and other AR-Rs. The system will perform assisted replication for traffic from known VTEPs only (that is, where the routes have been received and programmed toward a VTEP).</p> <p>The <b>no</b> version of this command removes the AR function from the service.</p> |
| <b>Default</b>     | no assisted-replication                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><b>replicator-activation-time</b> <i>seconds</i> — Optional parameter that can be added to the leaf parameter. It specifies the wait time before the leaf can begin sending traffic to a new replicator and is used to allow some time for the replicator to learn about the leaf.</p> <p><b>Values</b> 1 to 255</p> <p><b>Default</b> 0 seconds (indicates <b>no replicator-activation-time</b> and no delay in sending packets to the AR-R)</p> <p><b>replicator   leaf</b> — Selects the AR role of the router for the service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | This command enters the context to configure network ingress parameters for the VPLS VXLAN service. |

## qos

|                    |                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>qos</b> <i>network-policy-id</i> <b>fp-redirect-group</b> <i>queue-group-name</i> <b>instance</b> <i>instance-id</i><br><b>no qos</b>                                                                                       |
| <b>Context</b>     | config>service>vpls>vxlan>network>ingress                                                                                                                                                                                      |
| <b>Description</b> | This command is used to redirect traffic arriving on VXLAN tunnels in an EVPN VXLAN service as a single entity (per forwarding class) to policers in an ingress forwarding plane queue group for the purpose of rate-limiting. |

For the policer to be used, the following must be true:

- The configured queue group template name must be applied to the forwarding plane on which the ingress traffic arrives using the instance id specified.
- The policer referenced in the FC-to-policer mappings in the ingress context of a network QoS policy must be present in the specified queue group template.

The command will fail if the queue group template name does not exist or if the policer specified in the network QoS policy does not exist in the queue group template. If the queue group template name with the specified instance is not applied to the forwarding plane on which the VXLAN traffic arrives, then this traffic will use the ingress network queues related to the network interface; however, the ingress classification is still based on the applied network QoS policy.

The unicast traffic can be redirected to a policer under the forwarding class **fp-redirect-group** command in the ingress section of a network QoS policy. Similarly, broadcast, unknown and multicast traffic can be redirected to a **broadcast-policer**, **unknown-policer** or **mcast-policer**, respectively, also under the forwarding class **fp-redirect-group** command in the ingress section of a network QoS policy.

Ingress classification is based on the configuration of the ingress section of the specified network QoS policy, noting that the dot1p and DSCP classification is based on the outer Ethernet header and IP header, and the use of **ler-use-dscp**, **ip-criteria** and **ipv6-criteria** statements are ignored.

When this command is applied, it overrides the QoS applied to the related network interfaces for traffic arriving on VXLAN tunnels in that service but does not affect traffic received on a spoke-SDP in the same service.

The **no** version of this command removes the redirection of VXLAN tunnel traffic from the queue group policers.

| <b>Description</b> | <p>This command configures the number of missing hello PDUs from a neighbor SPB declares the adjacency down. This command is valid only for interfaces on control B-VPLS.</p> <p>The no form of the command reverts to the default value.</p> |
| <b>Default</b>     | hello-multiplier 3                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>multiplier</i> — Specifies the multiplier for the hello interval expressed as a decimal integer<br><b>Values</b> 2 to 100                                                                                                                  |

## metric

|                |                                                                    |
|----------------|--------------------------------------------------------------------|
| <b>Syntax</b>  | <b>metric</b> <i>ipv4-metric</i><br><b>no metric</b>               |
| <b>Context</b> | config>service>vpls>spb>level<br>config>service>vpls>sap>spb>level |

config>service>vpls>spoke-sdp>spb>level

**Description** This command configures the IS-IS interface metric for IPv4 unicast.

**Parameters** *ipv4-metric* — Specifies the IS-IS interface metric for IPv4 unicast

**Values** 1 to 16777215

### 3.7.2.3 General Switch Management Protocol Commands

#### gsmp

**Syntax** **gsmp**

**Context** config>service>vpls

**Description** This command enters the context to configure General Switch Management Protocol (GSMP) connections maintained in this service.

**Default** not enabled

#### group

**Syntax** [**no**] **group** *name*

**Context** config>service>vpls>gsmp

**Description** This command specifies a GSMP name. A GSMP group name is unique only within the scope of the service in which it is defined.

#### ancp

**Syntax** **ancp**

**Context** config>service>vpls>gsmp>group

**Description** This command configures Access Node Control Protocol (ANCP) parameters for this GSMP group.

#### dynamic-topology-discover

**Syntax** [**no**] **dynamic-topology-discover**

**Context** config>service>vpls>gsmp>group>ancp

---

**Description** This command enables the ANCP dynamic topology discovery capability.  
The **no** form of this command disables the feature.

## oam

**Syntax** **[no] oam**

**Context** config>service>vpls>gsmp>group>ancp

**Description** This command specifies whether or not the GSMP ANCP OAM capability should be negotiated at startup of the GSMP connection.  
The **no** form of this command disables the feature.

## hold-multiplier

**Syntax** **hold-multiplier** *multiplier*  
**no hold-multiplier**

**Context** config>service>vpls>gsmp>group

**Description** This command configures the hold-multiplier for the GSMP connections in this group.

**Parameters** *multiplier* — Specifies the GSMP hold multiplier value  
**Values** 1 to 100

## keepalive

**Syntax** **keepalive** *seconds*  
**no keepalive**

**Context** config>service>vpls>gsmp>group

**Description** This command configures keepalive values for the GSMP connections in this group.

**Parameters** *seconds* — Specifies the GSMP keepalive timer value in seconds  
**Values** 1 to 25

## neighbor

**Syntax** **neighbor** *ip-address* [create]  
**no neighbor** *ip-address*

---

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>gsmp>group                                         |
| <b>Description</b> | This command configures a GSMP ANCP neighbor.                          |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address of the GSMP ANCP neighbor |

## local-address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>gsmp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the source ip-address used in the connection toward the neighbor. The local address is optional. If specified the node will accept connections only for that address in the service running ANCP. The address may be created after the reference but connections will not be accepted until it is created. If the local address is not used, the system accepts connections on any interface within the routing context. |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the source IP address to be used in the connection toward the neighbor                                                                                                                                                                                                                                                                                                                                             |

## priority-marking

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] idle-filter</b>                                                                                              |
| <b>Context</b>     | config>service>vpls>gsmp                                                                                             |
| <b>Description</b> | This command when applied will filter out new subscriber's ANCP messages from subscriber with "DSL-line-state" IDLE. |
| <b>Default</b>     | no idle-filter                                                                                                       |

## persistency-database

|                    |                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] persistency-database</b>                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vpls>gsmp                                                                                                                                                                                            |
| <b>Description</b> | This command enables the system to store DSL line information in memory. If the GSMP connection terminates, the DSL line information will remain in memory and accessible for Radius authentication and accounting. |
| <b>Default</b>     | no persistency-database                                                                                                                                                                                             |

### 3.7.2.3.1 VPLS DHCP Commands

## dhcp

|                    |                                                                                          |
|--------------------|------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                                              |
| <b>Context</b>     | config>service>vpls>sap<br>config>service>vpls>spoke-sdp<br>config>service>vpls>mesh-sdp |
| <b>Description</b> | This command enters the context to configure DHCP parameters.                            |

## lease-populate

|                |                                                                           |
|----------------|---------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>lease-populate</b> <i>[nmb-of-entries]</i><br><b>no lease-populate</b> |
| <b>Context</b> | config>service>vpls>sap>dhcp                                              |

**Description** This command enables and disables dynamic host lease state management for VPLS SAPs. For VPLS, DHCP snooping must be explicitly enabled (using the **snoop** command) at all points where DHCP messages requiring snooping enter the VPLS instance (both from the DHCP server and from the subscribers). Lease state information is extracted from snooped DHCP ACK messages to populate lease state table entries for the SAP.

The optional number-of-entries parameter is used to define the number of lease state table entries allowed for this SAP or IP interface. If number-of-entries is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCP ACK messages are discarded.

The retained lease state information representing dynamic hosts may be used to:

- populate a SAP based anti-spoof filter table to provide dynamic anti-spoof filtering. If the system is unable to populate the dynamic host information in the anti-spoof filter table on the SAP, the DHCP ACK message must be discarded without adding a new lease state entry or updating an existing lease state entry.
- generate dynamic ARP replies if **arp-reply-agent** is enabled.

**Default** no lease-populate

**Parameters** *nbr-of-entries* — Specifies the number of DHCP leases allowed

**Values** 1 to 8000

## option

**Syntax** [no] option

**Context** config>service>vpls>sap>dhcp  
config>service>vpls>sap>dhcp6

**Description** This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options.

The **no** form of this command returns the system to the default.

**Default** no option

## action

**Syntax** action [*dhcp-action*]  
no action

**Context** config>service>vpls>sap>dhcp>option

**Description** This command configures the Relay Agent Information Option (Option 82) processing.

The **no** form of this command returns the system to the default value.

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | The default is to keep the existing information intact.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b> | <p><i>dhcp-action</i> — Specifies the DHCP option action</p> <p><b>replace</b> — In the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (toward the user) the Option 82 field is stripped (in accordance with RFC 3046).</p> <p><b>drop</b> — The DHCP packet is dropped if an Option 82 field is present, and a counter is incremented</p> <p><b>keep</b> — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on toward the client.</p> <p>The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.</p> <p>If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.</p> |

## circuit-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>circuit-id [ascii-tuple   vlan-ascii-tuple]</b><br><b>circuit-id hex [0x0..0xFFFFFFFF...(64 hex nibbles)]</b><br><b>no circuit-id</b>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>sap>dhcp>option                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>When enabled, the router sends an ASCII-encoded tuple in the <b>circuit-id</b> sub-option of the DHCP packet. This ASCII-tuple consists of the access-node-identifier, service-id, and SAP-ID, separated by " ". If no keyword is configured, then the circuit-id sub-option will not be part of the information option (Option 82).</p> <p>When the command is configured without any parameters, it equals to <b>circuit-id ascii-tuple</b>.</p> <p>If disabled, the <b>circuit-id</b> sub-option of the DHCP packet will be left empty.</p>                       |
| <b>Default</b>     | no circuit-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>ascii-tuple</b> — Specifies that the ASCII-encoded concatenated tuple consisting of the access-node-identifier, service-id, and interface-name is used</p> <p><b>hex</b> — Specifies the circuit-id hex string</p> <p><b>vlan-ascii-tuple</b> — Specifies that the format will include VLAN ID and dot1p bits as well as what is included in ascii-tuple already. The format is supported on dot1q and qinq encapsulated ports only. Therefore, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p> |

## remote-id

| <b>Description</b> | <p>This command defines the length of lease time that will be provided to DHCP clients. By default, the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server.</p> <p>The <b>no</b> form of this command disables the use of the lease-time command. The local proxy server will use the lease time offered by either a RADIUS or DHCP server.</p> |
| <b>Default</b>     | 7 days 0 hours 0 seconds                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>days</i> — Specifies the number of days that the specified IP address is valid</p> <p><b>Values</b> 0 to 3650</p> <p><i>hours</i> — Specifies the number of hours that the specified IP address is valid</p> <p><b>Values</b> 0 to 23</p> <p><i>minutes</i> — Specifies the number of minutes that the specified IP address is valid</p> <p><b>Values</b> 0 to 59</p>                                  |

---

*seconds* — Specifies the number of seconds that the specified IP address is valid.

**Values** 0 to 59

## snoop

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vpls>sap>dhcp6<br>config>service>vpls>sap>dhcp<br>config>service>vpls>spoke-sdp>dhcp<br>config>service>vpls>mesh-sdp>dhcp                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables DHCP snooping of DHCP messages on the SAP or SDP. Enabling DHCP snooping on VPLS interfaces (SAPs and SDP bindings) is required where DHCP messages important to lease state table population are received, or where Option 82 information is to be inserted. This includes interfaces that are in the path to receive messages from either DHCP servers or from subscribers.</p> <p>Use the <b>no</b> form of the command to disable DHCP snooping on the specified VPLS SAP or SDP binding.</p> |
| <b>Default</b>     | no snoop                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 3.7.2.3.2 VPLS STP Commands

## stp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command enters the context to configure the Spanning Tree Protocol (STP) parameters. Nokia's STP is simply the Spanning Tree Protocol (STP) with a few modifications to better suit the operational characteristics of VPLS services. The most evident change is to the root bridge election. Since the core network operating between Nokia's service routers should not be blocked, the root path is calculated from the core perspective.</p> |

## auto-edge

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command configures automatic detection of the edge port characteristics of the SAP or spoke-SDP.</p> <p>If auto-edge is enabled, and STP concludes there is no bridge behind the spoke-SDP, the OPER_EDGE variable will dynamically be set to true. If auto-edge is enabled, and a BPDU is received, the OPER_EDGE variable will dynamically be set to true (see <a href="#">edge-port</a>).</p> <p>The <b>no</b> form of this command returns the auto-detection setting to the default value.</p> |
| <b>Default</b>     | auto-edge                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## edge-port

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] edge-port</b>                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap>stp<br>config>service>template>vpls-sap-template>stp<br>config>service>vpls>spoke-sdp>stp                                                  |
| <b>Description</b> | This command configures the SAP or SDP as an edge or non-edge port. If <b>auto-edge</b> is enabled for the SAP, this value will be used only as the initial value. |

**Note:** The function of the **edge-port** command is similar to the **rapid-start** command. It tells RSTP that it is on the edge of the network (for example, there are no other bridges connected to that port) and, as a consequence, it can immediately transition to a forwarding state if the port becomes available.

RSTP, however, can detect that the actual situation is different from what **edge-port** may indicate.

Initially, the value of the SAP or spoke-SDP parameter is set to edge-port. This value will change if:

- A BPDU is received on that port. This means that after all there is another bridge connected to this port. Then the edge-port becomes disabled.
- If auto-edge is configured and no BPDU is received within a certain period of time, RSTP concludes that it is on an edge and enables the edge-port.

The **no** form of this command returns the edge port setting to the default value.

---

**Default**    no edge-port

## forward-delay

**Syntax**    **forward-delay** *seconds*  
**no forward-delay**

**Context**    config>service>vpls>stp  
 config>service>template>vpls-template>stp

**Description**    RSTP, as defined in the IEEE 802.1D-2004 standards, will normally transition to the forwarding state via a handshaking mechanism (rapid transition), without any waiting times. If handshaking fails (e.g. on shared links, see below), the system falls back to the timer-based mechanism defined in the original STP (802.1D-1998) standard.

A shared link is a link with more than two nodes (for example, a shared 10/100BaseT segment). The port-type command is used to configure a link as point-to-point or shared.

For timer-based transitions, the 802.1D-2004 standard defines an internal variable forward-delay, which is used in calculating the default number of seconds that a SAP or spoke-SDP spends in the discarding and learning states when transitioning to the forwarding state.

The value of the forward-delay variable depends on the STP operating mode of the VPLS instance:

- in rstp or mstp mode, but only when the SAP or spoke-SDP has not fallen back to legacy STP operation, the value configured by the hello-time command is used;
- in all other situations, the value configured by the forward-delay command is used.

**Default**    forward-delay 15

**Parameters**    *seconds* — The forward delay timer for the STP instance in seconds

**Values**    4 to 30

## hello-time

**Syntax**    **hello-time** *hello-time*  
**no hello-time** [*hello-time*]

**Context**    config>service>vpls>stp  
 config>service>template>vpls-template>stp

**Description**    This command configures the Spanning Tree Protocol (STP) hello time for the Virtual Private LAN Service (VPLS) STP instance.

The hello time parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

The active hello time for the spanning tree is determined by the root bridge (except when the STP is running in RSTP mode, then the hello time is always taken from the locally configured parameter).

The configured hello-time can also be used to calculate the forward delay. See [auto-edge](#).

The **no** form of this command returns the hello time to the default value.

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <b>Default</b>    | hello-time 2                                                       |
| <b>Parameters</b> | <i>hello-time</i> — The hello time for the STP instance in seconds |
| <b>Values</b>     | 1 to 10                                                            |

## hold-count

|                    |                                                                                                                                                                                           |

| <b>Description</b> | This command configures the peak number of BPDUs that can be transmitted in a period of one second.<br><br>The <b>no</b> form of this command returns the hold count to the default value |
| <b>Default</b>     | hold-count 6                                                                                                                                                                              |
| <b>Parameters</b>  | <i>BDPU tx hold count</i> — The hold count for the STP instance in seconds                                                                                                                |
| <b>Values</b>      | 1 to 10                                                                                                                                                                                   |

## link-type

|                |                                                                                                                   |
|----------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>link-type</b> {pt-pt   shared}<br><b>no link-type</b> [pt-pt   shared]                                         |
| <b>Context</b> | config>service>vpls>sap>stp<br>config>service>template>vpls-sap-template>stp<br>config>service>vpls>spoke-sdp>stp |

**Description** This command instructs STP on the maximum number of bridges behind this SAP or spoke-SDP. If there is only a single bridge, transitioning to forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected via a shared media, their SAP or spoke-SDPs should all be configured as shared, and timer-based transitions are used.

The **no** form of this command returns the link type to the default value.

**Default** link-type pt-pt

## mst-instance

**Syntax** **mst-instance** *mst-inst-number*

**Context** config>service>vpls>sap>stp

**Description** This command enters the context to configure MSTI related parameters at SAP level. This context can be open only for existing mst-instances defined at the service level (see [mst-instance](#)).

**Default** none

**Parameters** *mst-inst-number* — Specifies an existing Multiple Spanning Tree Instance number

**Values** 1 to 4094

## mst-path-cost

**Syntax** **mst-path-cost** *inst-path-cost*  
**no mst-path-cost**

**Context** config>service>vpls>sap>stp>mst-instance

**Description** This commands specifies path-cost within a specified instance, expressing probability that a specified port will be put into the forwarding state in case a loop occurs (the highest value expresses lowest priority).

The **no** form of this command sets port-priority to its default value.

**Default** The path-cost is proportional to link speed.

**Parameters** *inst-path-cost* — Specifies the contribution of this port to the MSTI path cost of paths toward the spanning tree regional root which include this port

**Values** 1 to 200000000

## mst-port-priority

|                    |                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>vpls>stp<br>config>service>template>vpls-template>stp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command indicates how many hops a BPDU can traverse the network starting from the root bridge. The message age field in a BPDU transmitted by the root bridge is initialized to 0. Each other bridge will take the message_age value from BPDUs received on their root port and increment this value by 1. The message_age therefore reflects the distance from the root bridge. BPDUs with a message age exceeding max-age are ignored.<br><br>STP uses the max-age value configured in the root bridge. This value is propagated to the other bridges via the BPDUs.<br><br>The <b>no</b> form of this command returns the max age to the default value. |
| <b>Default</b>     | max-age 20                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>max-age</i> — The max info age for the STP instance in seconds. Allowed values are integers in the range 6 to 40.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command creates the context to configure MST instance (MSTI) related parameters. Up to 16 instances will be supported by MSTP. The instance 0 is mandatory by protocol and therefore, it cannot be created by the CLI. The software will maintain this instance automatically.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>mst-inst-number</i> — Specifies the Multiple Spanning Tree instance</p> <p><b>Values</b>      1 to 4094</p>                                                                                                                                                                          |

## mst-priority

|                |                                                                      |
|----------------|----------------------------------------------------------------------|
| <b>Syntax</b>  | <b>mst-priority</b> <i>bridge-priority</i><br><b>no mst-priority</b> |
| <b>Context</b> | config>service>vpls>stp>mst-instance                                 |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command specifies the bridge priority for this specific Multiple Spanning Tree Instance for this service. The <i>bridge-priority</i> value reflects likelihood that the switch will be chosen as the regional root switch (65535 represents the least likely). It is used as the highest 4 bits of the Bridge ID included in the MSTP BPDUs generated by this bridge.</p> <p>The priority can only take on values that are multiples of 4096 (4k). If a value is specified that is not a multiple of 4K, then the value will be replaced by the closest multiple of 4K, which is lower than the value entered.</p> <p>The <b>no</b> form of this command sets the bridge-priority to its default value.</p> |
| <b>Default</b>     | mst-priority 32768 — All instances created by <a href="#">vlan-range</a> command and not having explicit definition of bridge-priority will inherit default value                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>bridge-priority</i> — Specifies the priority of this specific Multiple Spanning Tree Instance for this service</p> <p><b>Values</b>      0 to 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## vlan-range

|----------------|-----------------------------------------------------------------|
| <b>Syntax</b>  | <b>mst-max-hops</b> <i>hops-count</i><br><b>no mst-max-hops</b> |
| <b>Context</b> | config>service>vpls>stp                                         |

---

**Description** This command specifies the number of hops in the region before BPDU is discarded and the information held for the port is aged out. The root bridge of the instance sends a BPDU (or M-record) with remaining-hop-count set to configured *<max-hops>*. When a bridge receives the BPDU (or M-record), it decrements the received remaining-hop-count by 1 and propagates it in BPDU (or M-record) it generates.

The **no** form of this command sets the *hops-count* to its default value.

**Default** mst-max-hops 20

**Parameters** *hops-count* — Specifies the maximum number of hops

**Values** 1 to 40

## mst-name

**Syntax** **mst-name** *region-name*  
**no mst-name**

**Context** config>service>vpls>stp

**Description** This command defines an MST region name. Two bridges are considered as a part of the same MST region as soon as their configuration of the MST region name, the MST-revision and VLAN-to-instance assignment is identical.

The **no** form of this command removes *region-name* from the configuration.

**Default** no mst-name

**Parameters** *region-name* — Specifies an MST-region name up to 32 characters in length

## mst-revision

**Syntax** **mst-revision** *revision-number*  
**no mst-revision**

**Context** config>service>vpls>stp

**Description** This command defines the MST configuration revision number. Two bridges are considered as a part of the same MST region as soon as their configuration of MST-region name, MST-revision and VLAN-to-instance assignment is identical.

The **no** form of this command returns MST configuration revision to its default value.

**Default** mst-revision 0

---

| <b>Description</b> | <p>This command configures the Spanning Tree Protocol (STP) path cost for the SAP or spoke-SDP.</p> <p>The path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that SAP or spoke-SDP. When BPDUs are sent out of other egress SAPs or spoke-SDPs, the newly calculated root path cost is used. These are the values used for CIST when running MSTP.</p> <p>STP suggests that the path cost is defined as a function of the link bandwidth. Since SAPs and spoke-SDPs are controlled by complex queuing dynamics, in the 7450 ESS, 7750 SR, and 7950 XRS the STP path cost is a purely static configuration.</p> <p>The <b>no</b> form of this command returns the path cost to the default value.</p> |
| <b>Parameters</b>  | <i>path-cost</i> — The path cost for the SAP or spoke-SDP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Values</b>      | 1 to 200000000 (1 is the lowest cost)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default</b>     | 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## port-num

|                |                                                                                                 |
|----------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>port-num</b> <i>virtual-port-number</i><br><b>no port-num</b> [ <i>virtual-port-number</i> ] |
| <b>Context</b> | config>service>vpls>sap>stp<br>config>service>vpls>spoke-sdp>stp                                |

**Description** This command configures the virtual port number which uniquely identifies a SAP within configuration bridge protocol data units (BPDUs). The internal representation of a SAP is unique to a system and has a reference space much bigger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a SAP and identifies it with it's own virtual port number that is unique to every other SAP defined on the TLS. The virtual port number is assigned at the time that the SAP is added to the TLS. Since the order that the SAP was added to the TLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance.

The virtual port number cannot be administratively modified.

## priority

**Syntax** **priority** *bridge-priority*  
**no priority** [*bridge-priority*]

**Context** config>service>vpls>stp  
config>service>template>vpls-sap-template>stp  
config>service>template>vpls-template>stp

**Description** The bridge-priority command is used to populate the priority portion of the bridge ID field within outbound BPDUs (the most significant 4 bits of the bridge ID). It is also used as part of the decision process when determining the best BPDU between messages received and sent. All values will be truncated to multiples of 4096, conforming with IEEE 802.1t and 802.1D-2004.

The **no** form of this command returns the bridge priority to the default value.

**Default** By default, the bridge priority is configured to 4096 which is the highest priority.

**Parameters** *bridge-priority* — The bridge priority for the STP instance

**Values** Allowed values are integers in the range of 4096 to 65535 with 4096 being the highest priority. The actual bridge priority value stored/used is the number entered with the lowest 12 bits masked off which means the actual range of values is 4096 to 61440 in increments of 4096.

## priority

**Syntax** **priority** *stp-priority*  
**no priority**

**Context** config>service>vpls>sap>stp  
config>service>vpls>spoke-sdp

**Description** This command configures the Nokia Spanning Tree Protocol (STP) priority for the SAP or spoke-SDP.

STP priority is a configurable parameter associated with a SAP or spoke-SDP. When configuration BPDUs are received, the priority is used in some circumstances as a tie breaking mechanism to determine whether the SAP or spoke-SDP will be designated or blocked.

In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (0 to 255 also) to create a 16 bit value. In the latest STP standard (802.1D-2004) only the upper 4 bits of the port priority field are used to encode the SAP or spoke-SDP priority. The remaining 4 bits are used to extend the port ID field into a 12 bit virtual port number field. The virtual port number uniquely references a SAP or spoke-SDP within the STP instance.

STP computes the actual priority by taking the input value and masking out the lower four bits. The result is the value that is stored in the SDP priority parameter. For instance, if a value of 0 is entered, masking out the lower 4 bits results in a parameter value of 0. If a value of 255 is entered, the result is 240.

The **no** form of this command returns the STP priority to the default value.

|                   |                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | priority128                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b> | <i>stp-priority</i> — The STP priority value for the SAP or spoke-SDP. Allowed values are integer in the range of 0 to 255, 0 being the highest priority. The actual value used for STP priority (and stored in the configuration) will be the result of masking out the lower 4 bits, therefore the actual value range is 0 to 240 in increments of 16. |

## root-guard

|                    |                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] root-guard</b>                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>sap>stp<br>config>service>template>vpls-sap-template>stp<br>config>service>vpls>spoke-sdp>stp                                                                                  |
| <b>Description</b> | This command specifies whether this port is allowed to become an STP root port. It corresponds to the restrictedRole parameter in 802.1Q. If set, it can cause lack of spanning tree connectivity. |
| <b>Default</b>     | no root-guard                                                                                                                                                                                      |

### 3.7.2.3.3 VPLS SAP Commands

## sap

|               |                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b> | <b>sap sap-id [split-horizon-group group-name] [capture-sap] [create] [eth-ring ring-index] [root-leaf-tag   leaf-ac]</b> |
|---------------|---------------------------------------------------------------------------------------------------------------------------|

| <b>Context</b>       | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b>   | <p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the 7450 ESS, 7750 SR, and 7950 XRS. Each SAP must be unique.</p> <p>All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the <b>config interface port-type port-id mode access</b> command.</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The <b>no</b> form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Enhanced Service (IES), the IP interface must be shutdown before the SAP on that interface may be removed.</p> |
| <b>Default</b>       | No SAPs are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Special Cases</b> | <p><b>VPLS service SAP limits</b> — A VPLS SAP can be defined with Ethernet ports, SONET/SDH or TDM channels. The limits of the number of SAPs and SDPs supported in a VPLS service depends on the hardware used. Each SDP must have a unique destination or an error will be generated. Split horizon groups can only be created in the scope of a VPLS service.</p> <p>A default SAP has the following format: port-id:*. This type of SAP is supported only on Ethernet MDAs and its creation is allowed only in the scope of Layer 2 services (Epipe and VPLS). This type of SAP is mutually exclusive with a SAP defined by explicit null encapsulation (for example, 1/1/1:0).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | <p><b>sap-id</b> — Specifies the physical port identifier portion of the SAP definition</p> <p><b>create</b> — Keyword used to create a SAP instance. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> <p><b>eth-ring</b> — When used with Ethernet Rings control the split horizon group accepts the major ring instance "value". This parameter applies to the 7450 ESS or 7750 SR only. The split horizon group prevents loops in the cases where a Ethernet Virtual Ring is miss configured on the main ring. Each path a and path b major ring are configured in the group and associated with the sub-ring control instance in the VPLS service.</p> <p><b>ring-index</b> — Specifies the ring index of the Ethernet ring</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**root-leaf-tag** — Specifies a SAP as a root leaf tag SAP. Only SAPs of the form dot1q (for example, 1/1/1:X) or qinq (for example, 1/1/1:X.Y, 1/1/1:X.\*) are supported. The default E-Tree SAP type is a root-ac, if *root-leaf-tag* (or *leaf-ac*) is not specified at SAP creation. This option is only available when the VPLS is designated as an E-Tree VPLS; it is not available on BGP EVPN-enabled E-Tree VPLS services.

**leaf-tag-vid** — Specified after *root-leaf-tag* to replace the outer SAP-ID for leaf traffic. The leaf tag VID is only significant between peering VPLS but the values must be consistent on each end. This option is not available on BGP EVPN-enabled E-Tree VPLS services.

**leaf-ac** — Specifies a SAP as a leaf access (AC) SAP. The default E-Tree SAP type is root-ac if *leaf-ac* (or *root-leaf-tag*) is not specified at SAP creation. This option is available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services also support the leaf-ac option.

**split-horizon-group** *group-name* — Specifies the name of the split horizon group to which the SAP belongs. This parameter applies to the 7450 ESS or 7750 SR only.

**capture-sap** — Specifies a capturing SAP in which triggering packets will be sent to the CPM. Non-triggering packets captured by the capture SAP will be dropped. This parameter applies to the 7450 ESS or 7750 SR only.

## cflowd

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables cflowd to collect traffic flow samples through a service interface (SAP) for analysis. When cflowd is enabled on an Ethernet service SAP, the Ethernet traffic can be sampled and processed by the system's cflowd engine and exported to IPFIX collectors with the l2-ip template enabled.</p> <p>cflowd is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement. When cflowd is enabled at the SAP level, all packets forwarded by the interface are subjected to analysis according to the cflowd configuration.</p> <p>For Layer 2 services, only ingress sampling is supported.</p> |
| <b>Default</b>     | no cflowd                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## discard-unknown-source

|                |                                                          |
|----------------|----------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] discard-unknown-source</b>                       |
| <b>Context</b> | config>service>vpls>sap<br>config>service>vpls>spoke-sdp |

---

```
config>service>template>vpls-sap-template
```

**Description** When this command is enabled, packets received on a SAP or a spoke-SDP with an unknown source MAC address will be dropped only if the maximum number of MAC addresses for that SAP or spoke-SDP (see [max-nbr-mac-addr](#)) has been reached. If **max-nbr-mac-addr** has not been set for the SAP or spoke-SDP, enabling **discard-unknown-source** has no effect.

When disabled, the packets are forwarded based on the destination MAC addresses.

The **no** form of this command causes packets with an unknown source MAC addresses to be forwarded by destination MAC addresses in VPLS.

**Default** no discard-unknown-source

### 3.7.2.3.4 VPLS SAP ATM Commands

#### atm

**Syntax** atm

**Context** config>service>vpls>sap

**Description** This command enables access to the context to configure ATM-related attributes. This command can only be used when a specified context (for example, a channel or SAP) supports ATM functionality such as:

- Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality
- Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality.

If ATM functionality is not supported for a specified context, the command returns an error.

#### egress

**Syntax** egress

**Context** config>service>vpls>sap>atm

**Description** This command enters the context to configure egress ATM attributes for the SAP.

## encapsulation

|                    |                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vpls>sap>atm                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies the data encapsulation for an ATM PVCC delimited SAP. The definition references RFC 2684, <i>Multiprotocol Encapsulation over ATM AAL5</i>, and to the ATM Forum LAN Emulation specification.</p> <p>Ingress traffic that does not match the configured encapsulation will be dropped.</p>                                         |
| <b>Default</b>     | encapsulation aal5snap-bridged                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>atm-encap-type</i> — Specifies the encapsulation type</p> <p><b>Values</b></p> <p><b>aal5snap-bridged</b> — Bridged encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.</p> <p><b>aal5mux-bridged-eth-nofcs</b> — Bridged IP encapsulation for VC multiplexed circuit as defined in RFC 2684.</p> |

## ingress

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                   |
| <b>Context</b>     | config>service>vpls>sap>atm                                                      |
| <b>Description</b> | This command enters the context to configure ingress ATM attributes for the SAP. |

## traffic-desc

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>traffic-desc</b> <i>traffic-desc-profile-id</i><br><b>no traffic-desc</b>                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vpls>sap>atm>ingress<br>config>service>vpls>sap>atm>egress                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command assigns an ATM traffic descriptor profile to a specified context (for example, a SAP).</p> <p>When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction.</p> <p>When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.</p> |

The **no** form of the command reverts the traffic descriptor to the default traffic descriptor profile.

**Default** The default traffic descriptor (trafficDescProfileId.=1) is associated with newly created PVCC-delimited SAPs.

**Parameters** *traffic-desc-profile-id* — Specifies a defined traffic descriptor profile (see the QoS atm-td-profile command)

## oam

**Syntax** **oam**

**Context** config>service>vpls>sap>atm

**Description** This command enters the context to configure OAM functionality for a PVCC delimiting a SAP.

The ATM-capable MDAs support F5 end-to-end OAM functionality (AIS, RDI, Loopback):

- ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance Principles and Functions version 11/95
- GR-1248-CORE - Generic Requirements for Operations of ATM Network Elements (NEs). Issue 3 June 1996
- GR-1113-CORE - Bellcore, Asynchronous Transfer Mode (ATM) and ATM Adaptation Layer (AAL) Protocols Generic Requirements, Issue 1, July 1994

## alarm-cells

**Syntax** [**no**] **alarm-cells**

**Context** config>service>vpls>sap>atm

**Description** This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.

When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes operationally down, or enters a fault state and becomes operationally up, or exits that fault state). RDI cells are generated when PVCC is operationally down. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).

The **no** command disables **alarm-cells** functionality for a PVCC. When **alarm-cells** functionality is disabled, the PVCC's operational status is no longer affected by the PVCC's OAM state changes due to AIS/RDI processing. When **alarm-cells** is disabled, a PVCC will change operational status to operationally up from operationally down due to alarm-cell processing). RDI cells are not generated as result of PVCC going into an AIS or RDI state, however, the PVCC's OAM status will record OAM faults as described above.

**Default** Enabled for PVCCs delimiting VPLS SAPs

### 3.7.2.4 ETH-CFM Service Commands

#### eth-cfm

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-cfm</b>                                                                                                  |
| <b>Context</b>     | config>service>vpls<br>config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp<br>config>service>vpls>sap |
| <b>Description</b> | This command enters the context to configure ETH-CFM parameters.                                                |

#### eth-tunnel

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-tunnel</b>                                                            |
| <b>Context</b>     | config>service>vpls>sap                                                      |
| <b>Description</b> | The command enables the context to configure Ethernet tunnel SAP parameters. |

#### eth-ring

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-ring</b> <i>ring-id</i><br><b>no eth-ring</b>                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures a VPLS SAP to be associated with an Ethernet ring. The SAP port ID is associated with the corresponding Ethernet ring path configured on the same port ID. The encapsulation type must be compatible with the Ethernet ring path encapsulation.<br><br>The <b>no</b> form of this command removes the Ethernet ring association from this SAP. |
| <b>Default</b>     | no eth-ring                                                                                                                                                                                                                                                                                                                                                            |

---

**Parameters**    *ring-id* — Specifies the ring ID.  
**Values**        1 to 128

## path

**Syntax**        **path** *path-index* **tag** *qtag* [*qtag*]  
                 **no path** *path-index*

**Context**        config>service>vpls>sap>eth-tunnel

**Description**    This command configures Ethernet tunnel SAP path parameters.  
  
                 The **no** form of the command removes the values from the configuration.

**Default**        none

**Parameters**    *path-index* — Specifies the path index value.  
**Values**        1 to 16  
  
                 **tag** *qtag* [*qtag*] — Specifies the qtag value.  
**Values**        0 to 4094, \* (wildcard)

## collect-lmm-fc-stats

**Syntax**        **collect-lmm-fc-stats**

**Context**        config>service>vpls>mesh-sdp>eth-cfm  
                 config>service>vpls>sap>eth-cfm  
                 config>service>vpls>spoke-sdp>eth-cfm

**Description**    This command enters the context to configure per-forwarding class (FC) LMM information collection.  
  
                 This command is mutually exclusive with the **collect-lmm-stats** command when there is entity resource contention.

## fc

**Syntax**        **fc** *fc-name* [*fc-name*]  
                 **no fc**

**Context**        config>service>vpls>mesh-sdp>eth-cfm>collect-lmm-fc-stats  
                 config>service>vpls>sap>eth-cfm>collect-lmm-fc-stats  
                 config>service>vpls>spoke-sdp>eth-cfm>collect-lmm-fc-stats

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command creates individual counters for the specified FCs without regard for profile. All countable packets that match a configured FC, regardless of profile, will be included in this counter.</p> <p>A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.</p> <p>Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-aware FC using the <b>fc-in-profile</b> command under the same context.</p> <p>The <b>no</b> form of the command removes all previously defined FCs and stops counting for those FCs.</p> |
| <b>Default</b>     | no fc                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>fc-name</i> — Specifies up to eight names of the FC for which to create an individual profile-unaware counter. In order for the counter to be used, the <b>config&gt;oam-pm&gt;session&gt;ethernet&gt;priority</b> command must be configured with a numerical value representing the FC name (7 = NC, 6 = H1, 5 = EF, 4 = H2, 3 = L1, 2 = AF, 1 = L2, 0 = BE), and the <b>config&gt;oam-pm&gt;session&gt;ethernet&gt;lmm&gt;enable-fc-collection</b> command must be enabled.</p> <p><b>Values</b>      nc, h1, ef, h2, l1, af, l2, be</p>                                                                                                                                                                                         |

## fc-in-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <p><b>fc-in-profile</b> <i>fc-name</i> [<i>fc-name</i>]</p> <p><b>no fc-in-profile</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | <p>config&gt;service&gt;vpls&gt;mesh-sdp&gt;eth-cfm&gt;collect-lmm-fc-stats</p> <p>config&gt;service&gt;vpls&gt;sap&gt;eth-cfm&gt;collect-lmm-fc-stats</p> <p>config&gt;service&gt;vpls&gt;spoke-sdp&gt;eth-cfm&gt;collect-lmm-fc-stats</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command creates individual counters for the specified FCs with regard for profile. All countable packets that match a configured FC and are deemed to be in-profile will be included in this counter.</p> <p>A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.</p> <p>Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-unaware FC using the <b>fc</b> command under the same context.</p> <p>The <b>no</b> form of the command removes all previously defined FCs and stops counting for those FCs.</p> |
| <b>Default</b>     | no fc-in-profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Parameters** *fc-name* — Specifies up to eight names of the FC for which to create an individual profile-aware counter. In order for the counter to be used, the **config>oam-pm>session>ethernet>priority** command must be configured with a numerical value representing the FC name (7 = NC, 6 = H1, 5 = EF, 4 = H2, 3 = L1, 2 = AF, 1 = L2, 0 = BE), and the **config>oam-pm>session>ethernet>lmm>enable-fc-collection** command must be enabled.

**Values** nc, h1, ef, h2, l1, af, l2, be

## collect-lmm-stats

**Syntax** **[no] collect-lmm-stats**

**Context** config>service>epipe>sap>eth-cfm  
config>service>epipe>spoke-sdp>eth-cfm  
config>service>vpls>sap>eth-cfm  
config>service>vpls>spoke-sdp>eth-cfm  
config>service>vpls>mesh-sdp>eth-cfm  
config>service>ipipe>sap>eth-cfm

**Description** This command enables the collection of statistics on the SAP or MPLS SDP binding on which the ETH- LMM test is configured. The collection of LMM statistics must be enabled if a MEP is launching or responding to ETH-LMM packets. If LMM statistics collection is not enabled, the counters in the LMM and LMR PDU do not represent accurate measurements and all measurements should be ignored. The **show sap-using eth-cfm collect-lmm-stats** command and the **show sdp-using eth-cfm collect-lmm-stats** command can be used to display which entities are collecting stats.

The **no** form of the command disables and deletes the counters for this SAP or MPLS SDP binding.

**Default** no collect-lmm-stats

## mep

**Syntax** **mep mep-id domain md-index association ma-index [direction {up | down}] [primary-vlan-enable]**  
**no mep mep-id domain md-index association ma-index**

**Context** config>service>vpls>mesh-sdp>eth-cfm  
config>service>vpls>spoke-sdp>eth-cfm  
config>service>vpls>eth-cfm  
config>service>vpls>sap>eth-cfm

**Description** This command configures the ETH-CFM maintenance endpoint (MEP). A MEP created at the VPLS service level **vpls>eth-cfm** creates a virtual MEP.

The **no** version of the command will remove the MEP.

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><i>mep-id</i> — Specifies the MEP identifier.</p> <p><b>Values</b> 1 to 8191</p> <p><i>md-index</i> — Specifies the maintenance domain (MD) index value.</p> <p><b>Values</b> 1 to 4294967295</p> <p><i>ma-index</i> — Specifies the maintenance association (MA) index value.</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>direction up   down</b> — Indicates the direction in which the MEP faces on the bridge port. Direction is not supported when a MEP is created directly under the vpls&gt;eth-cfm construct (vMEP).</p> <p>down — Sends ETH-CFM messages away from the MAC relay entity</p> <p>up — Sends ETH-CFM messages toward the MAC relay entity</p> <p><b>primary-vlan-enable</b> — Provides a method for linking the MEP with the primary VLAN configured under the bridge-identifier for the MA. MEPs cannot be changed from or to primary VLAN functions. This must be configured as part of the creation step and can only be changed by deleting the MEP and re-creating it. Primary VLANs are only supported under Layer 2 Epipe and VPLS services.</p> |

| <b>Description</b> | <p>This command allows Maintenance Intermediate Points (MIPs). The creation rules of the MIP are dependent on the mhf-creation configuration for the MA.</p> <p>The <b>no</b> form of the command removes the MIP creation request.</p>                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | no mip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>mac-address</i> — Specifies the MAC address of the MEP.</p> <p><b>Values</b> 6-byte MAC address in the form of xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx of the MIP. The MAC must be unicast. Using the all-zeros address is equivalent to the <b>no</b> form of this command.</p> <p><b>default-mac</b> — Using the <b>no</b> command deletes the MIP. If the operator wants to change the MAC back to the default MAC without having to delete the MIP and reconfiguring, this command is useful.</p> |

**primary-vlan-enable** — Provides a method for linking the MIP with the primary VLAN configured under the bridge-identifier for the MA. This is only allowed if the mhf-creation method is static. MIPs cannot be changed from or to primary VLAN functions without first being deleted. Primary VLANs are only supported under Layer 2 Epipe and VPLS services.

*vlan-id* — Must match the vlan-id under the bridge-identifier for the MA that is appropriate for this service.

**Values** 0 to 4094

| <b>Description</b> | This command allows Maintenance Intermediate Points (MIPs). The creation rules of the MIP are dependent on the mhf-creation configuration for the MA. This MIP option is only available for default and static mhf-creation methods.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><b>primary-vlan-enable</b> — Provides a method for linking the MIP with the primary VLAN configured under the bridge-identifier for the MA. This is only allowed if the mhf-creation method is static. MIPs cannot be changed from or to primary VLAN functions without first being deleted. This must be configured as part of the creation step and can only be changed by deleting the MEP and re-creating it. Primary VLANs are only supported under Ethernet SAPs.</p> <p><b>vlan</b> — A required parameter when including primary-vlan-enable. Provides a method for associating the VLAN under the bride-identifier under the MA with the MIP.</p> <p><i>vlan-id</i> — Must match the vlan-id under the bridge-identifier for the MA that is appropriate for this service.</p> <p><b>Values</b> 0 to 4094</p> |

## ais-enable

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ais-enable</b>                                                                |
| <b>Context</b>     | config>service>vpls>mesh-sdp>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the generation and the reception of AIS messages.                |

## interface-support-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>vpls>sap>eth-cfm>mep>ais<br>config>service>vpls>spoke-sdp>eth-cfm>mep>ais<br>config>service>vpls>mesh-sdp>eth-cfm>mep>ais                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on operationally down MEPs will be triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled then transmission of the AIS PDU will be based on either the non-operational state of the entity or on any CCM defect condition. AIS generation will cease if BOTH operational state is UP and CCM has no defect conditions. If the MEP is not CCM enabled then the operational state of the entity is the only consideration assuming this command is present for the MEP. |
| <b>Default</b>     | no interface-support-enabled (AIS will not be generated or stopped based on the state of the entity on) which the operationally down MEP is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Set the byte size of the optional Data TLV to be included in the ETH-CC PDU. This will increase the size of the ETH-CC PDU by the configured value. The base size of the ETH-CC PDU, including the Interface Status TLV and Port Status TLV, is 83 bytes not including the Layer Two encapsulation. CCM padding is not supported when the CCM-Interval is less than one second. |
| <b>Default</b>     | no ccm-padding-size                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>ccm-padding</i> — Specifies the byte size of the Optional Data TLV.                                                                                                                                                                                                                                                                                                          |
| <b>Values</b>      | 3 to 1500                                                                                                                                                                                                                                                                                                                                                                       |

## csf-enable

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] csf-enable</b>                                                                                                       |
| <b>Context</b>     | config>service>vpls>mesh-sdp>eth-cfm>mep<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the reception and local processing of ETH-CSF frames.                                                   |

## multiplier

|                    |                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>multiplier multiplier-value</b><br><b>no multiplier</b>                                                                                                    |
| <b>Context</b>     | config>service>vpls>mesh-sdp>eth-cfm>mep>csf-enable<br>config>service>vpls>sap>eth-cfm>mep>csf-enable<br>config>service>vpls>spoke-sdp>eth-cfm>mep>csf-enable |
| <b>Description</b> | This command enables the multiplication factor applied to the receive time used to clear the CSF condition in increments of .5.                               |
| <b>Default</b>     | 3.5                                                                                                                                                           |
| <b>Parameters</b>  | <i>multiplier-value</i> — Specifies the multiplier used for timing out CSF                                                                                    |
| <b>Values</b>      | 0.0, 2.0 to 30.0                                                                                                                                              |

## interval

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>interval {1   60}</b><br><b>no interval</b>                                                              |
| <b>Context</b> | config>service>vpls>mesh-sdp>eth-cfm>mep>ais-enable<br>config>service>vpls>spoke-sdp>eth-cfm>mep>ais-enable |

---

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies the transmission interval of AIS messages in seconds. |
| <b>Parameters</b>  | <b>1   60</b> — The transmission interval of AIS messages in seconds         |
| <b>Default</b>     | 1                                                                            |

## priority

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority</b> <i>priority-value</i><br><b>no priority</b>                                                 |
| <b>Context</b>     | config>service>vpls>mesh-sdp>eth-cfm>mep>ais-enable<br>config>service>vpls>spoke-sdp>eth-cfm>mep>ais-enable |
| <b>Description</b> | This command specifies the priority of AIS messages originated by the node.                                 |
| <b>Parameters</b>  | <i>priority-value</i> — Specifies the priority value of the AIS messages originated by the node             |
| <b>Values</b>      | 0 to 7                                                                                                      |
| <b>Default</b>     | 1                                                                                                           |

## ccm-enable

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-enable</b>                                                                                                                                  |
| <b>Context</b>     | config>service>vpls>eth-cfm>mep<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>mesh-sdp>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the generation of CCM messages.<br><br>The <b>no</b> form of the command disables the generation of CCM messages.                  |

## ccm-ltm-priority

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-ltm-priority</b> <i>priority</i><br><b>no ccm-ltm-priority</b>                                                                                                           |
| <b>Context</b>     | config>service>vpls>eth-cfm>mep<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>mesh-sdp>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep                         |
| <b>Description</b> | This command specifies the priority value for CCMs and LTMs transmitted by the MEP.<br><br>The <b>no</b> form of the command removes the priority value from the configuration. |

---

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| <b>Default</b>    | The highest priority on the bridge-port.                         |
| <b>Parameters</b> | <i>priority</i> — Specifies the priority of CCM and LTM messages |
| <b>Values</b>     | 0 to 7                                                           |

| <b>Description</b> | This command specifies the lowest priority defect that is allowed to generate a fault alarm.                                                                                                                                    |
| <b>Default</b>     | bit-error-threshold 1                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>bit-errors</i> — Specifies the lowest priority defect.                                                                                                                                                                       |
| <b>Values</b>      | 0 to 11840                                                                                                                                                                                                                      |

## test-pattern

|                |                                                                                                                  |
|----------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>test-pattern {all-zeros   all-ones} [crc-enable]</b><br><b>no test-pattern</b>                                |
| <b>Context</b> | config>service>vpls>sap>eth-cfm>mep>eth-test-enable<br>config>service>vpls>spoke-sdp>eth-cfm>mep>eth-test-enable |

```
config>service>vpls>mesh-sdp>eth-cfm>mep>eth-test-enable
```

- Description** This command configures the test pattern for eth-test frames.
- The **no** form of the command removes the values from the configuration.
- Parameters**
- all-zeros** — Specifies to use all zeros in the test pattern
  - all-ones** — Specifies to use all ones in the test pattern
  - crc-enable** — Generates a CRC checksum
  - Default** all-zeros

## fault-propagation-enable

- Syntax** **fault-propagation-enable {use-if-tlv | suspend-ccm}**  
**no fault-propagation-enable**
- Context** config>service>vpls>mesh-sdp>eth-cfm>mep  
config>service>vpls>sap>eth-cfm>mep  
config>service>vpls>spoke-sdp>eth-cfm>mep
- Description** This command configures the fault propagation for the MEP.
- Parameters**
- use-if-tlv** — Specifies to use the interface TLV.
  - suspend-ccm** — Specifies to suspend the continuity check messages.

## grace

- Syntax** **grace**
- Context** config>service>vpls>eth-cfm>mep  
config>service>vpls>mesh-sdp>eth-cfm>mep  
config>service>vpls>spoke-sdp>eth-cfm>mep  
config>service>vpls>sap>eth-cfm>mep
- Description** This command enters the context to configure Nokia ETH-CFM Grace and ITU-T Y.1731 ETH-ED expected defect functional parameters.

## eth-ed

- Syntax** **eth-ed**
- Context** config>service>vpls>eth-cfm>mep>grace  
config>service>vpls>mesh-sdp>eth-cfm>mep>grace  
config>service>vpls>spoke-sdp>eth-cfm>mep>grace  
config>service>vpls>sap>eth-cfm>mep>grace

---

**Description** This command enters the context to configure ITU-T Y.1731 ETH-ED expected defect functional parameters.

## max-rx-defect-window

**Syntax** **max-rx-defect-window** *seconds*  
**no max-rx-defect-window**

**Context** config>service>vpls>eth-cfm>mep>grace>eth-ed  
config>service>vpls>mesh-sdp>eth-cfm>mep>grace>eth-ed  
config>service>vpls>spoke-sdp>eth-cfm>mep>grace>eth-ed  
config>service>vpls>sap>eth-cfm>mep>grace>eth-ed

**Description** This command limits the duration of the received ETH-ED expected defect window to the lower value of either the received value from the peer or this parameter.

The **no** form of the command removes the limitation, and any valid defect window value received from a peer MEP in the ETH-ED PDU will be used.

**Default** no max-rx-defect-window

**Parameters** *seconds* — Specifies the duration, in seconds, of the maximum expected defect window.

**Values** 1 to 86400

## priority

**Syntax** **priority** *priority*  
**no priority**

**Context** config>service>vpls>eth-cfm>mep>grace>eth-ed  
config>service>vpls>mesh-sdp>eth-cfm>mep>grace>eth-ed  
config>service>vpls>spoke-sdp>eth-cfm>mep>grace>eth-ed  
config>service>vpls>sap>eth-cfm>mep>grace>eth-ed

**Description** This command sets the priority bits and determines the forwarding class based on the mapping of priority to FC.

The **no** form of the command disables the local priority configuration and sets the priority to the **ccm-ltm-priority** associated with this MEP.

**Default** no priority

**Parameters** *priority* — Specifies the priority bit.

**Values** 0 to 7

---

**Description** This command enters the context to configure Nokia ETH-CFM Grace functional parameters.

## rx-eth-vsm-grace

**Syntax** [no] rx-eth-vsm-grace

**Context** config>service>vpls>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>mesh-sdp>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>spoke-sdp>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>sap>eth-cfm>mep>grace>eth-vsm-grace

**Description** This command enables the reception and processing of the Nokia ETH-CFM Grace PDU on the MEP.

The Nokia Grace function is a vendor-specific PDU that informs MEP peers that the local node may be entering a period of expected defect.

The **no** form of the command disables the reception of the Nokia ETH-CFM Grace PDU on the MEP.

**Default** rx-eth-vsm-grace

## tx-eth-vsm-grace

**Syntax** [no] tx-eth-vsm-grace

**Context** config>service>vpls>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>mesh-sdp>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>spoke-sdp>eth-cfm>mep>grace>eth-vsm-grace  
 config>service>vpls>sap>eth-cfm>mep>grace>eth-vsm-grace

**Description** This command enables the transmission of the Nokia ETH-CFM Grace PDU from the MEP when a system soft reset notification is received for one or more cards.

The Nokia Grace function is a vendor-specific PDU that informs MEP peers that the local node may be entering a period of expected defect.

The **config>eth-cfm>system>grace-tx-enable** command must be configured to instruct the system that the node is capable of transmitting expected defect windows to the peers. Only one form of ETH-CFM grace (Nokia ETH-CFM Grace or ITU-T Y.1731 ETH-ED) may be transmitted.

The **no** form of the command disables the transmission of the Nokia ETH-CFM Grace PDU from the MEP.

**Default** tx-eth-vsm-grace

| <b>Description</b> | <p>This command enables the MEP to process service activation streams encapsulated in ETH-CFM LBM frames that are directed to the MEP. The MEP will be allocated additional resources to rapidly respond to a high-speed stream of LBM messages. A MEP created with this option will not validate any TLVs, will not validate the ETH-LBM MAC Address, and will not increment or compute any loopback statistics. Statistical computation and reporting is the responsibility of the test head-end. The ETH-CFM level of the high speed ETH-LBM stream must match the level of a MEP configured with this command. It must not target any lower ETH-CFM level the MEP will terminate. When the service activation test is complete, the MEP may be returned to standard processing by removing this command. If there is available bandwidth, the MEP will respond to other ETH-CFM PDUs, such as ETH-DMM marker packets, using standard processing.</p> <p>The interaction between this command and the <b>tools perform service id service-id loopback eth</b> command must be carefully considered. It is recommended that either the <b>lbm-svc-act-responder</b> or the <b>tools perform service id service-id loopback eth</b> command be used at any given time within a service. If both commands must be configured, and the target reflection point is the MAC Swap Loopback function, the inbound stream of data must not include ETH-CFM traffic that is equal to or lower than the domain level of any configured MEP which would otherwise extract and process the ETH-CFM message. If the reflection target is a MEP configured with the <b>lbm-svc-act-responder</b> option, the mode (ingress or egress) of the SAP or SDP specified with this tools command and the MEP <b>direction</b> (up or down) must match when the functions are enabled on the same reflection point, and the domain level of the inbound ETH-LBM must be the same as that of the MEP configured with the <b>lbm-svc-act-responder</b> option. At no time should the two functions be conflicting with each other along the path of the stream. This conflict would lead to unpredictable and possibly destabilizing situations.</p> <p>The <b>no</b> form of the command reverts to MEP LBM standard processing.</p> |
| <b>Default</b>     | no lbm-svc-act-responder                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## low-priority-defect

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>low-priority-defect {allDef   macRemErrXcon   remErrXcon   errXcon   xcon   noXcon}</b>   |
| <b>Context</b>     | config>service>vpls>mesh-sdp>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep        |
| <b>Description</b> | This command specifies the lowest priority defect that is allowed to generate a fault alarm. |
| <b>Default</b>     | macRemErrXcon                                                                                |

---

**Parameters**    **low-priority-defect** — The low priority defect values are defined below.

**Values**

|               |                                                                    |
|---------------|--------------------------------------------------------------------|
| allDef        | DefRDICCM, DefMACstatus, DefRemoteCCM, DefErrorCCM, and DefXconCCM |
| macRemErrXcon | Only DefMACstatus, DefRemoteCCM, DefErrorCCM, and DefXconCCM       |
| remErrXcon    | Only DefRemoteCCM, DefErrorCCM, and DefXconCCM                     |
| errXcon       | Only DefErrorCCM and DefXconCCM                                    |
| xcon          | Only DefXconCCM; or                                                |
| noXcon        | No defects DefXcon or lower are to be reported                     |

## mac-address

**Syntax**    **mac-address** *mac-address*  
**no mac-address**

**Context**    config>service>vpls>eth-cfm>mep  
              config>service>vpls>sap>eth-cfm>mep  
              config>service>vpls>spoke-sdp>eth-cfm>mep  
              config>service>vpls>mesh-sdp>eth-cfm>mep

**Description**    This command specifies the MAC address of the MEP.

                  The **no** form of this command reverts the MAC address of the MEP back to that of the port (if the MEP is on a SAP) or the bridge (if the MEP is on a spoke).

**Parameters**    *mac-address* — Specifies the MAC address of the MEP

**Values**        6-byte mac-address in the form of xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx of the MEP. Must be unicast. Using the all zeros address is equivalent to the no form of this command.

## one-way-delay-threshold

**Syntax**        **one-way-delay-threshold** *seconds*

**Context**        config>service>vpls>sap>eth-cfm>mep

**Description**    This command enables/disables eth-test functionality on MEP.

**Parameters**    *seconds* — Specifies the one way delay threshold, in seconds

**Values**        0 to 600

**Default**        3

## tunnel-fault

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel-fault {accept   ignore}</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpls>eth-cfm<br>config>service>vpls>sap>eth-cfm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | Allows the individual service SAPs to react to changes in the tunnel MEP state. When tunnel-fault accept is configured at the service level, the SAP will react according to the service type, Epipe will set the operational flag and VPLS, IES and VPRN SAP operational state will become down on failure or up on clear. This command triggers the OAM mapping functions to mate SAPs and bindings in an Epipe service as well as setting the operational flag. If AIS generation is the requirement for the Epipe services this command is not required. See the command ais-enable under epipe>sap>eth-cfm>ais-enable for more details. This works in conjunction with the tunnel-fault accept on the individual SAPs. Both must be set to accept to react to the tunnel MEP state. By default the service level command is "ignore" and the sap level command is "accept". This means simply changing the service level command to "accept" will enable the feature for all SAPs. This is not required for Epipe services that only wish to generate AIS on failure. |
| <b>Default</b>     | tunnel-fault ignore (Service Level)<br><br>tunnel-fault accept (SAP Level for Epipe and VPLS)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | This command defines the levels of the ETH-CFM PDUs that will silently be discarded on ingress into the SAP or SDP binding from the wire. All ETH-CFM PDUs inbound to the SAP or SDP binding will be dropped that match the configured levels without regard for any other ETH-CFM criteria. No statistical information or drop count will be available for any ETH-PDU that is silently discarded by this option. The operator must configure a complete contiguous list of md-levels up to the highest level that will be dropped. The command must be retyped in complete form to modify a previous configuration, if the operator does not want to delete it first. |

The **no** form of the command removes the silent discarding of previously matching ETH-CFM PDUs.

|                   |                                         |

| <b>Context</b>     | config>service>vpls>sap>msap-defaults                                                                                                                                                                                                                                 |
| <b>Description</b> | This command sets default msap-policy for all subscribers created based on trigger packets received on the specified capture-sap in case the corresponding VSA is not included in the RADIUS authentication response. This command is applicable to capture SAP only. |
| <b>Default</b>     | no policy                                                                                                                                                                                                                                                             |

## multi-service-site

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>multi-service-site</b> <i>customer-site-name</i><br><b>no multi-service-site</b>                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command associates the SAP with a <i>customer-site-name</i> . If the specified <i>customer-site-name</i> does not exist in the context of the service customer ID an error occurs and the command will not execute. If <i>customer-site-name</i> exists, the current and future defined queues on the SAP (ingress and egress) will attempt to use the scheduler hierarchies created within <i>customer-site-name</i> as parent schedulers. |

This command is mutually exclusive with the SAP ingress and egress **scheduler-policy** commands. If a **scheduler-policy** has been applied to either the ingress or egress nodes on the SAP, the **multi-service-site** command will fail without executing. The locally applied scheduler policies must be removed prior to executing the **multi-service-site** command.

The **no** form of the command removes the SAP from any multi-service customer site the SAP belongs to. Removing the site can cause existing or future queues to enter an orphaned state.

**Default**      None

**Parameters**    *customer-site-name* — Specifies the customer name site. The customer-site-name must exist in the context of the customer-id defined as the service owner. If customer-site-name exists and local scheduler policies have not been applied to the SAP, the current and future queues defined on the SAP will look for their parent schedulers within the scheduler hierarchies defined on customer-site-name.

**Values**          Any valid customer-site-name created within the context of the customer-id

## precedence

**Syntax**          **precedence** [*precedence-value* | **primary**]  
**no precedence**

**Context**          config>service>vpls>spoke-sdp

**Description**      This command configures the precedence of this SDP bind when there are multiple SDP binds attached to one service endpoint. When an SDP bind goes down, the next highest precedence SDP bind begins forwarding traffic.

**Parameters**      *precedence-value* — Specifies the precedence of this SDP bind

**Values**          1 to 4

*primary* — Assigns this as the primary spoke-SDP

## static-isid

**Syntax**          [**no**] **static-isid range** *entry-id isid* [**to isid**] [**create**]

**Context**          config>service>vpls>sap  
config>service>vpls>vpls>spokesdp

**Description** This command identifies a set of ISIDs for I-VPLS services that are external to SPBM. These ISIDs are advertised as supported locally on this node unless altered by an `isid-policy`. This allows communication from I-VPLS services external to SPBM through this node. The SAP may be a regular SAP or MC-LAG SAP. The spoke-SDP may be an active/standby spoke. When used with MC-Lag or active/stand-by PWs the conditional static-mac must be configured. ISIDs declared this way become part of the ISID multicast and consume MFIBs. Multiple SPBM static-isid ranges are allowed under a SAP/spoke-SDP.

The static-isids are associated with a remote BMAC that must be declared as a static-mac for unicast traffic. ISIDs are advertised as if they were attached to the local BMAC. Only remote I-VPLS ISIDs need to be defined. In the MFIB, the group MACs are then associated with the active SAP or spoke-SDP. An ISID policy may be defined to suppress the advertisement of an ISID if the ISID is primarily used for unicast services. The following rules govern the usage of multiple ISID statements:

- overlapping values are allowed:
  - isid from 301 to 310
  - isid from 305 to 315
  - isid 316
- the minimum and maximum values from overlapping ranges are considered and displayed. The above entries will be equivalent with “ISID from 301 to 316” statement.
- there is no consistency check with the content of ISID statements from other entries. The entries will be evaluated in the order of their IDs and the first match will cause the implementation to execute the associated action for that entry.

The **no** form of the command removes all the previous statements under one interface

`no isid value | from value to higher-value` - removes a specific ISID value or range. Must match a previously used positive statement: for example if the command “isid 316 to 400” was used using “no isid 316 to 350” will not work but “no isid 316 to 400 will be successful.

**Parameters** *entry-id* — Sets context for specified entry ID for the static-isids

**Values** 1— 65535

*isid* — Configures the ISID or the start of an ISID range. Specifies the ISID value in 24 bits. When just one present identifies a particular ISID to be used for matching.

**Values** 0 to 16777215

*to isid* — Identifies upper value in a range of ISIDs to be used as matching criteria

**Values** 0 to 16777215

## static-mac

**Syntax** [**no**] **static-mac** *ieee-mac-address* [*create*]

**Context** config>service>vpls>sap  
config>service>vpls>mesh-sdp

```
config>service>vpls>spoke-sdp
```

- Description** This command creates a local static MAC entry in the Virtual Private LAN Service (VPLS) forwarding database (FDB) associated with the Service Access Point (SAP).
- In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.
- Local static MAC entries create a permanent MAC address to SAP association in the forwarding database for the VPLS instance so that MAC address will not be learned on the edge device.
- Static MAC definitions on one edge device are not propagated to other edge devices participating in the VPLS instance, that is, each edge device has an independent forwarding database for the VPLS.
- Only one static MAC entry (local or remote) can be defined per MAC address per VPLS instance.
- By default, no static MAC address entries are defined for the SAP.
- The **no** form of this command deletes the static MAC entry with the specified MAC address associated with the SAP from the VPLS forwarding database.
- Parameters** *ieee-mac-address* — Specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.
- create** — This keyword is mandatory when specifying a static MAC address

## managed-vlan-list

- Syntax** **managed-vlan-list**
- Context** config>service>vpls>sap
- Description** This command enters the context to configure VLAN ranges to be managed by a management VPLS. The list indicates, for each SAP, the ranges of associated VLANs that will be affected when the SAP changes state. This managed-vlan-list is not used when STP mode is MSTP in which case the vlan-range is taken from the **config>service>vpls>stp>msti** configuration.
- This command is only valid when the VPLS in which it is entered was created as a management VPLS.

## default-sap

|                    |                                                                                                                                                      |

| <b>Parameters</b>  | <i>vlan-range</i> — Specify the VLAN start value and VLAN end value. The end-vlan must be greater than start-vlan. The format is <start-vlan>-<end-vlan>.<br><br><table> <tr> <td><b>Values</b></td><td>start-vlan: 0 to 4094<br/>end-vlan: 0 to 4094</td></tr> </table>                                                                                                                                                                                                                                                                                           | <b>Values</b> | start-vlan: 0 to 4094<br>end-vlan: 0 to 4094 |
| <b>Values</b>      | start-vlan: 0 to 4094<br>end-vlan: 0 to 4094                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |               |                                              |

### 3.7.2.4.1 VPLS Filter and QoS Policy Commands

## egress

|                    |                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                       |
| <b>Description</b> | This command enters the context to configure egress filter policies.<br><br>If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If <b>no</b> egress filter is defined, no filtering is performed. |

---

## ingress

|                    |                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enters the context to configure ingress SAP Quality of Service (QoS) policies and filter policies.</p> <p>If no sap-ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter is defined, no filtering is performed.</p> |

## agg-rate

|                    |                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] agg-rate</b>                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vpls>sap>egress><br>config>service>template>vpls-sap-template>egress<br>config>service>vpls>sap>egress>encap-defined-qos>encap-group                                                                    |
| <b>Description</b> | This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: <b>rate</b> , <b>limit-unused-bandwidth</b> , and <b>queue-frame-based-accounting</b> . |

## rate

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rate {max   rate}</b><br><b>no rate</b>                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vpls>sap>egress>agg-rate<br>config>service>template>vpls-sap-template>egress>agg-rate<br>config>service>vpls>sap>egress>encap-defined-qos>encap-group>agg-rate                                                                 |
| <b>Description</b> | This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered active on the context's object (SAP, subscriber, Vport, and so on.). |

## limit-unused-bandwidth

|                    |                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] limit-unused-bandwidth</b>                                                                                                                                            |
| <b>Context</b>     | config>service>vpls>sap>egress>agg-rate<br>config>service>template>vpls-sap-template>egress>agg-rate<br>config>service>vpls>sap>egress>encap-defined-qos>encap-group>agg-rate |
| <b>Description</b> | This command is used to enable aggregate rate overrun protection on the agg-rate context.                                                                                     |

The **no** form of the command disables the overrun protection.

## queue-frame-based-accounting

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] queue-frame-based-accounting</b>                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vpls>sap>egress>agg-rate<br>config>service>template>vpls-sap-template>egress>agg-rate                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command is used to enabled frame-based accounting on all policers and queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSMDA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured; however the offsets are applied to the statistics.<br><br>The <b>no</b> form of the command disables the-frame based accounting. |

## dest-mac-rewrite

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dest-mac-rewrite</b> <i>ieee-address</i><br><b>no dest-mac-rewrite</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vpls>sap>egress>agg-rate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This commands enables the overwriting of a destination MAC address to an operator-configured value for all unicast packets egressing the specified SAP. The command is intended to be deployed with L2 PBF SAP redirect when a remote end of the SAP interface is an L3 interface with a MAC address different from the MAC address of the non-PBF-ed L3 interface. See Filter Policy in the <i>7450 ESS, 7750 SR, 7950 XRS, and VSR Router Configuration Guide</i> for more details.<br><br>The <b>no</b> form disables the option. |
| <b>Default</b>     | no dest-mac-rewrite                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>ieee-address</i> — Specifies the MAC address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## encap-defined-qos

|                |                                |
|----------------|--------------------------------|
| <b>Syntax</b>  | <b>encap-defined-qos</b>       |
| <b>Context</b> | config>service>vpls>sap>egress |

**Description** This command creates a new QoS sub-context in B-VPLS SAP egress context. The user can define encapsulation groups, referred to as *encap-group*, based on the ISID value in the packet's encapsulation and assign a QoS policy and a scheduler policy or aggregate rate limit to the group.

## encap-group

**Syntax** **encap-group** *group-name* [**type** *group-type*] [**qos-per-member**] [**create**]  
**no encap-group** *group-name*

**Context** config>service>vpls>sap>egress>encap-defined-qos

**Description** This command defines an encapsulation group which consists of a group of ISID values. All packets forwarded on the egress of a B-VPLS SAP which payload header matches one of the ISID value in the *encap-group* will use the same QoS policy instance and scheduler policy or aggregate rate limit instance.

The user adds or removes members to the *encap-group* one at a time or as a range of contiguous values using the *member* command. However, when the *qos-per-member* option is enabled, members must be added or removed one at a time. These members are also referred to as ISID contexts.

The user can configure one or more *encap-groups* in the egress context of the same B-SAP, therefore defining different ISID values and applying each a different SAP egress QoS policy, and optionally a different scheduler policy/**agg-rate**. ISID values are unique within the context of a B-SAP. The same ISID value cannot be re-used in another *encap-group* under the same B-SAP but can be re-used in an *encap-group* under a different B-SAP. Finally, if the user adds to an *encap-group* an ISID value which is already a member of this *encap-group*, the command causes no effect. The same if the user attempts to remove an ISID value which is not a member of this *encap-group*.

Once a group is created, the user will assign a SAP egress QoS policy, and optionally a scheduler policy or aggregate rate limit, using the following commands:

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group>qos sap-egress-  
policy-id
```

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group>scheduler-  
policy scheduler-policy-name
```

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group>agg-rate kilobits-  
per-second
```

A SAP egress QoS policy must first be assigned to the created *encap group* before the user can add members to this group. Conversely, the user cannot perform the **no qos** command until all members are deleted from the *encap-group*.

An explicit or the default SAP egress QoS policy will continue to be applied to the entire B-SAP but this will serve to create the set of egress queues which will be used to store and forward a packet which does not match any of the defined ISID values in any of the encap-groups for this SAP.

Only the queue definition and fc-to-queue mapping from the encap-group SAP egress QoS policy is applied to the ISID members. All other parameters configurable in a SAP egress QoS policy must be inherited from egress QoS policy applied to the B-SAP.

Furthermore, any other CLI option configured in the egress context of the B-SAP will continue to apply to packets matching a member of any encap-group defined in this B-SAP.

The keyword **qos-per-member** allows the user to specify that a separate queue set instance and scheduler/**agg-rate** instance will be created for each ISID value in the encap-group. By default, shared instances will be created for the entire encap-group.

When the B-SAP is configured on a LAG port, the ISID queue instances defined by all the encap-groups applied to the egress context of the SAP will be replicated on each member link of the LAG. The set of scheduler/**agg-rate** instances will be replicated per link or per IOM or XMA depending if the adapt-qos option is set to link/port-fair mode or distribute mode. This is the same behavior as that applied to the entire B-SAP in the current implementation.

The **no** form of this command deletes the encap-group.

|                   |                                                                                                                                                                     |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>group-name</b> — Specifies the name of the encap-group and can be up to 32 ASCII characters in length                                                            |
|                   | <b>type</b> — Specifies the type of the encapsulation ID used by this encap-group                                                                                   |
|                   | <b>Values</b> isid                                                                                                                                                  |
|                   | <b>Default</b> None                                                                                                                                                 |
|                   | <b>qos-per-member</b> — Specifies that a separate queue set instance and scheduler/ <b>agg-rate</b> instance will be created for each ISID value in the encap-group |

## member

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command associates an IP filter policy or MAC filter policy with an ingress or egress Service Access Point (SAP) or IP interface.</p> <p>Filter policies control the forwarding and dropping of packets based on IP or MAC matching criteria. There are two types of filter policies: IP and MAC. Only one type may be applied to a SAP at a time.</p> <p>The <b>filter</b> command is used to associate a filter policy with a specified <i>filter ID</i> with an ingress or egress SAP. The <i>filter ID</i> must already be defined before the <b>filter</b> command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> |

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

This command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**).

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Special Cases</b> | <b>VPLS</b> — Both MAC and IP filters are supported on a VPLS service SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>    | <p><b>ip</b> <i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.</p> <p><b>Values</b> 1 to 65535</p> <p><b>ipv6</b> <i>ipv6-filter-id</i> — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.</p> <p><b>Values</b> 1 to 65535</p> <p><b>mac</b> <i>mac-filter-id</i> — Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.</p> <p><b>Values</b> 1 to 65535</p> |

## hsmda-queue-override

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] hsmda-queue-override</b>                                     |
| <b>Context</b>     | config>service>vpls>sap>egress                                       |
| <b>Description</b> | This command enters the context to configure HSM DA queue overrides. |

## queue

|                    |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <p><b>queue</b> <i>queue-id</i> <b>[create]</b></p> <p><b>no queue</b> <i>queue-id</i></p>                                       |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-override                                                                              |
| <b>Description</b> | This command configures overrides for a HSM DA queue. The actual valid values are those defined in the specified SAP QoS policy. |

---

|                   |                                                                 |
|-------------------|-----------------------------------------------------------------|
| <b>Parameters</b> | <i>queue-id</i> — Specifies the queue ID to override            |
| <b>Values</b>     | 1 to 8                                                          |
| <b>create</b>     | — This keyword is mandatory while creating a new queue override |

## packet-byte-offset

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>packet-byte-offset</b> { <b>add</b> <i>add-bytes</i>   <b>subtract</b> <i>sub-bytes</i> }<br><b>no packet-byte-offset</b>                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4 byte CRC (everything except the preamble and inter-frame gap). As an example, the packet-byte-offset command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions. |

The accounting functions affected include:

- Offered High Priority / In-Profile Octet Counter
- Offered Low Priority / Out-of-Profile Octet Counter
- Discarded High Priority / In-Profile Octet Counter
- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 31 bytes may be added to the packet and up to 32 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As inferred above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. The packet-byte-offset, when set, applies to all queues in the queue group. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscribers packets on an Ethernet aggregation network.

The packet-byte-offset value may be overridden at the queue-group level.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><b>add</b> <i>add-bytes</i> — Indicates that the byte value should be added to the packet for queue and queue group level accounting functions. Either the <b>add</b> or <b>subtract</b> keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command. The <b>add</b> keyword is mutually exclusive with the <b>subtract</b> keyword.</p> <p><b>Values</b>      0 to 31</p> <p><b>subtract</b> <i>sub-bytes</i> — Indicates that the byte value should be subtracted from the packet for queue and queue group level accounting functions. The <b>subtract</b> keyword is mutually exclusive with the <b>add</b> keyword. Either the <b>add</b> or <b>subtract</b> keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command.</p> <p><b>Values</b>      1 to 64</p> |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## slope-policy

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <p><b>slope-policy</b> <i>hsmda-slope-policy-name</i></p> <p><b>no slope-policy</b></p> |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over>queue                                   |
| <b>Description</b> | This command specifies an existing slope policy name.                                   |

## rate

|                    |                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <p><b>rate</b> <i>pir-rate</i></p> <p><b>no rate</b></p>                                                                  |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over>queue                                                                     |
| <b>Description</b> | This command specifies the administrative PIR by the user.                                                                |
| <b>Parameters</b>  | <p><i>pir-rate</i> — Configures the administrative PIR specified by the user.</p> <p><b>Values</b>      1 to 40000000</p> |

---

## wrr-weight

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>wrr-weight value</b><br><b>no wrr-weight</b>                                                                                                                 |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over>queue                                                                                                           |
| <b>Description</b> | This command assigns the weight value to the HSMDA queue.<br><br>The <b>no</b> form of the command returns the weight value for the queue to the default value. |
| <b>Parameters</b>  | <i>percentage</i> — Specifies the weight for the HSMDA queue<br><b>Values</b> 1 to 32                                                                           |

## wrr-policy

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>wrr-policy hsmda-wrr-policy-name</b><br><b>no wrr-policy</b>                                                 |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over                                                                 |
| <b>Description</b> | This command associates an existing HSMDA Weighted Round Robin (WRR) scheduling loop policy to the HSMDA queue. |
| <b>Parameters</b>  | <i>hsmda-wrr-policy-name</i> — Specifies the existing HSMDA WRR policy name to associate to the queue           |

## secondary-shaper

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-shaper secondary-shaper-name</b><br><b>no secondary-shaper</b>                                  |
| <b>Context</b>     | config>service>vpls>sap>egress>hsmda-queue-over                                                              |
| <b>Description</b> | This command configures an HSMDA secondary shaper. A shaper override can only be configured on an HSMDA SAP. |
| <b>Parameters</b>  | <i>secondary-shaper-name</i> — Specifies a secondary shaper name up to 32 characters in length               |

## qinq-mark-top-only

|                |                                |
|----------------|--------------------------------|
| <b>Syntax</b>  | <b>[no] qinq-mark-top-only</b> |
| <b>Context</b> | config>service>vpls>sap>egress |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>When enabled (the encapsulation type of the access port where this SAP is defined as qinq), the <b>qinq-mark-top-only</b> command specifies which P-bits/DEI bit to mark during packet egress. When disabled, both set of P-bits/DEI bit are marked. When enabled, only the P-bits/DEI bit in the top Q-tag are marked.</p> <p>The <b>no</b> form of this command disables the command.</p> |
| <b>Default</b>     | no qinq-mark-top-only                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, creates a CLI node for specific overrides to the applied policer-control-policy. A policy must be applied for a policer-control-overrides node to be created. If the policer-control-policy is removed or changed, the policer-control-overrides node is automatically deleted from the SAP.</p> <p>The <b>no</b> form of the command removes any existing policer-control-policy overrides and the policer-control-overrides node from the SAP.</p> |
| <b>Default</b>     | no policer-control-override                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <b>create</b> — The create keyword is required when the policer-control-overrides node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit confirmation, the create keyword is not required.                                                                                                                                                                                                  |

## max-rate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command within the SAP ingress and egress contexts is used to override the root arbiter's parent policer min-thresh-separation parameter that is defined within the policer-control-policy applied to the SAP.</p> <p>When the override is defined, modifications to the policer-control-policy min-thresh-separation parameter have no effect on the SAP's parent policer until the override is removed using the no min-thresh-separation command within the SAP.</p> <p>The no form of the command removes the override and allows the min-thresh-separation setting from the policer-control-policy to control the root arbiter's parent policer's minimum discard threshold separation size.</p> |
| <b>Default</b>     | no min-thresh-separation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><b>bytes</b> — Signifies that size is expressed in bytes. The bytes and kilobytes keywords are mutually exclusive and are optionally used to qualify whether size is expressed in bytes or kilobytes. The default is kilobytes.</p> <p><b>kilobytes</b> — The size parameter is required when specifying the min-thresh-separation override. It is specified as an integer representing either a number of bytes or kilobytes that are the minimum separation between the parent policer's priority level discard thresholds.</p> <p><b>Values</b>      0 to 16777216</p> <p><b>Default</b>      kilobytes</p>                                                                                             |

## priority

|                |                                                                   |
|----------------|-------------------------------------------------------------------|

---

**Description** This command, within the qos CLI node, is used to create, delete or modify policer control policies. A policer control policy is very similar to the scheduler-policy which is used to manage a set of queues by defining a hierarchy of virtual schedulers and specifying how the virtual schedulers interact to provide an aggregate SLA. In a similar fashion, the policer-control-policy controls the aggregate bandwidth available to a set of child policers. Once created, the policy can be applied to ingress or egress SAPs. The policy may also be applied to the ingress or egress context of a sub-profile.

### **Policer Control Policy Instances**

On the SAP side, an instance of a policy is created each time a policy is applied. When applied to a sub-profile, an instance of the policy is created each time a subscriber successfully maps one or more hosts to the profile per ingress SAP.

Each instance of the policer-control-policy manages the policers associated with the object that owns the policy instance (SAP or subscriber). If a policer on the object is parented to an appropriate arbiter name that exists within the policy, the policer will be managed by the instance. If a policer is not parented or is parented to a non-existent arbiter, the policer will be orphaned and will not be subject to bandwidth control by the policy instance.

### **Maximum Rate and Root Arbiter**

The policer-control-policy supports an overall maximum rate (max-rate) that defines the total amount of bandwidth that may be distributed to all associated child policers. By default, that rate is set to max which provides an unlimited amount of bandwidth to the policers. Once the policy is created, an actual rate should be configured in order for the policy instances to be effective. At the SAP level, the maximum rate may be overridden on a per instance basis. For subscribers, the maximum rate may only be overridden on the subscriber profile which will then be applied to all instances associated with the profile.

The maximum rate is defined within the context of the root arbiter which is always present in a policer-control-policy. The system creates a parent policer which polices the output of all child policers attached to the policy instance to the configured rate. Child policers may be parented directly to the root arbiter (parent root) or parented to one of the tiered arbiters (parent arbiter-name). Since each tiered arbiter must be parented to either another tiered arbiter or the root arbiter (default), every parented child policer is associated with the root arbiter and therefore the root arbiter's parent policer.

### **Parent Policer PIR Leaky Bucket Operation**

The parent policer is a single leaky bucket that monitors the aggregate throughput rate of the associated child policers. Forwarded packets increment the bucket by the size of each packet. The rate of the parent policer is implemented as a bucket decrement function which attempts to drain the bucket. If the rate of the packets flowing through the bucket is less than the decrement rate, the bucket does not accumulate depth. Each packet that flows through the bucket is accompanied by a derived discard threshold. If the current depth of the bucket is less than the discard threshold, the packet is allowed to pass through, retaining the colors derived from the packet's child policer. If the current depth is equal to or greater than the threshold value, the packet is colored red and the bucket depth is not incremented by the packet size. Also, any increased bucket depths in the child policer are canceled making any discard event an atomic function between the child and the parent.

Due to the fact that multiple thresholds are supported by the parent policer, the policer control policy is able to protect the throughput of higher priority child policers from the throughput of the lower priority child policers within the aggregate rate.

### **Tier 1 and Tier 2 Arbiters**

As stated above, each child is attached either to the always available root arbiter or to an explicitly created tier 1 or tier 2 arbiter. Unlike the hardware parent policer based root arbiter, the arbiters at tier 1 and tier 2 are only represented in software and are meant to provide an arbitrary hierarchical bandwidth distribution capability. An arbiter created on tier 2 must parent to either to an arbiter on tier 1 or to the root arbiter. Arbiters created on tier 1 always parent to the root arbiter. In this manner, every arbiter ultimately is parented or grand-parented by the root arbiter.

Each tiered arbiter supports an optional rate parameter that defines a rate limit for all child arbiters or child policers associated with the arbiter. Child arbiters and policers attached to the arbiter have a level attribute that defines the strict level at which the child is given bandwidth by the arbiter. Level 8 is the highest and 1 is the lowest. Also a weight attribute defines each child's weight at that strict level in order to determine how bandwidth is distributed to multiple children at that level when insufficient bandwidth is available to meet each child's required bandwidth.

### **Fair and Unfair Bandwidth Control**

Each child policer supports three leaky buckets. The PIR bucket manages the policer's peak rate and maximum burst size, the CIR leaky bucket manages the policer's committed rate and committed burst size. The third leaky bucket is used by the policer control policy instance to manage the child policer's fair rate (FIR). When multiple child policers are attached to the root arbiter at the same priority level, the policy instance uses each child's FIR bucket rate to control how much of the traffic forwarded by the policer is fair and how much is unfair.

In the simplest case where all the child policers in the same priority level are directly attached to the root arbiter, each child's FIR rate is set according to the child's weight divided by the sum of the active children's weights multiplied by the available bandwidth at the priority level. The result is that the FIR bucket will mark the appropriate amount of traffic for each child as fair-based on the weighted fair output of the policy instance.

The fair/unfair forwarding control in the root parent policer is accomplished by implementing two different discard thresholds for the priority. The first threshold is discard-unfair and the second is discard-all for packet associated with the priority level. As the parent policer PIR bucket fills (due the aggregate forwarded rate being greater than the parent policers PIR decrement rate) and the bucket depth reaches the first threshold, all unfair packets within the priority are discarded. This leaves room in the bucket for the fair packets to be forwarded.

In the more complex case where one or more tiered arbiters are attached at the priority level, the policer control policy instance must consider more than just the child policer weights associated with the attached arbiter. If the arbiter is configured with an aggregate rate limit that its children cannot exceed, the policer control policy instance will switch to calculating the rate each child serviced by the arbiter should receive and enforces that rate using each child policers PIR leaky bucket.

When the child policer PIR leaky bucket is used to limit the bandwidth for the child policer and the child's PIR bucket discard threshold is reached, packets associated with the child policer are discarded. The child policer's discarded packets do not consume depth in the child policer's CIR or FIR buckets. The child policers discarded packets are also prevented from impacting the parent policer and will not consume the aggregate bandwidth managed by the parent policer.

### **Parent Policar Priority Level Thresholds**

As stated above, each child policer is attached either to the root arbiter or explicitly to one of the tier 1 or tier 2 arbiters. When attached directly to the root arbiter, its priority relative to all other child policers is indicated by the parenting level parameter. When attached through one of the tiered arbiters, the parenting hierarchy of the arbiters must be traced through to the ultimate attachment to the root arbiter. The parenting level parameter of the arbiter parented to the root arbiter defines the child policer's priority level within the parent policer.

The priority level is important since it defines the parent policer discard thresholds that will be applied at the parent policer. The parent policer has 8 levels of strict priority and each priority level has its own discard-unfair and discard-all thresholds. Each priority's thresholds are larger than the thresholds of the lower priority levels. This ensures that when the parent policer is discarding, it will be priority sensitive.

To visualize the behavior of the parent policer, picture that when the aggregate forwarding rate of all child policers is currently above the decrement rate of the parent PIR leaky bucket, the bucket depth will increase over time. As the bucket depth increases, it will eventually cross the lowest priority's discard-unfair threshold. If this amount of discard sufficiently lowers the remaining aggregate child policer rate, the parent PIR bucket will hover around this bucket depth. If however, the remaining aggregate child rate is still greater than the decrement rate, the bucket will continue to rise and eventually reach the lowest priority's discard-all threshold which will cause all packets associated with the priority level to be discarded (fair and unfair). Again, if the remaining aggregate child rate is less than or equal to the bucket decrement rate, the parent PIR bucket will hover around this higher bucket depth. If the remaining aggregate child rate is still higher than the decrement rate, the bucket will continue to rise through the remaining priority level discards until equilibrium is achieved.

As noted above, each child's rate feeding into the parent policer is governed by the child policer's PIR bucket decrement rate. The amount of bandwidth the child policer offers to the parent policer will not exceed the child policer's configured maximum rate.

### **Root Arbiter's Parent Policar's Priority Aggregate Thresholds**

Each policer-control-policy root arbiter supports configurable aggregate priority thresholds which are used to control burst tolerance within each priority level. Two values are maintained per priority level; the shared-portion and the fair-portion. The shared-portion represents the amount of parent PIR bucket depth that is allowed to be consumed by both fair and unfair child packets at the priority level. The fair-portion represents the amount of parent PIR bucket depth that only the fair child policer packets may consume within the priority level. It should be noted that the fair and unfair child packets associated with a higher parent policer priority level may also consume the bucket depth set aside for this priority.

While the policy maintains a parent policer default or explicit configurable values for shared-portion and fair-portion within each priority level, it is possible that some priority levels will not be used within the parent policer. Most parent policer use cases require fewer than eight strict priority levels.

To derive the actual priority level discard-unfair and discard-all thresholds while only accounting for the actual in-use priority levels, the system maintains a child policer to parent policer association counter per priority level for each policer control policy instance. As a child policer is parented to either the root or a tiered arbiter, the system determines the parent policer priority level for the child policer and increments the association counter for that priority level on the parent policer instance.

The shared-portion for each priority level is affected by the parent policer global min-thresh-separation parameter that defines the minimum separation between any in-use discard thresholds. When more than one child policer is associated with a parent policer priority level, the shared-portion for that priority level will be the current value of min-thresh-separation. When only a single child policer is associated, the priority level's shared-portion is zero since all packets from the child will be marked fair and the discard-unfair threshold is meaningless. When the association counter is zero, both the shared-portion and the fair-portion for that priority level are zero since neither discard thresholds will be used. Whenever the association counter is greater than 0, the fair-portion for that priority level will be derived from the current value of the priority's mbs-contribution parameter and the global min-thresh-separation parameter.

Each priority level's discard-unfair and discard-all thresholds are calculated based on an accumulation of lower priorities shared-portions and fair-portions and the priority level's own shared-portion and fair-portion. The base threshold value for each priority level is equal to the sum of all lower priority level's shared-portions and fair-portions. The discard-unfair threshold is the priority level's base threshold plus the priority level's shared-portion. The discard-all threshold for the priority level is the priority level's base threshold plus both the shared-portion and fair-portion values of the priority. As can be seen, an in-use priority level's thresholds are always greater than the thresholds of lower priority levels.

### Policer Control Policy Application

A policer-control-policy may be applied on any Ethernet ingress or egress SAP that is associated with a port (or ports in the case of LAG).

The **no** form of the command removes a non-associated policer control policy from the system. The command will not execute when policer-name is currently associated with any SAP or subscriber management sub-profile context.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b> | <p><i>policy-name</i> — Specifies the policy name. Each policer-control-policy must be created with a unique policy name. The name must be given as policy-name must adhere to the system policy ASCII naming requirements. If the defined policy-name already exists, the system will enter that policy's context for editing purposes. If policy-name does not exist, the system will attempt to create a policy with the specified name. Creating a policy may require use of the create parameter when the system is configured for explicit object creation mode.</p> |

**create** — The keyword is required when a new policy is being created and the system is configured for explicit object creation mode.

| <b>Parameters</b>  | <p><i>policy-id</i> — The ingress policy ID to associate with SAP or IP interface on ingress. The policy ID must already exist.</p> <p>This variant of the command is only supported in 'classic' configuration-mode (<b>configure system management-interface configuration-mode classic</b>). The <b>qos name</b> <i>sap-ingress-policy-name</i> variant can be used in all configuration modes.</p> <p><b>Values</b> 1 to 65535</p> <p><b>shared-queuing</b> — This keyword can only be specified on SAP ingress. Specify the ingress shared queue policy used by this SAP. When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.</p> <p><b>multipoint-shared</b> — This keyword can only be specified on SAP ingress. Multipoint shared queuing is a superset of shared queuing. When multipoint shared queuing keyword is set, as well as the unicast packets, multipoint packets also used shared queues.</p> <p>Ingress unicast service queues are mapped one-for-one with hardware queues and unicast packets traverse the ingress forwarding plane twice, similar to the shared-queuing option. In addition, the multipoint queues defined in the ingress SAP QoS policy are not created. Instead, multipoint packets (broadcast, multicast and unknown unicast destined) are treated to the same dual pass ingress forwarding plane processing as unicast packets.</p> <p>When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.</p> <p>When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.</p> <p><b>Values</b> Multipoint or not present</p> <p><b>Default</b> Present (the queue is created as non-multipoint)</p> <p><i>sap-ingress-policy-name</i> — The SAP ingress QoS policy name to associate with the SAP on ingress, up to 64 characters.</p> |

| <b>Context</b>     | config>service>vpls>sap>egress>policer-override<br>config>service>vpls>sap>ingress>policer-override                                                                                                   |
| <b>Description</b> | This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to a specific policer created on the SAP through a sap-ingress or sap-egress QoS policy. |

The **no** form of the command is used to remove any existing overrides for the specified policer-id.

**Parameters** *policer-id* — The policer-id parameter is required when executing the policer command within the policer-overrides context. The specified policer-id must exist within the sap-ingress or sap-egress QoS policy applied to the SAP. If the policer is not currently used by any forwarding class or forwarding type mappings, the policer will not actually exist on the SAP. This does not preclude creating an override context for the policer-id.

**create** — The create keyword is required when a policer policer-id override node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit confirmation, the create keyword is not required.

## cbs

**Syntax** **cbs size [bytes | kilobytes]**  
**no cbs**

**Context** config>service>vpls>sap>egress>policer-override  
config>service>vpls>sap>ingress>policer-override

**Description** This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured CBS parameter for the specified policer-id.

The **no** form of this command returns the CBS size to the default value.

**Default** no cbs

**Parameters** *size-in-kbytes* — This parameter is required when specifying mbs override and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional **byte** and **kilobyte** keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.

**Values** 0 to 16777216 or default

## mbs

**Syntax** **mbs {size [bytes | kilobytes] | default}**  
**no mbs**

**Context** config>service>vpls>sap>egress>policer-override>policer  
config>service>vpls>sap>ingress>policer-override>policer

**Description** This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured mbs parameter for the specified policer-id.

The **no** form of the command restores the policer's mbs setting to the policy defined value.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured packet-byte-offset parameter for the specified policer-id. Packet byte offset settings are not included in the applied rate when (queue) frame based accounting is configured, however the offsets are applied to the statistics.</p> <p>The <b>no</b> form of the command restores the policer's packet-byte-offset setting to the policy defined value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Default</b>     | no packet-byte-offset                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><b>add</b> <i>add-bytes</i> — The add keyword is mutually exclusive to the subtract keyword. Either add or subtract must be specified. When add is defined the corresponding bytes parameter specifies the number of bytes that is added to the size each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is increased by the amount being added to the size of each packet.</p> <p><b>Values</b> 1 to 31</p> <p><b>subtract</b> <i>sub-bytes</i> — The subtract keyword is mutually exclusive to the add keyword. Either add or subtract must be specified. When subtract is defined the corresponding bytes parameter specifies the number of bytes that is subtracted from the size of each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is reduced by the amount being subtracted from the size of each packet.</p> <p><b>Values</b> 1 to 64</p> |

| <b>Description</b> | <p>This command within the SAP ingress and egress policer-overrides contexts is used to override the sap-ingress and sap-egress QoS policy configured rate parameters for the specified policer-id.</p> <p>The <b>no</b> form of the command restores the policy defined metering and profiling rate to a policer.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><b>{rate   max}</b> — Specifying the keyword <b>max</b> or an explicit kilobits per second parameter directly following the rate override command is required and identifies the policer instance's metering rate for the PIR leaky bucket. The kilobits per second value must be expressed as an integer and defines the rate in kilobits per second. The integer value is multiplied by 1,000 to derive the actual rate in bits per second. When <b>max</b> is specified, the maximum policer rate used will be equal to the maximum capacity of the card on which the policer is configured. If the policer rate is set to a value larger than the maximum rate possible for the card, then the PIR used is equivalent to <b>max</b>.</p> <p><b>Values</b> 1 to 2000000000, <b>max</b></p> <p><b>cir {max   rate}</b> — The optional <b>cir</b> keyword is used to override the policy derived profiling rate of the policer. Specifying the keyword <b>max</b> or an explicit kilobits per second parameter directly following the <b>cir</b> keyword is required. The kilobits per second value must be expressed as an integer and defines the rate in kilobits per second. The integer value is multiplied by 1,000 to derive the actual rate in bits per second. When <b>max</b> is specified, the maximum policer rate used will be equal to the maximum capacity of the card on which the policer is configured. If the policer rate is set to a value larger than the maximum rate possible for the card, then the CIR used is equivalent to <b>max</b>.</p> <p><b>Values</b> 0 to 2000000000, <b>max</b></p> |

## stat-mode

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | The SAP-egress QoS policy's policer stat-mode command is used to configure the forwarding plane counters that allow offered, output and discard accounting to occur for the policer. A policer has multiple types of offered packets (for example, soft in-profile and out-of-profile from ingress and hard in-profile and out-of-profile due to egress profile overrides) and each of these offered types is interacting with the policers metering and profiling functions resulting |

in colored output packets (green, yellow and red). Due to the potential large number of egress policers, it is not economical to allocate counters in the forwarding plane for all possible offered packet types and output conditions. Many policers will not be configured with a CIR profiling rate and not all policers will receive explicitly re-profiled offered packets. The stat-mode command allows provisioning of the number of counters each policer requires and how the offered packet types and output conditions should be mapped to the counters.

While a no-stats mode is supported which prevents any packet accounting, the use of the policer's parent command requires that the policer's stat-mode to be set at least to the minimal setting so that offered stats are available for the policer's Fair Information Rate (FIR) to be calculated.

Each time the policer's stat-mode is changed, any previous counter values are lost and any new counters are set to zero.

Each mode uses a certain number of counters per policer instance that are allocated from the forwarding plane's policer counter resources. You can view the total/allocated/free stats by using the **tools dump system-resources** command. If insufficient counters exist to implement a mode on any policer instance, the stat-mode change will fail and the previous mode will continue unaffected for all instances of the policer.

The default stat-mode when a policer is created within the policy is minimal.

The stat-mode setting defined for the policer in the QoS policy may be overridden on a SAP where the policy is applied. If insufficient policer counter resources exist to implement the override, the stat-mode override command will fail. The previous stat-mode setting active for the policer will continue to be used by the policer.

The **no** form of the command returns the policer's stat-mode setting to minimal.

Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Quality of Service Guide* for detailed information about the **policer stat-mode** command parameters.

## qos

| <b>Context</b>     | config>service>vpls>sap>ingress                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP).<br><br>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the policy-id does not exist, an error will be returned. |

The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a specified type will return an error.

When an ingress QoS policy is defined on IES ingress IP interface that is bound to a VPLS, the policy becomes associated with every SAP on the VPLS and augments the QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPLS SAP; packets that are routed will be processed using the policy defined in the IES IP interface-binding context.

By default, if no specific QoS policy is associated with the SAP for ingress or egress, the default QoS policy is used.

The no form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.

**Default** none

**Parameters** *policy-id* — The ingress policy ID to associate with SAP or IP interface on ingress. The policy ID must already exist.

**Values** 1 to 65535

**shared-queuing** — This keyword can only be specified on SAP ingress. Specify the ingress shared queue policy used by this SAP. When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.

**multipoint-shared** — This keyword can only be specified on SAP ingress. Multipoint shared queuing is a superset of shared queuing. When multipoint shared queuing keyword is set, as well as the unicast packets, multipoint packets also used shared queues.

Ingress unicast service queues are mapped one-for-one with hardware queues and unicast packets traverse the ingress forwarding plane twice, similar to the shared-queuing option. In addition, the multipoint queues defined in the ingress SAP QoS policy are not created. Instead, multipoint packets (broadcast, multicast and unknown unicast destined) are treated to the same dual pass ingress forwarding plane processing as unicast packets.

When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.

When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.

**Values** Multipoint or not present

**Default** Present (the queue is created as non-multipoint)

**fp-redirect-group** — Creates an instance of a named queue group template on the ingress forwarding plane of a specified IOM/IMM/XMA. The queue-group-name and instance-id are mandatory parameters when executing the command. The named queue group template can contain only policers. If it contains queues, then the command will fail.

**queue-group-name** — Specifies the name of the queue group template to be instantiated on the forwarding plane of the IOM/IMM/XMA, up to 32 characters in length. The queue-group-name must correspond to a valid ingress queue group template name, configured under config>qos>queue- group-templates.

**instance-id** — Specifies the instance of the named queue group to be created on the IOM/IMMXMA ingress forwarding plane.

## qos

| <b>Context</b>     | config>service>vpls>sap>egress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an egress Service Access Point (SAP).</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the policy-id does not exist, an error will be returned.</p> <p>The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a specified type will return an error.</p> <p>When an egress QoS policy is associated with an IES IP interface that has been bound to a VPLS, the policy becomes associated with every SAP on the VPLS and augments the egress QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPLS SAP; packets that are routed will be processed using the policy defined in the IES IP interface- binding context.</p> <p>By default, if no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.</p> <p>The <b>no</b> form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> |

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case the configuration of the adaptation rule is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Default</b>    | no adaptation-rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b> | <p><b>pir</b> — This parameter defines the constraints enforced when adapting the PIR rate defined within the <b>queue queue-id rate</b> command. The <b>pir</b> parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the <b>rate</b> command is not specified, the default applies.</p> <p><b>cir</b> — This parameter defines the constraints enforced when adapting the CIR rate defined within the <b>queue queue-id rate</b> command. The <b>cir</b> parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the <b>cir</b> parameter is not specified, the default constraint applies.</p> <p><b>adaptation-rule</b> — Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset</p> <p><b>Values</b></p> <p><b>max</b> — This keyword is mutually exclusive with the <b>min</b> and <b>closest</b> options. When <b>max</b> is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the <b>rate</b> command.</p> <p><b>min</b> — This keyword is mutually exclusive with the <b>max</b> and <b>closest</b> options. When <b>min</b> is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the <b>rate</b> command.</p> <p><b>closest</b> — This is mutually exclusive with the <b>min</b> and <b>max</b> parameter. When <b>closest</b> is defined, the operational PIR for the queue will be the rate closest to the rate specified using the <b>rate</b> command.</p> |

## avg-frame-overhead

|                |                                                                          |
|----------------|--------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>avg-frame-overhead</b> <i>percent</i><br><b>no avg-frame-overhead</b> |
| <b>Context</b> | config>service>vpls>sap>egress>queue-override>queue                      |

**Description** This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- Offered-load — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- Frame encapsulation overhead — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be  $10000 \times 0.1$  or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be  $50 \times 20$  or 1000 octets.

- Frame based offered-load — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- Packet to frame factor — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- Frame based CIR — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.
- Frame based within-cir offered-load — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue’s frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler’s within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue’s configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be 7500 x 1.1 or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to calculate the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

**SAP and subscriber SLA-profile average frame overhead override** — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

**Parameters** *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

**Values** 0 to 100

burst-limit

**Syntax** burst-limit {default | size [bytes | kilobytes]}

**no burst-limit**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>The queue <b>burst-limit</b> command defines an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.</p> <p>The <b>no</b> form of this command restores the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies. When specified within a queue-override queue context, any current burst limit override for the queue is removed and the queue's burst limit is controlled by its defining policy.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>     | no burst-limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>default</b> — Reverts the queue's burst limit to the system default value.</p> <p><b>size</b> — When a numeric value is specified (size), the system interprets the value as an explicit burst limit size. The value is expressed as an integer and by default is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the <b>bytes</b> qualifier must be added following size.</p> <p><b>Values</b>      1 to 13671 kilobytes<br/>                  1 to 14000000 bytes</p> <p><b>Default</b>      No default for size; use the <b>default</b> keyword to specify default burst limit.</p> <p><b>bytes</b> — Specifies that the value given for size must be interpreted as the burst limit in bytes.</p> <p><b>kilobytes</b> — Specifies that the value given for size must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is <b>kilobytes</b>.</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's CBS parameters.</p> <p>It is permissible to oversubscribe the total CBS reserved buffers for a specified access port egress buffer pool. Over-subscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.</p> |

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

The **no** form of this command returns the CBS to the default value.

|                   |                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no cbs                                                                                                                                                                                                                                                                      |
| <b>Parameters</b> | <i>size-in-kbytes</i> — Specifies the number of kilobytes reserved for the queue. For a value of 10 kbytes, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimum reserved size can be applied for scheduling purposes). |
| <b>Values</b>     | 0 to 131072 or default                                                                                                                                                                                                                                                      |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command overrides the low queue drop tail as a percentage reduction from the MBS of the queue. For example, if a queue has an MBS of 600 kbytes and the percentage reduction is configured to be 30% for the low drop tail, then the low drop tail will be at 420 kbytes and out-of-profile packets are not accepted into the queue if the queue depth is greater than the low drop tail value, and so will be discarded. |
| <b>Parameters</b>  | <i>percent</i> — Specifies the percentage reduction from the MBS for a queue drop tail.<br><b>Values</b> 0 to 100, default                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command overrides specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.</p> <p>The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting correct CBS parameters and controlling CBS over-subscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The <b>no</b> form of this command returns the MBS assigned to the queue to the default setting.</p> |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>size</i> — The size parameter is required when specifying <b>mbs</b> and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional <b>bytes</b> and <b>kilobytes</b> keywords are mutually exclusive and are used to explicitly define whether the size represents bytes or kilobytes.</p> <p><b>Values</b> 0 to 1073741824<br/>default</p> <p><b>bytes</b> — When <b>byte</b> is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p> <p><b>kilobytes</b> — When <b>kilobytes</b> is defined, the value is interpreted as the queue's MBS value given in kilobytes.</p> <p><b>default</b> — Specifying the keyword <b>default</b> sets the MBS to its default value.</p>                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>vpls>sap>ingress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command overrides specific attributes of the specified queue's MBS parameters. The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueueing packets. Once the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.</p> <p>The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS is not guaranteed that a buffer will be available when needed or that the packets RED slope will not force the discard of the packet. Setting correct CBS parameters and controlling CBS over-subscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The <b>no</b> form of this command returns the MBS assigned to the queue to the default value.</p> |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>size</b> — The size parameter is required when specifying mbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional <b>bytes</b> and <b>kilobytes</b> keywords are mutually exclusive and are used to explicitly define whether the size represents bytes or kilobytes.</p> <p><b>Values</b>      0 to 1073741824<br/>                 default</p> <p><b>bytes</b> — When <b>byte</b> is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p> <p><b>kilobytes</b> — When <b>kilobytes</b> is defined, the value is interpreted as the queue's MBS value given in kilobytes.</p> <p><b>default</b> — Specifying the keyword <b>default</b> sets the MBS to its default value.</p>                                                                                                                                                                                                                                                                                                                                                                                  |

## parent

|                |                                                                                                             |
|----------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>parent</b> {[ <b>weight</b> <i>weight</i> ] [ <b>cir-weight</b> <i>cir-weight</i> ]}<br><b>no parent</b> |
| <b>Context</b> | config>service>vpls>sap>egress>queue-override>queue<br>config>service>vpls>sap>ingress>queue-override>queue |

**Description** This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers and/or queues share a child status with the parent scheduler, the **weight** or **level** parameters define how this queue contends with the other children for the parent's bandwidth.

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the **config>qos>scheduler-policy>tier level** context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multi-service customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The orphaned state must generate a log entry and a trap message. The SAP which the queue belongs to must also depict an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state mentioned above and automatically return to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of the command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. Once a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

**Parameters** *weight* — These optional keywords are mutually exclusive to the **level** keyword. The weight defines the relative weight of this queue in comparison to other child schedulers, policers, and queues while vying for bandwidth on the parent *scheduler-name*. Any policers, queues, or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active policers, queues, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the policer, queue, or scheduler. A weight is considered to be active when the pertaining policer, queue, or scheduler has not reached its maximum rate and still has packets to transmit. All child policers, queues, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted policers, queues, and schedulers at that level are operating at the maximum bandwidth or are idle.

**Values** 0 to 100

**Default** 1

*cir-weight* — Defines the weight the queue or scheduler will use at the within-cir port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the policer, queue, or scheduler does not receive bandwidth during the port schedulers within-cir pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

**Values** 0 to 100

## percent-rate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | The <b>percent-rate</b> command supports a queue's shaping rate and CIR rate as a percentage of the egress port's line rate. When the rates are expressed as a percentage within the template, the actual rate used per instance of the queue group queue-id will vary based on the port speed. For example, when the same template is used to create a queue group on a 1-Gb and a 10-Gb Ethernet port, the queue's rates will be 10 times greater on the 10-Gb port due to the difference in port speeds. This enables the same template to be used on multiple ports without needing to use port based queue overrides to modify a queue's rate to get the same relative performance from the queue. |

If the port's speed changes after the queue is created, the queue's shaping and CIR rates will be recalculated based on the defined percentage value.

The **rate** and **percent-rate** commands override one another. If the current rate for a queue is defined using the percent-rate command and the **rate** command is executed, the percent-rate values are deleted. In a similar fashion, the **percent-rate** command causes any **rate** command values to be deleted. A queue's rate may dynamically be changed back and forth from a percentage to an explicit rate at any time.

An egress port queue group queue rate override may be expressed as either a percentage or an explicit rate independent on how the queue's template rate is expressed.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case the configuration of the **percent-rate** is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of this command returns the queue to its default shaping **rate** and **cir** rate. When **no percent-rate** is defined within a port egress queue group queue override, the queue reverts to the defined shaping and CIR rates within the egress queue group template associated with the queue.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | <p>config&gt;service&gt;vpls&gt;sap&gt;egress&gt;queue-override&gt;queue</p> <p>config&gt;service&gt;vpls&gt;sap&gt;ingress&gt;queue-override&gt;queue</p> <p>config&gt;service&gt;vpls&gt;sap&gt;egress&gt;hsmda-queue-over&gt;queue</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.</p> <p>The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by over-subscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile and then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> |

The CIR can be used by the queue's parent commands *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case, the configuration of the **rate** is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

**Default** rate max cir 0

**Parameters** *pir-rate* — Defines the administrative PIR rate, in kilobits, for the queue. When the **rate** command is executed, a valid PIR setting must be explicitly defined. When the **rate** command has not been executed, the default PIR of **max** is assumed.

Fractional values are not allowed and must be given as a positive integer.

The actual PIR rate is dependent on the queue's **adaptation-rule** parameters and the actual hardware where the queue is provisioned.

For **egress>queue-override>queue** and **ingress>queue-override>queue**:

**Values** 1 to 2000000000, **max** in kb/s

**Default** max

For **egress>hsmda-queue-over>queue**:

**Values** 1 to 1000000000, **max** in kb/s

**Default** max

*cir cir-rate* — The **cir** parameter overrides the default administrative CIR used by the queue. When the **rate** command is executed, a CIR setting is optional. When the **rate** command has not been executed or the **cir** parameter is not explicitly specified, the default CIR (0) is assumed.

Fractional values are not allowed and must be given as a positive integer. The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers, policers, or queues.

For **egress>queue-override>queue** and **ingress>queue-override>queue**:

**Values** 0 to 2000000000, **max** in kb/s

**Default** 0

## queue-override

**Syntax** [no] queue-override

**Context** config>service>vpls>sap>egress

```
config>service>vpls>sap>ingress
config>service>vpls>sap>egress>hsmda-queue-over>queue
config>service>vpls>sap>ingress>hsmda-queue-over>queue
```

**Description** This command enters the context to configure override values for the specified SAP egress or ingress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy.

## queue

**Syntax** **[no] queue** *queue-id*

**Context** config>service>vpls>sap>egress>queue-override  
config>service>vpls>sap>ingress>queue-override

**Description** This command specifies the ID of the queue whose parameters are to be overridden.

**Parameters** *queue-id* — Specifies the queue ID whose parameters are to be overridden

**Values** 1 to 32

## adaptation-rule

**Syntax** **adaptation-rule** [*pir adaptation-rule*] [*cir adaptation-rule*]  
**no adaptation-rule**

**Context** config>service>vpls>sap>egress>queue-override>queue  
config>service>vpls>sap>ingress>queue-override>queue

**Description** This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case the configuration of the adaptation rule is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

**Default** no adaptation-rule

**Parameters** **pir** — This parameter defines the constraints enforced when adapting the PIR rate defined within the **queue queue-id rate** command. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **rate** command is not specified, the default applies.

**cir** — This parameter defines the constraints enforced when adapting the CIR rate defined within the **queue queue-id rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

**adaptation-rule** — Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset.

**Values**

**max** — This keyword is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.

**min** — This keyword is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.

**closest** — This is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue will be the rate closest to the rate specified using the **rate** command.

| <b>Context</b>     | config>service>vpls>sap>egress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap). |

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be  $50 \times 20$  or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.
- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be  $7500 \times 1.1$  or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

Port scheduler operation using frame transformed rates — The port scheduler uses the frame based rates to calculate the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

**Parameters** *percent* — Sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

**Values** 0 to 100

cbs

**Syntax** **cbs** *size-in-kbytes*  
**no cbs**

**Context** config>service>vpls>sap>egress>queue-override>queue  
config>service>vpls>sap>ingress>queue-override>queue

**Description** This command can be used to override specific attributes of the specified queue's CBS parameters.

It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a specified access port egress buffer pool. Over-subscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

The **no** form of this command returns the CBS size to the default value.

**Default** no cbs

**Parameters** *size-in-kbytes* — Specifies an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is needed, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).

**Values** 0 to 131072 or default

## mbs

**Syntax** **mbs** {*size* [**bytes** | **kilobytes**] | **default**}  
**no mbs**

**Context** config>service>vpls>sap>egress>queue-override>queue

**Description** This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.

The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting correct CBS parameters and controlling CBS over-subscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

The **no** form of this command returns the MBS size assigned to the queue.

**Default** default

**Parameters** *size* — The size parameter is required when specifying mbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional **bytes** and **kilobytes** keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.

**Values** 0 to 1073741824  
default

**bytes** — When **bytes** is defined, the value given for size is interpreted as the queue's MBS value given in bytes.

**kilobytes** — When **kilobytes** is defined, the value is interpreted as the queue's MBS value given in kilobytes.

**default** — Specifying the keyword **default** sets the MBS to its default value.

## mbs

Setting correct CBS parameters and controlling CBS over-subscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The <b>no</b> form of this command returns the MBS size assigned to the queue to the default value.</p> |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>size</i> — The size parameter is required when specifying mbs and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional <b>bytes</b> and <b>kilobytes</b> keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p><b>Values</b>      0 to 1073741824<br/>                 default</p> <p><b>bytes</b> — When <b>bytes</b> is defined, the value given for size is interpreted as the queue's MBS value given in bytes.</p> <p><b>kilobytes</b> — When <b>kilobytes</b> is defined, the value is interpreted as the queue's MBS value given in kilobytes.</p> <p><b>default</b> — Specifying the keyword <b>default</b> sets the MBS to its default value.</p>                                                                                                                                                                                                                                                                                                                                                                                                             |

## rate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.</p> <p>The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by over-subscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile and then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue's parent commands <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> <p>The <b>rate</b> command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the <i>queue-id</i>.</p> <p>The <b>no</b> form of the command returns all queues created with the <i>queue-id</i> by association with the QoS policy to the default PIR and CIR parameters (<b>max</b>, 0).</p> |
| <b>Default</b>     | rate max cir 0                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the <b>rate</b> command is executed, a valid PIR setting must be explicitly defined. When the <b>rate</b> command has not been executed, the default PIR of <b>max</b> is assumed. Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's <b>adaptation-rule</b> parameters and the actual hardware where the queue is provisioned.</p> <p><b>Values</b> 1 to 100000000</p> <p><b>Default</b> max</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

*cir cir-rate* — Overrides the default administrative CIR used by the queue. When the **rate** command is executed, a CIR setting is optional. When the **rate** command has not been executed or the **cir** parameter is not explicitly specified, the default CIR (0) is assumed.

Fractional values are not allowed and must be given as a positive integer. The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers, policers, or queues.

**Values** 0 to 1000000000, **max**, **sum**

**Default** 0

| <b>Description</b> | This command can be used to override specific attributes of the specified scheduler name. A scheduler defines a bandwidth controls that limit each child (other schedulers, policers, and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have policers, queues or other schedulers defined as child associations. The scheduler can be a child which takes bandwidth from a scheduler in a higher tier. A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers. |

Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If *scheduler-name* already exists within the policy tier level (regardless of the inclusion of the keyword **create**), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause policers, queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).

If the *scheduler-name* exists within the policy on a different tier (regardless of the inclusion of the keyword **create**), an error occurs and the current CLI context will not change.

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

**Step 1.** The maximum number of schedulers has not been configured.

**Step 2.** The provided *scheduler-name* is valid.

**Step 3.** The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.

**Parameters** *scheduler-name* — Specifies the name of the scheduler.

**Values** Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.

**Default** None. Each scheduler must be explicitly created.

**create** — Specifies that it is acceptable to create a scheduler with the given *scheduler-name*. If the **create** keyword is omitted, **scheduler-name** is not created when the system environment variable **create** is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists.

| <b>Context</b>     | config>service>vpls>sap>ingress>sched-override>scheduler<br>config>service>vpls>sap>egress>sched-override>scheduler                                                                                                                                                                                                     |
| <b>Description</b> | This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site. |

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.

The **no** form of the command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Default</b>    | no parent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b> | <p><b>weight</b> — Defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict <b>level</b> defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue, or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.</p> <p>A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.</p> <p><b>Values</b> 0 to 100</p> <p><b>cir-weight</b> — Specifies the relative weight of this scheduler in comparison to other child schedulers and queues at the same <i>cir-level</i> defined by the <b>cir-level</b> parameter in the applied scheduler policy. Within the strict <b>cir-level</b>, all <b>cir-weight</b> values from active children at that level are summed and the ratio of each active child's <b>cir-weight</b> to the total is used to distribute the available bandwidth at that level. A <b>cir-weight</b> is considered to be active when the policer, queue, or scheduler that the <b>cir-weight</b> pertains to has not reached the CIR and still has packets to transmit.</p> <p>A 0 (zero) <b>cir-weight</b> value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.</p> <p><b>Values</b> 0 to 100</p> |

## rate

|                |                                                                                                                     |
|----------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>rate</b> <i>pir-rate</i> [ <b>cir</b> <i>cir-rate</i> ]<br><b>no rate</b>                                        |
| <b>Context</b> | config>service>vpls>sap>egress>sched-override>scheduler<br>config>service>vpls>sap>ingress>sched-override>scheduler |

**Description** This command can be used to override specific attributes of the specified scheduler rate. The **rate** command defines the maximum bandwidth that the scheduler can offer its child policers, queues, or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase.

The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child policers, queues, and schedulers to operate at their maximum rates.

The **no** form of this command returns the scheduler's PIR and CIR parameters to the value configured in the applied scheduler policy.

**Parameters** *pir-rate* — Specifies a value of 1 to 3200000000, or the keyword **max**. Any other value will result in an error without modifying the current PIR rate.

**Values** 1 to 3200000000, **max**

*cir* *cir-rate* — Specifies a value of 0 to 3200000000, or the keyword **max** or **sum**. Any other value will result in an error without modifying the current CIR rate.

If **cir** is set to max, then the CIR rate is set to infinity, but bounded by the PIR rate.

The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers, policers or queues.

**Values** 0 to 3200000000, **max**, **sum**

## scheduler-policy

**Syntax** **scheduler-policy** *scheduler-policy-name*  
**no scheduler-policy**

**Context** config>service>vpls>sap>ingress  
config>service>vpls>sap>egress

**Description** This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues and, at egress only, policers associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created after the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the **config>qos>scheduler-policy** *scheduler-policy-name* context.

The **no** form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the SAP policers and queues associated with the customer site. Policers and queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have policers or queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more policers or queues. When the **no scheduler-policy** command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.

**Parameters** *scheduler-policy-name*: — Applies an existing scheduler policy that was created in the **config>qos>scheduler-policy scheduler-policy-name** context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.

**Values** Any existing valid scheduler policy name.

## match-qinq-dot1p

**Syntax** **match-qinq-dot1p {top | bottom}**  
**no match-qinq-dot1p de**

**Context** config>service>vpls>sap>ingress

**Description** This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

The setting also applies to classification based on the DE indicator bit.

The **no** form of this command reverts the dot1p and de bits matching to the default tag.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. [Table 38](#) defines the default behavior for Dot1P evaluation.

**Table 38** Default QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| Null            | None                 | None                 |
| Null            | Dot1P (VLAN ID 0)    | Dot1P PBits          |
| Null            | Dot1Q                | Dot1Q PBits          |
| Null            | TopQ BottomQ         | TopQ PBits           |

**Table 38 Default QinQ and TopQ SAP Dot1P Evaluation (Continued)**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Default** no match-qinq-dot1p (no filtering based on p-bits)  
(top or bottom must be specified to override the default QinQ dot1p behavior)

**Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. The following table defines the dot1p evaluation behavior when the top parameter is specified.

**Table 39 Top Position QinQ dot1P Evaluation Behavior**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | None                          | None                 |
| Null            | Dot1P (VLAN ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | TopQ PBits           |

**bottom** — The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. The following table defines the dot1p evaluation behavior when the bottom parameter is specified; see [Table 40](#).

**Table 40 Bottom Position QinQ and TopQ SAP Dot1P Evaluation**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | None                          | None                 |
| Null            | Dot1P (VLAN ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Table 41 Egress SAP Types**

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| Null            | No preserved Dot1P bits                               | None                                                         |
| Null            | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | No preserved Dot1P bits                               | New PBits marked using dot1p-value                           |
| Dot1Q           | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| TopQ            | No preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |

**Table 41 Egress SAP Types (Continued)**

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                            |
|-----------------|-------------------------------------------------------|-------------------------------------------------------|
| QinQ            | No preserved Dot1P bits                               | TopQ PBits and BottomQ PBits marked using dot1p-value |
| QinQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits and BottomQ PBits marked using dot1p-value |

The QinQ and TopQ SAP PBit/DEI bit marking follows the default behavior defined in the table above when **qinq-mark-top-only** is not specified.

The dot1p *dot1p-value* command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

A QinQ-encapsulated Ethernet port can have two different sap types:

For a TopQ SAP type, only the outer (top) tag is explicitly specified. For example, **sap 1/1/1:10.\***

For QinQ SAP type, both inner (bottom) and outer (top) tags are explicitly specified. For example, **sap 1/1/1:10.100**.

## authentication-policy

|                    |                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-policy</b> <i>name</i><br><b>no authentication-policy</b>                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                      |
| <b>Description</b> | This command defines which subscriber authentication policy must be applied when a DHCP message is received on the interface. The authentication policies must already be defined. The policy will only be applied when DHCP snooping is enabled on the SAP. |

## bandwidth

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bandwidth</b> <i>bandwidth</i><br><b>no bandwidth</b>                                                        |
| <b>Context</b>     | config>service>vpls>sap                                                                                         |
| <b>Description</b> | This command specifies the admin bandwidth assigned to SAPs, ports and LAGs which is used by SAP bandwidth CAC. |

SAP: Attempts to increase the SAP admin bandwidth will fail if there is insufficient available admin bandwidth on its port or LAG, otherwise the port or LAG available admin bandwidth will be reduced by the incremental SAP admin bandwidth. Reducing the SAP admin bandwidth will increase the available admin bandwidth on its port or LAG. This is not supported for PW-SAPs, Ethernet tunnels or subscriber group interface SAPs.

The **no** version of the command reverts to the default value.

|                   |                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Default</b>    | no bandwidth                                                                                |
| <b>Parameters</b> | <i>bandwidth</i> — Specifies the admin bandwidth assigned to the SAP, port or LAG, in kb/s. |
| <b>Values</b>     | 1 to 3200000000                                                                             |

| <b>Description</b> | <p>This command enables accounting and statistical data collection for either the SAP or SDP, network port, or IP interface. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.</p> <p>When the <b>no collect-stats</b> command is issued the statistics are still accumulated by the IOM or XCM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent <b>collect-stats</b> command is issued then the counters written to the billing file include all the traffic while the <b>no collect-stats</b> command was in effect.</p> |
| <b>Default</b>     | no collect-stats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] control-channel-status</b>                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpls>spoke-sdp                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command enables the configuration of static pseudowire status signaling on a spoke SDP for which signaling for its SDP is set to OFF.</p> <p>A control-channel-status <b>no shutdown</b> is allowed only if all of the following are true:</p> |

- SDP signaling is off.
- The control-word is enabled (the control-word is disabled by default)
- The service type is Epipe, Apipe, VPLS, Cpipe, or IES/VRN
- Mate SDP signaling is off (in vc-switched services)
- The pw-path-id is configured for this spoke SDP.

The **no** form of this command removes control channel status signaling from a spoke SDP. It can only be removed if control channel status is shut down.

**Default** no control-channel-status

## acknowledgment

**Syntax** [no] acknowledgment

**Context** config>service>vpls>spoke-sdp>control-channel-status

**Description** This command enables the acknowledgment of control channel status messages. By default, no acknowledgment packets are sent.

## refresh-timer

**Syntax** refresh-timer *value*  
no refresh-timer

**Context** config>service>vpls>spoke-sdp>control-channel-status

**Description** This command configures the refresh timer for control channel status signaling packets. By default, no refresh packets are sent.

**Default** no refresh-timer

**Parameters** *value* — Specifies the refresh timer value, in seconds.

|                |             |
|----------------|-------------|
| <b>Values</b>  | 10 to 65535 |
| <b>Default</b> | 0 (off)     |

## request-timer

**Syntax** request-timer *timer1* retry-timer *timer2* timeout-multiplier *multiplier*  
no request-timer

**Context** config>service>vpls>spoke-sdp>control-channel-status

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures the control channel status request mechanism. When it is configured, control channel status request procedures are used. These augment the procedures for control channel status messaging from RFC 6478, <i>Pseudowire Status for Static Pseudowires</i> . This command cannot be used with a non-zero refresh-timer value.                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>timer1</i> — Specifies the interval, in seconds, at which pseudowire status messages, including a reliable delivery TLV with the “request” bit set, are sent.</p> <p><b>Values</b> 10 to 65535</p> <p><i>timer2</i> — specifies the timeout interval, in seconds, if no response to a pseudowire status request is received. This parameter must be configured. A value of zero (0) disables retries.</p> <p><b>Values</b> 0, 3 to 60</p> <p><i>multiplier</i> — If a requesting node does not receive a valid response to a pseudowire status request within a number of seconds equal to the retry timer multiplied by this multiplier, then it will assume the pseudowire is down. This parameter is optional.</p> <p><b>Values</b> 3 to 20</p> |

## control-word

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>The control word command provides the option to add a control word as part of the packet encapsulation for pseudowire types for which the control word is optional. These are Ethernet pseudowires (Epipe). For the 7750 SR only, ATM N:1 cell mode pseudowires (apipe vc-types atm-vcc and atm-vpc) and VT pseudowire (apipe vc-type atm-cell).</p> <p>The configuration for the two directions of the pseudowire must match because the control word negotiation procedures described in Section 6.2 of RFC 4447 are not supported. The C-bit in the pseudowire FEC sent in the label mapping message is set to 1 when the control word is enabled. Otherwise, it is set to 0.</p> <p>The service will only come up if the same C-bit value is signaled in both directions. If a spoke-sdp is configured to use the control word but the node receives a label mapping message with a C-bit clear, the node releases the label with the an “Illegal C-bit” status code as per Section 6.1 of RFC 4447. As soon as the user also enabled the control the remote peer, the remote peer will withdraw its original label and will send a label mapping with the C-bit set to 1 and the VLL service will be up in both nodes. The control word must be enabled to allow MPLS-TP OAM to be used on a static spoke-sdp in a Apipe, Epipe and Cpipe service.</p> |

| <b>Description</b> | <p>This command is used to create a vpls-template to be used to auto-instantiate a range of VPLS services. Only certain existing VPLS attributes specified in the command reference section can be changed in the vpls-template, not in the instantiated VPLS. The following attributes will be automatically set in the instantiated VPLSs (no template configuration necessary) and the operator cannot change these values.</p> <p>vpn-id: none</p> <p>description: "Service &lt;svc id&gt; auto-generated by control VPLS &lt;svc-id&gt;"</p> <p>service-name: "Service &lt;svc id&gt;" (Auto-generated)</p> <p>shutdown: no shutdown</p> <p>Following existing attributes can be set by the user in the instantiated VPLSs:</p> <p>[no] sap</p> <p>All the other VPLS attributes are not supported.</p> |               |                    |               |                       |
| <b>Parameters</b>  | <p><i>name/id</i> — Specifies the name in ASCII or the template ID</p> <table> <tr> <td><b>Values</b></td><td>name: ASCII string</td></tr> <tr> <td><b>Values</b></td><td>ID: [1 to 2147483647]</td></tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           | <b>Values</b> | name: ASCII string | <b>Values</b> | ID: [1 to 2147483647] |
| <b>Values</b>      | name: ASCII string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |               |                    |               |                       |

| <b>Description</b> | The temporary flooding is designed to minimize failover times by eliminating the time it takes to flush the MAC tables and if MVRP is enabled the time it takes for MVRP registration. Temporary flooding is initiated only upon xSTP TCN reception. During this procedure while the MAC flush takes place the frames received on one of the VPLS SAPs/pseudowires are flooded in a VPLS context which for MVRP case includes also the unregistered MVRP trunk ports. The MAC Flush action is initiated by the STP TCN reception or if MVRP is enabled for the data VPLS, by the reception of a MVRP New message for the SVLAN ID associated with the data VPLS. As soon as the MAC Flush is done, regardless of whether the temp-flooding timer expired or not, traffic will be delivered according to the regular FDB content which may be built from MAC Learning or based on MVRP registrations. This command provides a flood-time value that configures a fixed amount of time, in seconds, during which all traffic is flooded (BUM or known unicast) as a safety mechanism. Once the flood-time expires, traffic will be |

delivered according to the regular FDB content which may be built from MAC Learning or based on MVRP registrations. The temporary flooding timer should be configured in such a way to allow auxiliary processes like MAC Flush, MMRP and/or MVRP to complete/converge. The temporary flooding behavior applies to regular VPLS, VPLS instantiated with VPLS-template, IVPLS and BVPLS when MMRP is disabled.

The **no** form of the command disables the temporary flooding behavior.

|                   |                                                          |
|-------------------|----------------------------------------------------------|
| <b>Default</b>    | no temp-flooding                                         |

| <b>Syntax</b>      | <b>inclusive</b>                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vpls>provider-tunnel                                                                                                                                                                                                                                                                     |
| <b>Description</b> | This command creates the context to configure the use of a P2MP LSP as the default tree for forwarding Broadcast, Unicast unknown, and Multicast (BUM) packets of a VPLS or B-VPLS instance. The P2MP LSP is referred to, in this case, as the Inclusive Provider Multicast Service Interface (I-PMSI). |

When enabled, this feature relies on BGP Auto-Discovery (BGP-AD) or BGP-VPLS to discover the PE nodes participating in a specified VPLS/B-VPLS instance. The AD route contains the information required to signal both the point-to-point (P2P) PWs used for forwarding unicast known Ethernet frames and the RSVP or mLDP P2MP LSP used to forward the BUM frames.

The root node signals the RSVP P2MP LSP based on an LSP template associated with the I-PMSI at configuration time. The leaf node will join automatically the P2MP LSP, which matches the I-PMSI tunnel information discovered via BGP.

With a mLDP I-PMSI, each leaf node will initiate the signaling of the mLDP P2MP LSP upstream using the P2MP FEC information in the I-PMSI tunnel information discovered via BGP-AD.

If IGMP or PIM snooping are configured on the VPLS instance, multicast packets matching an L2 multicast Forwarding Information Base (FIB) record will also be forwarded over the P2MP LSP.

The user enables the use of an RSVP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS/B-VPLS instance using the following commands:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>rsvp>lsp-template p2mp-lsp-template-name
```

The user enables the use of an LDP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS instance using the following command:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>mldp
```

After the user performs a **no shutdown** under the context of the inclusive node and the expiration of a delay timer, BUM packets will be forwarded over an automatically signaled mLDP P2MP LSP or over an automatically signaled instance of the RSVP P2MP LSP specified in the LSP template.

The user can specify if the node is both root and leaf in the VPLS instance:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>root-and-leaf
```

The **root-and-leaf** command is required otherwise this node will behave as a leaf-only node by default. When the node is leaf only for the I-PMSI of type P2MP RSVP LSP, no PMSI Tunnel Attribute is included in BGP-AD route update messages and therefore no RSVP P2MP LSP is signaled but the node can join RSVP P2MP LSP rooted at other PE nodes participating in this VPLS/B-VPLS service. The user must still configure a LSP template even if the node is a leaf only. For the I-PMSI of type mLDP, the leaf-only node will join I-PMSI rooted at other nodes it discovered but will not include a PMSI Tunnel Attribute in BGP-AD route update messages. This way a leaf-only node will forward packets to other nodes in the VPLS/B-VPLS using the point-to-point spoke-SDPs.

BGP-AD must have been enabled in this VPLS/B-VPLS instance or the execution of the **no shutdown** command under the context of the inclusive node is failed and the I-PMSI will not come up.

Any change to the parameters of the I-PMSI, such as disabling the P2MP LSP type or changing the LSP template requires that the inclusive node be first shutdown. The LSP template is configured in MPLS.

If the P2MP LSP instance goes down, VPLS/B-VPLS immediately reverts the forwarding of BUM packets to the P2P PWs. The user can however restore at any time the forwarding of BUM packets over the P2P PWs by performing a **shutdown** under the context of the inclusive node.

This feature is supported with VPLS, H-VPLS, and B-VPLS. It is not supported with I-VPLS and Routed VPLS.

## data-delay-interval

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>data-delay-interval</b> <i>seconds</i><br><b>no data-delay-interval</b> |
| <b>Context</b>     | config>service>vpls>provider-tunnel>inclusive                              |
| <b>Description</b> | This command configures the I-PMSI data delay timer.                       |

This delay timer is intended to allow time for the RSVP control plane to signal and bring up the S2L sub-LSP to each destination PE participating in the VPLS/B-VPLS service. The delay timer is started as soon as the P2MP LSP instance becomes operationally up after the user performed a 'no shutdown' under the inclusive node, i.e., as soon as the first S2L sub-LSP is up. In general, it is started when the P2MP LSP instance transitions from the operationally down state to the up state.

For a mLDP P2MP LSP, the delay timer is started as soon as the P2MP FEC corresponding to the I-PMSI is resolved and installed at the root node. The user must factor in the value configured in the data-delay-interval at the root node any delay configured in IGP-LDP sync timer (**config>router>if>ldp-sync-timer**) on interfaces over the network. This is because the mLDP P2MP LSP may move to a different interface at the expiry of this timer since the routing upstream of the LDP Label Mapping message may change when this timer expires and the interface metric is restored.

At the expiry of this timer, the VPLS/B-VPLS will begin forwarding of BUM packets over the P2MP LSP instance even if not all the S2L paths are up.

The **no** version of this command re-instates the default value for this delay timer.

|                   |                                                            |
|-------------------|------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — Specifies the delay time value in seconds |
| <b>Values</b>     | 3 to 180                                                   |
| <b>Default</b>    | 15                                                         |

## mldp

|                    |                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mldp</b>                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpls>provider-tunnel>inclusive                                                                                                                                             |
| <b>Description</b> | This command creates the context to configure the parameters of an LDP P2MP LSP used for forwarding Broadcast, Unicast unknown and Multicast (BUM) packets of a VPLS or B-VPLSs instance. |

## root-and-leaf

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] root-and-leaf</b>                                                                                            |
| <b>Context</b>     | config>service>vpls>provider-tunnel>inclusive                                                                        |
| <b>Description</b> | This command configures the node to operate as both root and leaf of the I-PMSI in a specified VPLS/B-VPLS instance. |

By default, a node will behave as a leaf-only node. When the node is leaf only for the I-PMSI of type P2MP RSVP LSP, no PMSI Tunnel Attribute is included in BGP-AD route update messages and therefore no RSVP P2MP LSP is signaled but the node can join RSVP P2MP LSP rooted at other PE nodes participating in this VPLS/B-VPLS service. The user must still configure a LSP template even if the node is a leaf only.

For the I-PMSI of type mLDP, the leaf-only node will join I-PMSI rooted at other nodes it discovered but will not include a PMSI Tunnel Attribute in BGP-AD route update messages. This way a leaf-only node will forward packets to other nodes in the VPLS/B-VPLS using the point-to-point spoke-SDPs.

The **no** version of this command re-instates the default value.

## rsvp

|                    |                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] rsvp</b>                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpls>provider-tunnel>inclusive                                                                                                                                             |
| <b>Description</b> | This command creates the context to configure the parameters of an RSVP P2MP LSP used for forwarding Broadcast, Unicast unknown and Multicast (BUM) packets of a VPLS or B-VPLS instance. |

## lsp-template

|                    |                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lsp-template</b> <i>p2mp-lsp-template-name</i><br><b>no lsp-template</b>                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>provider-tunnel>inclusive>rsvp                                                                                                                                                                                                         |
| <b>Description</b> | This command specifies the template name of the RSVP P2MP LSP instance to be used by the leaf node or the root-and-leaf node that participates in BGP-AD VPLS. The P2MP LSP is referred to as the Inclusive Provider Multicast Service Interface (I-PMSI). |

After the user performs a **no shutdown** under the context of the inclusive node and the delay timer expires, BUM packets will be forwarded over an automatically signaled instance of the RSVP P2MP LSP specified in the LSP template.

The **no** version of this command removes the P2MP LSP template from the I-PMSI configuration.

**Parameters** *p2mp-lsp-template-name* — Specifies the name of the P2MP LSP template up to 32 characters in length.

**Default** None

### 3.7.2.4.4 VPLS SDP Commands

#### mesh-sdp

**Syntax** **mesh-sdp** *sdp-id[:vc-id]* [**vc-type** {**ether** | **vlan**}] [**root-leaf-tag** | **leaf-ac**]  
**no mesh-sdp** *sdp-id[:vc-id]*

**Context** config>service>vpls

**Description** This command binds a VPLS service to an existing Service Distribution Point (SDP). Mesh SDPs bound to a service are logically treated like a single bridge “port” for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke-SDPs and SAPs) and not transmitted on any mesh SDPs.

This command creates a binding between a service and an SDP. The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.

The SDP must already be defined in the **config>service>sdp** context in order to associate the SDP with a valid service. If the **sdp sdp-id** is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

**Default** No *sdp-id* is bound to a service.

**Special Cases** **VPLS** — Several SDPs can be bound to a VPLS. Each SDP must be destined for a different router. If two *sdp-id* bindings terminate on the same router, an error occurs and the second SDP binding is rejected.

**Parameters** *sdp-id* — Specifies the SDP identifier

**Values** 1 to 17407

**vc-id** — Specifies the virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID. Any value may be used for the **vc-id** when there is no existing mesh SDP within the service; if a mesh SDP exists then all other mesh SDPs in the service must be configured with the same **vc-id**.

**Values** 1 to 4294967295

**vc-type** — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the **vc-type** command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the bindings VC type causes the binding to signal the new VC type to the far end when signaling is enabled.

VC types are derived according to IETF *draft-martini-l2circuit-trans-mpls*.

The VC type value for Ethernet is 0x0005.

The VC type value for an Ethernet VLAN is 0x0004.

**ether** — Defines the VC type as Ethernet. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke-SDP binding. (hex 5)

**vlan** — Defines the VC type as VLAN. The top VLAN tag, if a VLAN tag is present, is stripped from traffic received on the pseudowire, and a vlan-tag is inserted when forwarding into the pseudowire. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for mesh SDP bindings.

Note: The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

**root-leaf-tag** — Specifies a tagging mesh SDP under an E-Tree VPLS. When a tag SDP binding is required, it is created with a root-leaf-tag flag. Only VLAN tag SDP bindings are supported. The VLAN type must be set to VC VLAN type. The root-leaf-tag parameter indicates this SDP binding is a tag SDP that will use a default VID 1 for root and 2 for leaf. The SDP binding tags egress E-Tree traffic with root and leaf VIDs as appropriate. Root and leaf VIDs are only significant between peering VPLS but the values must be consistent on each end. On ingress a tag SDP binding removes the VID tag on the interface between VPLS in the same E-Tree service. The tag SDP receives root tagged traffic and marks the traffic with a root indication internally. This option is not available on BGP EVPN-enabled E-Tree services.

**leaf-ac** — Specifies an access (AC) mesh SDP binding under a E-Tree VPLS as a leaf access (AC) SDP. The default E-Tree SDP type is a root-ac if *leaf-ac* or *root-leaf-tag* is not specified at SDP binding creation. This option is only available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services support the **leaf-ac** option.

## spoke-sdp

**Syntax** **spoke-sdp** *sdp-id[:vc-id]* [**vc-type** {**ether** | **vlan**}] [**split-horizon-group** *group-name*]  
endpoint [**no-endpoint**] [**root-leaf-tag** | **leaf-ac**]  
**no spoke-sdp** *sdp-id[:vc-id]*

**Context** config>service>vpls

**Description** This command binds a service to an existing Service Distribution Point (SDP). A spoke-SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke-SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.

The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.

The SDP must already be defined in the **config>service>sdp** context in order to associate an SDP with a VPLS service. If the **sdp sdp-id** is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.

**Default** No *sdp-id* is bound to a service.

**Special Cases** **VPLS** — Several SDPs can be bound to a VPLS service. Each SDP must use unique *vc-ids*. An error message is generated if two SDP bindings with identical *vc-ids* terminate on the same router. Split horizon groups can only be created in the scope of a VPLS service.

**Parameters** *sdp-id* — Specifies the SDP identifier  
**Values** 1 to 17407  
*vc-id* — Specifies the virtual circuit identifier  
**Values** 1 to 4294967295

**vc-type** — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the **vc-type** command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the bindings VC type causes the binding to signal the new VC type to the far end when signaling is enabled.

VC types are derived according to IETF *draft-martini-l2circuit-trans-mpls*.

The VC type value for Ethernet is 0x0005.

The VC type value for an Ethernet VLAN is 0x0004.

**Values** ether, vlan

**ether** — Defines the VC type as Ethernet. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke-SDP binding. (hex 5)

**vlan** — Defines the VC type as VLAN. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings.

The VLAN VC-type inserts one dot1q tag within each encapsulated Ethernet packet transmitted to the far end and strips one dotQ tag, if a tag is present, from traffic received on the pseudowire.

Note: The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

**group-name** — Specifies the name of the split horizon group to which the SDP belongs

**endpoint** — Specifies the service endpoint to which this SDP bind is attached. The service ID of the SDP binding must match the service ID of the service endpoint.

**no endpoint** — Removes the association of a spoke-SDP with an explicit endpoint name

**root-leaf-tag** — Specifies a tagging spoke-SDP under an E-Tree VPLS. When a tag SDP binding is required, it is created with a root-leaf-tag flag. Only VLAN tag SDP bindings are supported. The VLAN type must be set to VC VLAN type. The root-leaf-tag parameter indicates this SDP binding is a tag SDP that will use a default VID tag of 1 for root and 2 for leaf. The SDP binding tags egress E-Tree traffic with root and leaf VIDs as appropriate. Root and leaf VIDs are only significant between peering VPLS but the values must be consistent on each end. On ingress a tag SDP binding removes the VID tag on the interface between VPLS in the same E-Tree service. The tag SDP receives root tagged traffic and marks the traffic with a root indication internally. This option is not available on BGP EVPN-enabled E-Tree services.

**leaf-ac** — Specifies an access (AC) spoke-SDP binding under a E-Tree VPLS as a leaf access (AC) SDP. The default E-Tree SDP binding type is a root-ac if *leaf-ac* or *root-leaf-tag* is not specified at SDP creation. This option is only available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services support the **leaf-ac** option.

## control-word

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command enables the use of the control word on pseudowire packets in VPLS and enables the use of the control word individually on each mesh SDP or spoke-SDP. By default, the control word is disabled. When the control word is enabled, all VPLS packets, including the BPDU frames, are encapsulated with the control word when sent over the pseudowire. The T-LDP control plane behavior is the same as in the implementation of control word for VLL services. The configuration for the two directions of the Ethernet pseudowire should match. The <b>no</b> form of the command reverts the mesh SDP or spoke-SDP to the default behavior of not using the control word. The control word must be enabled to use MPLS-TP OAM on a static spoke-sdp terminating in a VPLS. |
| <b>Default</b>     | no control word                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

config>service>pw-template>egress

**Description**

This command is used to redirect pseudowire packets to an egress port queue-group for the purpose of shaping.

The egress pseudowire shaping provisioning model allows the mapping of one or more pseudowires to the same instance of queues, or policers and queues, which are defined in the queue-group template.

Operationally, the provisioning model consists of the following steps:

1. Create an egress queue-group template and configure queues only or policers and queues for each FC that needs to be redirected.
2. Apply the queue-group template to the network egress context of all ports where there exists a network IP interface on which the pseudowire packets can be forwarded. This creates one instance of the template on the egress of the port. One or more instances of the same template can be created.
3. Configure FC-to-policer or FC-to-queue mappings together with the redirect to a queue-group in the egress context of a network QoS policy. No queue-group name is specified in this step, which means the same network QoS policy can redirect different pseudowires to different queue-group templates.
4. Apply this network QoS policy to the egress context of a spoke-SDP inside a service or to the egress context of a pseudowire template and specify the redirect queue-group name.

One or more spoke-sdps can have their FCs redirected to use queues only or queues and policers in the same queue-group instance.

The following are the constraints and rules of this provisioning model:

1. When a pseudowire FC is redirected to use a queue or a policer and a queue in a queue-group and the queue-group name does not exist, the association is failed at the time the user associates the egress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface on which the pseudowire packet is forwarded. This queue can be a queue-group queue, or the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port. This is the existing implementation and default behavior for a pseudowire packet.
2. When a pseudowire FC is redirected to use a queue or a policer, and a queue in a queue-group and the queue-group name exists, but the policer-id and/or the queue-id is not defined in the queue-group template, the association is failed at the time the user associates the egress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface the pseudowire packet is forwarded on.
3. When a pseudowire FC is redirected to use a queue, or a policer and a queue in a queue-group, and the queue-group name exists and the policer-id or policer-id plus queue-id exist, it is not required to check that an instance of that queue-group exists in all egress network ports which have network IP interfaces. The handling of this is dealt with in the data path as follows:

When a pseudowire packet for that FC is forwarded and an instance of the referenced queue-group name exists on that egress port, the packet is processed by the queue-group policer and will then be fed to the queue-group queue.

When a pseudowire packet for that FC is forwarded and an instance of the referenced queue-group name does not exist on that egress port, the pseudowire packet will be fed directly to the corresponding egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.

1. If a network QoS policy is applied to the egress context of a pseudowire, any pseudowire FC, which is not explicitly redirected in the network QoS policy, will have the corresponding packets feed directly the corresponding the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.

When the queue-group name the pseudowire is redirected to exists and the redirection succeeds, the marking of the packet DEI/dot1-p/DSCP and the tunnel DEI/dot1-p/DSCP/EXP is performed; according to the relevant mappings of the (FC, profile) in the egress context of the network QoS policy applied to the pseudowire. This is true regardless of whether an instance of the queue-group exists or not on the egress port to which the pseudowire packet is forwarded. If the packet profile value changed due to egress child policer CIR profiling, the new profile value is used to mark the packet DEI/dot1-p and the tunnel DEI/dot1-p/EXP, and the DSCP/prec will be remarked if **enable-dscp-prec-marking** is enabled under the policer.

When the queue-group name the pseudowire is redirected does not exist, the redirection command is failed. In this case, the marking of the packet DEI/dot1-p/DSCP and the tunnel DEI/dot1-p/DSCP/EXP fields is performed according to the relevant commands in the egress context of the network QoS policy applied to the network IP interface to which the pseudowire packet is forwarded.

The **no** version of this command removes the redirection of the pseudowire to the queue-group.

**Parameters** *network-policy-id* — Specifies the network policy identification. The value uniquely identifies the policy on the system.

**Values** 1 to 65535

**queue-redirect-group** *queue-group-name* — This optional parameter specifies that the *queue-group-name* will be used for all egress forwarding class redirections within the network QoS policy ID. The specified *queue-group-name* must exist as a port egress queue group on the port associated with the IP interface.

**egress-instance** *instance-id* — Specifies the identification of a specific instance of the queue-group

**Values** 1 to 16384

## ingress

**Syntax** **ingress**

| <b>Description</b> | <p>This command is used to redirect pseudowire packets to an ingress forwarding plane queue-group for the purpose of rate-limiting.</p> <p>The ingress pseudowire rate-limiting feature uses a policer in queue-group provisioning model. This model allows the mapping of one or more pseudowires to the same instance of policers, which are defined in a queue-group template.</p> <p>Operationally, the provisioning model in the case of the ingress pseudowire shaping feature consists of the following steps:</p> <ul style="list-style-type: none"> <li><b>Step 1.</b> Create an ingress queue-group template and configure policers for each FC that needs to be redirected and optionally, for each traffic type (unicast or multicast).</li> <li><b>Step 2.</b> Apply the queue-group template to the network ingress forwarding plane where there exists a network IP interface to which the pseudowire packets can be received. This creates one instance of the template on the ingress of the FP. One or more instances of the same template can be created.</li> <li><b>Step 3.</b> Configure FC-to-policer mappings together with the policer redirect to a queue-group in the ingress context of a network QoS policy. No queue-group name is specified in this step, which means the same network QoS policy can redirect different pseudowires to different queue-group templates.</li> <li><b>Step 4.</b> Apply this network QoS policy to the ingress context of a spoke-SDP inside a service, or to the ingress context of a pseudowire template, and specify the redirect queue-group name.</li> <li><b>Step 5.</b> One or more spoke-SDPs can have their FCs redirected to use policers in the same policer queue-group instance.</li> </ul> |

The following are the constraints and rules of this provisioning model when used in the ingress pseudowire rate-limiting feature:

- Step 1.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name does not exist, the association is failed at the time the user associates the ingress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- Step 2.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name exists but the policer-id is not defined in the queue-group template, the association is failed at the time the user associates the ingress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- Step 3.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name exists and the policer-id is defined in the queue-group template, it is not required to check that an instance of that queue-group exists in all ingress FPs which have network IP interfaces. The handling of this is dealt with in the data path as follows:

When a pseudowire packet for that FC is received and an instance of the referenced queue-group name exists on that FP, the packet is processed by the policer and will then feed the per-FP ingress shared queues referred to as *policer-output-queues*.

When a pseudowire packet for that FC is received and an instance of the referenced queue-group name does not exist on that FP, the pseudowire packets will be fed directly into the corresponding ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.

- If a network QoS policy is applied to the ingress context of a pseudowire, any pseudowire FC which is not explicitly redirected in the network QoS policy will have the corresponding packets feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- If no network QoS policy is applied to the ingress context of the pseudowire, then all packets of the pseudowire will feed:
  - the ingress network shared queue for the packet FC defined in the network-queue policy applied to the ingress of the MDA/FP. This is the default behavior.
  - a queue-group policer followed by the per-FP ingress shared queues referred to as *policer-output-queues* if the ingress context of the network IP interface from which the packet is received is redirected to a queue-group. The only exceptions to this behavior are for packets received from a IES/VP RN spoke interface and from an R-VPLS spoke-SDP, which is forwarded to the R-VPLS IP interface. In these two cases, the ingress network shared queue for the packet FC defined in the network-queue policy applied to the ingress of the MDA/FP is used.

When a pseudowire is redirected to use a policer queue-group, the classification of the packet for the purpose of FC and profile determination is performed according to default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the pseudowire. This is true regardless of whether an instance of the named policer queue-group exists on the ingress FP on which the pseudowire packet is received. The user

can apply a QoS filter matching the dot1-p in the VLAN tag corresponding to the Ethernet port encapsulation, the EXP in the outer label when the tunnel is an LSP, the DSCP in the IP header if the tunnel encapsulation is GRE, and the DSCP in the payload IP header if the user enabled the **ler-use-dscp** option and the pseudowire terminates in IES or VPRN service (spoke-interface).

When the policer queue-group name the pseudowire is redirected does not exist, the redirection command is failed. In this case, the packet classification is performed according to default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the network IP interface on which the pseudowire packet is received.

The **no** version of this command removes the redirection of the pseudowire to the queue-group.

**Parameters**    *network-policy-id* — Specifies the network policy identification. The value uniquely identifies the policy on the system.

**Values**        1 to 65535

*queue-group-name* — Specifies the name of the queue group template up to 32 characters in length

*instance-id* — Specifies the identification of a specific instance of the queue-group

**Values**        1 to 16384

## mfib-allowed-mda-destinations

**Syntax**        **mfib-allowed-mda-destinations**

**Context**        config>service>vpls>mesh-sdp>egress  
config>service>vpls>spoke-sdp>egress

**Description**    This command enters the context to configure MFIB-allowed MDA destinations.

The allowed-mda-destinations node and the corresponding **mda** command are used on spoke and mesh SDP bindings to provide a list of MDA destinations in the chassis that are allowed as destinations for multicast streams represented by [\* ,g] and [s,g] multicast flooding records on the VPLS service. The MDA list only applies to IP multicast forwarding when IGMP snooping is enabled on the VPLS service. The MDA list has no effect on normal VPLS flooding such as broadcast, L2 multicast, unknown destinations or non-snooped IP multicast.

At the IGMP snooping level, a spoke or mesh SDP binding is included in the flooding domain for an IP multicast stream when it has either been defined as a multicast router port, received a IGMP query through the binding or has been associated with the multicast stream through an IGMP request by a host over the binding. Due to the dynamic nature of the way that a spoke or mesh SDP binding is associated with one or more egress network IP interfaces, the system treats the binding as appearing on all network ports. This causes all possible network destinations in the switch fabric to be included in the multicast streams flooding domain. The MDA destination list provides a simple mechanism that narrows the IP multicast switch fabric destinations for the spoke or mesh SDP binding.

If no MDAs are defined within the `allowed-mda-destinations` node, the system operates normally and will forward IP multicast flooded packets associated with the spoke or mesh SDP binding to all switch fabric taps containing network IP interfaces.

The MDA inclusion list should include all MDAs that the SDP binding may attempt to forward through. A simple way to ensure that an MDA that is not included in the list is not being used by the binding is to define the SDP the binding is associated with as MPLS and use an RSVP-TE LSP with a strict egress hop. The MDA associated with the IP interface defined as the strict egress hop should be present in the inclusion list. If the inclusion list does not currently contain the MDA that the binding is forwarding through, the multicast packets will not reach the destination represented by the binding.

By default, the MDA inclusion list is empty.

If an MDA is removed from the list, the MDA is automatically removed from the flooding domain of any snooped IP multicast streams associated with a destination on the MDA unless the MDA was the last MDA on the inclusion list. Once the inclusion list is empty, all MDAs are eligible for snooped IP multicast flooding for streams associated with the SDP binding.

|                    |                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] static-mac</b> <i>ieee-mac-address</i>                                                                                                                           |
| <b>Context</b>     | config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                                                                                                            |
| <b>Description</b> | This command creates a remote static MAC entry in the Virtual Private LAN Service (VPLS) forwarding database (FDB) associated with the Service Distribution Point (SDP). |

In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.

Remote static MAC entries create a permanent MAC address to SDP association in the forwarding database for the VPLS instance so that MAC address will not be learned on the edge device.

Static MAC definitions on one edge device are not propagated to other edge devices participating in the VPLS instance, that is, each edge device has an independent forwarding database for the VPLS.

Only one static MAC entry (local or remote) can be defined per MAC address per VPLS instance.

The **no** form of this command deletes the static MAC entry with the specified MAC address associated with the SDP from the VPLS forwarding database.

**Default** none

**Parameters** *ieee-mac-address* — Specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

## transit-policy

**Syntax** **transit-policy** *prefix* *prefix-aasub-policy-id*  
**no transit-policy**

**Context** config>service>vpls>spoke-sdp

**Description** This command assigns a transit policy id.

The **no** form of the command removes the transit policy ID from the spoke-SDP configuration.

**Default** no transit-policy

**Parameters** *prefix-aasub-policy-id* — Specifies the transit policy ID

**Values** 1 to 65535

## vlan-vc-tag

**Syntax** **vlan-vc-tag** *0 to 4094*  
**no vlan-vc-tag** [*0 to 4094*]

**Context** config>service>vpls>spoke-sdp  
config>service>vpls>mesh-sdp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command specifies an explicit dot1q value used when encapsulating to the SDP far end. When signaling is enabled between the near and far end, the configured dot1q tag can be overridden by a received TLV specifying the dot1q value expected by the far end. This signaled value must be stored as the remote signaled dot1q value for the binding. The provisioned local dot1q tag must be stored as the administrative dot1q value for the binding.</p> <p>When the dot1q tag is not defined, the default value of zero is stored as the administrative dot1q value. Setting the value to zero is equivalent to not specifying the value.</p> <p>The <b>no</b> form of this command disables the command.</p> |
| <b>Default</b>     | no vlan-vc-tag                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | 0 to 4094 — Specifies a valid VLAN identifier to bind an 802.1Q VLAN tag ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## default-msap-policy

|                    |                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-msap-policy</b> <i>policy-name</i><br><b>no default-msap-policy</b>                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                     |
| <b>Description</b> | This command specifies an existing managed SAP policy. Managed SAPs allow the use of policies and a SAP template for the creation of a SAP. Managed SAP policies are created in the <b>config&gt;subscr-mgmt</b> context. This command is only applicable to SAPs created as a capture-sap. |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>msap-policy-name</i> — Specifies an existing managed SAP policy name up to 32 characters in length                                                                                                                                                                                       |

## sub-sla-mgmt

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sub-sla-mgmt</b>                                                                    |
| <b>Context</b>     | config>service>vpls>sap                                                                     |
| <b>Description</b> | This command enters the context to configure subscriber management parameters for this SAP. |
| <b>Default</b>     | no sub-sla-mgmt                                                                             |

## def-inter-dest-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>def-inter-dest-id</b> { <b>string</b> <i>string</i>   <b>use-top-q</b> }<br><b>no def-inter-dest-id</b>                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vpls>sap>sub-sla-mgmt                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies a default destination string for all subscribers associated with the SAP. The command also accepts the <b>use-top-q</b> flag that automatically derives the string based on the top most delineating Dot1Q tag from the SAP's encapsulation.</p> <p>The <b>no</b> form of the command removes the default subscriber identification string from the configuration.</p> <p>no def-sub-id</p> |
| <b>Default</b>     | no def-inter-dest-id                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <b>use-top-q</b> — Specifies to derive the string based on the top most delineating Dot1Q tag from the SAP's encapsulation                                                                                                                                                                                                                                                                                            |

**string** *string* — Specifies the subscriber identification applicable for a subscriber host.

## def-sla-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |
| <b>Default</b>     | no def-sla-profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>default-sla-profile-name</i> — Specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sla-profile</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## def-sub-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vpls>sap>sub-sla-mgmt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context.</p> <p>A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |

---

**Parameters**    *default-sub-profile* — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the **config>subscr-mgmt>sub-profile** context.

## mac-da-hashing

**Syntax**    **[no] mac-da-hashing**

**Context**    config>service>vpls>sap>sub-sla-mgmt

**Description**    This command specifies whether subscriber traffic egressing a LAG SAP has its egress LAG link selected by a function of the MAC destination address instead of the subscriber ID.

                    This command is only meaningful if subscriber management is enabled and can be configured for this VPLS service.

## multi-sub-sap

**Syntax**    **multi-sub-sap** [*subscriber-limit*]  
              **no multi-sub-sap**

**Context**    config>service>vpls>sap>sub-sla-mgmt

**Description**    This command configures the maximum number of subscribers for this SAP.

                    The **no** form of this command returns to the default value of 1.

**Default**    no multi-sub-sap

**Parameters**    *number-of-sub* — Specifies the maximum number of subscribers for this SAP

**Values**        2 to 8000

## non-sub-traffic

**Syntax**    **non-sub-traffic sub-profile** *sub-profile-name* **sla-profile** *sla-profile-name* [**subscriber** *sub-ident-string*]  
              **no non-sub-traffic**

**Context**    config>service>vpls>sap>sub-sla-mgmt>single-sub

**Description**    This command configures non-subscriber traffic profiles. It is used in conjunction with the **profiled-traffic-only** command on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.

                    The **no** form of the command removes the profiles and disables the feature.

- Parameters**
- sub-profile-name* — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.
  - sla-profile-name* — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.
  - subscriber sub-ident-string* — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-policy** context. The subscriber information is used by the SAP arp-reply-agent to determine the correct handling of received ARP requests from subscribers.
- For SAPs with **arp-reply-agent** enabled with the optional *sub-ident* parameter, the static subscriber host's *sub-ident-string* is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the service destinations.
- If the static subscriber host's *sub-ident* string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.
- If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.
- If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.
- ARP requests are never forwarded back to the same SAP or within the receiving SAP's Split Horizon Group.

## profiled-traffic-only

- Syntax** **[no] profiled-traffic-only**
- Context** config>service>vpls>sap>sub-sla-mgmt>single-sub
- Description** This command enables profiled traffic only for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the *sla-profile* and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1).
- The **no** form of the command disables the command.

| <b>Context</b>     | config>service>vpls>sap>sub-sla-mgmt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context.</p> <p>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.</p> <p>For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.</p> <p>When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.</p> <p>The <b>no</b> form of the command removes the default subscriber identification policy from the SAP configuration.</p> |
| <b>Default</b>     | no sub-ident-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>sub-ident-policy-name</i> — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 3.7.2.5 VPLS Multicast Commands

## fast-leave

| <b>Description</b> | <p>This command enables fast leave. When IGMP or MLD fast leave processing is enabled, the SR OS will immediately remove a SAP or SDP from the multicast group when it detects an IGMP or MLD “leave” on that SAP or SDP. Fast leave processing allows the switch to remove a SAP or SDP that sends a 'leave' from the forwarding table without first sending out group-specific queries to the SAP or SDP, and therefore speeds up the process of changing channels ('zapping').</p> <p>Fast leave should only be enabled when there is a single receiver present on the SAP or SDP. When fast leave is enabled, the configured last-member-query-interval value is ignored.</p> |
| <b>Default</b>     | no fast-leave                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                    |                                                                                                                                                                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enters the context to add a static multicast group as a (*, G) or as one or more (S,G) records. When a static MLD or IGMP group is added, multicast data for that (*,G) or (S,G) is forwarded to the specific SAP or SDP without receiving any membership report from a host.                                           |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>grp-ip-address</i> — Specifies an IGMP multicast group address that receives data on an interface. The IP address must be unique for each static group.</p> <p><i>grp-ipv6-address</i> — Specifies an MLD multicast group address that receives data on an interface. The IP address must be unique for each static group.</p> |
| <b>Values</b>      | <p>ipv6-address:</p> <ul style="list-style-type: none"> <li>• x:x:x:x:x:x:x (eight 16-bit pieces)</li> <li>• x:x:x:x:x:d.d.d.d</li> <li>• x: [0 to FFFF]H</li> <li>• d: [0 to 255]D</li> </ul>                                                                                                                                       |

| <b>Description</b> | <p>This command configures associated BMAC addresses for fault propagation on a B-VPLS SAP or SDP binding. The statement can appear up to four times in the configuration to support four remote BMAC addresses in the same remote B-VPLS. The configured VPLS must be a B-VPLS.</p> <p>The <b>no</b> form of the command removes the specified MAC name or MAC address from the list of Fault Propagation BMAC addresses associated with the SAP (or SDP).</p> |
| <b>Parameters</b>  | <p><i>mac-name</i> — Specifies a (predefined) MAC name to associate with the SAP or SDP, indirectly specifying a Fault Propagation BMAC address. Up to 32 characters in length</p> <p><i>ieee-address</i> — Specifies a MAC address to associate with the SAP or SDP, directly specifying a Fault Propagation BMAC address. The value should be input in either a xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx format.</p>                                            |

| <b>Description</b> | <p>This command forces two VLAN tags to be inserted and removed for spoke and mesh SDPs that have either <b>vc-type ether</b> or <b>vc-type vlan</b>. The use of this command is mutually exclusive with the <b>force-vlan-vc-forwarding</b> command.</p> <p>The VLAN identifiers and dot 1p/DE bits inserted in the two VLAN tags are taken from the inner tag received on a qinq SAP or qinq mesh/spoke-SDP, or from the VLAN tag received on a dot1q SAP or mesh/spoke-SDP (with <b>vc-type vlan</b> or <b>force-vlan-vc-forwarding</b>), or taken from the outer tag received on a qtag.* SAP or 0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP. The VLAN identifiers in both VLAN tags can be set to the value configured in the <b>vlan-vc-tag</b> parameter in the <b>pw-template</b> or under the mesh/spoke-SDP configuration. In the received direction, the VLAN identifiers are ignored and the dot1p/DE bits are not used for ingress classification. However, the inner dot1p/DE bits are propagated to the egress QoS processing.</p> <p>The Ethertype inserted and used to determine the presence of a received VLAN tag for both VLAN tags is 0x8100. A different Ethertype can be used for the outer VLAN tag by configuring the pseudowire template with the <b>use-provisioned-sdp</b> or <b>prefer-provisioned-sdp</b> options and setting the Ethertype using the <b>sdp vlan-vc-etype</b> parameter (this Ethertype value is then used for all mesh and spoke-SDPs using that SDP).</p> <p>The <b>no</b> form of this command sets the default behavior.</p> |

| <b>Description</b> | <p>This command forces vc-vlan-type forwarding in the data path for spoke or mesh SDPs which have <b>ether</b> vc-type. This command is not allowed on vlan-vc-type SDPs.</p> <p>The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.</p> |

---

The **no** form of this command sets default behavior.

**Default** disabled

## hash-label

**Syntax** **hash-label [signal-capability]**  
**no hash-label**

**Context** config>service>vpls>spoke-sdp  
config>service>vpls>mesh-sdp

**Description** This command enables the use of the hash label on a VLL, VPRN, or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The 7450 ESS, 7750 SR, and 7950 XRS local PE will insert the flow label interface parameters sub-TLV with F=1 in the pseudowire ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the pseudowire but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the pseudowire received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7450 ESS, 7750 SR, and 7950 XRS must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the pseudowire ID FEC element.

The **no** form of this command disables the use of the hash label.

|                   |                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no hash-label                                                                                                                                                                                                  |
| <b>Parameters</b> | <b>signal-capability</b> — Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The <b>signal-capability</b> option is not supported on a VPRN spoke-sdp. |

## disable-router-alert-check

|                |                                                                                                                                                                                                                                                                                                                                             |

---

config>service>vpls>spoke-sdp>mld-snooping

**Description** This command disables the IGMP or MLD router alert check option.

The **no** form of the command enables the router alert check.

**Default** no disable-router-alert-check

## import

**Syntax** **import** *policy-name*  
**no import**

**Context** config>service>vpls>sap>igmp-host-tracking

**Description** This command associates an import policy to filter IGMP packets.

The **no** form of the command removes the values from the configuration.

**Default** no import

**Parameters** *policy-name* — Specifies the import policy name

## max-num-groups

**Syntax** **max-num-groups** *max-num-groups*  
**no max-num-groups**

**Context** config>service>vpls>sap>igmp-host-tracking

**Description** This command configures the maximum number of multicast groups allowed to be tracked.

The **no** form of the command removes the values from the configuration.

**Default** no max-num-groups

**Parameters** *max-num-groups* — Specifies the maximum number of multicast groups allowed to be tracked

**Values** 1 to 196607

## max-num-grp-sources

**Syntax** **max-num-grp-sources** [1 to 32000]  
**no max-num-grp-sources**

**Context** config>service>vpls>mesh-sdp>igmp-snooping  
config>service>vpls>sap>igmp-host-tracking

| <b>Context</b>     | config>service>vpls>sap>igmp-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>spoke-sdp>mld-snooping<br>config>service>vpls>mesh-sdp>mld-snooping                                                                                                                                                                                                       |
| <b>Description</b> | This command configures the maximum response time used in group-specific queries sent in response to 'leave' messages, and is also the amount of time between 2 consecutive group-specific queries. This value may be tuned to modify the leave latency of the network. A reduced value results in reduced time to detect the loss of the last member of a group.<br><br>The configured last-member-query-interval is ignored when fast-leave is enabled on the SAP or SDP. |
| <b>Default</b>     | last-member-query-interval 10                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the frequency, in tenths of seconds, at which query messages are sent.<br><br><b>Values</b> 1 to 50                                                                                                                                                                                                                                                                                                                                              |

## mcac

|                    |                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mcac</b>                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vpls>mesh-sdp>igmp-snooping<br>config>service>vpls>mesh-sdp>mld-snooping<br>config>service>vpls>sap>igmp-snooping<br>config>service>vpls>sap>mld-snooping<br>config>service>vpls>spoke-sdp>igmp-snooping<br>config>service>vpls>spoke-sdp>mld-snooping |
| <b>Description</b> | This command configures multicast CAC policy and constraints for this interface.                                                                                                                                                                                      |

**Default** none

## if-policy

**Syntax** **if-policy** *mcac-if-policy-name*  
**no if-policy**

**Context** config>service>vpls>mesh-sdp>igmp-snooping>mcac  
config>service>vpls>mesh-sdp>mld-snooping>mcac  
config>service>vpls>sap>igmp-snooping>mcac  
config>service>vpls>sap>mld-snooping>mcac  
config>service>vpls>spoke-sdp>igmp-snooping>mcac  
config>service>vpls>spoke-sdp>mld-snooping>mcac

**Description** This command assigns existing MCAC interface policy to this interface. MCAC interface policy is not supported with MLD-snooping, therefore executing the command in the mld-snooping contexts will return an error.

The **no** form of the command removes the MCAC interface policy association.

**Default** no if-policy

**Parameters** *mcac-if-policy-name* — Specifies an existing MCAC interface policy

## policy

**Syntax** **policy** *policy-name*  
**no policy**

**Context** config>service>vpls>mesh-sdp>igmp-snooping>mcac  
config>service>vpls>mesh-sdp>mld-snooping>mcac  
config>service>vpls>sap>mld-snooping>mcac  
config>service>vpls>sap>igmp-snooping>mcac  
config>service>vpls>spoke-sdp>igmp-snooping>mcac  
config>service>vpls>spoke-sdp>mld-snooping>mcac

**Description** This command configures the multicast CAC policy name. MCAC policy is not supported with MLD-snooping, therefore executing the command in the mld-snooping contexts will return an error.

**Parameters** *policy-name* — Specifies the multicast CAC policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.

| <b>Description</b> | This command configures the bandwidth for the interface's multicast CAC policy traffic. When disabled ( <b>no unconstrained-bw</b> ) there will be no checking of bandwidth constraints on the interface level. When enabled and a policy is defined, enforcement is performed. The allocated bandwidth for optional channels should not exceed the <b>unconstrained-bw</b> minus the <b>mandatory-bw</b> and the mandatory channels have to stay below the specified value for the <b>mandatory-bw</b> . After this interface check, the bundle checks are performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

If <i>bandwidth</i> is not configured, then all mandatory and optional channels are allowed.<br>If the value of <i>mandatory-bw</i> is equal to the value of <i>bandwidth</i> , then all the unconstrained bandwidth on a specified interface is allocated to mandatory channels configured through multicast CAC policy on that interface and no optional groups (channels) are allowed.<br>The value of <i>mandatory-bw</i> should always be less than or equal to that of <i>bandwidth</i> , An attempt to set the value of <i>mandatory-bw</i> greater than that of <i>bandwidth</i> , will result in inconsistent value error.<br><br><b>Values</b> 0 to 2147483647 |

## use-lag-port-weight

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>use-lag-port-weight</b><br><b>no use-lag-port-weight</b>                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>sap>igmp-snooping>mcac>mc-constraints<br>config>service>vpls>sap>igmp-snooping>mcac>mc-constraints                                                                                                                                   |
| <b>Description</b> | This command enables port weight to be used when determining available bandwidth per level when LAG ports go down/come up. The command is required for correct operation on mixed port-speed LAGs and can be used for non-mixed port-speed LAGs as well. |

**Default** no use-lag-port-weight — The port number is used when determining available BW per level when LAG ports go down/come up.

## mc-constraints

**Syntax** **mc-constraints**

**Context** config>service>vpls>sap>igmp-snooping>mcac  
config>service>vpls>sap>mld-snooping>mcac

**Description** This command enters the context to configure multicast CAC constraints.

**Default** none

## level

**Syntax** **level** *level-id* **bw** *bandwidth*  
**no level** *level-id*

**Context** config>service>vpls>sap>igmp-snooping>mcac>mc-constraints  
config>service>vpls>sap>mld-snooping>mcac>mc-constraints

**Description** This command configures levels and their associated bandwidth for multicast cac policy on this interface.

**Parameters** *level-id* — Specifies has an entry for each multicast CAC policy constraint level configured on this system

**Values** 1 to 8

*bandwidth* — Specifies the bandwidth in kilobits per second (kb/s) for the level.

**Values** 1 to 2147483647

## number-down

**Syntax** **number-down** *number-lag-port-down*  
**no number-down**

**Context** config>service>vpls>sap>igmp-snooping>mcac>mc-constraints  
config>service>vpls>sap>mld-snooping>mcac>mc-constraints

**Description** This command configure the number of ports down along with level for multicast cac policy on this interface.

**Default** not enabled

---

|                   |                                                                                                                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>number-lag-port-down</i> — Specifies that the number of ports available in the LAG is reduced by the number of ports configured in this command here then bandwidth allowed for bundle and/or interface will be as per the levels configured in this context. |
| <b>Values</b>     | 1 to 64 (for 64-link LAG)<br>1 to 32 (for other LAGs)                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command specifies whether a multicast router is attached behind this SAP, SDP, or routed VPLS IP interface.</p> <p>Configuring these objects as an mrouter-port will have a double effect. Firstly, all multicast traffic received on another SAP, SDP, or routed VPLS IP interface will be copied to this SAP, SDP, or routed VPLS IP interface. Secondly, IGMP/MLD reports generated by the system as a result of a router joining or leaving a multicast group, will be sent to this SAP, SDP, or routed VPLS IP interface.</p> <p>If two multicast routers exist in the network, one of them will become the active querier. While the other multicast router (non-querier) stops sending IGMP queries, it should still receive reports to keep its multicast trees up-to-date. To support this, the mrouter-port should be enabled on all SAPs, SDPs, or routed VPLS IP interfaces connecting to a multicast router.</p> <p>The IGMP version to be used for the reports (v1, v2, or v3) can only be determined after an initial query has been received. Until such time, no reports are sent on the SAP, spoke-SDP, or routed VPLS IP interface, even if <b>mrouter-port</b> is enabled.</p> <p>If the <b>send-queries</b> command is enabled on this SAP or spoke-SDP, the <b>mrouter-port</b> parameter cannot be set.</p> <p>When PIM-snooping is enabled within a VPLS service, all IP multicast traffic and PIM messages will be sent to any SAP or SDP binding configured with an IGMP-snooping mrouter port. This will occur even without IGMP-snooping enabled, but is not supported in a BGP-VPLS or M-VPLS service.</p> |
| <b>Default</b>     | no mrouter-port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command controls the period of time that the Registrar state machine will wait in the leave state before transitioning to the MT state when it is removed. An instance of the timer is required for each state machine that is in the leave state. The Leave Period Timer is set to the value leave-time when it is started.</p> <p>A registration is normally in “in” state where there is an MFIB entry and traffic is being forwarded. When a “leave all” is performed (periodically around every 10-15 seconds per SAP/SDP binding - see leave-all-time-below), a node sends a message to its peer indicating a leave all is occurring and puts all of its registrations in leave state.</p> <p>The peer refreshes its registrations based on the leave all PDU it receives and sends a PDU back to the originating node with the state of all its declarations.</p> <p>Refer to IEEE 802.1ak-2007 section 10.7.4.2.</p> |
| <b>Default</b>     | leave-time 30                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>value</i> — Specifies the timer value in 10th of seconds to hold attributes in a leave-state,<br><b>Values</b> 30 to 60                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vpls>sap>mrp<br>config>service>vpls>spoke-sd>mrp<br>config>service>vpls>mesh-sdp>mrp                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command instructs MMRP to use the mrp-policy specified in the command to control which Group BMAC attributes will be declared and registered on the egress SAP/Mesh-SDP/Spoke-SDP. The Group BMACs will be derived from the ISIDs using the procedure used in the PBB solution. The Group MAC is standard OUI with the last 24 bits being the ISID value. If the policy-name refers to a non-existing mrp-policy the command should return error. Changes to a mrp-policy are allowed and applied to the SAP/SDPs under which the policy is referenced. |
| <b>Default</b>     | no mrp-policy is defined                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the redirect policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                                |

## periodic-time

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>periodic-time</b> <i>value</i><br><b>no periodic-time</b>                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>sap>mrp<br>config>service>vpls>spoke-sdp>mrp<br>config>service>vpls>mesh-sdp>mrp                                                                                                                                                                     |
| <b>Description</b> | This command controls the frequency the Periodic Transmission state machine generates periodic events if the Periodic Transmission Timer is enabled. The timer is required on a per-Port basis. The Periodic Transmission Timer is set to one second when it is started. |
| <b>Default</b>     | periodic-time 10                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>value</i> — Specifies the timer value in 10th of seconds for re-transmission of attribute declarations<br><br><b>Values</b> 10 to 100                                                                                                                                 |

## periodic-timer

|               |                            |
|---------------|----------------------------|
| <b>Syntax</b> | <b>[no] periodic-timer</b> |
|---------------|----------------------------|

---

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>sap>mrp<br>config>service>vpls>spoke-sdp>mrp<br>config>service>vpls>mesh-sdp>mrp |
| <b>Description</b> | This command enables or disables the Periodic Transmission Timer.                                    |
| <b>Default</b>     | no periodic-timer                                                                                    |

## max-num-groups

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-num-groups</b> <i>num-groups</i><br><b>no max-num-groups</b>                           |
| <b>Context</b>     | config>service>vpls>spoke-sdp>pim-snooping<br>config>service>vpls>sap>pim-snooping            |
| <b>Description</b> | This command configures the maximum groups for PIM snooping.                                  |
| <b>Parameters</b>  | <i>num-groups</i> — Specifies the maximum groups for PIM snooping<br><b>Values</b> 1 to 16000 |

## oper-group

|                    |                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] oper-group</b> <i>name</i>                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>sap<br>config>service>vpls>spoke-sdp<br>config>service>vpls>bgp>pw-template-binding                                                                                                                                                                                                           |
| <b>Description</b> | This command associates the context to which it is configured to the operational group specified in the <i>name</i> . The oper-group <i>name</i> must be already configured under config>service before its name is referenced in this command.<br><br>The <b>no</b> form of the command removes the association. |
| <b>Default</b>     | no oper-group                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>name</i> — Specifies a character string of maximum 32 ASCII characters identifying the group instance.                                                                                                                                                                                                         |

## monitor-oper-group

|                |                                                           |
|----------------|-----------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] monitor-oper-group</b> <i>name</i>                |
| <b>Context</b> | config>service>vpls>site<br>config>service>vpls>spoke-sdp |

```
config>service>vpls>sap
```

**Description** This command specifies the operational group to be monitored by the object under which it is configured. The **oper-group** *name* must be already configured under **config>service** before its name is referenced in this command.

The **no** form of the command removes the association.

**Default** no monitor-oper-group

**Parameters** *name* — Specifies a character string of maximum 32 ASCII characters identifying the group instance

## precedence

**Syntax** **precedence** *precedence-value* | **primary**  
**no precedence**

**Context** config>service>vpls>spoke-sdp

**Description** This command configures the spoke-SDP precedence.

**Default** 4

**Parameters** *precedence-value* — Specifies the spoke-SDP precedence

**Values** 0 to 4

**primary** — Specifies that the precedence is primary

## pw-path-id

**Syntax** [**no**] **pw-path-id**

**Context** config>service>vpls>spoke-sdp

**Description** This command enters the context to configure an MPLS-TP Pseudowire Path Identifier for a spoke-sdp. All elements of the PW path ID must be configured in order to enable a spoke-sdp with a PW path ID.

For an IES or VPRN spoke-sdp, the pw-path-id is only valid for ethernet spoke-sdps.

The **pw-path-id** is only configurable if all of the following is true:

- SDP signaling is off
- control-word is enabled (control-word is disabled by default)
- the service type is Epipe, VPLS, Cpipe, Apipe, or IES/VPRN interface
- mate SDP signaling is off for vc-switched services

The **no** form of the command deletes the PW path ID.

**Default** no pw-path-id

## agi

**Syntax** **agi** *agi*  
**no agi**

**Context** config>service>vpls>spoke-sdp>pw-path-id

**Description** This command configures the attachment group identifier for an MPLS-TP PW.

**Parameters** *agi* — Specifies the attachment group identifier.

**Values** 0 to 4294967295

## saii-type2

**Syntax** **saii-type2** *global-id:node-id:ac-id*  
**no saii-type2**

**Context** config>service>vpls>spoke-sdp>pw-path-id

**Description** This command configures the Source Individual Attachment Identifier (SAII) for an MPLS-TP spoke-sdp. If this is configured on a spoke-sdp for which vc-switching is also configured (for example, it is at an S-PE), then the values must match those of the taii-type2 of the mate spoke-sdp.

**Parameters** *global-id* — Specifies the global ID at the source PE or T-PE for the MPLS-TP PW for a spoke SDP.

**Values** 0 to 4294967295

*node-id* — Specifies the node ID at the source PE or T-PE for the MPLS-TP PW for a spoke SDP.

**Values** a.b.c.d or 0 to 4294967295

*ac-id* — Specifies the attachment circuit ID at the source PE or T-PE for the MPLS-TP PW for a spoke SDP. If this node is the source of the PW, then the AC ID must be set to a locally unique value.

**Values** 1 to 4294967295

## taii-type2

**Syntax** **taii-type2** *global-id:node-id:ac-id*  
**no taii-type2**

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command specifies the type of signaling used by this multi-segment pseudowire provider-edge for this service.</p> <p>When no pw-status-signaling is enabled, a 7450 ESS, 7750 SR, and 7950 XRS will not include the pseudowire status TLV in the initial label mapping message of the pseudowire used for a spoke-SDP. This will force both 7450 ESS, 7750 SR, and 7950 XRS PEs to use the pseudowire label withdrawal method for signaling pseudowire status.</p> <p>If pw-status-signaling is configured, the node will include the use of the pseudowire status TLV in the initial label mapping message for the pseudowire.</p> |

## propagate-mac-flush

|                    |                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] propagate-mac-flush                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command specifies whether MAC flush messages received from the specified LDP are propagated to all spoke and mesh SDPs within the context of this VPLS service. The propagation will follow the split-horizon principle and any data-path blocking in order to avoid the looping of these messages. |

**Default** no propagate-mac-flush

## send-queries

**Syntax** [no] send-queries

**Context** config>service>vpls>sap>igmp-snooping  
config>service>vpls>spoke-sdp>igmp-snooping  
config>service>vpls>mesh-sdp>igmp-snooping  
config>service>vpls>sap>mld-snooping  
config>service>vpls>spoke-sdp>mld-snooping  
config>service>vpls>mesh-sdp>mld-snooping

**Description** This command specifies whether to send IGMP general query messages on the SAP or SDP.

When send-queries is configured, all type of queries generate ourselves are of the configured version. If a report of a version higher than the configured version is received, the report will get dropped and a new wrong version counter will get incremented. If send-queries is not configured, the version command has no effect. The version used will be the version of the querier. This implies that, for example, when we have a v2 querier, we will never send out a v3 group or group-source specific query when a host wants to leave a certain group.

**Default** no send-queries

## source

**Syntax** [no] source *ip-address*  
[no] source *src-ipv6-address*

**Context** config>service>vpls>sap>igmp-snooping>static>group  
config>service>vpls>spoke-sdp>igmp-snooping>static>group  
config>service>vpls>mesh-sdp>igmp-snooping>static>group  
config>service>vpls>sap>mld-snooping>static>group  
config>service>vpls>spoke-sdp>mld-snooping>static>group  
config>service>vpls>mesh-sdp>mld-snooping>static>group

**Description** This command specifies a IPv4 or IPv6 unicast address that sends data on an interface. This enables a multicast receiver host to signal a router the group to receive multicast traffic from, and from the sources that the traffic is expected.

The **source** command is mutually exclusive with the specification of individual sources for the same group.

The **source** command in combination with the group is used to create a specific (S,G) static group entry.

Use the **no** form of the command to remove the source from the configuration.

| <b>Description</b> | <p>This command specifies the version of IGMP or MLD which is running on this SAP or SDP. This object can be used to configure a router capable of running either value. For IGMP or MLD to function correctly, all routers on a LAN must be configured to run the same version of IGMP or MLD on that LAN.</p> <p>When the <b>send-query</b> command is configured, all type of queries generate ourselves are of the configured <b>version</b>. If a report of a version higher than the configured version is received, the report gets dropped and a new “wrong version” counter is incremented.</p> <p>If the <b>send-query</b> command is not configured, the <b>version</b> command has no effect. The version used on that SAP or SDP will be the version of the querier. This implies that, for example, when there is a v2 querier, a v3 group or group-source specific query when a host wants to leave a certain group will never be sent.</p> |
| <b>Parameters</b>  | <p><i>version</i> — Specifies the IGMP or MLD version</p> <p><b>Values</b>      1, 2, 3</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## to-sap

|                    |                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <pre>to-sap sap-id no to-sap</pre>                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vpls>sap>igmp-snooping>mvr                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>In some situations, the multicast traffic should not be copied from the MVR VPLS to the SAP on which the IGMP message was received (standard MVR behavior) but to another SAP.</p> <p>This command configures the SAP to which the multicast data needs to be copied.</p> |
| <b>Default</b>     | no to-sap                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the SAP to which multicast channels should be copied                                                                                                                                                                                               |

### 3.7.2.5.1 VPLS DHCP and Anti-Spoofing Commands

## anti-spoof

|               |                                       |
|---------------|---------------------------------------|
| <b>Syntax</b> | <b>anti-spoof {ip   mac   ip-mac}</b> |
|---------------|---------------------------------------|

**no anti-spoof**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (<b>ip</b>, <b>mac</b>, <b>ip-mac</b>) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The <b>no</b> form of the command disables anti-spoof filtering on the SAP.</p>                                                                                                                                                                                             |
| <b>Default</b>     | no anti-spoof                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>ip</b> — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the <b>anti-spoof ip</b> command will fail.</p> <p><b>mac</b> — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. If a static host exists on the SAP without a specified MAC address, the <b>anti-spoof mac</b> command will fail.</p> <p><b>ip-mac</b> — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the <b>anti-spoof ip-mac</b> command will fail.</p> |

## app-profile

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                                                                                |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                            |
| <b>Description</b> | This command configures the application profile name.                                                                                              |
| <b>Parameters</b>  | <i>app-profile-name</i> — Specifies an existing application profile name configured in the <b>config&gt;app-assure&gt;group&gt;policy</b> context. |

## arp-host

|                    |                                                                   |
|--------------------|-------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-host</b>                                                   |
| <b>Context</b>     | config>service>vpls>sap                                           |
| <b>Description</b> | This command enters the context to configure ARP host parameters. |

## host-limit

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>host-limit</b> <i>max-num-hosts</i><br><b>no host-limit</b>                                                                      |
| <b>Context</b>     | config>service>vpls>sap>arp-host                                                                                                    |
| <b>Description</b> | This command configures the maximum number of ARP hosts.<br><br>The <b>no</b> form of the command returns the value to the default. |
| <b>Default</b>     | host-limit 1                                                                                                                        |
| <b>Parameters</b>  | <i>max-num-hosts</i> — Specifies the maximum number of ARP hosts allowed on this SAP<br><br><b>Values</b> 1 to 32767                |

## min-auth-interval

|                    |                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-auth-interval</b> <i>min-auth-interval</i><br><b>no min-auth-interval</b>                                                        |
| <b>Context</b>     | config>service>vpls>sap>arp-host                                                                                                        |
| <b>Description</b> | This command configures the minimum authentication interval.<br><br>The <b>no</b> form of the command returns the value to the default. |
| <b>Default</b>     | min-auth-interval 15                                                                                                                    |
| <b>Parameters</b>  | <i>min-auth-interval</i> — Specifies the minimum authenticated interval, in minutes<br><br><b>Values</b> 1 to 6000                      |

## arp-reply-agent

|                    |                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-reply-agent</b> [sub-ident]<br><b>no arp-reply-agent</b>                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vpls>sap                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command enables a special ARP response mechanism in the system for ARP requests destined for static or dynamic hosts associated with the SAP. The system responds to each ARP request using the hosts MAC address as the both the source MAC address in the Ethernet header and the target hardware address in the ARP header. |

ARP replies and requests received on a SAP with **arp-reply-agent** enabled will be evaluated by the system against the anti-spoof filter entries associated with the ingress SAP (if the SAP has anti-spoof filtering enabled). ARPs from unknown hosts on the SAP will be discarded when anti-spoof filtering is enabled.

The ARP reply agent only responds if the ARP request enters an interface (SAP, spoke-SDP or mesh-SDP) associated with the VPLS instance of the SAP.

A received ARP request that is not in the ARP reply agent table is flooded to all forwarding interfaces of the VPLS capable of broadcast except the ingress interface while honoring split-horizon constraints.

Static hosts can be defined on the SAP using the **host** command. Dynamic hosts are enabled on the system by enabling the **lease-populate** command in the SAP's **dhcp** context. If both a static host and a dynamic host share the same IP and MAC address, the VPLS ARP reply agent will retain the host information until both the static and dynamic information are removed. If both a static and dynamic host share the same IP address, but different MAC addresses, the VPLS ARP reply agent is populated with the static host information.

The **arp-reply-agent** command will fail if an existing static host on the SAP does not have both MAC and IP addresses specified. Once the ARP reply agent is enabled, creating a static host on the SAP without both an IP address and MAC address will fail.

The ARP-reply-agent may only be enabled on SAPs supporting Ethernet encapsulation.

The **no** form of the command disables ARP-reply-agent functions for static and dynamic hosts on the SAP.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>Enabling force-l2pt-boundary will force all SAPs managed by the specified m-vpls instance on the corresponding port to have l2pt-termination enabled. This command is applicable only to SAPs created under m-vpls regardless of the flavor of STP currently active. It is not applicable to spoke-SDPs.</p> <p>The execution of this command will fail as soon as at least one of the currently managed SAPs (all SAPs falling within the specified managed-vlan-range) does not have l2pt-termination enabled regardless of its admin/operational status.</p> <p>If force-l2pt-boundary is enabled on a specified m-vpls SAP, all newly created SAPs falling into the specified managed-vlan-range will have l2pt-termination enabled per default.</p> <p>Extending or adding new range into a managed-vlan-range declaration will fail as soon as there is at least one SAPs falling into the specified vlan-range does not have l2pt-termination enabled.</p> <p>Disabling l2pt-termination on currently managed SAPs will fail as soon as the force-l2pt-boundary is enabled under corresponding m-vpls SAP.</p> |
| <b>Parameters</b>  | <p><b>cdp</b> — Specifies the Cisco discovery protocol</p> <p><b>dtp</b> — Specifies the dynamic trunking protocol</p> <p><b>pagp</b> — Specifies the port aggregation protocol</p> <p><b>stp</b> — Specifies all spanning tree protocols: stp, rstp, mstp, pvst (default)</p> <p><b>udld</b> — Specifies unidirectional link detection</p> <p><b>vtp</b> — Specifies the virtual trunk protocol</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## frame-relay

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>frame-relay</b>                                                   |
| <b>Context</b>     | config>service>vpls>sap                                              |
| <b>Description</b> | This command enters the context to configure frame-relay parameters. |

## frf-12

|               |                    |
|---------------|--------------------|
| <b>Syntax</b> | <b>[no] frf-12</b> |
|---------------|--------------------|

---

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vpls>sap>fr                                                                                                                                                             |
| <b>Description</b> | <p>This command enables FRF12 headers. This must be set to disabled for this entry to be added to an MLFR bundle.</p> <p>The <b>no</b> form of the command disables FRF12 headers.</p> |

## ete-fragment-threshold

|                    |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ete-fragment-threshold</b> <i>threshold</i><br><b>no ete-fragment-threshold</b>                                             |
| <b>Context</b>     | config>service>vpls>sap>fr>frf-12                                                                                              |
| <b>Description</b> | <p>This command configures the FRF.12 fragmentation threshold.</p> <p>The <b>no</b> form of the command removes the value.</p> |
| <b>Default</b>     | ete-fragment-threshold 128                                                                                                     |
| <b>Parameters</b>  | <i>threshold</i> — Specifies the maximum length of a fragment to be transmitted.                                               |
| <b>Values</b>      | 128 to 512                                                                                                                     |

## interleave

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Context</b>     | config>service>vpls>sap>frame-relay>frf.12                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command enables interleaving of high priority frames and low priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation.</p> <p>When this option is enabled, only frames of the FR SAP non-expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).</p> <p>When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.</p> <p>The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.</p> <p>The <b>no</b> form of this command restores the default mode of operation.</p> |

---

**Default**    no interleave

## scheduling-class

**Syntax**    **scheduling-class** *class-id*  
              **no scheduling-class**

**Context**    config>service>vpls>sap>frame-relay

**Description**    This command specifies the scheduling class to use for this SAP. This object is only applicable for a SAP whose bundle type is set to MLFR.

**Parameters**    *class-id* — Specifies the scheduling class

**Values**    0 to 3

### 3.7.2.6 BGP Auto-Discovery Commands

## bgp

**Syntax**    **bgp**

**Context**    config>service>vpls

**Description**    This command enters the context to configure the BGP related parameters for both BGP AD and BGP VPLS.

## bgp-ad

**Syntax**    **[no] bgp-ad**

**Context**    config>service>vpls

**Description**    This command configures BGP auto-discovery.

## bgp-vpls

**Syntax**    **bgp-vpls**

**Context**    config>service>vpls

**Description**    This command enters the context to configure the BGP-VPLS parameters and addressing.

---

## pw-template-binding

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pw-template-binding</b> <i>policy-id</i> [ <b>split-horizon-group</b> <i>group-name</i> ] [ <b>import-rt</b> { <i>ext-community</i> , ...(up to 5 max)}]<br><b>no pw-template-bind</b> <i>policy-id</i>                                                |
| <b>Context</b>     | config>service>vpls>bgp-ad<br>config>service>vpls>bgp                                                                                                                                                                                                     |
| <b>Description</b> | This command binds the advertisements received with the route target (RT) that matches the configured list (either the generic or the specified import) to a specific pw-template. If the RT list is not present the pw-template is used for all of them. |

The pw-template-binding applies to both BGP-AD and BGP-VPLS if these features are enabled in the VPLS.

For BGP VPLS the following additional rules govern the use of pseudowire-template:

- On transmission the settings for the L2-Info extended community in the BGP update are derived from the pseudowire template attributes. If multiple pseudowire template bindings (with or without import-rt) are specified, the first pw-template entry will be used for the information in the BGP update sent.
- On reception the values of the parameters in the L2-Info extended community of the BGP update are compared with the settings from the corresponding pw-template. The following steps are used to determine the local pw-template:
  - The RT values are matched to determine the pw-template. The route targets configured for each pw-template-binding are compared to the route targets within the BGP update. The PW template corresponding to pw-template-binding with the first matching route target is used to for the SDP. The matching is performed from the lowest PW template binding identifier to the highest
  - If no pw-templates matches are found from the previous step, the first (numerically lowest) configured pw-template entry without any route-target configured will be used.

If the values used for Layer 2 MTU (unless the value zero is received) or control word flag does not match, the pseudowire is created but with the operationally down state.

If the value used for the S (sequenced delivery) flags is not zero, the pseudowire is not created.

The tools perform commands can be used to control the application of changes in pw-template for both BGP-AD and BGP-VPLS.

The **no** form of the command removes the values from the configuration.

|                   |                                                    |
|-------------------|----------------------------------------------------|
| <b>Default</b>    | none                                               |
| <b>Parameters</b> | <i>policy-id</i> — Specifies an existing policy ID |
| <b>Values</b>     | 1 to 2147483647                                    |

*group-name* — The specified group-name overrides the split horizon group template settings

*import-rt ext-comm* — Specifies communities allowed to be accepted from remote PE neighbors. An extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. **x** and **y** are 16-bit integers.

**Values**      target:{*ip-addr:comm-val*| *2byte-asnumber:ext-comm-val*|*4byte-asnumber:comm-val*}  
                  *ip-addr*: a.b.c.d  
                  *comm-val*: [0 to 65535]  
                  *2byte-as-number*: [0 to 65535]  
                  *ext-comm-val*: [0 to 4294967295]  
                  *4byte-asnumber*: [0 to 4294967295]

## bfd-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vpls>sap<br>config>service>vpls>spoke-sdp<br>config>service>vpls>bgp>pw-template-binding                                                                                                                                                                                                                                                |
| <b>Description</b> | This command associates the context to which it is configured to the operational group specified in the <i>group-name</i> . The <b>oper-group</b> <i>group-name</i> must be already configured under <b>config&gt;service</b> context before its name is referenced in this command.<br><br>The <b>no</b> form of the command removes the association. |
| <b>Parameters</b>  | <i>group-name</i> — Specifies a character string of maximum 32 ASCII characters identifying the group instance                                                                                                                                                                                                                                         |

## route-distinguisher

|                    |                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>route-distinguisher</b> <i>rd</i><br><b>route-distinguisher auto-rd</b><br><b>no route-distinguisher</b>                                                                                                                                    |
| <b>Context</b>     | config>service>vpls>bgp                                                                                                                                                                                                                        |
| <b>Description</b> | This command configures the Route Distinguisher (RD) component that will be signaled in the MP-BGP NLRI for L2VPN and EVPN families. This value will be used for BGP-AD, BGP VPLS and BGP multi-homing NLRI, if these features are configured. |

If this command is not configured, the RD is automatically built using the BGP-AD VPLS ID. The following rules apply:

- if BGP AD VPLS-id is configured and no RD is configured under BGP node - RD is the VPLS-ID
- if BGP AD VPLS-id is not configured then an RD value must be configured under BGP node (this is the case when only BGP VPLS is configured)
- if BGP AD VPLS-id is configured and an RD value is also configured under BGP node, the configured RD value prevails

Values and format (6 bytes, other 2 bytes of type will be automatically generated)

Alternatively, the **auto-rd** option allows the system to automatically generate an RD based on the **bgp-auto-rd-range** command configured at service level.

**Parameters** *ip-addr:comm-val* — Specifies the IP address

**Values** *ip-addr:* a.b.c.d  
*comm-val:* [0 to 65535]

*as-number:ext-comm-val* — Specifies the AS number

**Values** *as-number:* 1 to 65535  
*ext-comm-val:* 0 to 4294967295

*auto-rd* — The system generates an RD for the service according to the IP address and range configured in the **bgp-auto-rd-range** command

## route-target

**Syntax** **route-target** {*ext-community*}[{**export** *ext-community*}[**import** *ext-community*]}  
**no route-target**

**Context** config>service>vpls>bgp-ad  
config>service>vpls>bgp

**Description** This command configures the route target (RT) component that will be signaled in the related MP-BGP attribute to be used for BGP auto-discovery, BGP VPLS and BGP multi-homing if these features are configured in this VPLS service.

If this command is not used, the RT is built automatically using the VPLS ID. The ext-comm can have the same two formats as the VPLS ID, a two-octet AS-specific extended community, IPv4 specific extended community.

The following rules apply:

- if BGP AD VPLS-id is configured and no RT is configured under BGP node, the RT is the VPLS-ID
- if BGP AD VPLS-id is not configured then an RT value must be configured under BGP node (this is the case when only BGP VPLS is configured)

- if BGP AD VPLS-id is configured and an RT value is also configured under BGP node, the configured RT value prevails

**Parameters**    **export** *ext-community* — Specifies communities allowed to be sent to remote PE neighbors

**import** *ext-community* — Specifies communities allowed to be accepted from remote PE neighbors

## vsi-export

**Syntax**        **vsi-export** *policy-name* [*policy-name*...(up to 5 max)]  
                  **no vsi-export**

**Context**        config>service>vpls>bgp-ad  
                  config>service>vpls>bgp

**Description**    This command specifies the name of the VSI export policies to be used for BGP auto-discovery, BGP VPLS and BGP multi-homing if these features are configured in this VPLS service. If multiple policy names are configured, the policies are evaluated in the order they are specified. The first policy that matches is applied.

                  The policy name list is handled by the SNMP agent as a single entity.

## vsi-import

**Syntax**        **vsi-import** *policy-name* [*policy-name*...(up to 5 max)]  
                  **no vsi-import**

**Context**        config>service>vpls>bgp-ad>vsi-id  
                  config>service>vpls>bgp

**Description**    This command specifies the name of the VSI import policies to be used for BGP auto-discovery, BGP VPLS and BGP multi-homing if these features are configured in this VPLS service. If multiple policy names are configured, the policies are evaluated in the order they are specified. The first policy that matches is applied.

                  The policy name list is handled by the SNMP agent as a single entity.

## vpls-id

**Syntax**        **vpls-id** *vpls-id*

**Context**        config>service>vpls>bgp-ad

**Description**    This command configures the VPLS ID component that will be signaled in one of the extended community attributes (*ext-comm*).

Values and format (6 bytes, other 2 bytes of type-subtype will be automatically generated)

**Parameters** *vpls-id* — Specifies a globally unique VPLS ID for BGP auto-discovery in this VPLS service

**Values** *vpls-id* : <ip-addr:comm-val>|<as-number:ext-comm-val>  
*ip-addr*: a.b.c.d  
*comm-val*: [0 to 65535]  
*as-number*: [1 to 65535]  
*ext-comm-val*: [0 to 4294967295]

## vsi-id

**Syntax** **vsi-id**

**Context** config>service>vpls>bgp-ad

**Description** This command enters the context to configure the Virtual Switch Instance Identifier (VSI-ID).

## prefix

**Syntax** **prefix** *low-order-vsi-id*  
**no prefix**

**Context** config>service>vpls>bgp-ad>vsi-id

**Description** This command specifies the low-order 4 bytes used to compose the Virtual Switch Instance Identifier (VSI-ID) to use for NLRI in BGP auto-discovery in this VPLS service.

If no value is set, the system IP address will be used.

**Default** no prefix

**Parameters** *low-order-vsi-id* — Specifies a unique VSI ID

**Values** 0— 4294967295

## max-ve-id

**Syntax** **max-ve-id** *value*  
**no max-ve-id**

**Context** config>service>vpls>bgp-vpls

**Description** This command configures the allowed range for the VE-id value: locally configured and received in a NLRI. Configuration of a VE-id higher than the value specified in this command is not allowed.

Also upon reception of a higher VE-id in an NLRI imported in this VPLS instance (RT is the configured import RT) the following action must be taken:

- a trap must be generated informing the operator of the mismatch.
- NLRI must be dropped
- no service labels are to be installed for this VE-id
- no new NLRI must be generated if a new offset is required for VE-id.

The **no** form of this command sets the max-ve-id to un-configured. The BGP VPLS status should be administratively down for “no max-ve-id” to be used.

The max-ve-id value can be changed without shutting down bgp-vpls if the newly provisioned value does not conflict with the already configured local VE-ID. If the value of the local-VE-ID is higher than the new max-ve-id value the command is rejected. The operator needs to decrease first the VE-ID before running the command.

The actions taken for other max-ve-id values are as follows:

- max-ve-id value higher than all VE-IDs (local and received) is allowed and there are no effects.
- max-ve-id higher than the local VE-ID but smaller than the remote VE-IDs:
  - Provisioning is allowed
  - A warning message will be generated stating that “Higher VE-ID values were received in the BGP VPLS context. Related pseudowires will be removed.”
  - The pseudowires associated with the higher VE-IDs will be removed locally.
  - This is a situation that should be corrected by the operator as the pseudowire may be down just at the local PE, consuming unnecessarily core bandwidth. The higher VE-IDs should be removed or lowered.

If the max-ve-id has increased a BGP route refresh is sent to the VPLS community to get the routes which might have been rejected earlier due to max-ve-id check. A max-ve-id value needs to be provisioned for BGP VPLS to be in “no shutdown” state.

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no max-ve-id                                                                                                                        |
| <b>Parameters</b> | <i>value</i> — Specifies the allowed range of [1-value] for the VE-id. The configured value must be bigger than the existing VE-ids |
| <b>Values</b>     | 1 to 65535                                                                                                                          |

## ve-name

|                |                                                 |
|----------------|-------------------------------------------------|
| <b>Syntax</b>  | <b>ve-name</b> <i>name</i><br><b>no ve-name</b> |
| <b>Context</b> | config>service>vpls>bgp-vpls                    |

---

|                    |                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command creates or edits a ve-name. Just one ve-name can be created per BGP VPLS instance.</p> <p>The <b>no</b> form of the command removes the configured ve-name from the bgp vpls node. It can be used only when the BGP VPLS status is shutdown. The <b>no shutdown</b> command cannot be used if there is no ve-name configured.</p> |
| <b>Default</b>     | no ve-name                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>name</i> — Specifies the A character string to identify the VPLS Edge instance up to 32 characters in length                                                                                                                                                                                                                                   |

## ve-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>vpls>bgp-vpls>ve-name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command configures a ve-id. Just one ve-id can be configured per BGP VPLS instance. The VE-ID can be changed without shutting down the VPLS Instance. When the VE-ID changes, BGP is withdrawing its own previously advertised routes and sending a route-refresh to all the peers which would result in reception of all the remote routes again. The old pseudowires are removed and new ones are instantiated for the new VE-ID value.</p> <p>The <b>no</b> form of the command removes the configured ve-id. It can be used just when the BGP VPLS status is shutdown. The <b>no shutdown</b> command cannot be used if there is no ve-id configured.</p> |
| <b>Default</b>     | no ve-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>value</i> — Specifies a two-byte identifier that represents the local instance in a VPLS and is advertised through the BGP NLRI. Must be lower or equal with the max-ve-id.<br><b>Values</b> 1 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## shutdown

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                                                                             |
| <b>Context</b>     | config>service>vpls>bgp-vpls                                                                                                                     |
| <b>Description</b> | This command administratively enables/disables the local BGP VPLS instance. On de-activation an MP-UNREACH-NLRI must be sent for the local NLRI. |

The **no** form of the command enables the BGP VPLS addressing and the related BGP advertisement. The associated BGP VPLS MP-REACH-NLRI will be advertised in an update message and the corresponding received NLRIs must be considered to instantiate the data plane. RT, RD usage: same like in the BGP AD solution, if the values are not configured here, the value of the VPLS-id from under the bgp-ad node is used. If VPLS-id value is not configured either the MH site cannot be activated – i.e. no shutdown returns an error. Same applies if a pseudowire template is not specified under the bgp node.

**Default**      shutdown

### 3.7.2.7 Redundancy Commands

#### redundancy

**Syntax**      **redundancy**

**Context**      config

**Description**      This command enters the context to perform redundancy operations.

#### multi-chassis

**Syntax**      **multi-chassis**

**Context**      config>redundancy

**Description**      This command enters the context to configure multi-chassis parameters.

#### peer

**Syntax**      **[no] peer *ip-address* create**

**Context**      config>redundancy>multi-chassis

**Description**      Use this command to configure up to 20 multi-chassis redundancy peers. It is only for mc-lag (20) not for mc-sync (4).

**Parameters**      *ip-address* — Specifies the IP address

**Values**

                    ipv4-address:      a.b.c.d

                    ipv6-address:      x:x:x:x:x:x:x      (eight 16-bit pieces)

                                            x:x:x:x:x:d.d.d.d

                                            x:-[0 —FFFF]H

d: [0 — 255]D

**create** — Specifies to create the peer

## sync

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sync</b>                                                         |
| <b>Context</b>     | config>redundancy>multi-chassis>peer                                     |
| <b>Description</b> | This command enters the context to configure synchronization parameters. |

## igmp-snooping

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] igmp-snooping</b>                                                                                    |
| <b>Context</b>     | config>redundancy>multi-chassis>peer>sync                                                                    |
| <b>Description</b> | This command specifies whether IGMP snooping information should be synchronized with the multi-chassis peer. |
| <b>Default</b>     | no igmp-snooping                                                                                             |

## mld-snooping

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mld-snooping</b>                                                                                                            |
| <b>Context</b>     | config>redundancy>multi-chassis>peer>sync                                                                                           |
| <b>Description</b> | This command is not supported. It is not blocked for backwards-compatibility reasons but has no effect on the system if configured. |

## pim-snooping

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim-snooping [saps] [spoke-sdps]</b><br><b>no pim-snooping</b>                                                                                                                                                                 |
| <b>Context</b>     | config>redundancy>multi-chassis>peer>sync                                                                                                                                                                                         |
| <b>Description</b> | This command specifies whether PIM snooping for IPv4 information should be synchronized with a multi-chassis peer. Entering <b>pim-snooping</b> without any parameters results in the synchronization being applied only to SAPs. |

Specifying the **spoke-sdps** parameter results in the synchronization being applied to manually configured spoke-SDPs. Specifying both the **saps** and **spoke-sdps** parameters results in the synchronization being applied to both SAPs and manually configured spoke-SDPs.

The synchronization of PIM snooping is only supported for manually configured spoke-SDPs but is not supported for spoke-SDPs configured within an endpoint. See PIM Snooping for IPv4 Synchronization for service support.

**Default** no pim-snooping

**Parameters** **saps** — Specifies that SAPs are to be synchronized with the multi-chassis peer according to the synchronization tags configured on the port. This is the default when no parameters are specified.

**spoke-sdps** — Specifies that spoke-SDPs are to be synchronized with the multi-chassis peer according to the synchronization tags configured on spoke-SDPs.

## port

**Syntax** **port** [*port-id* | *lag-id*] [**sync-tag** *sync-tag*] [**create**]  
**no port** [*port-id* | *lag-id*]

**Context** config>redundancy>multi-chassis>peer>sync

**Description** This command specifies the port to be synchronized with the multi-chassis peer and a synchronization tag to be used while synchronizing this port with the multi-chassis peer.

**Parameters** *port-id* — Specifies the port to be synchronized with the multi-chassis peer  
*lag-id* — Specifies the LAG ID to be synchronized with the multi-chassis peer  
**sync-tag** *sync-tag* — Specifies a synchronization tag to be used while synchronizing this port with the multi-chassis peer, up to 32 characters in length

## range

**Syntax** **range** *encap-range* **sync-tag** *sync-tag*  
**no range** *encap-range*

**Context** config>redundancy>multi-chassis>peer>sync>port

**Description** This command configures a range of encapsulation values.

**Parameters** *encap-range* — Specifies a range of encapsulation values on a port to be synchronized with a multi-chassis peer

### Values

Dot1q

*start-vlan-end-vlan*

QinQ

Q1.*start-vlan*-Q1.*end-vlan*

**sync-tag** *sync-tag* — Specifies a synchronization tag, up to 32 characters in length, to be used while synchronizing this encapsulation value range with the multi-chassis peer.

## sdp

**Syntax** **sdp** *sdp-id* [**sync-tag** *sync-tag*] [**create**]  
**no sdp** *sdp-id*

**Context** config>redundancy>multi-chassis>peer>sync

**Description** This command specifies the manually configured spoke-SDPs to be synchronized with the multi-chassis peer and a synchronization tag to be used while synchronizing these spoke-SDPs with the multi-chassis peer.

Manually configured spoke-SDPs with the specified *sdp-id* will be synchronized according to the synchronization tag. If synchronization is required only for a subset of the spoke-SDPs using the configured SDP, the **range** sub-command should be used. The **range** command and the **sync-tag** parameters are mutually exclusive.

The synchronization of PIM snooping is only supported for manually configured spoke-SDPs but is not supported for spoke-SDPs configured within an endpoint. See PIM Snooping for IPv4 Synchronization for service support.

The synchronization of PIM snooping is not supported on any of the following when used with the configured *sdp-id*:

- Mesh SDPs
- Spoke SDPs in non-VPLS services
- BGP-AD/BGP-VPLS (FEC 129) spoke-SDPs
- Spoke SDPs configured in endpoints
- Pseudowire SAPs
- ESM-over-MPLS Pseudowires

Non-existent spoke-SDPs may be specified. If these spoke-SDPs are created at a later time, then all states on the spoke-SDPs will be synchronized according to the synchronization tag and the synchronization protocols enabled.

A synchronization tag can be changed by entering the same command with a different synchronization tag. Changing the synchronization tag removes all states relating to the previous synchronization tag for the SDP and a new synchronization tag state is created.

**Parameters** *sdp-id* — Specifies the SDP of the spoke-SDPs to be synchronized with the multi-chassis peer

**Values** 1 to 17407

*sync-tag* — Specifies a synchronization tag, up to 32 characters in length, to be used when synchronizing with the multi-chassis peer.

## range

**Syntax**     **range** *vc-id-range* [**sync-tag** *sync-tag*]  
              **no range** *vc-id-range*

**Context**     config>redundancy>multi-chassis>peer>sync>sdp

**Description**     This command specifies a range of VC IDs for manually configured spoke-SDPs to be synchronized with the multi-chassis peer and a synchronization tag to be used while synchronizing each range with the multi-chassis peer. The **range** command and the configuration of a synchronization tag on the parent **sdp** command are mutually exclusive.

To synchronize a single spoke-SDP, the *start-vc-id* should be the same as the *end-vc-id*. If the configured *end-vc-id* is lower than the *start-vc-id*, the **range** command fails.

The synchronization tag can be changed by entering the same command with a different synchronization tag. Changing the synchronization tag removes all states relating to the previous synchronization tag for the SDP and a new synchronization tag state is created.

Multiple **range** commands can be configured, however, overlapping ranges for the same SDP (*sdp-id*) are not permitted.

The synchronization of PIM snooping is only supported for manually configured spoke-SDPs but is not supported for spoke-SDPs configured within an endpoint. See PIM Snooping for IPv4 Synchronization for service support.

The synchronization of the PIM snooping state is not supported on any of the following when used with the configured *sdp-id*:

- mesh SDPs
- spoke-SDPs in non-VPLS services
- BGP-AD/BGP-VPLS (FEC 129) spoke-SDPs
- spoke-SDPs configured in endpoints
- pseudowire SAPs
- ESM-over-MPLS pseudowires

Non-existent spoke-SDPs may be specified. If these spoke-SDPs are created at a later time, then all states on the spoke-SDPs will be synchronized according to the synchronization tag and the synchronization protocols enabled. The **sync-tag** can be changed by entering the same command with a different **sync-tag** value. If the synchronization tag is changed, then all states for the previous **sync-tag** are removed for the SDP configured in the command and the state is then built for the new synchronization tag.

**Parameters**    *vc-id-range* — Specifies a non-overlapping range of VC IDs for the spoke-SDPs of the SDP to be synchronized with the multi-chassis peer

**Values**        *start-vc-id-end-vc-id*  
                    *start-vc-id*: 1 to 4294967295  
                    *end-vc-id*: 1 to 4294967295

*sync-tag* — Specifies a synchronization tag, up to 32 characters in length, to be used when synchronizing with the multi-chassis peer

## 3.8 VPLS Show, Clear, Debug, and Tools Command Reference

## egress-label

- Syntax** `egress-label start-label [end-label]`
- Context** `show>service`
- Description** This command displays service information using the range of egress labels.
- If only the mandatory *egress-label/1* parameter is specified, only services using the specified label are displayed.
- If both *start-label* and *end-label* parameters are specified, the services using the range of labels X where *start-label* <= X <= *end-label* are displayed.
- Use the **show router ldp bindings** command to display dynamic labels.
- Parameters** *start-label* — The starting egress label value for the label range. If only *start-label* is specified, services only using *start-label* are displayed.
- Values** 0,18432 to 524287
- end-label* — The ending egress label value for the label range.
- Default** The *start-label* value.
- Values** 18432 to 524287
- Output** The following output displays an example of service egress label information.

### Sample Output

```

*A:ALA-12# show service egress-label 0 10000

[Table 42](#) describes show service egress label output fields.

**Table 42** Show Service Egress Command Output Fields

| Label                    | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| Svc Id                   | The ID that identifies a service.                                                                  |
| Sdp Id                   | The ID that identifies an SDP.                                                                     |
| Type                     | Indicates whether the SDP binding is a spoke or a mesh.                                            |
| I. Lbl                   | The VC label used by the far-end device to send packets to this device in this service by the SDP. |
| E. Lbl                   | The VC label used by this device to send packets to the far-end device in this service by the SDP. |
| Number of bindings found | The total number of SDP bindings that exist within the specified egress label range.               |

## fdb-info

**Syntax** fdb-info

**Context** show>service

**Description** Displays global FDB usage information.

**Output** The following output displays an example of service FDB information.

### Sample Output

```

*A:PE1# show service fdb-info

```

```

**Table 43 Show FDB Information Fields**

| Label  | Description                          |
|--------|--------------------------------------|
| ServID | Displays the service ID.             |
| MAC    | Displays the associated MAC address. |

**Table 43 Show FDB Information Fields (Continued)**

| Label            | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mac Move         | Displays the administrative state of the MAC movement feature associated with this service.                                                                                                                                                                                                                                                                                                                                           |
| Primary Factor   | Displays a factor for the primary ports defining how many MAC-relearn periods should be used to measure the MAC-relearn rate.                                                                                                                                                                                                                                                                                                         |
| Secondary Factor | Displays a factor for the secondary ports defining how many MAC-relearn periods should be used to measure the MAC-relearn rate.                                                                                                                                                                                                                                                                                                       |
| Mac Move Rate    | Displays the maximum rate at which MACs can be re-learned in this service, before the SAP where the moving MAC was last seen is automatically disabled in order to protect the system against undetected loops or duplicate MAs.<br>The rate is computed as the maximum number of re-learns allowed in a 5 second interval: for example, the default rate of 2 re-learns per second corresponds to 10 re-learns in a 5 second period. |
| Mac Move Timeout | Displays the time in seconds to wait before a SAP that has been disabled after exceeding the maximum re-learn rate is re-enabled.<br>A value of zero indicates that the SAP will not be automatically re-enabled after being disabled. If after the SAP is re-enabled it is disabled again, the effective retry timeout is doubled in order to avoid thrashing.                                                                       |
| Mac Move Retries | Displays the number of times retries are performed for re-enabling the SAP/SDP.                                                                                                                                                                                                                                                                                                                                                       |
| Table Size       | Specifies the maximum number of learned and static entries allowed in the FDB of this service.                                                                                                                                                                                                                                                                                                                                        |
| Allocated Count  | Displays the total number of allocated entries in the FDB of this service.                                                                                                                                                                                                                                                                                                                                                            |
| Total In Use     | Displays the total number of entries in use in the FDB of this service.                                                                                                                                                                                                                                                                                                                                                               |
| Learned Count    | Displays the current number of learned entries in the FDB of this service.                                                                                                                                                                                                                                                                                                                                                            |
| Static Count     | Displays the current number of static entries in the FDB of this service.                                                                                                                                                                                                                                                                                                                                                             |
| OAM MAC Count    | Displays the current number of OAM entries in the FDB of this service.                                                                                                                                                                                                                                                                                                                                                                |

**Table 43 Show FDB Information Fields (Continued)**

| Label            | Description (Continued)                                                                                                                                                                                                                                   |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DHCP MAC Count   | Displays the current number of DHCP-learned entries in the FDB of this service.                                                                                                                                                                           |
| Host MAC Count   | Displays the current number of host-learned entries in the FDB of this service.                                                                                                                                                                           |
| Intf MAC Count   | Displays the total number of interface MAC entries in the FDB of this service.                                                                                                                                                                            |
| SPB Count        | Displays the total number of SPB entries in the FDB of this service.                                                                                                                                                                                      |
| Cond MAC Count   | Displays the total number of conditional static MAC entries in the FDB of this service.                                                                                                                                                                   |
| BGP EVPN Count   | Displays the total number of BGP EVPN entries in the FDB of this service.                                                                                                                                                                                 |
| EVPN Static Cnt  | Displays the total number of BGP EVPN MAC entries with the sticky bit set in the FDB of this service.                                                                                                                                                     |
| EVPN Dup Det Cnt | Displays the total number of times a BGP EVPN duplicate MAC address has been detected in this service.                                                                                                                                                    |
| Remote Age       | Displays the number of seconds used to age out FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs.                                                                                                           |
| Local Age        | Displays the number of seconds used to age out FDB entries learned on local SAPs.                                                                                                                                                                         |
| High Watermark   | Displays the utilization of the FDB table of this service at which a table full alarm will be raised by the agent.                                                                                                                                        |
| Low Watermark    | Displays the utilization of the FDB table of this service at which a table full alarm will be cleared by the agent.                                                                                                                                       |
| Mac Learning     | Specifies whether the MAC learning process is enabled.                                                                                                                                                                                                    |
| Discard Unknown  | Specifies whether frames received with an unknown destination MAC are discarded.                                                                                                                                                                          |
| Mac Aging        | Indicates whether the MAC aging process is enabled.                                                                                                                                                                                                       |
| Relearn Only     | When one of the FDB table size limits (service, line card, system) has been reached, the learning of new MAC addresses is temporary disabled and only MAC relearns are allowed. When in this state, the Relearn Only flag is True, otherwise it is False. |
| Mac Subnet Len   | Displays the number of bits to be considered when performing MAC-learning or MAC-switching.                                                                                                                                                               |

**Table 43 Show FDB Information Fields (Continued)**

| Label             | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source-Identifier | The location where the MAC is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Type/Age          | <p>Type — Specifies the number of seconds used to age out TLS FDB entries learned on local SAPs.</p> <p>Age — Specifies the number of seconds used to age out TLS FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs.</p> <p>L — Learned - Dynamic entries created by the learning process.</p> <p>OAM — Entries created by the OAM process.</p> <p>H — Host, the entry added by the system for a static configured subscriber host.</p> <p>D or DHCP — DHCP-installed MAC. Learned addresses can be temporarily frozen by the DHCP snooping application for the duration of a DHCP lease.</p> <p>P — Indicates the MAC is protected by the MAC protection feature.</p> <p>Static — Statically configured.</p> |
| Last Change       | Indicates the time of the most recent state changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Sel Learned FDB   | Displays the administrative state of the selective learned FDB feature associated with this service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## fdb-mac

**Syntax** **fdb-mac** *ieee-address* [**expiry**]

**Context** show>service

**Description** This command displays the FDB entry for a specified MAC address.

**Parameters** *ieee-address* — The 48-bit MAC address for which the FDB entry will be displayed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers.

**expiry** — Shows the time until the MAC is aged out.

**Output** The following output displays an example of FDB MAC information.

### Sample Output

```
*A:ian2# show service fdb-mac
=====
Service Forwarding Database
=====
```

[Table 44](#) describes the show FDB-MAC command output fields.

**Table 44** Show FDB-MAC Command Output Fields

| Label             | Description                                                                                                                                    |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Service ID        | The service ID number.                                                                                                                         |
| MAC               | The specified MAC address.                                                                                                                     |
| Source-Identifier | The location where the MAC is defined.                                                                                                         |
| Type/Age          | Static — FDB entries created by management.                                                                                                    |
|                   | Learned — Dynamic entries created by the learning process.                                                                                     |
|                   | OAM — Entries created by the OAM process.                                                                                                      |
|                   | H — Host, the entry added by the system for a static configured subscriber host.                                                               |
|                   | D or DHCP — DHCP-installed MAC. Learned addresses can be temporarily frozen by the DHCP snooping application for the duration of a DHCP lease. |
|                   | P — Indicates the MAC is protected by the MAC protection feature.                                                                              |

## ingress-label

**Syntax** `ingress-label start-label [end-label]`

**Context** `show>service`

**Description** Display services using the range of ingress labels.

If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using the range of labels X where *start-label* <= X <= *end-label* are displayed.

Use the **show router ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — The starting ingress label value for the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 2048 to 131071

*end-label* — The ending ingress label value for the label range

**Default** The *start-label* value.

**Values** 2049 to 131071

**Output** The following output displays an example of service ingress label information.

### Sample Output

```
*A:ALA-12# show service ingress-label 0

| <b>Description</b> | <p>This command displays SAP information.</p> <p>If no optional parameters are specified, the command displays a summary of all defined SAPs.</p> <p>The optional parameters restrict output to only SAPs matching the specified properties.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>ingress</b> — Specifies matching an ingress policy</p> <p><b>egress</b> — Specifies matching an egress policy</p> <p><b>qos-policy-id</b> — The ingress or egress QoS Policy ID for which the matching SAPs will be displayed. This parameter applies to the 7450 ESS or 7750 SR only.</p> <p><b>Values</b> 1 to 65535</p> <p><b>td-profile-id</b> — Displays SAPs using this traffic description. This parameters applies to the 7750 SR only.</p> <p><b>filter-id</b> — The ingress or egress filter policy ID for which matching SAPs will be displayed</p> <p><b>Values</b> 1 to 65535</p> <p><b>dyn-script</b> — Displays dynamic service SAPs information</p> <p><b>sap-id</b> — Specifies the physical port identifier portion of the SAP definition</p> <p><b>interface</b> — Specifies matching SAPs with the specified IP interface. This parameter applies to the 7450 ESS or 7750 SR only.</p> <p><b>vlan-translation</b> — Keyword to display the SAPs where vlan-translation is enabled.</p> <p><b>msap</b> — Keyword to display MSAPs.</p> <p><b>anti-spoof</b> — Keyword to display the SAPs where anti-spoof can be enabled.</p> <p><b>etree</b> — Specifies matching of SAPs configured as E-Tree SAPs and the corresponding role in the E-Tree services: Leaf-AC, Root-AC or Root-leaf-tag SAPs. SAPs listed as Root-leaf-tag "Disabled" and Leaf-Ac "Disabled" function as Root-AC SAPs.</p> |
| <b>Output</b>      | <p>The following output displays an example of services associated so particular SAPs.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

[Table 46](#) describes show service SAP output fields.

**Table 46** Show Service SAP Fields

| Label   | Description                                         |
|---------|-----------------------------------------------------|
| Port ID | The ID of the access port where the SAP is defined. |
| Svc ID  | The service identifier.                             |
| SapMTU  | The SAP MTU value.                                  |

**Table 46 Show Service SAP Fields (Continued)**

| Label                  | Description (Continued)                                         |
|------------------------|-----------------------------------------------------------------|
| I.QoS                  | The SAP ingress QoS policy number specified on the ingress SAP. |
| I.MAC/IP               | The MAC or IP filter policy ID applied to the ingress SAP.      |
| Egr. Fltr              | The filter policy ID applied to the egress SAP.                 |
| A.Pol                  | The accounting policy ID assigned to the SAP.                   |
| Adm                    | The administrative state of the SAP.                            |
| Opr                    | The actual state of the SAP.                                    |
| E-Tree SAP Information |                                                                 |
| Svc ID                 | The service identifier.                                         |
| SAP                    | The root SAP including the outer tag used by the root frames.   |
| Leaf-Tag               | The outer tag used by the leaf frames on the referred SAP.      |
| Root-Leaf-Tag          | The state of the root leaf tag SAPs.                            |
| Leaf-AC                | The state of the leaf AC SAPs.                                  |

## sdp

**Syntax** **sdp** [*sdp-id* | **far-end** *ip-address*] [**detail** | **keep-alive-history**]  
**sdp** [*sdp-id*[:*vc-id*] | **far-end** *ip-address*]  
**sdp** [*sdp-id* | **far-end** *ip-addr*] [**detail** | **keep-alive-history**]

**Context** show>service>id

**Description** This command displays information for the SDPs associated with the service.  
If no optional parameters are specified, a summary of all associated SDPs is displayed.

**Parameters** *sdp-id* — Displays only information for the specified SDP ID. An SDP is a logical mechanism that ties a far-end 7450 ESS or 7750 SR to a particular service without having to specifically define far end SAPs. Each SDP represents a method to reach a router.

**Default** All SDPs

**Values** 1 to 17407

**far-end ip-addr** — Displays only SDPs matching with the specified system IP address of the far-end destination 7450 ESS or 7750 SR OS for the Service Distribution Point (SDP) that is the termination point for a service.

**Default** SDPs with any far-end IP address.

**detail** — Displays detailed SDP information.

**Output** The following output displays an example of service MAC protect information.

### Sample Output

```

[Table 47](#) describes show service-id SDP output fields.

**Table 47 Show Service-ID SDP Fields**

| Label               | Description                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sdp Id              | The SDP identifier.                                                                                                                                                          |
| Type                | Indicates whether the SDP is a spoke or a mesh.                                                                                                                              |
| Split Horizon Group | Name of the split horizon group where the SDP belongs.                                                                                                                       |
| VC Type             | Displays the VC type, ether or vlan.                                                                                                                                         |
| VC Tag              | Displays the explicit dot1q value used when encapsulating to the SDP far end.                                                                                                |
| I. Lbl              | The VC label used by the far-end device to send packets to this device in this service by the SDP.                                                                           |
| Admin Path MTU      | The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case.) |
| Oper Path MTU       | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.             |
| Far End             | Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.                                                                                    |
| Delivery            | Specifies the type of delivery used by the SDP: GRE or MPLS.                                                                                                                 |
| Admin State         | The administrative state of this SDP.                                                                                                                                        |
| Oper State          | The operational state of this SDP.                                                                                                                                           |
| Ingress Label       | The label used by the far-end device to send packets to this device in this service by this SDP.                                                                             |
| Egress Label        | The label used by this device to send packets to the far-end device in this service by the SDP.                                                                              |
| Last Changed        | The date and time of the most recent change to the SDP.                                                                                                                      |
| Signaling           | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.                                           |
| Admin State         | The administrative state of the Keepalive process.                                                                                                                           |

**Table 47 Show Service-ID SDP Fields (Continued)**

| Label               | Description (Continued)                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Oper State          | The operational state of the Keepalive process.                                                                                                                                                                                                                                           |
| Hello Time          | Specifies how often the SDP echo request messages are transmitted on this SDP.                                                                                                                                                                                                            |
| Max Drop Count      | Specifies the maximum number of consecutive SDP echo request messages that can be unacknowledged before the keepalive protocol reports a fault.                                                                                                                                           |
| Hello Msg Len       | Specifies the length of the SDP echo request messages transmitted on this SDP.                                                                                                                                                                                                            |
| Hold Down Time      | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.                                                                                                                                                                          |
| I. Fwd. Pkts.       | Specifies the number of forwarded ingress packets.                                                                                                                                                                                                                                        |
| I. Dro. Pkts        | Specifies the number of dropped ingress packets.                                                                                                                                                                                                                                          |
| E. Fwd. Pkts.       | Specifies the number of forwarded egress packets.                                                                                                                                                                                                                                         |
| E. Fwd. Octets      | Specifies the number of forwarded egress octets.                                                                                                                                                                                                                                          |
| Associated LSP List | When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the Far End field.<br><br>If the SDP type is GRE, then the following message displays:<br>SDP Delivery Mechanism is not MPLS. |

## sdp-using

**Syntax** **sdp-using** [*sdp-id[:vc-id]* | **far-end** *ip-address*]  
**sdp-using etree**

**Context** show>service

**Description** This command displays services using SDP or far-end address options.

**Parameters** *sdp-id* — Displays only services bound to the specified SDP ID

**Values** 1 to 17407

*vc-id* — Displays virtual circuit identifier information

**Values** 1 to 4294967295

**far-end ip-address** — Displays only services matching with the specified far-end IP address

**Default** Services with any far-end IP address.

**etree** — Specifies matching of SDP bindings configured as E-Tree SDP bindings and the corresponding role in the E-Tree services: Leaf-AC, Root-AC or Root-leaf-tag SDP binds. SDP binds listed as Root-leaf-tag "Disabled" and Leaf-Ac "Disabled" function as Root-AC SDP binds.

**Output** The following output displays an example of services using specific SDPs.

### Sample Output

```
*A:ALA-1# show service sdp-using 300
=====
Service Destination Point (Sdp Id : 300)
=====
SvcId      SdpId      Type Far End      Opr State I.Label  E.Label

Table 48 describes service sdp-using output fields.

**Table 48 Show Service SDP-Using Fields**

| Label  | Description             |
|--------|-------------------------|
| Svc ID | The service identifier. |

**Table 48 Show Service SDP-Using Fields (Continued)**

| Label                      | Description (Continued)                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------|
| Sdp ID                     | The SDP identifier.                                                                              |
| Type                       | Specifies the type of SDP: Spoke or Mesh.                                                        |
| Far End                    | The far-end address of the SDP.                                                                  |
| Oper State                 | The operational state of the service.                                                            |
| Ingress Label              | The label used by the far-end device to send packets to this device in this service by this SDP. |
| Egress Label               | The label used by this device to send packets to the far-end device in this service by this SDP. |
| Etree SDP Bind Information |                                                                                                  |
| Svc ID                     | The service identifier.                                                                          |
| SDP-Bind                   | The leaf tag SDP bind identifier.                                                                |
| Type                       | The type SDP bind.                                                                               |
| Root-Leaf-Tag              | The state of the root leaf tag SDP bind,                                                         |
| Leaf-AC                    | The state of the leaf AC SDP bind.                                                               |

## service-using

**Syntax** **service-using** [**epipe**] [**ies**] [**vpls**] [**vprn**] [**mirror**] [**b-vpls**] [**i-vpls**] [**m-vpls**] [**apipe**] [**fpipe**] [**ipipe**] **sdp** *sdp-id*] [**customer** *customer-id*]  
**service-using etree**

**Context** show>service

**Description** This command displays the services matching certain usage properties. If no optional parameters are specified, all services defined on the system are displayed.

**Parameters** **epipe** — Displays matching Epipe services  
**ies** — Displays matching IES instances. This parameter applies to the 7450 ESS or 7750 SR only.  
**vpls** — Displays matching VPLS instances  
**vprn** — Displays matching VPRN services. This parameter applies to the 7750 SR only.  
**mirror** — Displays matching mirror services  
**b-vpls** — Displays matching B-VPLS services. This parameter applies to the 7450 ESS or 7750 SR only.

**i-vpls** — Displays matching I-VPLS services. This parameter applies to the 7450 ESS or 7750 SR only.

**apipe** — Displays matching Apipe services. This parameter applies to the 7750 SR only

**fpipe** — Displays matching Fpipe services. This parameter applies to the 7750 SR only

**lpipe** — Displays matching Lpipe services. This parameter applies to the 7450 ESS or 7750 SR only

**sdp-id** — Displays only services bound to the specified SDP ID. This parameter applies to the 7450 ESS or 7750 SR only.

**Default** Services bound to any SDP ID

**Values** 1 to 17407

**customer-id** — Displays services only associated with the specified customer ID

**Default** Services associated with a customer

**Values** 1 to 2147483647

**etree** — Specifies matching of all VPLS services configured as E-Tree.

**Output** The following output displays an example of services using certain options.

### Sample Output

```
*A:ALA-12# show service service-using customer 10

[Table 49](#) describes show service service-using output fields.

**Table 49 Show Service Service-Using Fields**

| Label      | Description                                                                                                    |
|------------|----------------------------------------------------------------------------------------------------------------|
| Service Id | The service identifier.                                                                                        |
| Type       | Specifies the service type configured for the service ID including VPLS, VPRN, VPLS-ETR, VPRN, IES and INTVPLS |
| Adm        | The administrative state of the service.                                                                       |
| Opr        | The operating state of the service.                                                                            |
| CustomerId | The ID of the customer who owns this service.                                                                  |

| <b>Description</b> | This command displays information for a particular service ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>service-id</i> — Displays information for the unique service identification number that identifies the service in the service domain.</p> <p><b>Values</b>      <i>service-id</i>: 1 to 214748364<br/>                  <i>svc-name</i>: A string up to 64 characters in length</p> <p><b>all</b> — Displays detailed information about the service</p> <p><b>arp</b> — Displays ARP entries for the service. This parameter applies to the 7450 ESS or 7750 SR only.</p> <p><b>authentication</b> — Displays subscriber authentication information. This parameter applies to the 7450 ESS or 7750 SR only.</p> <p><b>base</b> — Displays basic service information</p> <p><b>dhcp</b> — Displays DHCP information. This parameter applies to the 7450 ESS or 7750 SR only.</p> |

**endpoint** — Displays service endpoint information

**epipe** — Displays Epipe services associated with the B-VPLS service. This parameter applies to the 7450 ESS or 7750 SR only.

**fdb** — Displays FDB entries

**gsmp** — Displays GSMP information. This parameter applies to the 7450 ESS or 7750 SR only.

**host** — Displays static hosts configured on the service. This parameter applies to the 7450 ESS or 7750 SR only.

**i-vpls** — Displays I-VPLS services associated with the B-VPLS. This parameter applies to the 7450 ESS or 7750 SR only.

**igmp-snooping** — Displays IGMP snooping information. This parameter applies to the 7450 ESS or 7750 SR only.

**interface** — Displays service interfaces. This parameter applies to the 7450 ESS or 7750 SR only.

**l2-route-table** — Displays Layer 2 route information associated with the service. This parameter applies to the 7450 ESS or 7750 SR only.

**l2pt** — Displays L2PT information of SAPs and Spokes. This parameter applies to the 7450 ESS or 7750 SR only.

**labels** — Displays labels being used by this service

**mac-move** — Displays Mac move-related information about the service. This parameter applies to the 7450 ESS or 7750 SR only.

**mac-protect** — Displays MAC protect information. This parameter applies to the 7450 ESS or 7750 SR only.

**mfib** — Displays MFIB related information. This parameter applies to the 7450 ESS or 7750 SR only.

**mld-snooping** — Displays MLD snooping information. This parameter applies to the 7450 ESS or 7750 SR only.

**mmrp** — Displays MMRP information. This parameter applies to the 7450 ESS or 7750 SR only.

**mrp** — Displays MRP information. This parameter applies to the 7450 ESS or 7750 SR only.

**msap** — Displays MSAPs associated to the service. This parameter applies to the 7450 ESS or 7750 SR only.

**pim-snooping** — Displays PIM snooping information. This parameter applies to the 7450 ESS or 7750 SR only.

**pppoe** — Displays PPPoE information. This parameter applies to the 7450 ESS or 7750 SR only.

**retailers** — Displays service retailer information. This parameter applies to the 7450 ESS or 7750 SR only.

- sap** — Displays SAPs associated to the service
- sdp** — Displays SDPs associated with the service
- source-address** — Displays source-address configured for applications. This parameter applies to the 7450 ESS or 7750 SR only.
- split-horizon-group** — Displays split horizon group information. This parameter applies to the 7450 ESS or 7750 SR only.
- stp** — Displays STP information
- subscriber-host** — Displays subscriber host information. This parameter applies to the 7450 ESS or 7750 SR only.
- wholesalers** — Displays service wholesaler information. This parameter applies to the 7450 ESS or 7750 SR only.

Table 50 describes the command output fields.

**Table 50 Show Service ID All Output Fields**

| Label               | Description                                                                                   |
|---------------------|-----------------------------------------------------------------------------------------------|
| Service Id          | The service identifier.                                                                       |
| VPN Id              | The number which identifies the VPN.                                                          |
| Service Type        | Specifies the type of service.                                                                |
| SDP Id              | The SDP identifier.                                                                           |
| Description         | Generic information about the service.                                                        |
| Customer Id         | The customer identifier.                                                                      |
| Last Mgmt Change    | The date and time of the most recent management-initiated change to this customer.            |
| SAP Count           | The number of SAPs specified for this service.                                                |
| SDP Bind Count      | The number of SDPs bound to this service.                                                     |
| Split Horizon Group | Name of the split horizon group for this service.                                             |
| Description         | Description of the split horizon group.                                                       |
| Last Changed        | The date and time of the most recent management-initiated change to this split horizon group. |

**Table 50 Show Service ID All Output Fields (Continued)**

| Label          | Description (Continued)                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDP Id         | The SDP identifier.                                                                                                                                               |
| Type           | Indicates whether this service SDP binding is a spoke or a mesh.                                                                                                  |
| Admin Path MTU | The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented. |
| Oper Path MTU  | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.  |
| Delivery       | Specifies the type of delivery used by the SDP: GRE or MPLS.                                                                                                      |
| Admin State    | The administrative state of this SDP.                                                                                                                             |
| Oper State     | The operational state of this SDP.                                                                                                                                |
| Ingress Label  | The label used by the far-end device to send packets to this device in this service by this SDP.                                                                  |
| Egress Label   | The label used by this device to send packets to the far-end device in this service by this SDP.                                                                  |
| Ingress Filter | The ID of the ingress filter policy.                                                                                                                              |
| Egress Filter  | The ID of the egress filter policy.                                                                                                                               |
| Far End        | Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.                                                                         |
| Last Changed   | The date and time of the most recent change to this customer.                                                                                                     |
| Hello Time     | Specifies how often the SDP echo request messages are transmitted on this SDP.                                                                                    |
| Hello Msg Len  | Specifies the length of the SDP echo request messages transmitted on this SDP.                                                                                    |
| Max Drop Count | Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault.                   |
| Hold Down Time | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.                                                  |

**Table 50 Show Service ID All Output Fields (Continued)**

| Label                  | Description (Continued)                                                                                                                                                                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SDP Delivery Mechanism | When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the Far End field.<br>If the SDP type is GRE, then the following message displays:<br>SDP Delivery Mechanism is not MPLS |
| Number of SDPs         | The total number SDPs applied to this service ID.                                                                                                                                                                                                                                    |
| Service Id             | The service identifier.                                                                                                                                                                                                                                                              |
| Port Id                | The ID of the access port where this SAP is defined.                                                                                                                                                                                                                                 |
| Description            | Generic information about the SAP.                                                                                                                                                                                                                                                   |
| Encap Value            | The value of the label used to identify this SAP on the access port.                                                                                                                                                                                                                 |
| Admin State            | The administrative state of the SAP.                                                                                                                                                                                                                                                 |
| Oper State             | The operating state of the SAP.                                                                                                                                                                                                                                                      |
| Last Changed           | The date and time of the last change.                                                                                                                                                                                                                                                |
| Admin MTU              | The desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.                                                                                                                    |
| Oper MTU               | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.                                                                                                                     |
| Ingress qos-policy     | The SAP ingress QoS policy ID.                                                                                                                                                                                                                                                       |
| Egress qos-policy      | The SAP egress QoS policy ID.                                                                                                                                                                                                                                                        |
| Ingress Filter-Id      | The SAP ingress filter policy ID.                                                                                                                                                                                                                                                    |
| Egress Filter-Id       | The SAP egress filter policy ID.                                                                                                                                                                                                                                                     |
| Multi Svc Site         | Indicates the multi-service site that the SAP is a member.                                                                                                                                                                                                                           |
| Ingress sched-policy   | Indicates the ingress QoS scheduler for the SAP.                                                                                                                                                                                                                                     |
| Egress sched-policy    | Indicates the egress QoS scheduler for the SAP.                                                                                                                                                                                                                                      |
| Acct. Pol              | Indicates the accounting policy applied to the SAP.                                                                                                                                                                                                                                  |
| Collect Stats          | Specifies whether accounting statistics are collected on the SAP.                                                                                                                                                                                                                    |
| Dropped                | The number of packets or octets dropped.                                                                                                                                                                                                                                             |

| Label                 | Description (Continued)                                                           |
|-----------------------|-----------------------------------------------------------------------------------|
| Offered Hi Priority   | The number of high priority packets, as determined by the SAP ingress QoS policy. |
| Offered Low Priority  | The number of low priority packets, as determined by the SAP ingress QoS policy.  |
| Offered Low Priority  | The number of low priority packets, as determined by the SAP ingress QoS policy.  |
| Forwarded In Profile  | The number of in-profile packets or octets (rate below CIR) forwarded.            |
| Forwarded Out Profile | The number of out-of-profile packets or octets (rate above CIR) forwarded.        |
| Dropped In Profile    | The number of in-profile packets or octets discarded.                             |
| Dropped Out Profile   | The number of out-of-profile packets or octets discarded.                         |
| Forwarded In Profile  | The number of in-profile packets or octets (rate below CIR) forwarded.            |
| Forwarded Out Profile | The number of out-of-profile packets or octets (rate above CIR) forwarded.        |
| Ingress Queue 1       | The index of the ingress QoS queue of this SAP.                                   |
| High priority offered | The packets or octets count of the high priority traffic for the SAP.             |
| High priority dropped | The number of high priority traffic packets/octets dropped.                       |
| Low priority offered  | The packets or octets count of the low priority traffic.                          |
| Low priority dropped  | The number of low priority traffic packets/octets dropped.                        |
| In profile forwarded  | The number of in-profile packets or octets (rate below CIR) forwarded.            |
| Out profile forwarded | The number of out-of-profile octets (rate above CIR) forwarded.                   |
| Egress Queue 1        | The index of the egress QoS queue of the SAP.                                     |
| In profile forwarded  | The number of in-profile packets or octets (rate below CIR) forwarded.            |
| In profile dropped    | The number of in-profile packets or octets dropped for the SAP.                   |
| Out profile forwarded | The number of out-of-profile packets or octets (rate above CIR) forwarded.        |
| Out profile dropped   | The number of out-of-profile packets or octets discarded.                         |

**Table 50 Show Service ID All Output Fields (Continued)**

| Label              | Description (Continued)                                                                     |
|--------------------|---------------------------------------------------------------------------------------------|
| State              | Specifies whether DHCP Relay is enabled on this SAP.                                        |
| Info Option        | Specifies whether Option 82 processing is enabled on this SAP.                              |
| Action             | Specifies the Option 82 processing on this SAP or interface: keep, replace or drop.         |
| Circuit ID         | Specifies whether the If Index is inserted in Circuit ID sub-option of Option 82.           |
| Remote ID          | Specifies whether the far-end MAC address is inserted in Remote ID sub-option of Option 82. |
| Managed by Service | Specifies the service-id of the management VPLS managing this SAP.                          |
| Managed by MSTI    | Specifies the MST instance inside the management VPLS managing this SAP.                    |
| Last BPDU from     | The bridge ID of the sender of the last BPDU received on this SAP.                          |
| Managed by SAP     | Specifies the sap-id inside the management VPLS managing this SAP.                          |
| Prune state        | Specifies the STP state inherited from the management VPLS.                                 |
| Managed by Service | Specifies the service-id of the management VPLS managing this spoke-SDP.                    |
| Last BPDU from     | The bridge ID of the sender of the last BPDU received on this SAP.                          |
| Managed by Spoke   | Specifies the sap-id inside the management VPLS managing this spoke-SDP.                    |
| Prune state        | Specifies the STP state inherited from the management VPLS.                                 |

**Table 50 Show Service ID All Output Fields (Continued)**

| Label        | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peer Pw Bits | <p>Indicates the bits set by the LDP peer when there is a fault on its side of the pseudowire. LAC failures occur on the SAP that has been configured on the pipe service, PSN bits are set by SDP-binding failures on the pipe service. The pwNotForwarding bit is set when none of the above failures apply, such as an MTU mismatch failure. This value is only applicable if the peer is using the pseudowire status signaling method to indicate faults.</p> <p>pwNotForwarding — Pseudowire not forwarding.</p> <p>lacIngressFault Local — Attachment circuit RX fault.</p> <p>lacEgressFault Local — Attachment circuit TX fault.</p> <p>psnIngressFault Local — PSN-facing PW RX fault.</p> <p>psnEgressFault Local — PSN-facing PW TX fault.</p> <p>pwFwdingStandby — Pseudowire in standby mode.</p> |

## arp

**Syntax** **arp** [*ip-address*] | [**mac** *ieee-address*] | [**sap** *sap-id*] | [**interface** *ip-int-name*]

**Context** show>service>id

**Description** This command displays the ARP table for the VPLS instance. The ARP entries for a subscriber interface are displayed uniquely. Each MAC associated with the subscriber interface child group-interfaces is displayed with each subscriber interface ARP entry for easy lookup.

**Parameters** *ip-address* — Displays all IP addresses

*ieee-address* — Displays only ARP entries in the ARP table with the specified 48-bit MAC address. The MAC address is in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers.

**Default** All MAC addresses.

*sap-id* — Displays SAP information for the specified SAP ID

**interface** — Specifies matching service ARP entries associated with the IP interface

*ip-address* — Displays the IP address of the interface for which the matching ARP entries will be displayed

**Values** 1.0.0.0 to 223.255.255.255

*ip-int-name* — Displays the IP interface name for which the matching ARPs will be displayed

**Output** The following output displays an example of service ARP information.

Table 51 describes show service-id ARP output fields.

**Table 51 Show Service-ID ARP Fields**

| Label       | Description                                                                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IP Address  | The IP address.                                                                                                                                                                                      |
| MAC Address | The specified MAC address.<br>Type Static — FDB entries created by management.<br>Learned — Dynamic entries created by the learning process.<br>Other — Local entries for the IP interfaces created. |
| Expiry      | The age of the ARP entry.                                                                                                                                                                            |
| Interface   | The interface applied to the service.                                                                                                                                                                |
| SAP         | The SAP ID.                                                                                                                                                                                          |

## arp-host

**Syntax** **arp-host** [**wholesaler** *service-id*] [**sap** *sap-id* | **interface** *interface-name* | **ip-address** *ip-address[/mask]* | **mac** *ieee-address* | {[**port** *port-id*] [**no-inter-dest-id** | **inter-dest-id** *inter-dest-id*]}] [**detail**]  
**arp-host statistics** [**sap** *sap-id* | **interface** *interface-name*]  
**arp-host summary** [**interface** *interface-name*]

**Context** show>service>id

**Description** This command displays ARP host related information.

**Output** The following output is an example of service ARP host information.

Table 52 describes show service-id base output fields.

**Table 52 Show Service-ID Base Fields**

| Label            | Description                                                                        |
|------------------|------------------------------------------------------------------------------------|
| Service Id       | The service identifier.                                                            |
| Vpn Id           | Specifies the VPN ID assigned to the service.                                      |
| Service Type     | Displays the type of service.                                                      |
| Description      | Generic information about the service.                                             |
| Customer Id      | The customer identifier.                                                           |
| Last Mgmt Change | The date and time of the most recent management-initiated change to this customer. |
| Adm              | The administrative state of the service.                                           |
| Oper             | The operational state of the service.                                              |

**Table 52 Show Service-ID Base Fields (Continued)**

| Label          | Description (Continued)                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mtu            | The largest frame size (in octets) that the service can handle.                                                                                                             |
| SAP Count      | The number of SAPs defined on the service.                                                                                                                                  |
| SDP Bind Count | The number of SDPs bound to the service.                                                                                                                                    |
| Identifier     | Specifies the service access (SAP) and destination (SDP) points.                                                                                                            |
| Type           | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP.                                           |
| AdmMTU         | Specifies the largest service frame size (in octets) that can be transmitted through this SDP to the far-end ESR, without requiring the packet to be fragmented.            |
| OprMTU         | Specifies the actual largest service frame size (in octets) that can be transmitted through this service to the far-end ESR, without requiring the packet to be fragmented. |
| Opr            | The operating state of the SAP.                                                                                                                                             |

## bgp-evpn

**Syntax** **bgp-evpn**

**Context** show>service>id

**Description** This command displays the bgp-evpn configured parameters for a specified service, including the admin status of vxlan, the configuration for mac-advertisement and unknown-mac-route as well as the mac-duplication parameters. The command shows the duplicate mac addresses that mac-duplication has detected.

**Output**

### Sample Output

```
*A:DutA# show service id 1 bgp-evpn
=====
BGP EVPN Table
=====
MAC Advertisement : Enabled          Unknown MAC Route : Disabled
VXLAN Admin Status : Enabled         Creation Origin   : manual
MAC Dup Detn Moves : 5               MAC Dup Detn Window: 3
MAC Dup Detn Retry : 9               Number of Dup MACs : 1

## statistics

**Syntax**     **statistics** [**sap** *sap-id*]  
**statistics** [**sdp** *sdp-id:vc-id*]  
**statistics** [**interface** *interface-name*]

**Context**    show>service>id>dhcp

**Description**    Displays DHCP statistics information.

**Parameters**    *sap-id* — Specifies the physical port identifier portion of the SAP definition  
*sdp-id* — The SDP identifier

**Values**        1 to 17407

*vc-id* — The virtual circuit ID on the SDP ID for which to display information

**Values**        1 to 4294967295

*interface-name* — Displays information for the specified IP interface

## summary

[Table 53](#) describes the output fields for DHCP summary.

**Table 53** Show DHCP Summary Output Fields

| Label          | Description                                                                                                                                                                                                                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface Name | Name of the router interface.                                                                                                                                                                                                                                                                                             |
| Arp Populate   | Specifies whether or not ARP populate is enabled.                                                                                                                                                                                                                                                                         |
| Used/Provided  | Used — The number of lease-states that are currently in use on a specific interface, that is, the number of clients on that interface got an IP address by DHCP. This value is always less than or equal to the 'Provided' field.<br><br>Provided — The lease-populate value that is configured for a specific interface. |
| Info Option    | Indicates whether Option 82 processing is enabled on the interface.                                                                                                                                                                                                                                                       |

**Table 53 Show DHCP Summary Output Fields (Continued)**

| Label       | Description (Continued)             |
|-------------|-------------------------------------|
| Admin State | Indicates the administrative state. |

## endpoint

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>endpoint</b> [ <i>endpoint-name</i> ]                                                                  |
| <b>Context</b>     | show>service>id                                                                                           |
| <b>Description</b> | This command displays service endpoint information.                                                       |
| <b>Parameters</b>  | <i>endpoint-name</i> — Specifies an endpoint name created in the <b>config&gt;service&gt;vpls</b> context |
| <b>Output</b>      |                                                                                                           |

### Sample Output

```

## epipe

|               |              |
|---------------|--------------|
| <b>Syntax</b> | <b>epipe</b> |
|---------------|--------------|

**Context** show>service>id

**Description** This command displays Epipe services associated with the B-VPLS service. The command only applies when the service is a B-VPLS.

**Output** The following output is an example of Epipe service information.

#### Sample Output

```
*A:term17>show>service>id# epipe
=====
Related Epipe services for bVpls service 2000

```

## etree

**Syntax** etree

**Context** show>service>id

**Description** This command displays the same information shown in the show service ID base context, with the addition of the role of each object in the VPLS E-Tree service.

The following labels identify the configuration of the SAPs and SDP bindings:

- (L) indicates leaf-ac
- (RL) indicates root-leaf-tag

**Output**

#### Sample Output

```
*A:PE-6# show service id 2005 etree

| Source Identifier | Displays the id of the source MAC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Type/Age          | <p>Type — Specifies the number of seconds used to age out TLS FDB entries learned on local SAPs.</p> <p>Age — Specifies the number of seconds used to age out TLS FDB entries learned on an SDP. These entries correspond to MAC addresses learned on remote SAPs.</p> <p>L — Learned - Dynamic entries created by the learning process.</p> <p>OAM — Entries created by the OAM process.</p> <p>H — Host, the entry added by the system for a static configured subscriber host.</p> <p>D or DHCP — DHCP-installed MAC. Learned addresses can be temporarily frozen by the DHCP snooping application for the duration of a DHCP lease.</p> <p>P — Indicates the MAC is protected by the MAC protection feature.</p> <p>Static — Statically configured.</p> |
| Last Change       | Indicates the time of the most recent state changes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

gsmP

**Syntax** gsmP

**Context** show>service>id

**Description** This command displays GSMP information.

## neighbors

**Syntax** **neighbors group** [*name*] [*ip-address*]

**Context** show>service>id>gsmp

**Description** This command displays GSMP neighbor information.

**Parameters** **group** — A GSMP group defines a set of GSMP neighbors which have the same properties.

*name* — Specifies a GSMP group name is unique only within the scope of the service in which it is defined.

*ip-address* — Specifies the ip-address of the neighbor.

**Output** The following output is an example of service GSMP neighbor information.

### Sample Output

These commands show the configured neighbors per service, regardless of the fact there exists an open TCP connection with this neighbor. The admin state is shown because for a neighbor to be admin enabled, the service, gsmp node, group node and the neighbor node in this service must all be in 'no shutdown' state. Session gives the number of session (open TCP connections) for each configured neighbor.

Table 55 describes show sessions neighbor output fields.

**Table 55 Show Sessions Neighbor Output Fields**

| Label            | Description                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------|
| State            | The current state of the ANCP session.                                                                                           |
| Peer Instance    | The instance number of the ANCP session at the neighbor's side.                                                                  |
| Sender Instance  | The instance number of the ANCP session at our side.                                                                             |
| Peer Port        | The port number of the ANCP session at the neighbor's side.                                                                      |
| Sender Port      | The port number of the ANCP session at the local side.                                                                           |
| Peer Name        | The MAC address of the ANCP session at the neighbor's side.                                                                      |
| Sender name      | The MAC address of the ANCP session at the local side.                                                                           |
| timeouts         | The number of adjacency protocol message timeouts.                                                                               |
| Max. Timeouts    | The maximum allowed of the above timeouts before closing.                                                                        |
| Peer Timer       | The timer value for the neighbor periodic adjacency protocol messages.                                                           |
| Sender Timer     | The timer value for the local periodic adjacency protocol messages.                                                              |
| Capabilities     | The negotiated capabilities for the Established ANCP session (DTD: dynamic topology discovery - OAM: operation and maintenance). |
| Conf Cap         | The configured local capabilities.                                                                                               |
| Priority Marking | The DSCP bits for the IP messages used in the ANCP session.                                                                      |
| Local Addr.      | The destination IP address for this ANCP session.                                                                                |
| Conf Local Addr. | The destination IP address accepted for ANCP connections.                                                                        |

## host-connectivity-verify

**Syntax** **host-connectivity-verify statistics** [**sap** *sap-id*]

**Context** show>service>id

**Description** This command displays host connectivity check statistics.

- Parameters**    **statistics** — Displays host connectivity verification data
- sap-id** — Specifies the physical port identifier portion of the SAP definition
- Output**        The following output is an example of service host connectivity information.

**Sample Output**

```
A:ALA-48>show>service>id# host-connectivity-verify statistics sap 1/1/9:0
=====
Host connectivity check statistics
=====
Svc   SapId/      DestIp      Last        Time        Oper
Id    SdpId      Address     Response    Expired     State
-----
10001/2/3:01.144.145.1                Up
=====

```

[Table 56](#) describes show service-id host connectivity verification output fields.

**Table 56**        **Show Service Id Host Connectivity Verify Fields**

| Label          | Description                                            |
|----------------|--------------------------------------------------------|
| Svc Id         | The service identifier.                                |
| SapId/SdpId    | The SAP and SDP identifiers.                           |
| DestIp Address | The destination IP address.                            |
| Last Response  | The time when the last response was received.          |
| Time Expired   | Displays whether the interval value has expired.       |
| Oper State     | Displays the current operational state of the service. |

## i-vpls

- Syntax**        **i-vpls**
- Context**        show>service>id
- Description**    Displays I-VPLS services associated with the B-VPLS service. This command only applies when the service is a B-VPLS.
- Output**        The following output is an example of service I-VPLS information.

**Sample Output**

```
*A:SetupCLI# show service id 2002 i-vpls

[Table 57](#) describes show service-id labels output fields.

**Table 57**     **Show Service-ID Labels Fields**

| Label  | Description                                 |
|--------|---------------------------------------------|
| Svc Id | The service identifier.                     |
| Sdp Id | The SDP identifier.                         |
| Type   | Indicates whether the SDP is spoke or mesh. |

**Table 57 Show Service-ID Labels Fields (Continued)**

| Label  | Description                                                                                        |
|--------|----------------------------------------------------------------------------------------------------|
| I. Lbl | The VC label used by the far-end device to send packets to this device in this service by the SDP. |
| E. Lbl | The VC label used by this device to send packets to the far-end device in this service by the SDP. |

Table 58 describes show L2PT output fields.

**Table 58 Show L2PT Fields**

| Label                  | Description                                                                                                                                                                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Service id             | Displays the 24 bit (0 to 16777215) service instance identifier for the service.                                                                                                                                                                                      |
| L2pt-term enabled      | Indicates if L2-PT-termination and/or Bpdu-translation is in use in this service by at least one SAP or spoke-SDP binding. If in use, at least one of L2PT-termination or Bpdu-translation is enabled. When enabled it is not possible to enable STP on this service. |
| L2pt-term disabled     | Indicates that L2-PT-termination is disabled.                                                                                                                                                                                                                         |
| Bpdu-trans auto        | Specifies the number of L2-PT PDUs are translated before being sent out on a port or sap.                                                                                                                                                                             |
| Bpdu-trans disabled    | Indicates that Bpdu-translation is disabled.                                                                                                                                                                                                                          |
| SAPs                   | Displays the number of SAPs with L2PT or BPDU translation enabled or disabled.                                                                                                                                                                                        |
| SDPs                   | Displays the number of SDPs with L2PT or BPDU translation enabled or disabled.                                                                                                                                                                                        |
| Total                  | Displays the column totals of L2PT entities.                                                                                                                                                                                                                          |
| Sapld                  | The ID of the access point where this SAP is defined.                                                                                                                                                                                                                 |
| L2pt-termination       | Indicates whether L2pt termination is enabled or disabled.                                                                                                                                                                                                            |
| Admin Bpdu-translation | Specifies whether Bpdu translation is administratively enabled or disabled.                                                                                                                                                                                           |
| Oper Bpdu-translation  | Specifies whether Bpdu translation is operationally enabled or disabled.                                                                                                                                                                                              |
| Sdpld                  | Specifies the SAP ID.                                                                                                                                                                                                                                                 |

## mac-move

## mmrp

- Syntax** `mmrp mac [ieee-address]`
- Context** `show>service>id`
- Description** This command displays information on MACs. If a MAC address is specified, information will be displayed relevant to the specific group. No parameter will display information on all group MACs on a server.
- Parameters** *ieee-address* — Displays hex string information
- Output** The following output is an example of service MMRP MAC information.

**Sample Output**

```

*A:PE-A# show service id 10 mmrp mac 01:1E:83:00:00:65

```

```

-----
SAP/SDP          MAC Address      Registered  Declared
-----
sap:1/1/4:10     01:1e:83:00:00:65 No           Yes
sap:1/2/2:10     01:1e:83:00:00:65 No           Yes
sap:2/2/5:10     01:1e:83:00:00:65 Yes          Yes

```

```

*A:PE-A#

```

```

*A:PE-A# show service id 10 mmrp mac

```

```

-----

## mstp-configuration

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mstp-configuration</b>                                                                                    |
| <b>Context</b>     | show>service>id                                                                                              |
| <b>Description</b> | This command displays the MSTP specific configuration data. This command is only valid on a management VPLS. |

## pim-snooping

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim-snooping</b>                                                   |
| <b>Context</b>     | show>service>id                                                       |
| <b>Description</b> | This command enables the context to display PIM snooping information. |

## group

|                    |                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>group</b> [ <i>grp-ip-address</i> ] [ <b>source</b> <i>ip-address</i> ] [ <b>type</b> { <b>starg</b>   <b>sg</b> }] [ <b>detail</b> ] [ <i>family</i> ]                                                                                                                                                                                                  |
| <b>Context</b>     | show>service>id>pim-snooping                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command displays the multicast group information.                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>grp-ip-address</i> — Specifies the IP multicast group address for which this entry contains information</p> <p><i>ip-address</i> — Specifies the source address for which this entry contains information.</p> <p><i>starg</i> — Specifies that only (*,G) entries be displayed</p> <p><i>sg</i> — Specifies that only (S,G) entries be displayed</p> |

**detail** — Displays detailed group information.

**family** — Displays either IPv4 or IPv6 information.

**Values**      ipv4 or ipv6

**Output**      The following output is an example of service PIM snooping information.

### Sample Output

```
*A:PE# show service id 1 pim-snooping group

## neighbor

**Syntax**      **neighbor** [{**sap** *sap-id* | **sdp** *sdp-id:vc-id*} [**address** *ip-address*]] [**detail**] [*family*]

**Context**      show>service>id>pim-snooping

**Description**      This command displays PIM neighbor information.

**Parameters**      *ip-int-name* — Only displays the interface information associated with the specified IP interface name

*sap-id* — Displays the neighbor information associated with the specified SAP

*sdp-id:vc-id* — Displays the neighbor information associated with the specified SDP

*ip-address* — Displays information for the neighbor with the specified IP address

**detail** — Displays detailed neighbor information

*family* — Displays either IPv4 or IPv6 information for the specified neighbor

**Values**      ipv4 or ipv6

**Output**      The following output is an example of service PIM snooping neighbor information.

### Sample Output

```
*A:PE# show service id 1 pim-snooping neighbor

## proxy-arp

**Syntax**    **proxy-arp** [**ip-address** *ip-address*] [**detail**]

**Context**    show>service

**Description** This command displays the proxy-ARP entries existing for a particular service. A 7750 SR, 7450 ESS or 7950 XRS router receiving an ARP request from a SAP or SDP-binding will perform a lookup in the proxy-arp table for the service. If the router finds a match, it will reply to the ARP and will not let the ARP be flooded in the VPLS service. If the router does not find a match, the ARP will be flooded within the service. The command allows for specific IP addresses to be shown.

The **detail** parameter allows the user to display all the entries. An individual IP address entry can also be shown.

**Output** The following output is an example of service proxy ARP information.

### Sample Output

```
:PE71(1)# show service id 600 proxy-arp
-----
Proxy Arp
-----

A:PE71(1)#

```

## retailers

**Syntax**     **retailers**

**Context**    show>service>id

**Description**    This command displays the service ID of the retailer subscriber service to which this DHCP lease belongs.

## wholesalers

**Syntax**     **wholesalers**

**Context**    show>service>id

**Description**    This command displays service wholesaler information.

## vxlan

**Syntax**     **vxlan**

**Context**    show>service>id  
show>service

**Description** This command displays the VXLAN bindings auto-created in a specified service. A VXLAN binding is composed of the remote VTEP (VXLAN Termination Endpoint) and the corresponding egress VNI (VXLAN Network Identifier) to identify the service at the egress node. The command shows the number of MACs associated to each binding as well as the operational status if the binding is part of the multicast list. The binding will be operationally down when the VTEP address is not found in the base routing table (the VTEP address cannot be reached). A binding will be part of the multicast list if a valid BGP EVPN inclusive multicast route exists for it.

**Output** The following output is an example of service VXLAN information.

### Sample Output

```
*A:DutA# show service id 1 vxlan

## sap

**Syntax** **sap** [*sap-id* [*filter*] [*detail*]]

**Context** show>service>id

**Description** This command displays information for the SAPs associated with the service.

If no optional parameters are specified, a summary of all associated SAPs is displayed.

**Parameters**     *sap-id* — The ID that displays SAPs for the service in the *slot/mdalport[.channel]* form  
**detail** — Displays detailed information for the SAP  
*filter* — Specifies a search term to narrow down the results. This parameter applies to the 7450 ESS or 7750 SR only.  
**Values**        atm, base, detail, dhcp, mc-ring, mcac, mrp, qos, sap-stats, stats, stp, sub-mgmt

**Output**        The following output is an example of service SAP information.

### Sample Output

```
*A:PE# show service id 1 sap 1/1/1 detail
```

Table 59 describes show service SAP fields.

**Table 59 Show Service-ID SAP Fields**

| Label       | Description                                    |
|-------------|------------------------------------------------|
| Service Id  | The service identifier.                        |
| SAP         | The SAP and qtag.                              |
| Encap       | The encapsulation type of the SAP.             |
| Ethertype   | Specifies an Ethernet type II Ethertype value. |
| Admin State | The administrative state of the SAP.           |
| Oper State  | The operational state of the SAP.              |

**Table 59 Show Service-ID SAP Fields (Continued)**

| Label                   | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Flags                   | Specifies the conditions that affect the operating status of this SAP.<br>Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode. |
| Last Status Change      | Specifies the time of the most recent operating status change to this SAP.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Last Mgmt Change        | Specifies the time of the most recent management-initiated change to this SAP.                                                                                                                                                                                                                                                                                                                                                                                                       |
| Admin MTU               | The largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.                                                                                                                                                                                                                                                                                                                             |
| Oper MTU                | The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.                                                                                                                                                                                                                                                                                                                      |
| Ingress qos-policy      | The ingress QoS policy ID assigned to the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Egress qos-policy       | The egress QoS policy ID assigned to the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Ingress Filter-Id       | The ingress filter policy ID assigned to the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Egress Filter-Id        | The egress filter policy ID assigned to the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Acct. Pol               | The accounting policy ID assigned to the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Collect Stats           | Specifies whether collect stats is enabled.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Forwarding Engine Stats |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Dropped                 | The number of packets and octets dropped due to SAP state, ingress MAC or IP filter, same segment discard, bad checksum, etc.                                                                                                                                                                                                                                                                                                                                                        |
| Received Valid          | The number of valid packets and octets received on the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Off. HiPrio             | The number of high priority packets and octets, as determined by the SAP ingress QoS policy.                                                                                                                                                                                                                                                                                                                                                                                         |

**Table 59 Show Service-ID SAP Fields (Continued)**

| Label                              | Description (Continued)                                                                                                                                     |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Off. LowPrio                       | The number of low priority packets and octets, as determined by the SAP ingress QoS policy.                                                                 |
| Off. Uncolor                       | The number of uncolored packets and octets, as determined by the SAP ingress QoS policy.                                                                    |
| Queuing Stats (Ingress QoS Policy) |                                                                                                                                                             |
| Dro. HiPrio                        | The number of high priority packets and octets, as determined by the SAP ingress QoS policy, dropped due to: MBS exceeded, buffer pool limit exceeded, etc. |
| Dro. LowPrio                       | The number of low priority packets and octets, as determined by the SAP ingress QoS policy, dropped due to: MBS exceeded, buffer pool limit exceeded, etc.  |
| For. InProf                        | The number of in-profile packets and octets (rate below CIR) forwarded.                                                                                     |
| For. OutProf                       | The number of out-of-profile packets and octets discarded due to MBS exceeded, buffer pool limit exceeded, etc.                                             |
| Queuing Stats (Egress QoS Policy)  |                                                                                                                                                             |
| Dro. InProf                        | The number of in-profile packets and octets discarded due to MBS exceeded, buffer pool limit exceeded, etc.                                                 |
| Dro. OutProf                       | The number of out-of-profile packets and octets due to MBS exceeded, buffer pool limit exceeded, etc.                                                       |
| For. InProf                        | The number of in-profile packets and octets (rate below CIR) forwarded.                                                                                     |
| For. OutProf                       | The number of out-of-profile packets and octets (rate above CIR) forwarded.                                                                                 |
| Ingress TD Profile                 | The profile ID applied to the ingress SAP.                                                                                                                  |
| Egress TD Profile                  | The profile ID applied to the egress SAP.                                                                                                                   |
| Alarm Cell Handling                | The indication that OAM cells are being processed.                                                                                                          |
| AAL-5 Encap                        | The AAL-5 encapsulation type.                                                                                                                               |

| <b>Description</b> | This command displays information for the SDPs associated with the service. If no optional parameters are specified, a summary of all associated SDPs is displayed.                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>sdp-id</i> — Displays only information for the specified SDP ID</p> <p><b>Default</b> All SDPs</p> <p><b>Values</b> 1 to 17407</p> <p><i>ip-addr</i> — Displays only SDPs matching with the specified far-end IP address</p> <p><b>Default</b> SDPs with any far-end IP address</p> <p><b>detail</b> — Displays detailed SDP information.</p> |
| <b>Output</b>      | The following output is an example of service SDP information.                                                                                                                                                                                                                                                                                      |

[Table 60](#) describes show service-id SDP output fields.

**Table 60**      **Show Service-ID SDP Fields**

| Label               | Description                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sdp Id              | The SDP identifier.                                                                                                                                                          |
| Type                | Indicates whether the SDP is spoke or mesh.                                                                                                                                  |
| Split Horizon Group | Indicates the name of the split horizon group that the SDP belongs to.                                                                                                       |
| VC Type             | Displays the VC type: ether, vlan, or vpls.                                                                                                                                  |
| VC Tag              | Displays the explicit dot1q value used when encapsulating to the SDP far end.                                                                                                |
| I. Lbl              | The VC label used by the far-end device to send packets to this device in this service by the SDP.                                                                           |
| Admin Path MTU      | The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case.) |
| Oper Path MTU       | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.             |
| Far End             | Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.                                                                                    |
| Delivery            | Specifies the type of delivery used by the SDP: GRE or MPLS.                                                                                                                 |
| Admin State         | The administrative state of this SDP.                                                                                                                                        |
| Oper State          | The current status of the SDP.                                                                                                                                               |
| Ingress Label       | The label used by the far-end device to send packets to this device in this service by this SDP.                                                                             |
| Egress Label        | The label used by this device to send packets to the far-end device in this service by the SDP.                                                                              |
| Last Changed        | The date and time of the most recent change to the SDP.                                                                                                                      |
| Signaling           | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.                                           |
| Admin State         | The administrative state of the Keepalive process.                                                                                                                           |
| Oper State          | The operational state of the Keepalive process.                                                                                                                              |
| Hello Time          | Specifies how often the SDP echo request messages are transmitted on this SDP.                                                                                               |

**Table 60 Show Service-ID SDP Fields (Continued)**

| Label               | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Drop Count      | Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Hello Msg Len       | Specifies the length of the SDP echo request messages transmitted on this SDP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Hold Down Time      | Specifies the amount of time to wait before the Keepalive operating status is eligible to enter the alive state.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| I. Fwd. Pkts.       | Specifies the number of forwarded ingress packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| I. Dro. | Associated LSP List | When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far end field.<br><br>If the SDP type is GRE, then the following message displays:<br>SDP delivery mechanism is not MPLS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Peer Pw Bits        | Indicates the bits set by the LDP peer when there is a fault on its side of the pseudowire. LAC failures occur on the SAP that has been configured on the pipe service, PSN bits are set by SDP-binding failures on the pipe service. The pwNotForwarding bit is set when none of the above failures apply, such as an MTU mismatch failure. This value is only applicable if the peer is using the pseudowire status signaling method to indicate faults.<br><br>pwNotForwarding — Pseudowire not forwarding.<br>lacIngressFault Local — Attachment circuit RX fault.<br>lacEgressFault Local — Attachment circuit TX fault.<br>psnIngressFault Local — PSN-facing PW RX fault.<br>psnEgressFault Local — PSN-facing PW TX fault.<br>pwFwdingStandby — Pseudowire in standby mode. |

site

**Syntax**    **site [detail]**  
              **site name**

**Context**    show>service>id

- Description** This command displays sites configured for the service.
- Parameters** *name* — Specifies the site name up to 32 characters in length

## split-horizon-group

- Syntax** **split-horizon-group** [*group-name*]
- Context** show>service>id
- Description** This command displays service split horizon groups.

```
*A:ALA-1# show service id 700 split-horizon-group
=====
Service: Split Horizon Group
=====
Name                               Description
-----
R DSL-group1                       Split horizon group for DSL
DSL-group1                         Split horizon group for DSL
-----
R = Residential Split Horizon Group
No. of Split Horizon Groups: 1

## stp

- Syntax** **stp** [*detail*]  
**stp mst-instance** *mst-inst-number*
- Context** show>service>id

**Description** This command displays information for the spanning tree protocol instance for the service.

**Parameters** **detail** — Displays detailed information.

*mst-inst-number* — Displays information about the specified MST.

**Values** 1 to 4094

## Output

### Sample Output

```
*A:ALA-12# show service id 11 stp

[Table 61](#) describes show service-id STP output fields.

**Table 61 Show Service-ID STP Output Fields**

| Label              | Description                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RSTP Admin State   | Indicates the administrative state of the Rapid Spanning Tree Protocol instance associated with this service.                                                                                                                                               |
| Core Connectivity  | Indicates the connectivity status to the core.                                                                                                                                                                                                              |
| RSTP Oper State    | Indicates the operational state of the Rapid Spanning Tree Protocol instance associated with this service. This field is applicable only when STP is enabled on the router.                                                                                 |
| Bridge-id          | Specifies the MAC address used to identify this bridge in the network.                                                                                                                                                                                      |
| Hold Time          | Specifies the interval length during which no more than two Configuration BPDUs shall be transmitted by this bridge.                                                                                                                                        |
| Bridge fwd delay   | Specifies how fast a bridge changes its state when moving toward the forwarding state.                                                                                                                                                                      |
| Bridge Hello time  | Specifies the amount of time between the transmission of Configuration BPDUs.                                                                                                                                                                               |
| Bridge max age     | Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded. This is the actual value that this bridge is currently using.                                                                  |
| Bridge priority    | Defines the priority of the Spanning Tree Protocol instance associated with this service.                                                                                                                                                                   |
| Topology change    | Specifies whether a topology change is currently in progress.                                                                                                                                                                                               |
| Last Top. change   | Specifies the time (in hundredths of a second) since the last time a topology change was detected by the Spanning Tree Protocol instance associated with this service.                                                                                      |
| Top. change count  | Specifies the total number of topology changes detected by the Spanning Tree Protocol instance associated with this service since the management entity was last reset or initialized.                                                                      |
| Root bridge-id     | Specifies the bridge identifier of the root of the spanning tree as determined by the Spanning Tree Protocol instance associated with this service. This value is used as the Root Identifier parameter in all Configuration BPDUs originated by this node. |
| Root path cost     | Specifies the cost of the path to the root bridge as seen from this bridge.                                                                                                                                                                                 |
| Root forward delay | Specifies how fast the root changes its state when moving toward the forwarding state.                                                                                                                                                                      |

**Table 61 Show Service-ID STP Output Fields (Continued)**

| Label                   | Description (Continued)                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Root hello time         | Specifies the amount of time between the transmission of configuration BPDUs.                                                                    |
| Root max age            | Specifies the maximum age of Spanning Tree Protocol information learned from the network on any port before it is discarded.                     |
| Root priority           | This object specifies the priority of the bridge that is currently selected as root-bridge for the network.                                      |
| Root port               | Specifies the port number of the port which offers the lowest cost path from this bridge to the root bridge.                                     |
| SAP Identifier          | The ID of the access port where this SAP is defined.                                                                                             |
| RSTP State              | The operational state of RSTP.                                                                                                                   |
| STP Port State          | Specifies the port identifier of the port on the designated bridge for this port's segment.                                                      |
| BPDU encap              | Specifies the type of encapsulation used on BPDUs sent out and received on this SAP.                                                             |
| Port Number             | Specifies the value of the port number field which is contained in the least significant 12 bits of the 16-bit port ID associated with this SAP. |
| Priority                | Specifies the value of the port priority field which is contained in the most significant 4 bits of the 16-bit port ID associated with this SAP. |
| Cost                    | Specifies the contribution of this port to the path cost of paths toward the spanning tree root which include this port.                         |
| Fast Start              | Specifies whether Fast Start is enabled on this SAP.                                                                                             |
| Designated Port         | Specifies the port identifier of the port on the designated bridge for this port's segment.                                                      |
| Designated Bridge       | Specifies the bridge identifier of the bridge which this port considers to be the designated bridge for this port's segment.                     |
| Service Access Points   |                                                                                                                                                  |
| Managed by Service      | Specifies the service ID of the management VPLS managing this SAP or spoke-SDP.                                                                  |
| Managed by SAP or spoke | Specifies the SAP ID or SDP ID inside the management VPLS managing this SAP or spoke-SDP.                                                        |
| Prune state             | Specifies the STP state inherited from the management VPLS.                                                                                      |

| <b>Description</b> | This command displays subscriber host information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>sap</b> <i>sap-id</i> — Displays the specified subscriber host SAP information</p> <p><b>ip</b> <i>ip-address/mask</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation.</p> <p><b>Values</b>      Allowed values are IP addresses in the range 1.0.0.0 to 223.255.255.255 (with support of /31 subnets).<br/>mask: 1 to 32</p> <p><b>mac</b> <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><b>sub-profile-name</b> — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context.</p> <p><b>sla-profile-name</b> — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> <p><b>detail</b> — Displays detailed information</p> |
| <b>Output</b>      | The following output is an example of service subscriber host information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

### Sample Output

## fdb-usage

- Syntax** `fdb-usage [card slot-id]`
- Context** `show>service>system`
- Description** This command displays the FDB usage, excluding the pending updates (which can be seen using the **tools dump service id id fdb {card-status | mac-status}** command) for the system and all line cards.
- Parameters** *slot-id* — Displays the information for the line card in the specified slot IDs, expressed as an integer.
- Values** 1 to 20
- Output** The following output is an example of FDB usage information.

### Sample Output

```

*A:PE1# show service system fdb-usage
=====

Table 62 describes the show all service-id command output fields.

**Table 62 IGMP Snooping Fields**

| Label        | Description                                                                                   |
|--------------|-----------------------------------------------------------------------------------------------|
| Admin State  | The administrative state of the IGMP instance.                                                |
| Querier      | Displays the address of the IGMP querier on the IP subnet to which the interface is attached. |
| Sap Id       | Displays the SAP IDs of the service ID.                                                       |
| Oper State   | Displays the operational state of the SAP IDs of the service ID.                              |
| Mrtr Port    | Specifies if the port is a multicast router port.                                             |
| Send Queries | Specifies whether the send-queries command is enabled or disabled.                            |

**Table 62 IGMP Snooping Fields (Continued)**

| Label          | Description (Continued)                                                          |
|----------------|----------------------------------------------------------------------------------|
| Max Num Groups | Specifies the maximum number of multicast groups that can be joined on this SAP. |
| MVR From VPLS  | Specifies MVR from VPLS.                                                         |
| Num Groups     | Specifies the actual number of multicast groups that can be joined on this SAP.  |

## mfib

**Syntax** **mfib** [ipv4 | ipv6 | mac]  
**mfib brief**  
**mfib group** *group-address* [statistics]  
**mfib statistics** [ipv4 | ipv6 | mac]

**Context** show>service>id

**Description** This command displays the multicast FIB on the VPLS service.

**Parameters** **brief** — Displays a brief output  
**statistics** — Displays statistics on the multicast FIB  
**ipv4** — Displays IPv4 address information  
**ipv6** — Displays IPv6 address information  
**mac** — Displays MAC address information  
*group-address* — Displays the multicast FIB for a specific multicast group address

## Output

*A:PE#

```

To show which ISIDs are local, the MFIB command will display ISIDs that are local and advertised. Static ISIDs are included in this display. However, ISID policy can override the ISIDs that are designated to use the default multicast tree and these do not show up in the MFIB. This is displayed on a B-VPLS control service.

**Table 63 Multicast FIB Fields**

| Label               | Description                                                                                                                                                                                        |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source Address      | IPv4 unicast source address.                                                                                                                                                                       |
| Group Address       | IPv4 multicast group address.                                                                                                                                                                      |
| SAP ID              | Indicates the SAP/SDP to which the corresponding multicast stream will be forwarded/blocked.                                                                                                       |
| Forwarding/Blocking | Indicates whether the corresponding multicast stream will be blocked/forwarded.                                                                                                                    |
| Number of Entries   | Specifies the number of entries in the MFIB.                                                                                                                                                       |
| Forwarded Packets   | Indicates the number of multicast packets forwarded for the corresponding source/group.                                                                                                            |
| Forwarded Octets    | Indicates the number of octets forwarded for the corresponding source/group.                                                                                                                       |
| Svc ID              | Indicates the service to which the corresponding multicast stream will be forwarded/blocked. Local means that the multicast stream will be forwarded/blocked to a SAP or SDP local to the service. |

Table 64 describes the show all service-id command output fields.

**Table 64 Show All Service-ID Fields**

| Label           | Description                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| MVR Admin State | Administrative state.                                                                                                                               |
| MVR Policy      | Policy name.                                                                                                                                        |
| Svc ID          | The service identifier.                                                                                                                             |
| Sap/Sdp Id      | Displays the SAP and SDP IDs of the service ID.                                                                                                     |
| Oper State      | Displays the operational state of the SAP and SDP IDs of the svcid.                                                                                 |
| Mrtr Port       | Specifies if the port is a multicast router port.                                                                                                   |
| From VPLS       | Specifies from which VPLS the multicast streams corresponding to the groups learned via this SAP will be copied. If local, it is from its own VPLS. |
| Num Groups      | Specifies the number of groups learned via this local SAP.                                                                                          |

## port-db

**Syntax** **port-db sap** *sap-id* [**detail**]  
**port-db sap** *sap-id* **group** *grp-address*  
**port-db sdp** *sdp-id:vc-id* [**detail**]  
**port-db sdp** *sdp-id:vc-id* **group** *grp-ip-address*  
**vxlan vtep** *ip-address vni vni-id*

**Context** show>service>id>igmp-snooping

**Description** This command displays information on the IGMP snooping port database for the VPLS service.

- Parameters**
- grp-ip-address* — Displays the IGMP snooping port database for a specific multicast group address
  - sap-id* — Displays the IGMP snooping port database for a specific SAP
  - sdp-id* — Displays only IGMP snooping entries associated with the specified mesh SDP or spoke-SDP. For a spoke-SDP, the VC ID must be specified, for a mesh SDP, the VC ID is optional.
  - Values** 1 to 17407
  - vc-id* — The virtual circuit ID on the SDP ID for which to display information
  - Default** For mesh SDPs only, all VC IDs
  - Values** 1 to 4294967295
  - grp-address* — Displays IGMP snooping statistics matching the specified group address. This parameter only applies to the 7450 ESS or 7750 SR.
  - ip-address* — Displays IGMP snooping statistics matching one particular source within the multicast group. This parameter only applies to the 7450 ESS or 7750 SR.
  - vxlan vtep ip-address vni <1..16777215>* — Displays the IGMP snooping entries associated with a specific VXLAN binding, given by the VXLAN Termination Endpoint (VTEP) and VXLAN Network Identifier (VNI). This parameter only applies to the 7450 ESS or 7750 SR.
  - vni* — The VXLAN Network Identifier (VNI) for which to display information. This parameter only applies to the 7450 ESS or 7750 SR.
  - Values** 1 to 16777215

**Table 65 IGMP Snooping Port Database Fields**

| Label              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group Address      | The IP multicast group address for which this entry contains information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Mode               | Specifies the type of membership reports received on the interface for the group.<br><br>In the include mode, reception of packets sent to the specified multicast address is requested only from those IP source addresses listed in the source-list parameter of the IGMP membership report.<br><br>In the exclude mode, reception of packets sent to the specified multicast address is requested from all IP source addresses except those listed in the <b>source-list</b> parameter.                                                                                                                                    |
| Type               | Indicates how this group entry was learned.<br><br>If this group entry was learned by IGMP, the value is set to dynamic.<br><br>For statically configured groups, the value is set to static.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Compatibility mode | Specifies the IGMP mode. This is used for routers to be compatible with older-version routers. IGMPv3 hosts must operate in Version 1 and Version 2 compatibility modes. IGMPv3 hosts must keep state per local interface regarding the compatibility mode of each attached network. A host's compatibility mode is determined from the host compatibility mode variable which can be in one of three states: IGMPv1, IGMPv2 or IGMPv3. This variable is kept per interface and is dependent on the version of general queries heard on that interface as well as the older-version querier present timers for the interface. |

**Table 65 IGMP Snooping Port Database Fields (Continued)**

| Label               | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V1 host expires     | The time remaining until the local router will assume that there are no longer any IGMP Version 1 members on the IP subnet attached to this interface. Upon hearing any IGMPv1 membership report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 leave messages for this group that it receives on this interface. |
| V2 host expires     | The time remaining until the local router will assume that there are no longer any IGMP Version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 membership report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv3 leave messages for this group that it receives on this interface. |
| Source address      | The source address for which this entry contains information.                                                                                                                                                                                                                                                                                                                                     |
| Up Time             | The time since the source group entry was created.                                                                                                                                                                                                                                                                                                                                                |
| Expires             | The amount of time remaining before this entry will be aged out.                                                                                                                                                                                                                                                                                                                                  |
| Number of sources   | Indicates the number of IGMP group and source specific queries received on this SAP.                                                                                                                                                                                                                                                                                                              |
| Forwarding/Blocking | Indicates whether this entry is on the forward list or block list.                                                                                                                                                                                                                                                                                                                                |
| Number of groups    | Indicates the number of groups configured for this SAP.                                                                                                                                                                                                                                                                                                                                           |

## proxy-db

**Syntax** **proxy-db [detail]**  
**proxy-db group** *grp-address*

**Context** show>service>id>igmp-snooping

**Description** This command displays information on the IGMP snooping proxy reporting database for the VPLS service.

**Parameters** *grp-ip-address* — Displays the IGMP snooping proxy reporting database for a specific multicast group address.

### Output

#### Sample Output

```
*A:ALA-1>show>service>id>snooping# proxy-db
```

```

[Table 68](#) describes the show output fields.

**Table 68 IGMP Snooping Source Groups Fields**

| Label  | Description                                          |
|--------|------------------------------------------------------|
| Source | Displays the IP source address used in IGMP queries. |

**Table 68 IGMP Snooping Source Groups Fields (Continued)**

| Label | Description                                                          |
|-------|----------------------------------------------------------------------|
| Group | Displays the static IGMP snooping source groups for a specified SAP. |

## statistics

- Syntax** `statistics [evpn-mpls | sap sap-id | sdp sdp-id:vc-id | vxlan vtep ip-address vni vni]`
- Context** `show>service>id>igmp-snooping`
- Description** This command displays IGMP snooping statistics for the VPLS service.
- Parameters**
- evpn-mpls** — Displays IGMP snooping statistics for EVPN-MPLS destinations
  - sap-id** — Displays IGMP snooping statistics for a specific SAP
  - sdp-id** — Displays the IGMP snooping statistics for a specific spoke or mesh SDP
    - Values** 1 to 17407
  - vc-id** — The virtual circuit ID on the SDP ID for which to display information
    - Default** For mesh SDPs only, all VC IDs.
    - Values** 1 to 4294967295
  - vxlan vtep ip-address vni <1..16777215>** — Displays the IGMP snooping entries associated with a specific VXLAN binding, given by the VXLAN Termination Endpoint (VTEP) and VXLAN Network Identifier (VNI). This parameter only applies to the 7450 ESS or 7750 SR.
  - vni** — The VXLAN Network Identifier (VNI) for which to display information. This parameter only applies to the 7450 ESS or 7750 SR.
    - Values** 1 to 16777215

### 3.8.2.3 MLD Snooping Show Commands

#### mld-snooping

**Syntax** **mld-snooping**

**Context** show>service>id

**Description** This command displays MLD snooping information.

#### all

**Syntax** **all**

**Context** show>service>id>mld-snooping

**Description** This command displays detailed information about MLD snooping.

#### base

**Syntax** **base**

**Context** show>service>id>mld-snooping

**Description** This command displays basic MLD snooping information.

---

## mrollers

|                    |                                              |
|--------------------|----------------------------------------------|
| <b>Syntax</b>      | <b>mrollers [detail]</b>                     |
| <b>Context</b>     | show>service>id>mld-snooping                 |
| <b>Description</b> | This command displays all multicast routers. |

## mvr

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Syntax</b>      | <b>mvr</b>                                                     |
| <b>Context</b>     | show>service>id>mld-snooping                                   |
| <b>Description</b> | This command displays multicast VPLS registration information. |

## port-db

|                    |                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>port-db sap <i>sap-id</i></b><br><b>port-db sap <i>sap-id</i> detail</b><br><b>port-db sap <i>sap-id</i> group <i>grp-ipv6-address</i></b><br><b>port-db sdp <i>sdp-id:vc-id</i> [detail]</b><br><b>port-db sdp <i>sdp-id:vc-id</i> group <i>grp-ipv6-address</i></b> |
| <b>Context</b>     | show>service>id>mld-snooping                                                                                                                                                                                                                                             |
| <b>Description</b> | This command displays MLD snooping information related to a specific SAP.                                                                                                                                                                                                |

## proxy-db

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>proxy-db [detail]</b><br><b>proxy-db group <i>grp-ip-address</i></b>                                                                                                                                  |
| <b>Context</b>     | show>service>id>mld-snooping                                                                                                                                                                             |
| <b>Description</b> | This command displays proxy-reporting database entries.                                                                                                                                                  |
| <b>Parameters</b>  | <i>grp-ip-address</i> — Displays the IGMP snooping proxy reporting database for a specific multicast group address.<br><b>detail</b> — Displays detailed information about the proxy-reporting database, |

## querier

|               |                |
|---------------|----------------|
| <b>Syntax</b> | <b>querier</b> |
|---------------|----------------|

---

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Context</b>     | show>service>id>mld-snooping                                 |
| <b>Description</b> | This command displays information about the current querier. |

## static

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static</b> [ <b>sap</b> <i>sap-id</i>   <b>sdp</b> <i>sdp-id:vc-id</i> ] |
| <b>Context</b>     | show>service>id>mld-snooping                                                |
| <b>Description</b> | This command displays MLD snooping static group membership data.            |

## statistics

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b> [ <b>sap</b> <i>sap-id</i>   <b>sdp</b> <i>sdp-id:vc-id</i> ] |
| <b>Context</b>     | show>service>id>mld-snooping                                                    |
| <b>Description</b> | This command displays MLD snooping statistics.                                  |

### 3.8.2.4 IGMP Commands

## group

|                    |                                                                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>group</b> [ <i>grp-ip-address</i> ]                                                                                                                                               |
| <b>Context</b>     | show>router>igmp                                                                                                                                                                     |
| <b>Description</b> | This command displays the multicast group and (s, g) addresses. If no <i>grp-ip-address</i> parameters are specified then all IGMP group, (*, g) and (s, g) addresses are displayed. |
| <b>Parameters</b>  | <i>grp-ip-address</i> — Displays specific multicast group addresses                                                                                                                  |
| <b>Output</b>      |                                                                                                                                                                                      |

```

Table 70 provides IGMP SSM-Translate output field descriptions.

**Table 70 IGMP SSM-Translate Output Fields**

| Label                 | Description                                                                             |
|-----------------------|-----------------------------------------------------------------------------------------|
| Group Range           | Displays the address ranges of the multicast groups for which this router can be an RP. |
| Source                | Displays the unicast address that sends data on an interface.                           |
| SSM Translate Entries | Displays the total number of SSM translate entries.                                     |

## interface

**Syntax** **interface** [*ip-int-name* | *ip-address*] [**group**] [*grp-address*] [**detail**]

**Context** show>router>igmp

**Description** This command displays IGMP interface information.

**Parameters** *ip-int-name* — Only displays the information associated with the specified IP interface name

*ip-address* — Only displays the information associated with the specified IP address

*grp-address* — Only displays IP multicast group address for which this entry contains information

**detail** — Displays detailed IP interface information along with the source group information learned on that interface

Table 71 provides IGMP Interface output field descriptions.

**Table 71 IGMP Interface Output Fields**

| Label                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface                             | Specifies the interfaces that participates in the IGMP protocol.                                                                                                                                                                                                                                                                                                                                                     |
| Adm<br>Admin Status                   | Displays the administrative state for the IGMP protocol on this interface.                                                                                                                                                                                                                                                                                                                                           |
| Oper<br>Oper Status                   | Displays the current operational state of IGMP protocol on the interface.                                                                                                                                                                                                                                                                                                                                            |
| Querier                               | Displays the address of the IGMP querier on the IP subnet to which the interface is attached.                                                                                                                                                                                                                                                                                                                        |
| Querier Up Time                       | Displays the time since the querier was last elected as querier.                                                                                                                                                                                                                                                                                                                                                     |
| Querier Expiry Timer                  | Displays the time remaining before the querier ages out. If the querier is the local interface address, the value will be zero.                                                                                                                                                                                                                                                                                      |
| Cfg/Opr Version<br>Admin/Oper version | Cfg — The configured version of IGMP running on this interface. For IGMP to function correctly, all routers on a LAN must be configured to run the same version of IGMP on that LAN.<br><br>Opr — The operational version of IGMP running on this interface. If the cfg value is 3 but all of the routers in the local subnet of this interface use IGMP version v1 or v2, the operational version will be v1 or v2. |
| Num Groups                            | The number of multicast groups which have been learned by the router on the interface.                                                                                                                                                                                                                                                                                                                               |
| Policy                                | Specifies the policy that is to be applied on the interface.                                                                                                                                                                                                                                                                                                                                                         |

**Table 71 IGMP Interface Output Fields (Continued)**

| Label         | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group Address | Specifies the IP multicast group address for which this entry contains information.                                                                                                                                                                                                                                                                                                                                                                                                |
| Up Time       | Specifies the time since this source group entry got created.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Last Reporter | Specifies the IP address of the source of the last membership report received for this IP Multicast group address on this interface. If no membership report has been received, this object has the value 0.0.0.0.                                                                                                                                                                                                                                                                 |
| Mode          | The mode is based on the type of membership report(s) received on the interface for the group. In the 'include' mode, reception of packets sent to the specified multicast address is requested only from those IP source addresses listed in the source-list parameter of the IGMP membership report. In 'exclude' mode, reception of packets sent to the specified multicast address is requested from all IP source addresses except those listed in the source-list parameter. |
| V1 Host Timer | The time remaining until the local router will assume that there are no longer any IGMP version 1 members on the IP subnet attached to this interface. Upon hearing any IGMPv1 Membership Report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv2 Leave messages for this group that it receives on this interface.                                                                                  |
| V2 Host Timer | The time remaining until the local router will assume that there are no longer any IGMP version 2 members on the IP subnet attached to this interface. Upon hearing any IGMPv2 Membership Report, this value is reset to the group membership timer. While this time remaining is non-zero, the local router ignores any IGMPv3 Leave messages for this group that it receives on this interface.                                                                                  |
| Type          | Indicates how this group entry was learned. If this group entry was learned by IGMP, it will be set to 'dynamic'. For statically configured groups, the value will be set to 'static'.                                                                                                                                                                                                                                                                                             |

**Table 71 IGMP Interface Output Fields (Continued)**

| Label       | Description (Continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Compat Mode | Used in order for routers to be compatible with older version routers. IGMPv3 hosts must operate in version 1 and version 2 compatibility modes. IGMPv3 hosts must keep state per local interface regarding the compatibility mode of each attached network. A host's compatibility mode is determined from the Host Compatibility Mode variable which can be in one of three states: IGMPv1, IGMPv2 or IGMPv3. This variable is kept per interface and is dependent on the version of General Queries heard on that interface as well as the Older Version Querier Present timers for the interface. |

## static

**Syntax** `static [ip-int-name | ip-addr]`

**Context** `show>router>igmp`

**Description** This command displays static IGMP, (\*, G) (S, G) information.

**Parameters** *ip-int-name* — Displays the information associated with the specified IP interface name  
*ip-addr* — Displays the information associated with the specified IP address

## Output

### Sample Output

```
A:BA# show router 100 igmp static
=====
IGMP Static Group Source
=====
Source          Group          Interface
-----
10.11.11.11     239.136.22.3   IGMP_to_CE
*               239.1.1.1      IGMP_to_CE
22.22.22.22     239.255.255.255 IGMP_to_CE
-----
Static (*,G)/(S,G) Entries : 3

```

[Table 72](#) provides static IGMP field descriptions.

**Table 72 Static IGMP Output Fields**

| Label     | Description                                                                                                                           |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------|
| Source    | Displays entries which represents a source address from which receivers are interested/not interested in receiving multicast traffic. |
| Group     | Displays the IP multicast group address for which this entry contains information.                                                    |
| Interface | Displays the interface name.                                                                                                          |

## statistics

**Syntax** **statistics** [*ip-int-name* | *ip-address*]

**Context** show>router>igmp

**Description** This command displays IGMP statistics information.

**Parameters** *ip-int-name* — Displays the information associated with the specified IP interface name  
*ip-addr* — Displays the information associated with the specified IP address.

## Output

### Sample Output

```
A:BA# show router 100 igmp statistics

[Table 73](#) provides statistical IGMP field descriptions.

**Table 73 IGMP Statistics Output Fields**

| Label                        | Description                                                                                                                                                                                                                                                              |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IGMP Interface Statistics    | The section listing the IGMP statistics for a particular interface.                                                                                                                                                                                                      |
| Message Type                 | Queries — The number of IGMP general queries transmitted or received on this interface.<br>Report — The total number of IGMP V1, V2, or V3 reports transmitted or received on this interface.<br>Leaves — The total number of IGMP leaves transmitted on this interface. |
| Received                     | Column that displays the total number of IGMP packets received on this interface.                                                                                                                                                                                        |
| Transmitted                  | Column that displays the total number of IGMP packets transmitted from this interface.                                                                                                                                                                                   |
| General Interface Statistics | The section listing the general IGMP statistics.                                                                                                                                                                                                                         |
| Bad Length                   | Displays the total number of IGMP packets with bad length received on this interface.                                                                                                                                                                                    |
| Bad Checksum                 | Displays the total number of IGMP packets with bad checksum received on this interface.                                                                                                                                                                                  |
| Unknown Type                 | Displays the total number of IGMP packets with unknown type received on this interface.                                                                                                                                                                                  |
| Bad Receive If               | Displays the total number of IGMP packets incorrectly received on this interface.                                                                                                                                                                                        |
| Rx Non Local                 | Displays the total number of IGMP packets received from a non-local sender.                                                                                                                                                                                              |
| Rx Wrong Version             | Displays the total number of IGMP packets with wrong versions received on this interface.                                                                                                                                                                                |

**Table 73 IGMP Statistics Output Fields (Continued)**

| Label           | Description (Continued)                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------|
| Policy Drops    | Displays the number of times IGMP protocol instance matched the host IP address or group/source addresses in the import policy. |
| No Router Alert | Displays the total number of IGMPv3 packets received on this interface which did not have the router alert flag set.            |

## status

**Syntax**     **status**

**Context**    show>router>igmp

**Description** This command displays IGMP status information.

If IGMP is not enabled, the following message appears:

```
A:NYC# show router igmp status
MINOR: CLI IGMP is not configured.
A:NYC#
```

## Output

### Sample Output

```
A:BA# show router 100 igmp status
=====
IGMP Status
=====
Admin State           : Up
Oper State            : Up
Query Interval        : 1024
Last Member Query Interval : 1024
Query Response Interval : 1023
Robust Count          : 10
=====
A:BA
```

[Table 74](#) provides IGMP status field descriptions.

**Table 74 IGMP Status Output Fields**

| Label       | Description                                 |
|-------------|---------------------------------------------|
| Admin State | Displays the administrative status of IGMP. |

**Table 74 IGMP Status Output Fields (Continued)**

| Label                      | Description (Continued)                                                                                                                                                        |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Oper State                 | Displays the current operating state of this IGMP protocol instance on this router.                                                                                            |
| Query Interval             | The frequency at which IGMP query packets are transmitted.                                                                                                                     |
| Last Member Query Interval | The maximum response time inserted into Group-Specific Queries sent in response to Leave Group messages, and is also the amount of time between Group-Specific Query messages. |
| Query Response Interval    | The maximum query response time advertised in IGMPv2 queries.                                                                                                                  |
| Robust Count               | Displays the number of times the router will retry a query.                                                                                                                    |

### 3.8.2.4.1 Show Multi-Chassis Endpoint Commands

#### multi-chassis

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>multi-chassis</b>                                                   |
| <b>Context</b>     | show>redundancy                                                        |
| <b>Description</b> | This command enables the context to display multi-chassis information. |

#### mc-endpoint

|                    |                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mc-endpoint statistics</b><br><b>mc-endpoint peer [ip-address] statistics</b><br><b>mc-endpoint endpoint [mcep-id] statistics</b><br><b>mc-endpoint peer [ip-address]</b>                                   |
| <b>Context</b>     | show>redundancy>multi-chassis                                                                                                                                                                                  |
| <b>Description</b> | This command displays multi-chassis endpoint information.                                                                                                                                                      |
| <b>Parameters</b>  | <b>statistics</b> — Displays the global statistics for the MC endpoint<br><i>ip-address</i> — Specifies the IP address of multi-chassis endpoint peer<br><i>mcep-id</i> — Specifies the multi-chassis endpoint |
| <b>Values</b>      | 1 to 4294967295                                                                                                                                                                                                |

### 3.8.2.5 VPLS Clear Commands

id

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                                           |
| <b>Context</b>     | clear>service<br>clear>service>statistics                                             |
| <b>Description</b> | This command clears commands for a specific service.                                  |
| <b>Parameters</b>  | <i>service-id</i> — Clears service ID information that uniquely identifies a service. |
| <b>Values</b>      | service-id: 1 to 214748364<br>svc-name: A string up to 64 characters in length.       |

arp-host

|                |                                                                                                                                                                                                                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>arp-host</b> {all   mac <i>ieee-address</i>   sap <i>sap-id</i>   ip-address <i>ip-address</i> [ <i>/mask</i> ] }<br><b>arp-host</b> {port <i>port-id</i>   {inter-dest-id <i>intermediate-destination-id</i>   no-inter-dest-id} [port<br><i>port-id</i> ] }<br><b>arp-host statistics</b> [sap <i>sap-id</i>   interface <i>interface-name</i> ] |
| <b>Context</b> | clear>service>id                                                                                                                                                                                                                                                                                                                                      |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command clears ARP host data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>ieee-address</i> — Clears the ARP host MAC address information. The 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><i>sap-id</i> — Clears the specified SAP information.</p> <p><i>ip-address[/mask]</i> — Clears the specified IP address and mask.</p> <p><b>Values</b>      a.b.c.d.<br/>                  mask: 1 to 32</p> <p><i>port-id</i> — Clear the specified port ID information.</p> <p><i>intermediate-destination-id</i> — Displays information about the specified intermediate destination ID. 32 characters maximum.</p> <p><b>no-inter-dest-id</b> — Displays the information about no intermediate destination ID.</p> <p><i>interface-name</i> — Clears the interface name. 32 characters maximum.</p> |

## authentication

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication</b>                                                         |
| <b>Context</b>     | clear>service>id                                                              |
| <b>Description</b> | This command enables the context to clear session authentication information. |

## statistics

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b>                                        |
| <b>Context</b>     | clear>service>id>authentication                          |
| <b>Description</b> | This command clears session statistics for this service. |

## dhcp

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                        |
| <b>Context</b>     | clear>service>id                                                   |
| <b>Description</b> | This command enables the context to clear and reset DHCP entities. |

## lease-state

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | This command clears DHCP lease state information for this service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>all</b> — Clears all lease state statistics.</p> <p><i>port-id</i> — Displays information about the specified port ID.</p> <p><i>intermediate-destination-id</i> — Displays information about the specified intermediate destination ID. 32 characters maximum.</p> <p><b>no-inter-dest-id</b> — Displays the information about no intermediate destination ID.</p> <p><i>ip-address[/mask]</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><b>Values</b>      a.b.c.d.<br/> mask: 1 to 32</p> <p><i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><b>Values</b>      xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx</p> <p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.</p> <p><i>sdp-id</i> — The SDP ID to be cleared.</p> <p><b>Values</b>      1 to 17407</p> <p><i>vc-id</i> — The virtual circuit ID on the SDP ID to be cleared.</p> <p><b>Values</b>      1 to 4294967295</p> <p><b>no-dhcp-release</b> — Specifies that the node will clear the state without sending the DHCP release message.</p> |

| <b>Description</b> | This command clears the information on the IGMP snooping port database for the VPLS service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>sap-id</i> — Clears IGMP snooping statistics matching the specified SAP ID and optional encapsulation value</p> <p><i>sdp-id</i> — Clears only IGMP snooping entries associated with the specified mesh SDP or spoke-SDP. For a spoke-SDP, the VC ID must be specified, for a mesh SDP, the VC ID is optional.</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — Clears information for the specified virtual circuit ID on the SDP ID</p> <p><b>Default</b> For mesh SDPs only, all VC IDs</p> <p><b>Values</b> 1 to 4294967295</p> <p><i>grp-ip-address</i> — Clears IGMP snooping statistics matching the specified group address</p> <p><i>src-ip-address</i> — Clears IGMP snooping statistics matching the specified particular source</p> <p><b>vxlan vtep ip-address vni &lt;1..16777215&gt;</b> — Clears the IGMP snooping statistics associated with a specific VXLAN destination given by the VXLAN Termination Endpoint (VTEP) and VXLAN Network Identifier (VNI).</p> <p><i>vni-id</i> — Displays information for the specified VXLAN Network Identifier (VNI)</p> <p><b>Values</b> 1 to 16777215</p> |

| <b>Description</b> | This command clears MLD snooping port-db group data.                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>sap-id</i> — Clears IGMP snooping statistics matching the specified SAP ID and optional encapsulation value<br><i>sdp-id</i> — Clears only IGMP snooping entries associated with the specified mesh SDP or spoke-SDP. For a spoke-SDP, the VC ID must be specified, for a mesh SDP, the VC ID is optional.<br><b>Values</b> 1 to 17407                                                                                                |

*vc-id* — Clears information for the specified virtual circuit ID on the SDP ID

**Default** For mesh SDPs only, all VC IDs

**Values** 1 to 4294967295

*grp-ip-address* — Clears IGMP snooping statistics matching the specified group address

*src-ip-address* — Clears IGMP snooping statistics matching the specified particular source

**vxlan vtep ip-address vni** <1..16777215> — Clears the IGMP snooping statistics associated with a specific VXLAN destination given by the VXLAN Termination Endpoint (VTEP) and VXLAN Network Identifier (VNI).

*vni-id* — Displays information for the specified VXLAN Network Identifier (VNI)

**Values** 1 to 16777215

## querier

**Syntax** **querier**

**Context** clear>service>id>mld-snooping

**Description** This command clears MLD snooping querier information.

## statistics

**Syntax** **statistics all**  
**statistics sap** *sap-id*  
**statistics sdp** *sdp-id:vc-id*

**Context** clear>service>id>mld-snooping

**Description** This command clears MLD snooping statistics.

## mesh-sdp

**Syntax** **mesh-sdp** *sdp-id[:vc-id]* **ingress-vc-label**

**Context** clear>service>id

**Description** This command clears and resets the mesh SDP bindings for the service.

**Parameters** *sdp-id* — Clears mesh SDP ID information

**Values** 1 to 17407

*vc-id* — Specifies virtual circuit ID on the SDP ID to be reset

**Default** All VC IDs on the SDP ID

**Values** 1 to 4294967295

## msap

**Syntax** **msap** *msap-id*

**Context** clear>service>id

**Description** This command clears the managed SAP (MSAP).

**Parameters** *msap-id* — Specifies the MSAP ID

**Values** dot1q*port-id* | lag-*id*:qtag1  
qinq*port-id* | lag-*id*::qtag1.qtag2  
qtag1 0 to 4094  
qtag20 to 4094

## pim-snooping

**Syntax** **pim-snooping**

**Context** clear>service>id

**Description** This command enables the context to clear PIM snooping information.

## database

**Syntax** **database** [**group** *grp-ip-address*] [**source** *src-ip-address*]] [**family**]  
**database evpn-mpls** [**group** *grp-ip-address*] [**source** *src-ip-address*] [**family**]  
**database sap** *sap-id* [**group** *grp-ip-address*] [**source** *src-ip-address*] [**family**]  
**database sdp** *sap-id:vc-id* [**group** *grp-ip-address*] [**source** *src-ip-address*] [**family**]  
**database vxlan vtep** *ip-address vni vni-id* [**group** *grp-ip-address*] [**source** *src-ip-address*]]  
[**family**]

**Context** clear>service>id>pim-snooping

**Description** This command clears PIM snooping source group database information.

**Parameters** *sap-id* — Clears PIM snooping SAP information

*sdp-id* — Clears PIM snooping entries associated with the specified SDP. For a spoke-SDP, the VC ID must be specified; for a mesh SDP, the VC ID is optional.

**Values** 1 to 17407

*grp-ip-address* — Clears PIM snooping information matching the specified group address

*src-ip-address* — Clears PIM snooping information matching one particular source within the multicast group

**family** — Displays either IPv4 or IPv6 information

**Values**      ipv4 or ipv6

**evpn-mpls** — Clears PIM snooping statistics for EVPN-MPLS destinations

## neighbor

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>spoke-sdp</b> <i>sdp-id[:vc-id]</i> { <b>all</b>   <b>counters</b>   <b>stp</b>   <b>l2pt</b>   <b>mrp</b> } |
| <b>Context</b>     | clear>service>statistics>id                                                                                     |
| <b>Description</b> | This command clears statistics for the spoke-SDP bound to the service.                                          |
| <b>Parameters</b>  | <i>sdp-id</i> — Specifies the spoke-SDP ID for which the statistics will be cleared<br><b>Values</b> 1 to 17407 |

*vc-id* — The virtual circuit ID on the SDP ID to be reset

**Values** 1 to 4294967295

**all** — Clears all queue statistics and STP statistics associated with the SDP

**counters** — Clears all queue statistics associated with the SDP

**stp** — Clears all STP statistics associated with the SDP

**l2pt** — Clears all L2PT statistics associated with the SDP

**mrp** — Clears all MRP statistics associated with the SDP. This parameter only applies to the 7450 ESS or 7750 SR.

## dhcp

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                        |
| <b>Context</b>     | clear>router                                                       |
| <b>Description</b> | This command enables the context to clear and reset DHCP entities. |

## statistics

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>statistics</b> [ <b>interface</b> <i>ip-int-name</i>   <i>ip-address</i> ]                                                                                                         |
| <b>Context</b>     | clear>router>dhcp                                                                                                                                                                     |
| <b>Description</b> | This command clears DHCP statistics.                                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-int-name</i> — Clears the statistics for the IP interface with the specified name<br><i>ip-addr</i> — Clears the statistics for the IP interface with the specified IP address. |

### 3.8.2.6 VPLS Debug Commands

## id

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                                                               |
| <b>Context</b>     | debug>service                                                                                             |
| <b>Description</b> | This command debugs commands for a specific service.                                                      |
| <b>Parameters</b>  | <i>service-id</i> — The ID that uniquely identifies a service<br><b>Values</b> service-id: 1 to 214748364 |

---

svc-name: A string up to 64 characters in length.

## arp-host

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] arp-host                                                                                                                 |
| <b>Context</b>     | debug>service>id                                                                                                              |
| <b>Description</b> | This command enables and configures ARP host debugging.<br><br>The <b>no</b> form of the command disables ARP host debugging. |

## ip

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] ip <i>ip-address</i>                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | debug>service>id>arp-host                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command displays ARP host events for a particular IP address.                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).<br><br><b>Values</b> a.b.c.d |

## mac

|                    |                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] mac <i>ieee-address</i>                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | debug>service>id>arp-host                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command displays ARP host events for a particular MAC address.                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.<br><br><b>Values</b> xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx (cannot be all zeros) |

## mode

|               |                                  |
|---------------|----------------------------------|
| <b>Syntax</b> | <b>mode</b> {all   dropped-only} |
|---------------|----------------------------------|

**no mode**

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Context</b>     | debug>service>id>arp-host                                                                        |
| <b>Description</b> | This command configures the ARP host tracing mode.                                               |
| <b>Parameters</b>  | <b>all</b> — Debugs all dropped packets.<br><b>dropped-only</b> — Only displays dropped packets. |

## sap

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] sap <i>sap-id</i>                                                                |
| <b>Context</b>     | debug>service>id>arp-host                                                             |
| <b>Description</b> | This command displays ARP host events for a particular SAP.                           |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition. |

## igmp-snooping

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | [no] igmp-snooping                                           |
| <b>Context</b>     | debug>service>id                                             |
| <b>Description</b> | This command enables and configures IGMP-snooping debugging. |

## detail-level

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>detail-level</b> {low   medium   high}<br><b>no detail-level</b>                                                                                 |
| <b>Context</b>     | debug>service>id>igmp-snooping                                                                                                                      |
| <b>Description</b> | This command enables and configures the IGMP tracing detail level.<br><br>The <b>no</b> form of the command disables the IGMP tracing detail level. |

## evpn-mpls

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] evpn-mpls                                                                                                                                  |
| <b>Context</b>     | debug>service>id>igmp-snooping                                                                                                                  |
| <b>Description</b> | This command shows IGMP packets for EVPN-MPLS destinations. The <b>no</b> form of the command disables the debugging for EVPN-MPLS destinations |

---

## mac

|                    |                                                                                                                                     |

## sdp

|                    |                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sdp</b> <i>sdp-id:vc-id</i>                                                                                                                                                                                           |
| <b>Context</b>     | debug>service>id>igmp-snooping                                                                                                                                                                                                |
| <b>Description</b> | This command shows IGMP packets for a specific SDP.<br><br>The <b>no</b> form of the command disables the debugging for the SDP.                                                                                              |
| <b>Parameters</b>  | <i>sdp-id</i> — Displays only IGMP snooping entries associated with the specified mesh SDP or spoke-SDP. For a spoke-SDP, the VC ID must be specified, for a mesh SDP, the VC ID is optional.<br><br><b>Values</b> 1 to 17407 |

---

*vc-id* — Displays information for the specified virtual circuit ID on the SDP ID

**Values** 1 to 4294967295

## vxlan

**Syntax** **[no] vxlan vtep vtep vni vni-id**

**Context** debug>service>id>igmp-snooping

**Description** This command shows IGMP packets for a specific VXLAN binding.  
The **no** form of the command disables the debugging for that VXLAN binding.

**Parameters** **vtep** — IP address of the VXLAN Termination Endpoint  
**vni** — VXLAN Network Identifier of the VXLAN binding

**Values** 1 to 16777215

## mld-snooping

**Syntax** **[no] mld-snooping**

**Context** debug>service>id

**Description** This command enables and configures MLD-snooping debugging.  
The **no** form of the command disables MLD-snooping debugging

## detail-level

**Syntax** **detail-level {low | medium | high}**  
**no detail-level**

**Context** debug>service>id>mld

**Description** This command enables and configures the MLD tracing detail level.  
The **no** form of the command disables the MLD tracing detail level.

## mac

**Syntax** **[no] mac ieee-address**

**Context** debug>service>id>mld

---

**Description** This command shows MLD packets for the specified MAC address.  
The **no** form of the command disables the MAC debugging.

## mode

**Syntax** **mode** {**dropped-only** | **ingr-and-dropped** | **egr-ingr-and-dropped**}  
**no mode**

**Context** debug>service>id>mld

**Description** This command enables and configures the MLD tracing mode.  
The **no** form of the command disables the configures the MLD tracing mode.

## sap

**Syntax** [**no**] **sap** *sap-id*

**Context** debug>service>id>mld

**Description** This command shows MLD packets for a specific SAP.  
The **no** form of the command disables the debugging for the SAP.

## sdp

**Syntax** [**no**] **sdp** *sdp-id:vc-id*

**Context** debug>service>id>mld

**Description** This command shows MLD packets for a specific SDP.  
The **no** form of the command disables the debugging for the SDP.

**Parameters** *sdp-id* — Displays only MLD entries associated with the specified mesh SDP or spoke-SDP  
**Values** 1 to 17407  
*vc-id* — Displays information for the specified virtual circuit ID on the SDP ID  
**Values** 1 to 4294967295

## vxlan

**Syntax** [**no**] **vxlan vtep** *vtep vni vni-id*

---

|                    |                                                                                                                                                         |

| <b>Description</b> | This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular IP address.                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 to 223.255.255.255 (with support of /31 subnets). |

## mac

|                    |                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mac <i>ieee-address</i></b>                                                                                                                                                                                                                                                |
| <b>Context</b>     | debug>service>id>host-connectivity-verify                                                                                                                                                                                                                                          |
| <b>Description</b> | This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular MAC address.                                                                                                                                                                        |
| <b>Parameters</b>  | <i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## sap

|                    |                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sap <i>sap-id</i></b>                                                                       |
| <b>Context</b>     | debug>service>id>host-connectivity-verify                                                           |
| <b>Description</b> | This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular SAP. |

---

**Parameters**     *sap-id* — Specifies the physical port identifier portion of the SAP definition

## pim-snooping

**Syntax**     **[no] pim-snooping**

**Context**     debug>service>id

**Description**     This command enables PIM-snooping debugging.

## adjacency

**Syntax**     **[no] adjacency**

**Context**     debug>service>id>pim-snooping

**Description**     This command enables or disables debugging for PIM adjacencies.

## all

**Syntax**     **all [group *grp-ip-address*] [source *ip-address*] [detail]**  
**no all**

**Context**     debug>service>id>pim-snooping

**Description**     This command enables or disables debugging for all the PIM modules.

**Parameters**     *grp-ip-address* — Debugs information associated with all PIM modules  
                    **Values**     multicast group address (IPv4 or IPv6)

*ip-address* — Debugs information associated with all PIM modules  
                    **Values**     IPv4 or IPv6 address

**detail** — Debugs detailed information on all PIM modules

## database

**Syntax**     **database [group *grp-ip-address*] [source *ip-address*] [detail]**  
**no database**

**Context**     debug>service>id>pim-snooping

**Description**     This command enables or disables debugging for the PIM database.

---

**Parameters**    *grp-ip-address* — Debugs information associated with all PIM modules  
                     **Values**        multicast group address (IPv4 or IPv6) or zero  
                     *ip-address* — Debugs information associated with the specified database

## jp

**Syntax**        **jp** [**group** *grp-ip-address*] [**source** *ip-address*] [**detail**]  
                     **no jp**

**Context**        debug>service>id>pim-snooping

**Description**    This command enables or disables debugging for the PIM Join-Prune mechanism.

**Parameters**    *grp-ip-address* — Debugs information associated with the specified Join-Prune mechanism.  
                     **Values**        multicast group address (ipv4 or ipv6) or zero  
                     *ip-address* — Debugs information associated with the specified Join-Prune mechanism  
                     **Values**        source IP address (IPv4 or IPv6)  
                     **detail** — Debugs detailed Join-Prune mechanism information

## mcs

**Syntax**        **mcs** [**detail**]  
                     **no mcs**

**Context**        debug>service>id>pim-snooping

**Description**    This command enables or disables debugging for PIM snooping multi-chassis synchronization.

**Parameters**    **detail** — Provides detailed debugging information

## packet

**Syntax**        **packet** [**hello** | **jp**]  
                     **packet** [**hello** | **jp**] **evpn-mpls**  
                     **packet** [**hello** | **jp**] [**sap** *sap-id*]  
                     **packet** [**hello** | **jp**] [**sdp** *sdp-id:vc-id*]  
                     **packet** [**hello** | **jp**] **vxlان vtep** *ip-address vni vni-id*  
                     **no packet**

**Context**        debug>service>id>pim-snooping

---

|                    |                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enables or disables debugging for PIM packets.                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>hello   jp</b> — PIM packet types</p> <p><b>sap-id</b> — Debugs packets associated with the specified SAP</p> <p><b>sdp-id:vc-id</b> — Debugs packets associated with the specified SDP</p> <p><b>evpn-mpls</b> — Debugs PIM snooping statistics for EVPN-MPLS destinations</p> |

## port

|                    |                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>port [evpn-mpls   sap sap-id   sdp sdp-id:vc-id   vxlan vtep ip-address vni vni-id] [detail]</b><br><b>no port</b>                                                                                                                                                                                              |
| <b>Context</b>     | debug>service>id>pim-snooping                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command enables or disables debugging for PIM ports.                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><b>sap-id</b> — Only debugs packets associated with the specified SAP</p> <p><b>sdp-id:vc-id</b> — Only debugs packets associated with the specified SDP</p> <p><b>detail</b> — Provides detailed debugging information</p> <p><b>evpn-mpls</b> — Debugs PIM snooping statistics for EVPN-MPLS destinations</p> |

## red

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>red [detail]</b><br><b>no red</b>                                                 |
| <b>Context</b>     | debug>service>id>pim-snooping                                                        |
| <b>Description</b> | This command enables or disables debugging for PIM messages sent to the standby CPM. |
| <b>Parameters</b>  | <b>detail</b> — Displays detailed debugging information                              |

## proxy-arp

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-arp [mac [ieee-address]] [ip [ipaddr] all]</b>                                                                                                                           |
| <b>Context</b>     | debug>service>id                                                                                                                                                                       |
| <b>Description</b> | This command enables the debug of the proxy-arp function for a specified service. Alternatively, the debug can be enabled only for certain entries given by their IP or MAC addresses. |

---

## proxy-nd

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-nd [mac <i>[ieee-address]</i>] [ip <i>[ipaddr]</i> all]</b>                                                                                                               |
| <b>Context</b>     | debug>service>id                                                                                                                                                                        |
| <b>Description</b> | This command enables the debug of the proxy-nd function for a specified service. Alternatively, the debug can be enabled only for certain entries given by their IPv6 or MAC addresses. |

## sap

|                    |                                                      |
|--------------------|------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sap <i>sap-id</i></b>                        |
| <b>Context</b>     | debug>service>id                                     |
| <b>Description</b> | This command enables debugging for a particular SAP. |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the SAP ID                 |

## stp

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <b>Syntax</b>      | <b>[no] stp</b>                                     |
| <b>Context</b>     | debug>service>id                                    |
| <b>Description</b> | This command enables the context for debugging STP. |

## all-events

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <b>Syntax</b>      | <b>all-events</b>                                  |
| <b>Context</b>     | debug>service>id>stp                               |
| <b>Description</b> | This command enables STP debugging for all events. |

## bpdu

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] bpdu</b>                                                       |
| <b>Context</b>     | debug>service>id>stp                                                   |
| <b>Description</b> | This command enables STP debugging for received and transmitted BPDUs. |

## core-connectivity

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] core-connectivity</b>                             |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for core connectivity. |

## exception

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <b>Syntax</b>      | <b>[no] exception</b>                              |
| <b>Context</b>     | debug>service>id>stp                               |
| <b>Description</b> | This command enables STP debugging for exceptions. |

## fsm-state-changes

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] fsm-state-changes</b>                             |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for FSM state changes. |

## fsm-timers

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] fsm-timers</b>                                    |
| <b>Context</b>     | debug>service>id>stp                                      |
| <b>Description</b> | This command enables STP debugging for FSM timer changes. |

## port-role

|                    |                                                               |
|--------------------|---------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] port-role</b>                                         |
| <b>Context</b>     | debug>service>id>stp                                          |
| <b>Description</b> | This command enables STP debugging for changes in port roles. |

## port-state

|               |                        |
|---------------|------------------------|
| <b>Syntax</b> | <b>[no] port-state</b> |
|---------------|------------------------|

---

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <b>Context</b>     | debug>service>id>stp                                |
| <b>Description</b> | This command enables STP debugging for port states. |

## sap

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>sap</b> <i>sap-id</i>                                                        |
| <b>Context</b>     | debug>service>id>stp                                                                 |
| <b>Description</b> | This command enables STP debugging for a specific SAP.                               |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition |

## sdp

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>sdp</b> <i>sdp-id:vc-id</i>                    |
| <b>Context</b>     | debug>service>id>stp                                   |
| <b>Description</b> | This command enables STP debugging for a specific SDP. |

## interface

|                    |                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>interface</b> [ <i>ip-int-name</i>   <i>ip-address</i> ]                                                                                                                                 |
| <b>Context</b>     | debug>router>igmp                                                                                                                                                                                |
| <b>Description</b> | This command enables debugging on the IGMP interface.                                                                                                                                            |
| <b>Parameters</b>  | <i>ip-int-name</i> — Only displays the information associated with the specified IP interface name<br><i>ip-address</i> — Only displays the information associated with the specified IP address |

## mcs

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>mcs</b> [ <i>ip-int-name</i> ]                                                             |
| <b>Context</b>     | debug>router>igmp                                                                                  |
| <b>Description</b> | This command enables debugging for IGMP MCS.                                                       |
| <b>Parameters</b>  | <i>ip-int-name</i> — Only displays the information associated with the specified IP interface name |

## misc

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] misc</b>                                       |
| <b>Context</b>     | debug>router>igmp                                      |
| <b>Description</b> | This command enables debugging for IGMP miscellaneous. |

## packet

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | tools>dump>service>id>fdb                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command displays the status of MAC addresses within the service, displaying the line cards on which FDB entries are allocated for the MAC addresses (if a MAC address has been allocated an entry on all cards provisioned in the system, it is displayed as "All") and those for which there are pending FDB entry updates (allocate, displayed as "PendAlloc", or free, displayed as "PendFree") for each MAC address. The MAC address status is displayed per service or line card and for a single MAC address. In addition, only MAC addresses with pending updates can be displayed.</p> |
| <b>Parameters</b>  | <p><i>ieee-address</i> — The 48-bit MAC address for which the FDB entry will be displayed in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers.</p>                                                                                                                                                                                                                                                                                                                                                                                              |

**slot-id** — The slot ID of the card in the chassis. The maximum slot ID is platform-dependent. See the hardware installation guides for more information.

**pending** — Displays only those MAC address with pending FDB entry line card updates (allocate or free).

## 4 IEEE 802.1ah Provider Backbone Bridging

### 4.1 IEEE 802.1ah Provider Backbone Bridging (PBB) Overview

IEEE 802.1ah draft standard (IEEE802.1ah), also known as Provider Backbone Bridges (PBB), defines an architecture and bridge protocols for interconnection of multiple Provider Bridge Networks (PBNs - IEEE802.1ad QinQ networks). PBB is defined in IEEE as a connectionless technology based on multipoint VLAN tunnels. IEEE 802.1ah employs Provider MSTP as the core control plane for loop avoidance and load balancing. As a result, the coverage of the solution is limited by STP scale in the core of large service provider networks.

Virtual Private LAN Service (VPLS), RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, provides a solution for extending Ethernet LAN services using MPLS tunneling capabilities through a routed, traffic-engineered MPLS backbone without running (M)STP across the backbone. As a result, VPLS has been deployed on a large scale in service provider networks.

The Nokia implementation fully supports a native PBB deployment and an integrated PBB-VPLS model where desirable PBB features such as MAC hiding, service aggregation and the service provider fit of the initial VPLS model are combined to provide the best of both worlds.

## 4.2 PBB Features

This section provides information about PBB features.

### 4.2.1 Integrated PBB-VPLS Solution

HVPLS introduced a service-aware device in a central core location in order to provide efficient replication and controlled interaction at domain boundaries. The core network facing provider edge (N-PE) devices have knowledge of all VPLS services and customer MAC addresses for local and related remote regions resulting in potential scalability issues as depicted in [Figure 106](#).

**Figure 106** Large HVPLS Deployment

OSSG190

In a large VPLS deployment, it is important to improve the stability of the overall solution and to speed up service delivery. These goals are achieved by reducing the load on the N-PEs and respectively minimizing the number of provisioning touches on the N-PEs.

The integrated PBB-VPLS model introduces an additional PBB hierarchy in the VPLS network to address these goals as depicted in [Figure 107](#).

**Figure 107 Large PBB-VPLS Deployment**

OSSG191

PBB encapsulation is added at the user facing PE (U-PE) to hide the customer MAC addressing and topology from the N-PE devices. The core N-PEs

need to only handle backbone MAC addressing and do not need to have visibility of each customer VPN. As a result, the integrated PBB-VPLS solution decreases the load in the N-PEs and improves the overall stability of the backbone.

The Nokia PBB-VPLS solution also provides automatic discovery of the customer VPNs through the implementation of IEEE 802.1ak MMRP minimizing the number of provisioning touches required at the N-PEs.

## 4.2.2 PBB Technology

IEEE 802.1ah specification encapsulates the customer or QinQ payload in a provider header as shown in [Figure 108](#).

**Figure 108** QinQ Payload in Provider Header Example

OSSG192

PBB adds a regular Ethernet header where the B-DA and B-SA are the backbone destination and respectively, source MACs of the edge U-PEs. The backbone MACs (B-MACs) are used by the core N-PE devices to switch the frame through the backbone.

A special group MAC is used for the backbone destination MAC (B-DA) when handling an unknown unicast, multicast or broadcast frame. This backbone group MAC is derived from the I-service instance identifier (ISID) using the rule: a standard group OUI (01-1E-83) followed by the 24 bit ISID coded in the last three bytes of the MAC address.

The BVID (backbone VLAN ID) field is a regular DOT1Q tag and controls the size of the backbone broadcast domain. When the PBB frame is sent over a VPLS pseudowire, this field may be omitted depending on the type of pseudowire used.

The following ITAG (standard Ether-type value of 0x88E7) has the role of identifying the customer VPN to which the frame is addressed through the 24 bit ISID. Support for service QoS is provided through the priority (3 bit I-PCP) and the DEI (1 bit) fields.

## 4.2.3 PBB Mapping to Existing VPLS Configurations

The IEEE model for PBB is organized around a B-component handling the provider backbone layer and an I-component concerned with the mapping of the customer/provider bridge (QinQ) domain (MACs, VLANs) to the provider backbone (B-MACs, B-VLANs): for example, the I-component contains the boundary between the customer and backbone MAC domains.

The Nokia implementation is extending the IEEE model for PBB to allow support for MPLS pseudowires using a chain of two VPLS context linked together as depicted in [Figure 109](#).

**Figure 109 PBB Mapping to VPLS Configurations**

A VPLS context is used to provide the backbone switching component. The white circle marked B, referred to as backbone-VPLS (B-VPLS), operates on backbone MAC addresses providing a core multipoint infrastructure that may be used for one or multiple customer VPNs. The Nokia B-VPLS implementation allows the use of both native PBB and MPLS infrastructures.

Another VPLS context (I-VPLS) can be used to provide the multipoint I-component functionality emulating the E-LAN service (see the triangle marked “I” in [Figure 109](#)). Similar to B-VPLS, I-VPLS inherits from the regular VPLS the pseudowire (SDP bindings) and native Ethernet (SAPs) handoffs accommodating this way different types of access: for example, direct customer link, QinQ or HVPLS.

To support PBB E-Line (point-to-point service), the use of an Epipe as I-component is allowed. All Ethernet SAPs supported by a regular Epipe are also supported in the PBB Epipe.

## 4.2.4 SAP and SDP Support

This section provides information about SAP and SDP support.

### 4.2.4.1 PBB B-VPLS

- SAPs
  - Ethernet DOT1Q and QinQ are supported — This is applicable to most PBB use cases, for example, one backbone VLAN ID used for native Ethernet tunneling. In the case of QinQ, a single tag x is supported on a QinQ encapsulation port for example (1/1/1:x.\* or 1/1/1:x.0).
  - Ethernet null is supported — This is supported for a direct connection between PBB PEs, for example, no BVID is required.
  - Default SAP types are blocked in the CLI for the B-VPLS SAP.
- The following rules apply to the SAP processing of PBB frames:
  - For “transit frames” (not destined for a local BMAC), there is no need to process the ITAG component of the PBB frames. Regular Ethernet SAP processing is applied to the backbone header (BMACs and BVID).
  - If a local I-VPLS instance is associated with the B-VPLS, “local frames” originated/terminated on local I-VPLS(s) are PBB encapsulated/de-encapsulated using the **pbb-etype** provisioned under the related port or SDP component.
- SDPs
  - For MPLS, both mesh and spoke-SDPs with split horizon groups are supported.
  - Similar to regular pseudowire, the outgoing PBB frame on an SDP (for example, B-pseudowire) contains a BVID qtag only if the pseudowire type is Ethernet VLAN. If the pseudowire type is ‘Ethernet’, the BVID qtag is stripped before the frame goes out.

#### 4.2.4.2 PBB I-VPLS

- Port Level
  - All existing Ethernet encapsulation types are supported (for example, null, dot1q, qinq).
- SAPs
  - The I-VPLS SAPs can co-exist on the same port with SAPs for other business services, for example, VLL, VPLS SAPs.
  - All existing Ethernet encapsulation are supported: null, dot1q, qinq.
- SDPs
  - GRE and MPLS SDP are spoke-sdp only. Mesh SDPs can just be emulated by using the same split horizon group everywhere.

Existing SAP processing rules still apply for the I-VPLS case; the SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service that the packet belongs to:

- Null encap defined on ingress — Any VLAN tags are ignored and the packet goes to a default service for the SAP;
- dot1q encap defined on ingress — only first VLAN tag is considered;
- Qinq encap defined on ingress — both VLAN tags are considered; wildcard support for the inner VLAN tag
- For dot1q/qinq encapsulations, traffic encapsulated with VLAN tags for which there is no definition is discarded.
- Any VLAN tag used for service selection on the I-SAP is stripped before the PBB encapsulation is added. Appropriate VLAN tags are added at the remote PBB PE when sending the packet out on the egress SAP.

I-VPLS services do not support the forwarding of PBB encapsulated frames received on SAPs or Spoke-SDPs through their associated B-VPLS service. PBB frames are identified based on the configured PBB Ethertype (0x88e7 by default).

#### 4.2.5 PBB Packet Walkthrough

This section describes the walkthrough for a packet that traverses the B-VPLS and I-VPLS instances using the example of a unicast frame between two customer stations as depicted in the following network diagram [Figure 110](#).

**Figure 110 PBB Packet Walkthrough**

OSSG194

The station with CMAC (customer MAC) X wants to send a unicast frame to CMAC Y through the PBB-VPLS network. A customer frame arriving at PBB-VPLS U-PE1 is encapsulated with the PBB header. The local I-VPLS FDB on U-PE1 is consulted to determine the destination BMAC of the egress U-PE for CMAC Y. In our example, B2 is assumed to be known as the B-DA for Y. If CMAC Y is not present in the U-PE1 forwarding database, the PBB packet is sent in the B-VPLS using the standard group MAC address for the ISID associated with the customer VPN. If the uplink to the N-PE is a spoke pseudowire, the related PWE3 encapsulation is added in front of the B-DA.

Next, only the Backbone Header in green is used to switch the frame through the green B-VPLS/VPLS instances in the N-PEs. At the receiving U-PE2, the CMAC X is learned as being behind BMAC B1; then the PBB encapsulation is removed and the lookup for CMAC Y is performed. In the case where a pseudowire is used between N-PE and U-PE2, the pseudowire encapsulation is removed first.

#### 4.2.5.1 PBB Control Planes

PBB technology can be deployed in a number of environments. Natively, PBB is an Ethernet data plane technology that offers service scalability and multicast efficiency.

Environment:

- MPLS (mesh and spoke-SDPs)
- Ethernet SAPs

Within these environments, SR OS offers a number of optional control planes:

- Shortest Path Bridging MAC (SPBM) (SAPs and spoke-SDPs); see [Shortest Path Bridging MAC Mode \(SPBM\)](#)
- Rapid Spanning Tree Protocol (RSTP) optionally with MMRP (SAPs and spoke-SDPs); see [MMRP Support Over B-VPLS SAPs and SDPs](#).
- MSTP optionally with MMRP (SAPs and spoke-SDPs); see the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 2 Services and EVPN Guide: VLL, VPLS, PBB, and EVPN* for more information.
- Multiple MAC registration Protocol (MMRP) alone (SAPs, spoke and mesh SDPs); see [IEEE 802.1ak MMRP for Service Aggregation and Zero Touch Provisioning](#).

In general a control plane is required on Ethernet SAPs, or SDPs where there could be physical loops. Some network configurations of Mesh and Spoke SDPs can avoid physical loops and no control plane is required.

The choice of control plane is based on the requirement of the networks. SPBM for PBB offers a scalable link state control plane without BMAC flooding and learning or MMRP. RSTP and MSTP offer Spanning tree options based on BMAC flooding and learning. MMRP is used with flooding and learning to improve multicast.

## 4.2.6 Shortest Path Bridging MAC Mode (SPBM)

Shortest Path Bridging (SPB) enables a next generation control plane for PBB based on IS-IS that adds the stability and efficiency of link state to unicast and multicast services. Specifically this is an implementation of SPBM (SPB MAC mode). Current SR OS PBB B-VPLS offers point-to-point and multipoint to multipoint services with large scale. PBB B-VPLS is deployed in both Ethernet and MPLS networks supporting Ethernet VLL and VPLS services. SPB removes the flooding and learning mode from the PBB Backbone network and replaces MMRP for ISID Group Mac Registration providing flood containment. SR OS SPB provides true shortest path forwarding for unicast and efficient forwarding on a single tree for multicast. It supports selection of shortest path equal cost tie-breaking algorithms to enable diverse forwarding in an SPB network.

### 4.2.6.1 Flooding and Learning Versus Link State

SPB brings a link state capability that improves the scalability and performance for large networks over the xSTP flooding and learning models. Flooding and learning has two consequences. First, a message invoking a flush must be propagated, second the data plane is allowed to flood and relearn while flushing is happening. Message based operation over these data planes may experience congestion and packet loss.

**Table 75 B-VPLS Control Planes**

| PBB B-VPLS Control Plane | Flooding and Learning | Multipath                                       | Convergence time               |
|--------------------------|-----------------------|-------------------------------------------------|--------------------------------|
| xSTP                     | Yes                   | MSTP                                            | xSTP + MMRP                    |
| G.8032                   | Yes                   | Multiple Ring instances<br>Ring topologies only | Eth-OAM based + MMRP           |
| SPB-M                    | No                    | Yes –ECT based                                  | IS-IS link state (incremental) |

Link state operates differently in that only the information that truly changes needs to be updated. Traffic that is not affected by a topology change does not have to be disturbed and does not experience congestion since there is no flooding. SPB is a link state mechanism that uses restoration to reestablish the paths affected by topology change. It is more deterministic and reliable than RSTP and MMRP mechanisms. SPB can handle any number of topology changes and as long as the network has some connectivity, SPB will not isolate any traffic.

### 4.2.6.2 SPB for B-VPLS

The SR OS model supports PBB Epipes and I-VPLS services on the B-VPLS. SPB is added to B-VPLS in place of other control planes (see [Table 75](#)). SPB runs in a separate instance of IS-IS. SPB is configured in a single service instance of B-VPLS that controls the SPB behavior (via IS-IS parameters) for the SPB IS-IS session between nodes. Up to four independent instances of SPB can be configured. Each SPB instance requires a separate control B-VPLS service. A typical SPB deployment uses a single control VPLS with zero, one or more user B-VPLS instances. SPB is multi-topology (MT) capable at the IS-IS LSP TLV definitions however logical instances offer the nearly the same capability as MT. The SR OS SPB implementation always uses MT topology instance zero. Area addresses are not used and SPB is assumed to be a single area. SPB must be consistently configured on nodes in the system. SPB Regions information and IS-IS hello logic that detect mismatched configuration are not supported.

SPB Link State PDUs (LSPs) contains BMACs, I-SIDs (for multicast services) and link and metric information for an IS-IS database. Epipe I-SIDs are not distributed in SR OS SPB allowing high scalability of PBB Epipes. I-VPLS I-SIDs are distributed in SR OS SPB and the respective multicast group addresses are automatically populated in forwarding in a manner that provides automatic pruning of multicast to the subset of the multicast tree that supports I-VPLS with a common I-SID. This replaces the function of MMRP and is more efficient than MMRP so that in the future SPB will scale to a greater number of I-SIDs.

SPB on SR OS can leverage MPLS networks or Ethernet networks or combinations of both. SPB allows PBB to take advantage of multicast efficiency and at the same time leverage MPLS features such as resiliency.

### 4.2.6.3 Control B-VPLS and User B-VPLS

Control B-VPLS are required for the configuration of the SPB parameters and as a service to enable SPB. Control B-VPLS therefore must be configured everywhere SPB forwarding is expected to be active even if there are no terminating services. SPB uses the logical instance and a Forwarding ID (FID) to identify SPB locally on the node. The FID is used in place of the SPB VLAN identifier (Base VID) in IS-IS LSPs enabling a reference to exchange SPB topology and addresses. More specifically, SPB advertises B-MACs and I-SIDs in a B-VLAN context. Since the service model in SR OS separates the VLAN Tag used on the port for encapsulation from the VLAN ID used in SPB the SPB VLAN is a logical concept and is represented by configuring a FID. B-VPLS SAPs use VLAN Tags (SAPs with Ethernet encapsulation) that are independent of the FID value. The encapsulation is local to the link in SR/ESS so the SAP encapsulation has be configured the same between

neighboring switches. The FID for a specified instance of SPB between two neighbor switches must be the same. The independence of VID encapsulation is inherent to SR OS PBB B-VPLS. This also allows spoke-SDP bindings to be used between neighboring SPB instances without any VID tags. The one exception is mesh SDPs are not supported but arbitrary mesh topologies are supported by SR OS SPB.

Figure 111 shows two switches where an SPB control B-VPLS configured with FID 1 and uses a SAP with 1/1/1:5 therefore using a VLAN Tag 5 on the link. The SAP 1/1/1:1 could also have been used but in SR OS the VID does not have to equal FID. Alternatively an MPLS PW (spoke-SDP binding) could be for some interfaces in place of the SAP. Figure 111 shows a control VPLS and two user B-VPLS. The User B-VPLS must share the same topology and are required to have interfaces on SAPs/ Spoke SDPs on the same links or LAG groups as the B-VPLS. To allow services on different B-VPLS to use a path when there are multiple paths a different ECT algorithm can be configured on a B-VPLS instance. In this case, the user B-VPLS still fate shared the same topology but they may use different paths for data traffic; see [Shortest Path and Single Tree](#).

**Figure 111 Control and User B-VPLS with FIDs**

Each user BVPLS offers the same service capability as a control B-VPLS and are configured to “follow” or fate share with a control B-VPLS. User B-VPLS must be configured as active on the whole topology where control B-VPLS is configured and active. If there is a mismatch between the topology of a user B-VPLS and the control B-VPLS, only the user B-VPLS links and nodes that are in common with the control B-VPLS will function. The services on any B-VPLS are independent of a particular user B-VPLS so a misconfiguration of one of the user B-VPLS will not affect other B-VPLS. For example if a SAP or spoke-SDP is missing in the user B-VPLS any traffic from that user B-VPLS that would use that interface, will be missing forwarding information and traffic will be dropped only for that B-VPLS. The computation of paths is based only on the control B-VPLS topology.

User B-VPLS instances supporting only unicast services (PBB-Epipes) may share the FID with the other B-VPLS (control or user). This is a configuration short cut that reduces the LSP advertisement size for B-VPLS services but results in the same separation for forwarding between the B-VPLS services. In the case of PBB-Epipes only BMACs are advertised per FID but BMACs are populated per B-VPLS in the FDB. If I-VPLS services are to be supported on a B-VPLS that B-VPLS must have an independent FID.

#### 4.2.6.4 Shortest Path and Single Tree

IEEE 802.1ah standard SPB uses a source specific tree model. The standard model is more computationally intensive for multicast traffic since in addition to the SPF algorithm for unicast and multicast from a single node, an all pairs shortest path needs to be computed for other nodes in the network. In addition, the computation must be repeated for each ECT algorithm. While the standard yields efficient shortest paths, this computation is overhead for systems where multicast traffic volume is low. Ethernet VLL and VPLS unicast services are popular in PBB networks and the SR OS SPB design is optimized for unicast delivery using shortest paths. Ethernet supporting unicast and multicast services are commonly deployed in Ethernet transport networks. SR OS SPB Single tree multicast (also called shared tree or \*,G) operates similarly today. The difference is that SPB multicast never floods unknown traffic.

The SR OS implementation of SPB with shortest path unicast and single tree multicast, requires only two SPF computations per topology change reducing the computation requirements. One computation is for unicast forwarding and the other computation is for multicast forwarding.

A single tree multicast requires selecting a root node much like RSTP. Bridge priority controls the choice of root node and alternate root nodes. The numerically lowest Bridge Priority is the criteria for choosing a root node. If multiple nodes have the same Bridge Priority, then the lowest Bridge Identifier (System Identifier) is the root.

In SPB the source-bmac can override the chassis-mac allowing independent control of tie breaking. The shortest path unicast forwarding does not require any special configuration other than selecting the ECT algorithm by configuring a B-VPLS use a FID with low-path-id algorithm or high-path-id algorithm to be the tiebreaker between equal cost paths. Bridge priority allows some adjustment of paths. Configuring link metrics adjusts the number of equal paths.

To illustrate the behavior of the path algorithms a sample network is shown in [Figure 112](#).

**Figure 112 Sample Partial Mesh network**

al\_0022

Assume that Node A is the lowest Bridge Identifier and the Multicast root node and all links have equal metrics. Also, assume that Bridge Identifiers are ordered such that Node A has a numerically lower Bridge identifier than Node B, and Node B has lower Bridge Identifier than Node C, etc. Unicast paths are configured to use shortest path tree (SPT). [Figure 113](#) shows the shortest paths computed from Node A and Node E to Node F. There are only two shortest paths from A to F. A choice of low-path-id algorithm uses Node B as transit node and a path using high-path-id algorithm uses Node D as transit node. The reverse paths from Node F to A are the same (all unicast paths are reverse path congruent). For Node E to Node F there are three paths E-A-B-F, E-A-D-F, and E-C-D-F. The low-path-id algorithm uses path E-A-B-F and the high-path-id algorithm uses E-C-D-F. These paths are also disjoint and are reverse path congruent. Any nodes that are directly connected in this network have only one path between them (not shown for simplicity).

**Figure 113 Unicast Paths for Low-path-id and High-path-id**

al\_0023

For Multicast paths the algorithms used are the same low-path-id or high-path-id but the tree is always a single tree using the root selected as described earlier (in this case Node A). [Figure 114](#) shows the multicast paths for low-path-id and high-path-id algorithm.

**Figure 114 Multicast Paths for Low-path-id and High-path-id**

al\_0024

All nodes in this network use one of these trees. The path for multicast to/from Node A is the same as unicast traffic to/from Node A for both low-path-id and high-path-id. However, the multicast path for other nodes is now different from the unicast paths for some destinations. For example, Node E to Node F is now different for high-path-id since the path must transit the root Node A. In addition, the Node E multicast path to C is E-A-C even though E has a direct path to Node C. A rule of thumb is that the node chosen to be root should be a well-connected node and have available resources. In this example, Node A and Node D are the best choices for root nodes.

The distribution of I-SIDs allows efficient pruning of the multicast single tree on a per I-SID basis since only MFIB entries between nodes on the single tree are populated. For example, if Nodes A, B and F share an I-SID and they use the low-path-id algorithm only those three nodes would have multicast traffic for that I-SID. If the high-path-id algorithm is used traffic from Nodes A and B must go through D to get to Node F.

---

### 4.2.6.5 Data Path and Forwarding

The implementation of SPB on SR OS uses the PBB data plane. There is no flooding of BMAC based traffic. If a BMAC is not found in the FDB, traffic is dropped until the control plane populates that BMAC. Unicast BMAC addresses are populated in all FDBs regardless of I-SID membership. There is a unicast FDB per B-VPLS both control B-VPLS and user BVPLS. B-VPLS instances that do not have any I-VPLS, have only a default multicast tree and do not have any multicast MFIB entries.

The data plane supports an ingress check (reverse path forwarding check) for unicast and multicast frames on the respective trees. Ingress check is performed automatically. For unicast or multicast frames the BMAC of the source must be in the FDB and the interface must be valid for that BMAC or traffic is dropped. The PBB encapsulation (See PBB Technology) is unchanged from current SR OS. Multicast frames use the PBB Multicast Frame format and SPBM distributes I-VPLS I-SIDs which allows SPB to populate forwarding only to the relevant branches of the multicast tree. Therefore, SPB replaces both spanning tree control and MMRP functionality in one protocol.

By using a single tree for multicast the amount of MFIB space used for multicast is reduced. (Per source shortest path trees for multicast are not currently offered on SR OS.) In addition, a single tree reduces the amount of computation required when there is topology change.

### 4.2.6.6 SPB Ethernet OAM

Ethernet OAM works on Ethernet services and use a combination of unicast with learning and multicast addresses (REF to OAM section). SPB on SR OS supports both unicast and multicast forwarding, but with no learning and unicast and multicast may take different paths. In addition, SR OS SPB control plane offers a wide variety of show commands. The SPB IS-IS control plane takes the place of many Ethernet OAM functions. SPB IS-IS frames (Hello and PDU etc) are multicast but they are per SPB interface on the control B-VPLS interfaces and are not PBB encapsulated.

All Client Ethernet OAM is supported from I-VPLS interfaces and PBB Epipe interfaces across the SPB domain. Client OAM is the only true test of the PBB data plane. The only forms of Eth-OAM supported directly on SPB B-VPLS are Virtual MEPS (vMEPs). Only CCM is supported on these vMEPs; vMEPs use a S-TAG encapsulation and follow the SPB multicast tree for the specified B-VPLS. Each MEP has a unicast associated MAC to terminate various ETH-CFM tools. However, CCM

messages always use a destination Layer 2 multicast using 01:80:C2:00:00:3x (where x = 0 to 7). vMEPs terminate CCM with the multicast address. Unicast CCM can be configured for point to point associations or hub and spoke configuration but this would not be typical (when unicast addresses are configured on vMEPs they are automatically distributed by SPB in IS-IS).

Up MEPs on services (I-VPLS and PBB Epipes) are also supported and these behave as any service OAM. These OAM use the PBB encapsulation and follow the PBB path to the destination.

Link OAM or 802.1ah EFM is supported below SPB as standard. This strategy of SPB IS-IS and OAM gives coverage.

**Table 76 SPB Ethernet OAM Operation Summary**

| OAM Origination                                                      | Data Plane Support                                                           | Comments                                                                                               |
|----------------------------------------------------------------------|------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| PBB-Epipe or Customer CFM on PBB Epipe.<br><br>Up MEPs on PBB Epipe. | Fully Supported.<br><br>Unicast PBB frames encapsulating unicast/multicast.  | Transparent operation.<br><br>Uses Encapsulated PBB with Unicast B-MAC address.                        |
| I-VPLS or Customer CFM on I-VPLS.<br><br>Up MEPs on I-VPLS.          | Fully Supported.<br><br>Unicast/Multicast PBB frames determined by OAM type. | Transparent operation.<br><br>Uses Encapsulated PBB frames with Multicast/Unicast BMAC address.        |
| vMEP on B-VPLS Service.                                              | CCM only. S-Tagged Multicast Frames.                                         | Ethernet CCM only. Follows the Multicast tree. Unicast addresses may be configured for peer operation. |

In summary SPB offers an automated control plane and optional Eth-CFM/Eth-EFM to allow monitoring of Ethernet Services using SPB. B-VPLS services PBB Epipes and I-VPLS services support the existing set of Ethernet capabilities.

#### 4.2.6.7 SPB Levels

Levels are part of IS-IS. SPB supports Level 1 within a control B-VPLS. Future enhancements may make use of levels.

---

## 4.2.7 SPBM to Non-SPBM Interworking

By using static definitions of B-MACs and ISIDs interworking of PBB Epipes and I-VPLS between SPBM networks and non-SPBM PBB networks can be achieved.

### 4.2.7.1 Static MACs and Static ISIDs

To extend SPBM networks to other PBB networks, static MACs and ISIDs can be defined under SPBM SAPs/SDPs. The declaration of a static MAC in an SPBM context allows a non-SPBM PBB system to receive frames from an SPBM system. These static MACs are conditional on the SAP/SDP operational state. (Currently this is only supported for SPBM since SPBM can advertise these B-MACs and ISIDs without any requirement for flushing.) The B-MAC (and B-MAC to ISID) must remain consistent when advertised in the IS-IS database.

The declaration of static-isids allows an efficient connection of ISID based services. The ISID is advertised as supported on the local nodal B-MAC and the static B-MACs which are the true destinations for the ISIDs are also advertised. When the I-VPLS learn the remote B-MAC they will associated the ISID with the true destination B-MAC. Therefore if redundancy is used the B-MACs and ISIDs that are advertised must be the same on any redundant interfaces.

If the interface is an MC-LAG interface the static MAC and ISIDs on the SAPs/SDPs using that interface are only active when the associated MC-LAG interface is active. If the interface is a spoke-SDP on an active/ standby pseudo wire (PW) the ISIDs and B-MACs are only active when the PW is active.

### 4.2.7.2 Epipe Static Configuration

For Epipe only, the B-MACs need to be advertised. There is no multicast for PBB epipes. Unicast traffic will follow the unicast path shortest path or single tree. By configuring remote B-MACs Epipes can be setup to non-SPBM systems. A special conditional static-mac is used for SPBM PBB B-VPLS SAPs/SDPs that are connected to a remote system. In the diagram ISID 500 is used for the PBB Epipe but only conditional MACs A and B are configured on the MC-LAG ports. The B-VPLS will advertise the static MAC either always or optionally based on a condition of the port forwarding.

### Figure 115 Static MACs Example

SPB\_staticMAC\_ISID\_01

#### 4.2.7.2.1 I-VPLS Static Config

I-VPLS static config consists of two components: static-mac and static ISIDs that represent a remote BMAC-ISID combination.

The static-MACs are configured as with Epipe, the special conditional static-mac is used for SPBM PBB B-VPLS SAPs/SDPs that are connected to a remote system. The B-VPLS will advertise the static MAC either always or optionally based on a condition of the port forwarding.

The static-ISIDs are created under the B-VPLS SAP/SDPs that are connected to a non-SPBM system. These ISIDs are typically advertised but may be controlled by ISID policy.

For I-VPLS ISIDs the ISIDs are advertised and multicast MAC are automatically created using PBB-OUI and the ISID. SPBM supports the pruned multicast single tree. Unicast traffic will follow the unicast path shortest path or single tree. Multicast/ and unknown Unicast follow the pruned single tree for that ISID.

**Figure 116 Static ISIDs Example**

### 4.2.7.3 SPBM ISID Policies

ISID policies are an optional aspect of SPBM which allow additional control of ISIDs for I-VPLS. PBB services using SPBM automatically populate multicast for I-VPLS and static-isids. Improper use of isid-policy can create black holes or additional flooding of multicast.

To enable more flexible multicast, ISID policies control the amount of MFIB space used by ISIDs by trading off the default Multicast tree and the per ISID multicast tree. Occasionally customers want services that use I-VPLS that have multiple sites but use primarily unicast. The ISID policy can be used on any node where an I-VPLS is defined or static ISIDs are defined.

The typical use is to suppress the installation of the ISID in the MFIB using use-def-mcast and the distribution of the ISID in SPBM by using no advertise-local.

The use-def-mcast policy instructs SPBM to use the default B-VPLS multicast forwarding for the ISID range. The ISID multicast frame remains unchanged by the policy (the standard format with the PBB OUI and the ISID as the multicast destination address) but no MFIB entry is allocated. This causes the forwarding to use the default BVID multicast tree which is not pruned. When this policy is in place it only governs the forwarding locally on the current B-VPLS.

The advertise local policy ISID policies are applied to both static ISIDs and I-VPLS ISIDs. The policies define whether the ISIDs are advertised in SPBM and whether they use the local MFIB. When ISIDs are advertised they will use the MFIB in the remote nodes. Locally the use of the MFIB is controlled by the **use-def-mcast** policy.

The types of interfaces are summarized in [Table 77](#).

**Table 77 SPBM ISID Policies Table**

| Service Type                                             | ISID Policy on B-VPLS                                             | Notes                                                                                                                                                                                  |
|----------------------------------------------------------|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Epipe                                                    | No effect                                                         | PBB Epipe ISIDs are not advertised or in MFIB.                                                                                                                                         |
| I-VPLS                                                   | None:<br>Uses ISID Multicast tree.<br>Advertised ISIDs of I-VPLS. | I-VPLS uses dedicated (pruned) multicast tree. ISIDs are advertised.                                                                                                                   |

| Static ISIDs for I-VPLS interworking                     | None: (recommended)<br>Uses ISID Multicast tree                   | I-VPLS uses dedicated (pruned) multicast tree. ISIDs are advertised.                                                                                                                   |
| Static ISIDs for I-VPLS interworking (defined locally)   | use-def-mcast                                                     | I-VPLS uses default Multicast. Policy only required where ISIDs are configured or where I-VPLS is located.                                                                             |
| No MFIB for any ISIDs<br><br>Policy defined on all nodes | use-def-mcast<br>no advertise-local                               | Each B-VPLS with the policy will not install MFIB. Policy defined on all switches ISIDs are defined. ISIDs advertised and pruned tree used elsewhere. May be inconsistent for an ISID. |

## **4.2.8 ISID Policy Control**

### **4.2.8.1 Static ISID Advertisement**

Static ISIDs are advertised between using the SPBM Service Identifier and Unicast Address sub-TLV in IS-IS when there is no ISID policy. This TLV advertises the local B-MAC and one or more ISIDs. The B-MAC used is the source-bmac of the Control/User VPLS. Typically remote B-MACs (the ultimate source-bmac) and the associated ISIDs are configured as static under the SPBM interface. This allows all remote B-MACs and all remote ISIDs can be configured once per interface.

### **4.2.8.2 I-VPLS for Unicast Service**

If the service is using unicast only an I-VPLS still uses MFIB space and SPBM advertises the ISID. By using the default multicast tree locally, a node saves MFIB space. By using the no advertise-local SPBM will not advertise the ISIDs covered by the policy. Note the actual PBB multicast frames are the same regardless of policy. Unicast traffic is the not changed for the ISID policies.

The Static B-MAC configuration is allowed under Multi-Chassis LAG (MC-LAG) based SAPs and active/standby PW SDPs.

Unicast traffic will follow the unicast path shortest path or single tree. By using the ISID policy Multicast/and unknown Unicast traffic (BUM) follows the default B-VPLS tree in the SPBM domain. This should be used sparingly for any high volume of multicast services.

**Figure 117 ISID Policy Example**

## 4.2.9 Default Behaviors

When static ISIDs are defined the default is to advertise the static ISIDs when the interface parent (SAP or SDP) is up.

If the advertisement is not needed, an ISID policy can be created to prevent advertising the ISID.

- **use-def-mcast:** If a policy is defined with use-def-mcast the local MFIB will not contain an Multicast MAC based on the PBB OUI+ ISID and the frame will be flooded out the local tree. This applies to any node where the policy is defined. On other nodes if the ISID is advertised the ISID will use the MFIB for that ISID.
- **No advertise-local:** If a policy of no advertise-local is defined the ISIDs in the policy will not be advertised. This combination should be used everywhere there is an I-VPLS with the ISID or where the Static ISID is defined to prevent black holes. If an ISID is to be moved from advertising to no advertising it is advisable to use **use-def-mcast** on all the nodes for that ISID which will allow the MFIB to not be installed and will start using the default multicast tree at each node with that policy. Then the no advertise-local option can be used.

Each Policy may be used alone or in combination.

## 4.2.10 Example Network Configuration

**Figure 118** Sample Network

**Figure 118** shows an example network showing four nodes with SPB B-VPLS. The SPB instance is configured on the B-VPLS 100001. B-VPLS 100001 uses FID 1 for SPB instance 1024. All BMACs and I-SIDs are learned in the context of B-VPLS 100001. B-VPLS 100001 has an i-vpls 10001 service, which also uses the I-SID 10001. B-VPLS 100001 is configured to use VID 1 on SAPs 1/2/2 and 1/2/3 and while the VID does not need to be the same as the FID the VID does however need to be the same on the other side (Dut-B and Dut-C).

A user B-VPLS service 100002 is configured and it uses B-VPLS 100001 to provide forwarding. It fate shares the control topology. In **Figure 118**, the control B-VPLS uses the low-path-id algorithm and the user B-VPLS uses high-path-id algorithm. Any B-VPLS can use any algorithm. The difference is illustrated in the path between Dut A and Dut D. The short dashed line through Dut-B is the low-path-id algorithm and the long dashed line thought Dut C is the high-path-id algorithm.

#### 4.2.10.1.1 Show Commands Outputs

The **show base** commands output a summary of the instance parameters under a control B-VPLS. The **show** command for a user B-VPLS indicates the control B-VPLS. The base parameters except for Bridge Priority and Bridge ID must match on neighbor nodes.

```
*A:Dut-A# show service id 100001 spb base

The **show routes** command shows the next hop if for the MAC addresses both unicast and multicast. The path to 00:10:00:01:00:04 (Dut-D) shows the low-path-id algorithm id. For FID one the neighbor is Dut-B and for FID 100 the neighbor is Dut-C. Since Dut-A is the root of the multicast single tree the multicast forwarding is the same for Dut-A. However, unicast and multicast routes will differ on most other nodes. Also the I-SIDs exist on all of the nodes so I-SID base multicast follows the multicast tree exactly. If the I-SID had not existed on Dut-B or Dut-D then for FID 1 there would be no entry. Note only designated nodes (root nodes) show metrics. Non-designated nodes will not show metrics.

### **4.2.11 IEEE 802.1ak MMRP for Service Aggregation and Zero Touch Provisioning**

IEEE 802.1ah supports an M:1 model where multiple customer services, represented by ISIDs, are transported through a common infrastructure (B-component). The Nokia PBB implementation supports the M:1 model allowing for a service architecture where multiple customer services (I-VPLS or Epipe) can be transported through a common B-VPLS infrastructure as depicted in [Figure 119](#).

**Figure 119 Customer Services Transported in 1 B-VPLS (M:1 Model)**

OSSG195

The B-VPLS infrastructure represented by the white circles is used to transport multiple customer services represented by the triangles of different colors. This service architecture minimizes the number of provisioning touches and reduces the load in the core PEs: for example, G and H use less VPLS instances and pseudowire.

In a real life deployment, different customer VPNs do not share the same community of interest – for example, VPN instances may be located on different PBB PEs. The M:1 model depicted in [Figure 120](#) requires a per VPN flood containment mechanism so that VPN traffic is distributed just to the B-VPLS locations that have customer VPN sites: for example, flooded traffic originated in the blue I-VPLS should be distributed just to the PBB PEs where blue I-VPLS instances are present – PBB PE B, E and F.

Per customer VPN distribution trees need to be created dynamically throughout the BVPLS as new customer I-VPLS instances are added in the PBB PEs.

The Nokia PBB implementation employs the IEEE 802.1ak Multiple MAC Registration Protocol (MMRP) to dynamically build per I-VPLS distribution trees inside a certain B-VPLS infrastructure.

IEEE 802.1ak Multiple Registration Protocol (MRP) – Specifies changes to IEEE Std 802.1Q that provide a replacement for the GARP, GMRP and GVRP protocols. MMRP application of IEEE 802.1ak specifies the procedures that allow the registration/de-registration of MAC addresses over an Ethernet switched infrastructure.

In the PBB case, as I-VPLS instances are enabled in a certain PE, a group BMAC address is by default instantiated using the standard based PBB Group OUI and the ISID value associated with the I-VPLS.

When a new I-VPLS instance is configured in a PE, the IEEE 802.1ak MMRP application is automatically invoked to advertise the presence of the related group B-MAC on all active B-VPLS SAPs and SDP bindings.

When at least two I-VPLS instances with the same ISID value are present in a B-VPLS, an optimal distribution tree is built by MMRP in the related B-VPLS infrastructure as depicted in [Figure 120](#).

**Figure 120 Flood Containment Requirement in M:1 Model**

OSSG196

## 4.2.12 MMRP Support Over B-VPLS SAPs and SDPs

MMRP is supported in B-VPLS instances over all the supported BVPLS SAPs and SDPs, including the primary and standby pseudowire scheme implemented for VPLS resiliency.

When a B-VPLS with MMRP enabled receives a packet destined for a specific group BMAC, it checks its own MFIB entries and if the group BMAC does not exist, it floods it everywhere. This should never happen as this kind of packet will be generated at the I-VPLS/PBB PE when a registration was received for a local I-VPLS group BMAC.

### 4.2.12.1 I-VPLS Changes and Related MMRP Behavior

This section describes the MMRP behavior for different changes in IVPLS.

1. When an ISID is set for a certain I-VPLS and a link to a related B-VPLS is activated (for example, through the **config>service>vpls>backbone-vpls vpls id:isid** command), the group BMAC address is declared on all B-VPLS virtual ports (SAPs or SDPs).
2. When the ISID is changed from one value to a new one, the old group BMAC address is undeclared on all ports and the new group BMAC address is declared on all ports in the B-VPLS.
3. When the I-VPLS is disassociated with the B-VPLS, the old group BMAC is no longer advertised as a local attribute in the B-VPLS if no other peer B-VPLS PEs have it declared.
4. When an I-VPLS goes operationally down (either all SAPs/SDPs are down) or the I-VPLS is shutdown, the associated group BMAC is undeclared on all ports in the B-VPLS.
5. When the I-VPLS is deleted, the group BMAC should already be un-declared on all ports in the B-VPLS because the I-VPLS has to be shutdown in order to delete it.

### 4.2.12.2 Limiting the Number of MMRP Entries on a Per B-VPLS Basis

The MMRP exchanges create one entry per attribute (group BMAC) in the B-VPLS where MMRP protocol is running. When the first registration is received for an attribute, an MFIB entry is created for it.

The Nokia implementation allows the user to control the number of MMRP attributes (group BMACs) created on a per B-VPLS basis. Control over the number of related MFIB entries in the B-VPLS FDB is inherited from previous releases through the use of the **config>service>vpls>mfib-table-size table-size** command. This ensures that no B-VPLS will take up all the resources from the total pool.

### 4.2.12.3 Optimization for Improved Convergence Time

Assuming that MMRP is used in a certain B-VPLS, under failure conditions the time it takes for the B-VPLS forwarding to resume may depend on the data plane and control plane convergence plus the time it takes for MMRP exchanges to settle down the flooding trees on a per ISID basis.

To minimize the convergence time, the Nokia PBB implementation offers the selection of a mode where B-VPLS forwarding reverts for a short time to flooding so that MMRP has enough time to converge. This mode can be selected through configuration using **config>service>vpls> b-vpls>mrp>flood-time** *value* command where *value* represents the amount of time in seconds that flooding will be enabled. Refer to the [PBB Configuration Command Reference](#) for command syntax and usage.

If this behavior is selected, the forwarding plane reverts to B-VPLS flooding for a configurable time period, for example, for a few seconds, then it reverts back to the MFIB entries installed by MMRP.

The following B-VPLS events initiate the switch from per I-VPLS (MMRP) MFIB entries to “B-VPLS flooding”:

- Reception or local triggering of a TCN
- B-SAP failure
- Failure of a B-SDP binding
- Pseudowire activation in a primary/standby HVPLS resiliency solution
- SF/CPM switchover due to STP reconvergence

#### 4.2.12.4 Controlling MRP Scope using MRP Policies

MMRP advertises the Group BMACs associated with ISIDs throughout the whole BVPLS context regardless of whether a specific IVPLS is present in one or all the related PEs or BEBs. When evaluating the overall scalability the resource consumption in both the control and data plane must be considered:

- Control plane - MMRP processing and number of attributes advertised
- Data plane – one tree is instantiated per ISID or Group BMAC attribute

In a multi-domain environment, for example multiple MANs interconnected through a WAN, the BVPLS and implicitly MMRP advertisement may span across domains. The MMRP attributes will be flooded throughout the BVPLS context indiscriminately, regardless of the distribution of IVPLS sites.

The solution described in this section limits the scope of MMRP control plane advertisements to a specific network domain using MRP Policy. ISID-based filters are also provided as a safety measure for BVPLS data plane.

**Figure 121 Inter-Domain Topology**

**Figure 121** shows the case of an Inter-domain deployment where multiple metro domains (MANs) are interconnected through a wide area network (WAN). A BVPLS is configured across these domains running PBB M:1 model to provide infrastructure for multiple IVPLS services. MMRP is enabled in the BVPLS to build per IVPLS flooding trees. To limit the load in the core PEs or PBB BCBs, the local IVPLS instances must use MMRP and data plane resources only in the MAN regions where they have sites. A solution to the above requirements is depicted in **Figure 122**. The case of native PBB metro domains inter-connected via a MPLS core is used in this example. Other technology combinations are possible.

**Figure 122 Limiting the Scope of MMRP Advertisements**

An MRP policy can be applied to the edge of MAN1 domain to restrict the MMRP advertisements for local ISIDs outside local domain. Or the MRP policy can specify the inter-domain ISIDs allowed to be advertised outside MAN1. The configuration of MRP policy is similar with the configuration of a filter. It can be specified as a template or exclusively for a specific endpoint under service mrp object. An ISID or a range of ISID(s) can be used to specify one or multiple match criteria that will be used to generate the list of Group MACs to be used as filters to control which MMRP attributes can be advertised. An example of a simple mrp-policy that allows the advertisement of Group BMACs associated with ISID range 100-150 is given below:

```
*A:ALA-7>config>service>mrp# info
-----
      mrp-policy "test" create
        default-action block
        entry 1 create
          match
            isid 100 to 150
          exit
        action allow
        exit
      exit
-----
```

A special action end-station is available under mrp-policy entry object to allow the emulation on a specific SAP/PW of an MMRP end-station. This is usually required when the operator does not want to activate MRP in the WAN domain for interoperability reasons or if it prefers to manually specify which ISID will be interconnected over the WAN. In this case the MRP transmission will be shutdown on that SAP/PW and the configured ISIDs will be used the same way as an IVPLS connection into the BVPLS, emulating a static entry in the related BVPLS MFIB. Also if MRP is active in the BVPLS context, MMRP will declare the related GBMAC(s) continuously over all the other BVPLS SAP/PW(s) until the mrp-policy end-station action is removed from the mrp-policy assigned to that BVPLS context.

The MMRP usage of the mrp-policy will ensure automatically that traffic using Group BMAC will not be flooded between domains. There could be though small transitory periods when traffic originated from PBB BEB with unicast BMAC destination may be flooded in the BVPLS context as unknown unicast in the BVPLS context for both IVPLS and PBB Epipe. To restrict distribution of this traffic for local PBB services a new ISID match criteria is added to existing mac-filters. The mac-filter configured with ISID match criteria can be applied to the same interconnect endpoint(s), BVPLS SAP or PW, as the mrp-policy to restrict the egress transmission any type of frames that contain a local ISID. An example of this new configuration option is as follows:

```
-----
A;ALA-7>config>filter# info
-----
mac-filter 90 create
description "filter-wan-man"
type isid
```

```
scope template
entry 1 create
description "drop-local-isids"
match
isid from 100 to 1000
exit
action drop
exit
-----
```

These filters will be applied as required on a per B-SAP or B-PW basis just in the egress direction. The ISID match criteria is exclusive with any other criteria under mac-filter. A new mac-filter type attribute is defined to control the use of ISID match criteria and must be set to isid to allow the use of isid match criteria. The ISID tag is identified using the PBB ethertype provisioned under **config>port>ethernet>pbb-etype**.

## 4.2.13 PBB and BGP-AD

BGP auto-discovery is supported only in the BVPLS to automatically instantiate the BVPLS pseudowires and SDPs as described in the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 2 Services and EVPN Guide: VLL, VPLS, PBB, and EVPN*.

## 4.2.14 PBB E-Line Service

E-Line service is defined in PBB (IEEE 802.1ah) as a point-to-point service over the B-component infrastructure. The Nokia implementation offers support for PBB E-Line through the mapping of multiple Epipe services to a Backbone VPLS infrastructure.

The use of Epipe scales the E-Line services as no MAC switching, learning or replication is required in order to deliver the point-to-point service.

All packets ingressing the customer SAP/spoke-SDP are PBB encapsulated and unicasted through the B-VPLS “tunnel” using the backbone destination MAC of the remote PBB PE. The Epipe service does not support the forwarding of PBB encapsulated frames received on SAPs or Spoke-SDPs through their associated B-VPLS service. PBB frames are identified based on the configured PBB Ethertype (0x88e7 by default).

All the packets ingressing the B-VPLS destined for the Epipe are PBB de-encapsulated and forwarded to the customer SAP/spoke-SDP.

---

A PBB E-Line service support the configuration of a SAP or non-redundant spoke-SDP.

#### **4.2.14.1 Non-Redundant PBB Epipe Spoke Termination**

This feature provides the capability to use non-redundant pseudowire connections on the access side of a PBB Epipe, where previously only SAPs could be configured.

### **4.2.15 PBB Using G.8031 Protected Ethernet Tunnels**

IEEE 802.1ah Provider Backbone Bridging (PBB) specification employs provider MSTP (PMSTP) to ensure loop avoidance in a resilient native Ethernet core. The usage of P-MSTP means failover times depend largely on the size and the connectivity model used in the network. The use of MPLS tunnels provides a way to scale the core while offering fast failover times using MPLS FRR. There are still service provider environments where Ethernet services are deployed using native Ethernet backbones. A solution based on native Ethernet backbone is required to achieve the same fast failover times as in the MPLS FRR case.

The Nokia PBB implementation offers the capability to use core Ethernet tunnels compliant with ITU-T G.8031 specification to achieve 50 ms resiliency for backbone failures. This is required to comply with the stringent SLAs provided by service providers in the current competitive environment. The implementation also allows a LAG-emulating Ethernet tunnel providing a complimentary native Ethernet E-LAN capability. The LAG-emulating Ethernet tunnels and G.8031 protected Ethernet tunnels operate independently.

The next section describes an applicability example where an Ethernet service provider using native PBB offers a carrier of carrier backhaul service for mobile operators.

#### **4.2.15.1 Solution Overview**

A simplified topology example for a PBB network offering a carrier of carrier service for wireless service providers is depicted in [Figure 123](#).

**Figure 123 Mobile Backhaul Use Case**

The wireless service provider in this example purchases an E-Line service between the ENNI on PBB edge nodes, BEB1 and BEBn. PBB services are employing a type of Ethernet tunneling (Eth-tunnels) between BEBs where primary and backup member paths controlled by G.8031 1:1 protection are used to ensure faster backbone convergence. Ethernet CCMs based on IEEE 802.1ag specification may be used to monitor the liveness for each individual member paths.

The Ethernet paths span a native Ethernet backbone where the BCBs are performing simple Ethernet switching between BEBs using an Epipe or a VPLS service.

Although the network diagram shows just the Epipe case, both PBB E-Line and E-LAN services are supported.

#### 4.2.15.2 Detailed Solution Description

This section discusses the details of the Ethernet tunneling for PBB. The main solution components are depicted in [Figure 124](#).

**Figure 124 PBB-Epipe with B-VPLS over Ethernet Tunnel**

al\_0157

The PBB E-Line service is represented in the BEBs as a combination of an Epipe mapped to a BVPLS instance. A eth-tunnel object is used to group two possible paths defined by specifying a member port and a control tag. In our example, the blue-circle representing the eth-tunnel is associating in a protection group the two paths instantiated as (port, control-tag/bvid): a primary one of port 1/1/1, control-tag 100 and respectively a secondary one of port 2/2/2, control tag 200.

The BCBs devices will stitch each BVID between different BEB-BCB links using either a VPLS or Epipe service. Epipe instances are recommended as the preferred option due to increased tunnel scalability.

Fast failure detection on the primary and backup paths is provided using IEEE 802.1ag CCMs that can be configured to transmit at 10 msec interval. Alternatively, the link layer fault detection mechanisms like LoS/RDI or 802.3ah can be employed.

Path failover is controlled by an Ethernet protection module, based on standard G.8031 Ethernet Protection Switching. The Nokia implementation of Ethernet protection switching supports only the 1:1 model which is common practice for packet based services since it makes better use of available bandwidth. The following additional functions are provided by the protection module:

- Synchronization between BEBs such that both send and receive on the same Ethernet path in stable state.
- Revertive / non-revertive choices.
- Compliant G.8031 control plane.

The secondary path requires a MEP to exchange the G.8031 APS PDUs. The following Ethernet CFM configuration in the **eth-tunnel>path>eth-cfm>mep** context can be used to enable the G.8031 protection without activating the Ethernet CCMs:

- Create the domain (MD) in CFM.
- Create the association (MA) in CFM. NOTE: Do not put remote MEPs.
- Create the MEP.
- Configure control-mep and no shutdown on the MEP.
- The CCM transmission should stay disabled using the **no ccm-enable** command.

If a MEP is required for troubleshooting issues on the primary path, the configuration described above for the secondary path must be used to enable the use of Link Layer OAM on the primary path.

LAG loadsharing is offered to complement G.8031 protected Ethernet tunnels for situations where unprotected VLAN services are to be offered on some or all of the same native Ethernet links.

**Figure 125 G.8031 P2P Tunnels and LAG-Like Loadsharing Co-Existence**

al\_0158

In [Figure 125](#), the G.8031 Ethernet tunnels are used by the B-SAP(s) mapped to the green BVPLS entities supporting the E-Line services. A LAG-like loadsharing solution is provided for the Multipoint BVPLS (white circles) supporting the E-LAN (IVPLS) services. The green G.8031 tunnels co-exist with LAG-emulating Ethernet tunnels (loadsharing mode) on both BEB-BCB and BCB-BCB physical links.

The G.8031-controlled Ethernet tunnels will select an active tunnel based on G.8031 APS operation, while emulated-LAG Ethernet tunnels will hash traffic within the configured links. Upon failure of one of the links the emulated-LAG tunnels will rehash traffic within the remaining links and fail the tunnel when the number of links breaches the minimum required (independent of G.8031-controlled Ethernet tunnels on the links shared emulated-LAG).

### 4.2.15.3 Detailed PBB Emulated LAG Solution Description

This section discusses the details of the emulated LAG Ethernet tunnels for PBB. The main solution components are depicted in [Figure 126](#) which overlays Ethernet Tunnels services on the network from [Figure 124](#).

**Figure 126 Ethernet Tunnel Overlay**

al\_0159

For a PBB Ethernet VLAN to make efficient use of an emulated LAG solution, a Management-VPLS (m-VPLS) is configured enabling Provider Multi-Instance Spanning Tree Protocol (P-MSTP). The m-VPLS is assigned to two SAPs; the eth-tunnels connecting BEB1 to BCB-E and BCB-F, respectively, reserving a range of VLANs for P-MSTP.

The PBB P-MSTP service is represented in the BEBs as a combination of an Epipe mapped to a BVPLS instance as before but now the PBB service is able to use the Ethernet tunnels under the P-MSTP control and load share traffic on the emulated LAN. In our example, the blue-circle representing the BVPLS is assigned to the SAPs which define two paths each. All paths are specified as primary precedence to load share the traffic.

A Management VPLS (m-VPLS) is first configured with a VLAN-range and assigned to the SAPs containing the path to the BCBs. The load shared eth-tunnel objects are defined by specifying a member ports and a control tag of zero. Then individual B-VPLS services can be assigned to the member paths of the emulated LAGs and defining the path encapsulation. Then individual services such as the IVPLS service can be assigned to the B-VPLS.

At the BCBs the tunnels are terminated the next BVPLS instance controlled by P-MSTP on the BCBs to forward the traffic.

In the event of link failure, the emulated LAG group will automatically adjust the number of paths. A threshold can be set whereby the LAG group is declared down. All emulated LAG operations are independent of any 8031-1to1 operation.

#### 4.2.15.4 Support Service and Solution Combinations

The following considerations apply when Ethernet tunnels are configured under a VPLS service:

- Only ports in access or hybrid mode can be configured as eth-tunnel path members. The member ports can be located on the same or different IOMs, MDAs, XCMs, or XMAAs.
- Dot1q and QinQ ports are supported as eth-tunnel path members.
- The same port cannot be used as member in both a LAG and an Ethernet-tunnel.
- A mix of regular and multiple eth-tunnel SAPs and PWs can be configured in the same BVPLS.
- Split horizon groups in BVPLS are supported on eth-tunnel SAPs. The use of split horizon groups allows the emulation of a VPLS model over the native Ethernet core, eliminating the need for P-MSTP.
- STP and MMRP are not supported in a BVPLS using eth-tunnel SAPs.
- Both PBB E-Line (Epipe) and E-LAN (IVPLS) services can be transported over a BVPLS using Ethernet-tunnel SAPs.
- MC-LAG access multi-homing into PBB services is supported in combination with Ethernet tunnels:
  - MC-LAG SAPs can be configured in IVPLS or Epipe instances mapped to a BVPLS that uses eth-tunnel SAPs
  - Blackhole Avoidance using native PBB MAC flush/MAC move solution is also supported

- Support is also provided for BVPLS with P-MSTP and MMRP control plane running as ships-in-the-night on the same links with the Ethernet tunneling which is mapped by a SAP to a different BVPLS.
  - Epipes must be used in the BCBs to support scalable point-to-point tunneling between the eth-tunnel endpoints when management VPLS is used.
- The following solutions or features are not supported in the current implementation for the 7450 ESS and 7750 SR and are blocked:
  - Capture SAP
  - Subscriber management
  - BSX
  - Eth-tunnels usage as a logical port in the **config>redundancy>multi-chassis>peer>sync>port** context

For further information, refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide*.

## 4.2.16 Periodic MAC Notification

Virtual BMAC learning frames (for example, the frames sent with the source MAC set to the virtual BMAC) can be sent periodically, allowing all BCBs/BEBs to keep the virtual BMAC in their Layer 2 forwarding database.

This periodic mechanism is useful in the following cases:

- A new BEB is added after the current mac-notification method has stopped sending learning frames.
- When a new combination of [MC-LAG:SAP|A/S PW]+[PBB-Epipe]+[associated B-VPLS]+[at least one B-SDP|B-SAP] becomes active. The current mechanism only sends learning frames when the first such combination becomes active.
- A BEB containing the remote endpoint of a dual-homed PBB-epipe is rebooted.
- When traffic is not seen for the MAC aging timeout (assuming that the new periodic sending interval is less than the aging timeout).
- When there is uni-directional traffic.

In each of the above cases, all of the remote BEB/BCBs will learn the virtual MAC in the worse case after the next learning frame is sent.

In addition, this will allow all of the above when to be used in conjunction with discard-unknown in the B-VPLS. Currently, if discard-unknown is enabled in all related B-VPLSs (to avoid any traffic flooding), all above cases could experience an increased traffic interruption, or a permanent loss of traffic, as only traffic toward the dual homed PBB-epipe can restart bi-directional communication. For example, it will reduce the traffic outage when:

The PBB-Epipe virtual MAC is flushed on a remote BEB/BCB due to the failover of an MC-LAG or A/S pseudowires within the customer's access network, for example, in between the dual homed PBB-Epipe peers and their remote tunnel endpoint.

There is a failure in the PBB core causing the path between the two BEBs to pass through a different BCB.

It should be noted that this will not help in the case where the remote tunnel endpoint BEB fails. In this case traffic will be flooded when the remote B-MAC ages out if discard-unknown is disabled. If discard-unknown is enabled, then the traffic will follow the path to the failed BEB but will eventually be dropped on the source BEB when the remote B-MAC ages out on all systems.

To scale the implementation it is expected that the timescale for sending the periodic notification messages is much longer than that used for the current notification messages.

## **4.2.17 MAC Flush**

### **4.2.17.1 PBB Resiliency for B-VPLS Over Pseudowire Infrastructure**

The following VPLS resiliency mechanisms are also supported in PBB VPLS:

- Native Ethernet resiliency supported in both I-VPLS and B-VPLS contexts
- Distributed LAG, MC-LAG, RSTP
- MSTP in a management VPLS monitoring (B- or I-) SAPs and pseudowire
- BVPLS service resiliency, loop avoidance solutions – Mesh, active/standby pseudowires and multi-chassis endpoint
- IVPLS service resiliency, loop avoidance solutions – Mesh, active/standby pseudowires (PE-rs only role), BGP Multi-homing

To support these resiliency options, extensive support for blackhole avoidance mechanisms is required.

#### 4.2.17.1.1 Porting existing VPLS LDP MAC Flush in PBB VPLS

Both the I-VPLS and B-VPLS components inherit the LDP MAC flush capabilities of a regular VPLS to fast age the related FDB entries for each domain: CMACs for I-VPLS and BMACs for B-VPLS. Both types of LDP MAC flush are supported for I-VPLS and B-VPLS domains:

- **flush-all-but-mine** - flush on positive event, for example:
  - Pseudowire activation — VPLS resiliency using active/standby pseudowire
  - Reception of a STP TCN
- **flush-all-from-me** - flush on negative event, for example:
  - SAP failure – link down or MC-LAG out-of-sync
  - Pseudowire or Endpoint failure

In addition, only for the B-VPLS domain, changing the backbone source MAC of a B-VPLS will trigger an LDP MAC flush-all-from-me to be sent in the related active topology. At the receiving PBB PE, a BMAC flush automatically triggers a flushing of the CMACs associated with the old source BMAC of the B-VPLS.

#### 4.2.17.1.2 PBB Blackholing Issue

In the PBB VPLS solution, a B-VPLS may be used as infrastructure for one or more I-VPLS instances. B-VPLS control plane (LDP Signaling or P-MSTP) replaces I-VPLS control plane throughout the core. This is raising an additional challenge related to blackhole avoidance in the I-VPLS domain as described in this section.

**PBB Blackholing Issue** — Assuming that the link between PE A1 and node 5 is active, the remote PEs participating in the orange VPN (for example, PE D) will learn the CMAC X associated with backbone MAC A1. Under failure of the link between node 5 and PE A1 and activation of link to PE A2, the remote PEs (for example, PE D) will blackhole the traffic destined for customer MAC X to BMAC A1 until the aging timer expires or a packet flows from X to Y through the PE A2. This may take a long time (default aging timer is 5 minutes) and may affect a large number of flows across multiple I-VPLSs.

A similar issue will occur in the case where node 5 is connected to A1 and A2 I-VPLS using active/standby pseudowires. For example, when node 5 changes the active pseudowire, the remote PBB PE will keep sending to the old PBB PE.

Another case is when the QinQ access network dual-homed to a PBB PE uses RSTP or MVPLS with MSTP to provide loop avoidance at the interconnection between the PBB PEs and the QinQ SWs. In the case where the access topology changes, a TCN event will be generated and propagated throughout the access network. Similarly, this change needs to be propagated to the remote PBB PEs to avoid blackholing.

A solution is required to propagate the I-VPLS events through the backbone infrastructure (B-VPLS) in order to flush the customer MAC to BMAC entries in the remote PBB. As there are no IVPLS control plane exchanges across the PBB backbone, extensions to B-VPLS control plane are required to propagate the I-VPLS MAC flush events across the B-VPLS.

#### 4.2.17.1.3 LDP MAC Flush Solution for PBB Blackholing

In the case of an MPLS core, B-VPLS uses T-LDP signaling to set up the pseudowire forwarding. The following I-VPLS events must be propagated across the core B-VPLS using LDP MAC **flush-all-but-mine** or **flush-all-from-me** indications:

For **flush-all-but-mine** indication (“positive flush”):

- TCN event in one or more of the I-VPLS or in the related M-VPLS for the MSTP use case.
- Pseudowire/SDP binding activation with active/standby pseudowire (standby, active or down, up)
- Reception of an LDP MAC withdraw “flush-all-but-mine” in the related I-VPLS

For **flush-all-from-me** indication (“negative flush”):

- MC-LAG failure - does not require send-flush-on-failure to be enabled in I-VPLS
- Failure of a local SAP – requires send-flush-on-failure to be enabled in I-VPLS
- Failure of a local pseudowires/SDP binding – requires send-flush-on-failure to be enabled in I-VPLS
- Reception of an LDP MAC withdraw flush-all-from-me in the related I-VPLS

To propagate the MAC flush indications triggered by the above events, the PE that originates the LDP MAC withdraw message must be identified. In regular VPLS “mine”/“me” is represented by the pseudowire associated with the FEC and the T-LDP session on which the LDP MAC withdraw was received. In PBB, this is achieved using the B-VPLS over which the signaling was propagated and the BMAC address of the originator PE.

Nokia PBB-VPLS solution addresses this requirement by inserting in the BVPLS LDP MAC withdraw message a new PBB-TLV (type-length-value) element. The new PBB TLV contains the source BMAC identifying the originator (“mine”/”me”) of the flush indication and the ISID list identifying the I-VPLS instances affected by the flush indication.

There are a number of advantages to this approach. Firstly, the PBB-TLV presence indicates this is a PBB MAC Flush. As a result, all PEs containing only the B-VPLS instance will automatically propagate the LDP MAC withdraw in the B-VPLS context respecting the split-horizon and active link topology. There is no flushing of the B-VPLS FDBs throughout the core PEs. Subsequently, the receiving PBB VPLS PEs use the BMAC and ISID list information to identify the specific I-VPLS FDBs and the CMAC entries pointing to the source BMAC included in the PBB TLV.

An example of processing steps involved in PBB MAC Flush is depicted in [Figure 127](#) for the case when a Topology Change Notification (TCN) is received on PBB PE 2 from a QinQ access in the I-VPLS domain.

**Figure 127 TCN Triggered PBB Flush-All-But-Mine Procedure**

The received TCN may be related to one or more I-VPLS domains. This will generate a MAC Flush in the local I-VPLS instance(s) and if configured, it will originate a PBB MAC **flush-all-but-mine** throughout the related B-VPLS context(s) represented by the white circles 1 to 8 in our example.

A PBB-TLV is added by PE2 to the regular LDP MAC **flush-all-but-mine**. B-MAC2, the source B-MAC associated with B-VPLS on PE2 is carried inside the PBB TLV to indicate who “mine” is. The ISID list identifying the I-VPLS affected by the TCN is also included if the number of affected I-VPLS is 100 or less. No ISID list is included in the PBB-TLV if more than 100 ISIDs are affected. If no ISID list is included, then the receiving PBB PE will flush all the local I-VPLS instances associated with the B-VPLS context identified by the FEC TLV in the LDP MAC withdraw message. This is done to speed up delivery and processing of the message.

Recognizing the PBB MAC flush, the B-VPLS only PEs 3, 4, 5 and 6 refrain from flushing their B-VPLS FDB tables and propagate the MAC flush message regardless of their “propagate-mac-flush” setting.

When LDP MAC withdraw reaches the terminating PBB PEs 1 and 7, the PBB-TLV information is used to flush from the I-VPLS FDBs all C-MAC entries except those associated with the originating B-MAC BM2. If specific I-VPLS ISIDs are indicated in the PBB TLV, then the PBB PEs will flush only the C-MAC entries from the specified I-VPLS except those mapped to the originating B-MAC. Flush-all-but-mine indication is not propagated further in the I-VPLS context to avoid information loops.

The other events that trigger Flush-all-but-mine propagation in the B-VPLS (pseudowire/SDP binding activation, Reception of an LDP MAC Withdraw) are handled similarly. The generation of PBB MAC flush-all-but-mine in the B-VPLS must be activated explicitly on a per I-VPLS basis with the command **send-bvpls-flush all-but-mine**. The generation of PBB MAC flush-all-from-me in the B-VPLS must be activated explicitly on a per I-VPLS basis with the command **send-bvpls-flush all-from-me**.

## 4.2.18 Access Multi-Homing for Native PBB (B-VPLS over SAP Infrastructure)

Nokia PBB implementation allows the operator to use a native Ethernet infrastructure as the PBB core. Native Ethernet tunneling can be emulated using Ethernet SAPs to interconnect the related B-VPLS instances. This kind of solution might fit certain operational environments where Ethernet services was provided in the past using QinQ solution. The drawback is that no LDP signaling is available to provide support for Access Multi-homing for Epipe (pseudowire active/standby status) or I-VPLS services (LDP MAC Withdraw). An alternate solution is required.

A PBB network using Native Ethernet core is depicted in [Figure 128](#). MC-LAG is used to multi-home a number of edge switches running QinQ to PBB BEBs.

**Figure 128 Access Dual-Homing into PBB BEBs - Topology View**

CLI0001B

The interrupted line from the MC-LAG represents the standby, inactive link; the solid line is the active link. The BEBs are dual-homed to two core switches BCB1 and BCB2 using native Ethernet SAPs on the B-VPLS side. Multi-point B-VPLS with MSTP for loop avoidance can be used as the PBB core tunneling. Alternatively point-to-point, G.8031 protected Ethernet tunnels can be also used to interconnect B-VPLS instances in the BEBs as described in the PBB over G.8031 protected Ethernet tunnels.

Nokia implementation provides a solution for both PBB E-Line (Epipe) and E-LAN (IVPLS) services that avoids PBB blackholing when the active ES11-BEB1 link fails. It also provides a consistent behavior for both service type and for different backbone types: for example, native Ethernet, MPLS, or a combination. Only MC-LAG is supported initially as the Access-Multi-homing mechanism.

#### 4.2.18.1 Solution Description for I-VPLS Over Native PBB Core

The use case described in the previous section is addressed by enhancing the existing native PBB solution to provide for blackhole avoidance.

The topology depicted in [Figure 129](#) describes the details of the solution for the I-VPLS use case. Although the native PBB use case is used, the solution works the same for any other PBB infrastructure: for example, G.8031 Ethernet tunnels, pseudowire/MPLS, or a combination.

**Figure 129 PBB Active Topology and Access Multi-Homing**

ES1 and ES2 are dual-homed using MC-LAG into two BEB devices: ES1 to BEB C and BEB D, ES2 to BEB A and BEB B. MC-LAG P11 on BEB C and P9 on BEB A are active on each side.

In the service context, the triangles are I-VPLS instances while the small circles are B-VPLS components with the related, per BVPLS source BMACs indicated next to each BVPLS instances. P-MSTP or RSTP may be used for loop avoidance in the multi-point BVPLS. For simplicity, only the active SAPs (BEB P2, P4, P6 and P8) are shown in the diagram.

In addition to the source BMAC associated with each BVPLS, there is an additional BMAC associated with each MC-LAG supporting multi-homed I-VPLS SAPs. The BEBs that are in a multi-homed MC-LAG configuration share a common B-MAC on the related MC-LAG interfaces. For example, a common B-MAC C1 is associated in this example with ports P11 and P12 participating in the MC-LAG between BEB C and BEB D while B-MAC A1 is associated with ports P9 and P10 in the MC-LAG between BEB A and BEB B. While B-MAC C1 is associated through the I-VPLS SAPs with both BVPLS instances in BEB C and BEB D, it is actively used for forwarding to I-VPLS SAPs only on BEB C containing the active link P11.

MC-LAG protocol keeps track of which side (port or LAG) is active and which is standby for a specified MC-LAG grouping and activates the standby in case the active one fails. The source BMAC C1 and A1 are used for PBB encapsulation as traffic arrives at the IVPLS SAPs on P11 and P9, respectively. MAC Learning in the BVPLS instances installs MAC FDB entries in BCB-E and BEB A as depicted in [Figure 129](#).

Active link (P11) or access node (BEB C) failures are activating through MC-LAG protocol the standby link (P12) participating in the MC-LAG on the pair MC-LAG device (BEB D).

[Figure 130](#) shows the case of access link failure.

**Figure 130 Access Multi-Homing - Link Failure**

OSSG355

On failure of the active link P11 on BEB C the following processing steps apply:

- MC-LAG protocol activates the standby link P12 on the pair BEB D.
- BMAC C1 becomes active on BEB D and any traffic received on BEB D with destination BMAC C1 is forwarded on the corresponding I-VPLS SAPs on P12.
- BEB D determines the related B-VPLS instance(s) associated with all the I-VPLS SAP(s) mapped to P12, the newly activated MC-LAG link(s)/LAG component(s).
- Subsequently, BEB D floods in the related B-VPLS instance(s) an Ethernet CFM-like message using C1 as source BMAC. A vendor CFM opcode is used followed by an Nokia OUI.
- As a result, all the FDB entries in BCBs or BEBs along the path will be automatically updated to reflect the move of BMAC C1 to BEB D.

- In this particular configuration the entries on BEB A do not need to be updated saving MAC Flush operation.
- In other topologies, it is possible that the BMAC C1 FDB entries in the B-VPLS instance on the remote BEBs (like BEB A) will need to move between B-SAPs. This will involve a move of all CMAC using as next hop BMAC C1 and the new egress line card.

Identical procedure is used when the whole BEB C fails.

### 4.2.18.2 Solution Description for PBB Epipe over G.8031 Ethernet Tunnels

This section discusses the Access multi-homing solution for PBB E-Line over an infrastructure of G.8031 Ethernet tunnels. Although a specific use case is used, the solution works the same for any other PBB infrastructure: for example, native PBB, pseudowire/MPLS, or a combination.

The PBB E-Line service and the related BVPLS infrastructure are depicted in [Figure 131](#).

**Figure 131 Access Multi-Homing Solution for PBB Epipe**

OSSG353

The E-Line instances are connected through the B-VPLS infrastructure. Each B-VPLS is interconnected to the BEBs in the remote pair using the G.8031, Ethernet Protection Switched (EPS) tunnels. Only the active Ethernet paths are shown in the network diagram to simplify the explanation. Split Horizon Groups may be used on EPS tunnels to avoid running MSTP/RSTP in the PBB core.

The same BMAC addressing scheme is used as in the E-LAN case: a BMAC per B-VPLS and additional BMACs associated with each MC-LAG connected to an Epipe SAP. The BMACs associated with the active MC-LAG are actively used for forwarding into B-VPLS the traffic ingressing related Epipe SAPs.

MC-LAG protocol keeps track of which side is active and which is standby for a specified MC-LAG grouping and activates the standby link in a failure scenario. The source BMACs C1 and A1 are used for PBB encapsulation as traffic arrives at the Epipe SAPs on P11 and P9, respectively. MAC Learning in the B-VPLS instances installs MAC FDB entries in BEB C and BEB A as depicted in [Figure 131](#). The highlighted Ethernet tunnel (EPS) will be used to forward the traffic between BEB A and BEB C.

Active link (P11) or access node (BEB C) failures are activating through MC-LAG protocol, the standby link (P12) participating in the MC-LAG on the pair MC-LAG device (BEB D). The failure of BEB C is depicted in [Figure 132](#). The same procedure applies for the link failure case.

**Figure 132 Access Dual-Homing for PBB E-Line - BEB Failure**

The following process steps apply:

- BEB D will lose MC-LAG communication with its peer BEB C - no more keep-alives from BEB C or next-hop tracking may kick in.

- BEB D assumes BEB C is down and activates all shared MC-LAG links, including P12.
- B-MAC C1 becomes active on BEB D and any traffic received on BEB C with destination B-MAC C1 is forwarded on the corresponding Epipe SAPs on P12.
- BEB D determines the related B-VPLS instance(s) associated with all the Epipe SAP(s) mapped to P12, the newly activated MC-LAG link(s)/LAG component(s).
- Subsequently, BEB D floods in the related B-VPLS instance(s) the same Ethernet CFM message using C1 as source B-MAC.
- As a result, the FDB entries in BEB A and BEB B will be automatically updated to reflect the move of B-MAC C1 from EP1 to EP2 and from EP3 to EP4, respectively.

The same process is executed for all the MC-LAGs affected by BEB C failure so BEB failure will be the worst case scenario.

#### 4.2.18.2.1 Dual-Homing into PBB Epipe - Local Switching Use Case

When the service SAPs were mapped to MC-LAGs belonging to the same pair of BEBs in earlier releases, an IVPLS had to be configured even if there were just two SAPs active at any point in time. Since then, the PBB Epipe model has been enhanced to support configuring in the same Epipe instance two SAPs and a BVPLS uplink as depicted in [Figure 133](#).

**Figure 133** Solution for Access Dual-Homing with Local Switching for PBB E-Line/Epipe

al\_0161

The PBB Epipe represented by the yellow diamond on BEB1 points through the BVPLS uplink to the BMAC associated with BEB2. The destination BMAC can be either the address associated with the green BVPLS on BEB2 or the BMAC of the SAP associated with the pair MC-LAG on BEB2 (preferred option).

The Epipe information model is expanded to accommodate the configuration of two SAPs (I-SAPs) and of a BVPLS uplink in the same time. For this configuration to work in an Epipe environment, only two of them will be active in the forwarding plane at any point in time, specifically:

- SAP1 and SAP2 when both MC-LAG links are active on the local BEB1 (see [Figure 133](#))
- The Active SAP and the BVPLS uplink if one of the MC-LAG links is inactive on BEB1
  - PBB tunnel will be considered as a backup path only when the SAP is operationally down.
  - If the SAP is administratively down, then all traffic will be dropped.
- Although the CLI allows configuration of two SAPs and a BVPLS uplink in the same PBB Epipe, the BVPLS uplink is inactive as long as both SAPs are active.
  - Traffic received through PBB tunnel is dropped if BVPLS uplink is inactive.
- The same rules apply to BEB2.

## 4.2.19 BGP Multi-homing for I-VPLS

This section describes the application of BGP multi-homing to I-VPLS services. BGP multi-homing for I-VPLS uses the same mechanisms as those used when BGP multi-homing is configured in a non-PBB VPLS service, which are described in detail in this guide.

The multi-homed sites can be configured with either a SAP or spoke-SDP, and support both split horizon groups and fate-sharing by the use of oper-groups.

When the B-VPLS service is using LDP signaled pseudowires, blackhole protection is supported after a multi-homing failover event when **send-flush-on-failure** and **send-bvpls-flush flush-all-from-me** is configured within the I-VPLS. This causes the system on which the site object fails to send a MAC flush all-from-me message so that customer MACs are flushed on the remote backbone edge bridges using a flush-all-from-me message. The message sent includes a PBB TLV which contains the source BMAC identifying the originator (“mine”/“me”) of the flush indication and the ISID list identifying the I-VPLS instances affected by the flush indication, see section [LDP MAC Flush Solution for PBB Blackholing](#).

The VPLS preference sent in BGP multi-homing updates will always be set to zero, however, if a non-zero value is received in a valid BGP multi-homing update it will be used to influence the designated forwarder (DF) election.

## 4.2.20 Access Multi-Homing over MPLS for PBB Epipes

It is possible to connect backbone edge bridges (BEBs) configured with PBB Epipes to an edge device using active/standby pseudowires over an MPLS network. This is shown in [Figure 134](#).

**Figure 134 Active/Standby PW into PBB Epipes**

In this topology, the edge device (CE1) is configured with multiple Epipes to provide virtual lease line (VLL) connectivity across a PBB network. CE1 uses active/standby pseudowires (PWs) which terminate in PBB Epipe services on BEB1 and BEB2 and are signaled accordingly using the appropriate pseudowire status bits.

Traffic is sent from CE1 on the active pseudowires into the PBB epipe services, then onto the remote devices through the B-VPLS service. It is important that traffic sent to CE1 is directed to the BEB that is attached to the active pseudowire connected to CE1. To achieve this, a virtual backbone MAC (vBMAC) is associated with the services on CE1.

The vBMAC is announced into the PBB core by the BEB connected to the active pseudowire using SPBM configured in the B-VPLS services; therefore, SPBM is mandatory. In [Figure 134](#), the vBMAC would be announced by BEB1; if the pseudowires failed over to BEB2, BEB1 would stop announcing the vBMAC and BEB2 will start announcing it.

The remote services are configured to use the vBMAC as the backbone destination MAC (backbone-dest-mac) which results in traffic being sent to the specified BEB.

The vBMAC is configured under the SDP used to connect to the edge device's active/standby pseudowires using the command `source-bmac-lsb`. This command defines a sixteen (16) bit value which overrides the sixteen least-significant-bits of source backbone MAC (source-bmac) to create the vBMAC. The operator must ensure that the vBMACs match on the two peering BEBs for a corresponding SDP.

The PBB Epipe pseudowires are identified to be connected to an edge device active/standby pseudowire using the spoke-sdp parameter `use-sdp-bmac`. Enabling this parameter will cause traffic forwarded from this spoke-SDP into the B-VPLS domain to use the vBMAC as its source MAC address when both this, and the control pseudowire, are in the active state on this BEB.

PBB Epipe pseudowires connected to edge device's non-active/standby pseudowires are still able to use the same SDP.

To cater for the case where there are multiple edge device active/standby pseudowires using a specified SDP, one pseudowire must be identified to be the control pseudowire (using the `source-bmac-lsb` parameter `control-pw-vc-id`). The state of the control pseudowire determines the announcing of the vBMAC by SPBM into the B-VPLS based on the following conditions:

- The `source-bmac-lsb` and `control-pw-vc-id` have both been configured.
- The spoke-SDP referenced by the `control-pw-vc-id` has `use-sdp-bmac` configured.
- The spoke-SDP referenced by the `control-pw-vc-id` is operationally up and the "Peer Pw Bits" do not include `pwFwdingStandby`.
- If multiple B-VPLS services are used with different SPBM Forward IDs (FIDs), the vBMAC is advertised into any FID which has a PBB Epipe with a spoke-SDP configured with `use-sdp-bmac` that is using an SDP with `source-bmac-lsb` configured (regardless of whether the PBB Epipe spoke-SDP defined as the control pseudowire is associated with the B-VPLS).

It is expected that pseudowires configured using an SDP with `source-bmac-lsb` and with the parameter `use-sdp-bmac` are in the same state (up, down, active, standby) as the control pseudowire. If this is not the case, the following scenarios are possible (based on [Figure 134](#)):

- If any non-control pseudowires are active on BEB2 and standby on BEB1, then this will continue to allow bi-directional traffic for the related services as the return traffic to CE1 will be sent to BEB1, specifically to the BEB announcing the vBMAC. As the non-control PW is in standby state it will be used to send this traffic to the edge device. If this operation is not needed, it is possible to prevent traffic being sent on a standby PW using the standby-signaling-slave parameter under the spoke-SDP definition.
- If any non-control pseudowires are active on BEB2 but down on BEB1, then only uni-directional traffic is possible. The return traffic to CE1 will be sent to BEB1, as it is announcing the vBMAC but the pseudowire on BEB1 is down for this service.

Alarms are raised to track if, on the BEB with the control pseudowire in the standby/down state, any non-control pseudowires go active. Specifically, there will be an alarm when the first non-control pseudowire becomes active and another alarm when the last non-control pseudowire becomes standby/down.

If both control pseudowires are active (neither in standby) then both BEBs would announce the vBMAC – this would happen if the edge device was a 7450 ESS, 7750 SR, and 7950 XRS using an Epipe service without standby-signaling-master configured. Traffic from remote BEBs on any service related to the vBMAC would be sent to the nearest SPBM BEB and it would depend on the state of the pseudowires on each BEB as to whether it could reach the edge device. Similarly, the operator must ensure that the corresponding service pseudowires on each BEB are configured as the control pseudowire, otherwise SPBM might advertise the vBMAC from both BEBs resulting in the same consequences.

All traffic received from the edge device on a pseudowire into a PBB Epipe, on the BEB with the active control pseudowire, is forwarded by the B-VPLS using the vBMAC as the source backbone MAC, otherwise the source-bmac is used.

The control pseudowire can be changed dynamically without shutting down the spoke-SDPs, SDP or withdrawing the SPBM advertisement of the vBMAC; this allows a graceful change of the control pseudowire. Clearly, any change should be performed on both BEBs as closely in time as possible to avoid an asymmetric configuration, ensuring that the new control pseudowire is in the same state as the current control pseudowire on both BEBs during the change.

The following are not supported:

- Active/standby pseudowires within the PBB Epipe are not supported, consequently the following are not supported:
  - The configuration of endpoints.
  - The configuration of precedence under the spoke-SDP.
- The use of PW switching.

- BGP-MH support, namely configuring the pseudowires to be part of a multi-homed site.
- Network-domains.
- Support for the following tunneling technologies
  - RFC 3107
  - GRE
  - L2TPv3

## 4.2.21 PBB and IGMP/MLD Snooping

The IGMP/MLD snooping feature provided for VPLS is supported similarly in the PBB I-VPLS context, in order to provide efficient multicast replication in the customer domain. The difference from regular VPLS is the handling of IGMP/MLD messages arriving from the B-VPLS side over a B-VPLS SAP or SDP.

The first IGMP/MLD join message received over the local B-VPLS adds all the B-VPLS SAP and SDP components into the related multicast table associated with the I-VPLS context. This is in line with the PBB model, where the B-VPLS infrastructure emulates a backbone LAN to which every I-VPLS is connected by one virtual link.

When the querier is connected to a remote I-VPLS instance, over the B-VPLS infrastructure, its location is identified by the B-VPLS SDP and SAP on which the query was received. It is also identified by the source BMAC address used in the PBB header for the query message. This is the BMAC associated with the B-VPLS instance on the remote PBB PE.

It is also possible to configure that a multicast router exists in a remote I-VPLS service. This can be achieved using the **mrouter-dest** command to specify the MAC name of the destination BMAC to be used to reach the remote I-VPLS service. This command is available in the VPLS service PBB IGMP and MLD snooping contexts.

The following are not supported in a PBB I-VPLS context with IGMP snooping or MLD snooping:

- multicast VPLS Registration (MVR)
- multicast CAC
- configuration under a default SAP

The following are not supported in a PBB I-VPLS context with MLD snooping:

- configuration of the maximum number of multicast group sources allowed per group
- configuration of the maximum number of multicast sources allowed per group

## 4.2.22 PBB and PIM Snooping

The PIM snooping feature for IPv4 is supported in the PBB I-VPLS context in order to provide efficient multicast replication in the customer domain. This is similar to PIM snooping for IPv4 in a regular VPLS with the difference being the handling of PIM messages arriving from the B-VPLS side over a B-VPLS SAP or SDP.

The first PIM join message received over the local B-VPLS adds all the B-VPLS SAP and SDP components into the related multicast table associated with the I-VPLS context, and the multicast for the join is flooded throughout the B-VPLS. This is in line with the PBB model, where the B-VPLS infrastructure emulates a backbone LAN to which every I-VPLS is connected by one virtual link.

When a neighbor is located on a remote I-VPLS instance over the B-VPLS infrastructure, its location is identified by the B-VPLS SDP and SAP on which the hello message was received. The neighbor is also identified by the source BMAC address used in the PBB header of the hello message. This is the BMAC associated with the B-VPLS instance on the remote PBB PE.

PIM snooping for IPv4 in an I-VPLS is not supported with the following forms of default SAP:

- .\*
- \*.null
- \*.\*.

## 4.2.23 PBB QoS

For PBB encapsulation, the configuration used for DE and dot1p in SAP and SDP policies applies to the related bits in both backbone dot1q (BTAG) and ITAG fields.

The following QoS processing rules apply for PBB B-VPLS SAPs and SDPs:

### **B-VPLS SAP ingress**

- If dot1p, DE based classification is enabled, the BTAG fields will be used by default to evaluate the internal forwarding class (fc) and discard profile if there is a BTAG field. The 802.1ah ITAG will be used only if the BTAG is absent (null SAP).
- If either one of the dot1p or DE based classification is not explicitly enabled or the packets are untagged then the default fc and profile is assigned.

### **B-VPLS SAP egress**

- If the sap-egress policy for the SAP contains an fc to dot1p/de mapping, this entry is used to set the dot1p and DE bits from the BTAG of the frame going out from the SAP. The same applies for the ITAG on frames originated locally from an I-VPLS. The mapping does not have any effect on the ITAG of frames transiting the B-VPLS.
- If no explicit mapping exists, the related dot1p DE bits are set to zero on both ITAG and BTAG if the frame is originated locally from an I-VPLS. If the frame is transiting the B-VPLS the ITAG stays unchanged, the BTAG is set according to the type of ingress SAP.
  - If the ingress SAP is tagged, the values of the dot1p, DE bits are preserved in the BTAG going out on the egress SAP.
  - If the ingress SAP is untagged, the dot1p, DE bits are set to zero in the BTAG going out on the egress SAP.

### **B-VPLS SDP (network) ingress policy**

- QoS policies for dot1p and DE bits apply only for the outer VLAN ID: this is the VLAN ID associated with the link layer and not the PBB BTAG. As a result, the dot1p DE bits will be checked if an outer VLAN ID exists in the packets ingressing the SDP. If that VLAN ID is absent, nothing above the pseudowire SL will be checked - for example, no dot1p bits in the BTAG or ITAG will be checked. It is expected that the EXP bits will be used to transport QoS information across the MPLS backbone and into the PEs.

### **B-VPLS SDP (network) egress policy**

- When building PBB packets originating from a local I-VPLS, the BTAG and ITAG values (dot1p, DE bits) will be set according to the network egress policy. The same applies for newly added BTAG (VLAN mode pseudowires) in a packet transiting the B-VPLS (SAP/SDP to SDP). If either dot1p or DE based classification is not explicitly enabled in the CLI, the values from the default fc to dot1p, DE mapping are assumed.
- Dot1p, DE bits for existing BTAGs will remain unchanged - for example, applicable to packets transiting the B-VPLS and going out on SDP.

### 4.2.23.1 Transparency of Customer QoS Indication through PBB Backbone

Similar to PW transport, operators want to allow their customers to preserve all eight Ethernet CoS markings (three dot1p bits) and the discard eligibility indication (DE bit) while transiting through a PBB backbone.

This means any customer CoS marking on the packets inbound to the ingress SAP must be preserved when going out on the egress SAP at the remote PBB PE even if the customer VLAN tag is used for SAP identification at the ingress.

A solution to the above requirements is depicted in [Figure 135](#).

**Figure 135 PCP, DE Bits Transparency in PBB**

OSSG504

The PBB BVPLS is represented by the blue pipe in the middle with its associated CoS represented through both the service (I-tag) and tunnel CoS (BVID dot1p+DE or PW EXP bits).

The customer CoS is contained in the orange dot1q VLAN tags managed in the customer domains. There may be one (CVID) or two (CVID, SVID) tags used to provide service classification at the SAP. IVPLS or PBB Epipe instances (orange triangles) are used to provide a Carrier-of-Carrier service.

As the VLAN tags are stripped at the ingress SAP and added back at the egress SAP, the PBB implementation must provide a way to maintain the customer QoS marking. This is done using a force-qtag-forwarding configuration on a per IVPLS/Epipe basis under the node specifying the uplink to the related BVPLS. When force-qtag-forwarding is enabled, a new VLAN tag is added right after the CMAC addresses using the configured QTAG. The dot1p, DE bits from the specified outer/inner customer QTAG will be copied in the newly added tag.

When the force-qtag-forwarding is enabled in one IVPLS/PBB Epipe instance, it will be enabled in all of the related instances.

At the remote PBB PE/BEB on the egress SAPs or SDPs, the first QTAG after the CMAC addresses will be removed and its dot1p, DE bits will be copied in the newly added customer QTAGs.

#### 4.2.23.1.1 Configuration Examples

This section gives usage examples for the new commands under PBB Epipe or IVPLS instances.

PBB IVPLS usage:

**Example:**

```
configure service vpls 100 ivpls
  sap 1/1/1:101
  pbb
    backbone-vpls 10 isid 100
    force-qtag-forwarding
```

PBB Epipe Usage:

**Example:**

```
configure service epipe 200
  sap 1/1/1:201
  pbb
    tunnel 10 backbone-dest-mac ab-bc-cd-ef-
      01-01 isid 200
    force-qtag-forwarding
```

#### 4.2.23.1.2 Details Solution Description

[Figure 135](#) shows a specific use case. Keeping the same topology, an ingress PBB PE, a PBB core and an egress PBB PE, consider the generic use case where:

1. the packet arrives on the ingress PBB PE on an I-SAP or an I-SDP binding/PW and it is assigned to a PBB service instance (Epipe/IVPLS)
2. goes next through a PBB core (native Ethernet B-SAPs or PW/MPLS based B-SDP)
3. and finally, egresses at another PBB PE through a PBB service instance on either an I-SAP or I-SDP binding/PW.

Similar to the Ethernet-VLAN VC Type, the following packet processing steps apply for different scenarios.

- **Ingress PE, ingress I-SAP case** with force-qtag-forwarding enabled under PBB Epipe or IVPLS

The QTAG is inserted automatically right after CMAC addresses; an ethertype value of 8100 is used.

- **Case 1:** SAP type = null/dot1q default (1/1/1 or 1/1/1.\*) so there is no service delimiting tag used and stripped on the ingress side.
  - VLAN and Dot1p+DE bits on the inserted QTAG are set to zero regardless of ingress QoS policy
- **Case 2:** SAP type = dot1q or qinq default (1/1/1.100 or 1/1/1.100.\*) so there is a service delimiting tag used and stripped.
  - The service delimiting QTAG (dot1p + DE bits and VLAN) is copied as is in the inserted QTAG.
- **Case 3:** SAP type = qinq (1/1/1.100.10) so there are two service delimiting tags used and stripped.
  - The service delimiting QTAG (VLAN and dot1p + DE bits) is copied as is from the inner tag in the inserted QTAG.
- **Ingress PE, ingress I-SDP/PW case** with force-qtag-forwarding enabled under PBB Epipe or IVPLS

The QTAG is inserted automatically right after CMAC addresses; an ethertype value of 8100 is used.

- **Case 1:** SDP vc-type = Ethernet (force-vlan-vc-forwarding= not supported for I-PW) so there is no service delimiting tag stripped on the ingress side.
  - VLAN and Dot1p+DE bits on the inserted QTAG are set to zero regardless of ingress QoS policy
- **Case 2:** SDP vc-type = Ethernet VLAN so there is a service delimiting tag stripped.
  - VLAN and Dot1p + DE bits on the inserted QTAG are preserved from the service delimiting tag.

PBB packets are tunneled through the core the same way for native ETH/MPLS cases.

- **Egress PE, egress I-SAP case** with force-qtag-forwarding enabled under PBB Epipe or VPLS
  - The egress QoS policy (FC->dot1p+DE bits) is used to determine the QoS settings of the added QTAGs. If it required to preserve the ingress QoS, no egress policy should be added.
    - If QinQ SAP is used, at least qinq-mark-top-only option must be enabled to preserve the CTAG.
  - The “core QTAG” (core = received over the PBB core, 1st after CMAC addresses) is always removed after QoS information is extracted.
    - If no force-qtag-forwarding is used at egress PE, the inserted QTAG is maintained.

- 
- If egress SAP is on the ingress PE, then the dot1p+DE value is read directly from the procedures described in Ingress PE, ingress I-SAP and Ingress PE, ingress I-SDP/PW cases. The use cases below still apply.
  - **Case 1:** SAP type = null/dot1q default (2/2/2 or 2/2/2.\*) so there is no service delimiting tag added on the egress side.
    - Dot1p+DE bits and the VLAN value contained in the QTAG are ignored.
  - **Case 2:** SAP type = dot1q/qinq default (3/1/1.300 or 3/1/1.300.\*) so a service delimiting tag is added on egress
    - The FC->dot1p, DE bit entries in the SAP egress QoS policy are applied.
    - If there are no such entries, then the values of the dot1p+DE bits from the stripped QTAG are used.
  - **Case 3:** SAP type = qinq (3//1/1.300.30) so two service delimiting tags are added on egress
    - The FC->dot1p, DE bit entries in the SAP egress QoS policy are applied.
    - If the **qinq-mark-top-only** command under **vpls>sap>egress** is not enabled (default), the policy is applied to both service delimiting tags.
    - If the qinq-mark-top-only command is enabled, the policy is applied only to the outer service delimiting tag.
    - On the tags where the egress QoS policies do not apply the values of the dot1p+DE bits from the stripped QTAG are used.
  - **Egress PE, egress I-SDP case** with force-qtag-forwarding enabled under PBB Epipe or IVPLS
    - **Case 1:** I-SDP vc-type = Ethernet VLAN so there is service delimiting tag added after PW encapsulation.
      - The dot1p+DE bits from the QTAG received over the PBB core side are copied to the QTAG added on the I-SDP.
      - The VLAN value in the QTAG might change to match the provisioned value for the I-SDP configuration.
    - **Case 2:** I-SDP vc-type = Ethernet (force-vlan-vc-forwarding=not supported for I-SDPs) so there is no service delimiting tag added on egress PW
      - The QTAG received over the PBB core is stripped and the QoS information is lost.

## 4.2.24 Egress B-SAP per ISID Shaping

This feature allows users to perform egress data path shaping of packets forwarded within a B-VPLS SAP. The shaping is performed within a more granular context within the SAP. The context for a B-SAP is an ISID.

### 4.2.24.1 B-SAP Egress ISID Shaping Configuration

Users can enable the per-ISID shaping on the egress context of a B-VPLS SAP by configuring an encapsulation group, referred to as **encap-group** in CLI, under the QoS sub-context, referred to as **encap-defined-qos**.

```
config>service>vpls>sap>egress>encap-defined-qos>encap-group group-name [type group-type] [qos-per-member] [create]
```

The group name is unique across all member types. The **isid** type is currently the only option.

The user adds or removes members to the **encap-group**, one at a time or as a range of contiguous values. However, when the **qos-per-member** option is enabled, members must be added or removed one at a time. These members are also referred to as ISID contexts.

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group  
[no] member encap-id [to encap-id]
```

The user can configure one or more encap-groups in the egress context of the same B-SAP, defining different ISID values and applying each a different SAP egress QoS policy, and optionally a different scheduler policy/agg-rate-limit. ISID values are unique within the context of a B-SAP. The same ISID value cannot be re-used in another encap-group under the same B-SAP but can be re-used in an encap-group under a different B-SAP. Finally, if the user adds to an encap-group an ISID value which is already a member of this encap-group, the command causes no effect. The same if the user attempts to remove an ISID value which is not a member of this encap-group.

When a group is created, the user assigns a SAP egress QoS policy, and optionally a scheduler policy or aggregate rate limit, using the following commands:

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group>qos sap-egress-policy-id
```

```
config>service> vpls>sap>egress>encap-defined-qos>encap-  
group>scheduler-policy scheduler-policy-name
```

```
config>service> vpls>sap>egress>encap-defined-qos>encap-group>agg-  
rate-limit kilobits-per-second
```

A SAP egress QoS policy must first be assigned to the created encap-group before the user can add members to this group. Conversely, the user cannot perform the **no qos** command until all members are deleted from the **encap-group**.

An explicit or the default SAP egress QoS policy will continue to be applied to the entire B-SAP but this will serve to create the set of egress queues which will be used to store and forward a packet which does not match any of the defined ISID values in any of the encap-groups for this SAP.

Only the queue definition and fc-to-queue mapping from the encap-group SAP egress QoS policy is applied to the ISID members. All other parameters configurable in a SAP egress QoS policy must be inherited from egress QoS policy applied to the B-SAP.

Furthermore, any other CLI option configured in the egress context of the B-SAP will continue to apply to packets matching a member of any encap-group defined in this B-SAP.

Note also that the SAP egress QoS policy must not contain an active policer or an active queue-group queue or the application of the policy to the encap-group will be failed. A policer or a queue-group queue is referred to as active if one or more FC map to it in the QoS policy or the policer is referenced within the action statement of an IP or IPv6 criteria statement. Conversely, the user will not be allowed to assign a FC to a policer or a queue-group queue, or reference a policer within the action statement of an IP or IPv6 criteria statement, once the QoS policy is applied to an encap-group.

The **qos-per-member** keyword allows the user to specify that a separate queue set instance and scheduler/agg-rate-limit instance will be created for each ISID value in the encap-group. By default, shared instances will be created for the entire encap-group.

When the B-SAP is configured on a LAG port, the ISID queue instances defined by all the encap-groups applied to the egress context of the SAP will be replicated on each member link of the LAG. The set of scheduler/agg-rate-limit instances will be replicated per link or per IOM or XMA depending if the adapt-qos option is set to link/port-fair mode or distribute mode. This is the same behavior as that applied to the entire B-SAP in the current implementation.

## 4.2.24.2 Provisioning Model

The main objective of this proposed provisioning model is to separate the definition of the QoS attributes from the definition of the membership of an **encap-group**. The user can apply the same SAP egress QoS policy to a large number of ISID members without having to configure the QoS attributes for each member.

The following are conditions of the provisioning model:

- A SAP egress policy ID must be assigned to an **encap-group** before any member can be added regardless of the setting of the **qos-per-member** option.
- When **qos-per-member** is specified in the **encap-group** creation, the user must add or remove ISID members one at a time. The command is failed if a range is entered.
- When **qos-per-member** is specified in the **encap-group** creation, the sap-egress QoS policy ID and the scheduler policy name cannot be changed unless the group membership is empty. However, the **agg-rate-limit** parameter value can be changed or the command removed (**no agg-rate-limit**).
- When **qos-per-member** is not specified in the **encap-group** creation, the user may add or remove ISID members as a singleton or as a range of contiguous values.
- When **qos-per-member** is not specified in the **encap-group** creation, the sap-egress QoS policy ID and the scheduler policy name or **agg-rate-limit** parameter value may be changed at any time. Note however that the user cannot still remove the SAP egress QoS policy (**no qos**) while there are members defined in the **encap-group**.
- The QoS policy or the scheduler policy itself may be edited and modified while members are associated with the policy.
- There will be a maximum number of ISID members allowed in the lifetime of an **encap-group**.

Operationally, the provisioning consists of the following steps:

1. Create an **encap-group**.
2. Define and assign a SAP egress QoS policy to the **encap-group**. This step is mandatory else the user is allowed to add members to the **encap-group**.
3. Manage membership for the **encap-group** using the **member** command (or SNMP equivalent).
  - Supports both range and singleton ISIDs
  - Cannot add an ISID if it already exists on the SAP in another **encap-group**
    - The **member** command is all-or-nothing. No ISID in a range is added if one fails

- It the first ISID that fails in the error message is identified.
  - Must first remove the ISID using **no member** command.
  - Specifying an ISID in a group that already exists within the group is a no-op (no failure)
  - If insufficient queues or scheduler policies or FC-to-Queue lookup table space exist to support a new member or a modified membership range, the entire member command is failed
4. Define and assign a scheduling policy or agg-rate-limit for the encap-group. This step is optional.

Logically, the encap-group membership operation can be viewed as three distinct functions:

1. Creation or deletion of new queue sets and optionally scheduler/agg-rate-limit at QoS policy association time.
2. Mapping or un-mapping the member ISID to either the group queue set and scheduler (group QoS) or the ISID specific queue set and scheduler (**qos-per-member**).
3. Modifying the groups objective membership based on newly created or expanded ranges or singletons based on the membership operation.

4.2.24.3 Egress Queue Scheduling

Figure 136 Egress Queue Scheduling

Figure 136 displays an example of egress queue scheduling.

The queuing and scheduling re-uses existing scheduler policies and port scheduler policy with the difference that a separate set of FC queues are created for each defined ISID context according to the encap-group configured under the egress context of the B-SAP. This is in addition to the set of queues defined in the SAP egress QoS policy applied to the egress of the entire SAP.

The user type in [Figure 136](#) maps to a specific encap-group defined for the B-SAP in CLI. The operator has the flexibility of scheduling many user types by assigning different scheduling parameters as follows:

- A specific scheduler policy to each encap-group with a root scheduler which shapes the aggregate rate of all queues in the ISID context of the encap-group and provides strict priority scheduling to its children.  
A second tier scheduler can be used as a WFQ scheduler to aggregate a subset of the ISID context FC queues. Alternatively, the operator can apply an aggregate rate limit to the ISID context instead of a scheduler policy.
- A specific priority level when parenting the ISID queues or the root of the scheduler policy serving the ISID queues to the port scheduler.
- Ability to use the weighted scheduler group to further distribute the bandwidth to the queues or root schedulers within the same priority level according to configured weights.

To make the shaping of the ISID context reflect the SLA associated with each user type, it is required to subtract the operator's PBB overhead from the Ethernet frame size. For that purpose, a **packet byte-offset** parameter is added to the context of a queue.

**config>qos>sap-egress>queue>packet-byte-offset {add bytes | subtract bytes}**

When a packet-byte-offset value is applied to a queue instance, it adjusts the immediate packet size. This means that the queue rates, like the operational PIR and CIR, and queue bucket updates use the adjusted packet size. In addition, the queue statistics will also reflect the adjusted packet size. Scheduler policy rates, which are data rates, will use the adjusted packet size.

The port scheduler **max-rate** and **priority level** rates and weights, if a Weighted Scheduler Group is used, are always "on-the-wire" rates and thus use the actual frame size. The same applies to the agg-rate-limit on a SAP, a subscriber, or a Multi-Service Site (MSS) when the queue is port-parented.

When the user enables **frame-based-accounting** in a scheduler policy or **queue-frame-based-accounting** with agg-rate-limit in a port scheduler policy, the queue rate is capped to a user- configured "on-the-wire" rate and the **packet-byte-offset** is not included; however, the packet-byte-offset is applied to the statistics..

#### 4.2.24.4 B-SAP per-ISID Shaping Configuration Example

The following CLI configuration for B-SAP per-ISID shaping achieves the specific use case shown in [Egress Queue Scheduling](#).

```
config
  qos
    port-scheduler-policy "bvpls-backbone-port-scheduler"
    group scheduler-group1 create
    rate 1000
    level 3 rate 1000 group scheduler-group1 weight w1
    level 4 rate 1000 group scheduler-group1 weight w4
    level 5 rate 1000 cir-rate 100
    level 7 rate 5000 cir-rate 5000
    level 8 rate 500 cir-rate 500
  exit

  scheduler-policy "user-type1"
  tier 1

## 4.2.25 PBB OAM

The Nokia PBB implementation supports both MPLS and native Ethernet tunneling. In the case of an MPLS, SDP bindings are used as the B-VPLS infrastructure while T-LDP is used for signaling. As a result, the existing VPLS, MPLS diagnostic tools are supported in both I-VPLS and B-VPLS domains as depicted in [Figure 137](#).

**Figure 137 PBB OAM View for MPLS Infrastructure**

OSSG200

When an Ethernet switching backbone is used for aggregation between PBB PEs, a SAP is used as the B-VPLS uplink instead of an SDP. No T-LDP signaling is available.

The existing IEEE 802.1ag implemented for regular VPLS SAPs may be used to troubleshoot connectivity at I-VPLS and B-VPLS layers.

### 4.2.25.1 Mirroring

There are no restrictions for mirroring in I-VPLS or B-VPLS.

---

### 4.2.25.2 OAM Commands

All VPLS OAM commands may be used in both I-VPLS and B-VPLS instances.

#### I-VPLS

- The following OAM commands are meaningful only toward another I-VPLS service instance (spoke-SDP in I-VPLS):
  - LSP-ping, LSP-trace, SDP-ping, SDP-MTU
- The following I-VPLS OAM exchanges are transparently transported over the B-VPLS core:
  - SVC-ping, MAC-ping, MAC-trace, MAC-populate, MAC-purge, CPE-ping (toward customer CPE), 802.3ah EFM, SAA
- PBB uplinks using MPLS/SPP: there are no PBB specific OAM commands.

#### B-VPLS

- In case of Ethernet switching backbone (B-SAPs on B-VPLS), 802.1ag OAM is supported on B-SAP, operating on:
  - The customer level (C-SA/C-DA and C-type layer)
  - The tunnel level (B-SA/B-DA and B-type layer)

### 4.2.25.3 CFM Support

There is no special 802.1ag CFM (Connectivity Fault Management) support for PBB. B-component and I-components run their own maintenance domain and levels. CFM for I-components run transparently over the PBB network and will appear as directly connected.

---

## 4.3 Configuration Examples

Use the CLI syntax displayed to configure PBB.

### 4.3.1 PBB using G.8031 Protected Ethernet Tunnels

The following displays PBB configuration examples:

Ethernet links on BEB1:

BEB1 to BEB1 L1:

BEB1 to BCB1 L1: 1/1/1 – Member port of LAG-emulation ET1, terminate ET3

BEB1 to BCB1 L2: 2/1/1 – Member port of LAG-emulation ET1

BEB1 to BCB1 L3: 3/1/1 - Member port of LAG-emulation ET1

BEB1 to BCB2: 4/1/1 – terminate ET3

```
*A:7750_ALU>config>eth-tunnel 1

### 4.3.2 MC-LAG Multi-homing for Native PBB

This section describes a configuration example for BEB C configuration given the following assumptions:

- BEB C and BEB D are MC-LAG peers
- B-VPLS 100 on BEB C and BEB D
- VPLS 1000 on BEB C and BEB D
- MC-LAG 1 on BEB C and BEB D

**CLI Syntax:**

```

service pbb
  source-bmac ab-ac-ad-ef-00-00
port 1/1/1
  ethernet
    encap-type qinq
lag 1
  port 1/1/1 priority 20
  lacp active administrative-key 32768
redundancy
  multi-chassis
    peer 10.1.1.3 create
      source-address 10.1.1.1
    mc-lag
      lag 1 lacp-key 1 system-id
        00:00:00:01:01:01

```

```

                                system-priority 100
                                source-bmac-lsb use-lacp-key
service vpls 100 bvpls
    sap 2/2/2:100 // bvid 100
    mac-notification
    no shutdown

service vpls 101 bvpls
    sap 2/2/2:101 // bvid 101
    mac-notification
    no shutdown
// no per BVPLS source-bmac configuration, the chassis
one (ab-ac-ad-ef-00-00) is used

service vpls 1000 ivpls
    backbone-vpls 100
    sap lag-1:1000 //automatically associates the SAP
    with ab-ac-ad-ef-00-01 (first 36 bits from BVPLS
    100 sbmac+16bit source-bmac-lsb)

service vpls 1001 ivpls
    backbone-vpls 101
    sap lag-1:1001 //automatically associates the SAP
    with ab-ac-ad-ef-00-01 (first 36 bits from BVPLS
    101 sbmac+16bit source-bmac-lsb)

```

### 4.3.3 Access Multi-Homing over MPLS for PBB Epipes

This section gives an example configuration for BEB1 from [Figure 134](#).

```

*A:BEB1>config>service# info
-----
    pbb
        source-bmac 00:00:00:00:11:11
        mac-name "remote-BEB" 00:44:44:44:44:44
    exit
    sdp 1 mpls create
        far-end 10.1.1.4
        ldp
        keep-alive
        shutdown
    exit
    source-bmac-lsb 33:33 control-pw-vc-id 100
    no shutdown
    exit
    vpls 10 customer 1 b-vpls create
        service-mtu 1532
        stp
            shutdown
    exit

```

```

        spb 1024 fid 1 create
            no shutdown
        exit
        sap 1/1/1:10 create
            spb create
            no shutdown
        exit
    exit
    sap 1/1/5:10 create
        spb create
        no shutdown
    exit
    exit
    no shutdown
exit

### 4.4.1.2 SAP Commands

```

config
  — service
    — [no] vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls]
      [etree] [name name] [create]
    — sap sap-id [split-horizon-group group-name] [create] [capture-sap]
    — no sap sap-id
      — mrp
        — [no] join-time value
        — [no] leave-all-time value
        — [no] leave-time value
        — [no] mrp-policy policy-name
        — [no] periodic-time value
        — [no] periodic-timer
      — [no] spb create
        — [no] shutdown
        — lsp-pacing-interval milli-seconds
        — no lsp-pacing-interval
        — retransmit-interval seconds
        — no retransmit-interval
        — metric value
        — no metric
          — hello-interval seconds
          — no hello-interval
          — hello-multiplier multiplier
          — no hello-multiplier

```

### 4.4.1.3 Mesh SDP Commands

```

config
  — service
    — [no] vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls]
      [etree] [name name] [create]
    — mesh-sdp sdp-id[:vc-id] [vc-type {ether | vlan}]
    — no mesh-sdp sdp-id[:vc-id]
      — mrp
        — [no] join-time value
        — [no] leave-all-time value
        — [no] leave-time value
        — [no] mrp-policy policy-name
        — [no] periodic-time value
        — [no] periodic-timer

```

#### 4.4.1.4 Spoke SDP Commands

```

config
  — service
    — [no] vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls]
      [etree] [name name] [create]
    — spoke-sdp sdp-id[:vc-id] [vc-type {ether | vlan}] [split-horizon-group group-name]
    — no spoke-sdp sdp-id[:vc-id]
      — mrp
        — [no] join-time value
        — [no] leave-all-time value
        — [no] leave-time value
        — [no] mrp-policy policy-name
        — [no] periodic-time value
        — [no] periodic-timer
      — [no] spb create
        — [no] shutdown
        — lsp-pacing-interval milli-seconds
        — no lsp-pacing-interval
        — retransmit-interval seconds
        — no retransmit-interval
        — metric value
        — no metric
          — hello-interval seconds
          — no hello-interval
          — hello-multiplier multiplier
          — no hello-multiplier

```

#### 4.4.1.5 BGP-MH for I-VPLS Commands

```

config
  — service
    — vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls] [etree]
      [name name] [create]
    — no vpls service-id
      — no site name
        — boot-timer seconds
        — no boot-timer
        — failed-threshold [1..1000]
        — failed-threshold all
        — [no] mesh-sdp-binding
        — monitor-oper-group name
        — no monitor-oper-group
        — sap sap-id
        — no sap
        — [no] shutdown
        — site-activation-timer seconds
        — no site-activation-timer
        — site-min-down-timer min-down-time

```

- **no site-min-down-timer**
- **site-id** *value*
- **no site-id**
- **split-horizon-group** *group-name*
- **no split-horizon-group**
- **spoke-sdp** *sdp-id:vc-id*

| <b>Description</b> | <p>This command creates or edits a Virtual Private LAN Services (VPLS) instance. The <b>vpls</b> command is used to create or maintain a VPLS service. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>A VPLS service connects multiple customer sites together acting like a zero-hop, Layer 2 switched domain. A VPLS is always a logical full mesh.</p> <p>When a service is created, the <b>create</b> keyword must be specified if the <b>create</b> command is enabled in the <b>environment</b> context. When a service is created, the <b>customer</b> keyword and <i>customer-id</i> must be specified and associates the service with a customer. The <i>customer-id</i> must already exist having been created using the <b>customer</b> command in the service context. When a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>When a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>More than one VPLS service may be created for a single customer ID.</p> <p>By default, no VPLS instances exist until they are explicitly created.</p> |

The **no** form of this command deletes the VPLS service instance with the specified *service-id*. The service cannot be deleted until all SAPs and SDPs defined within the service ID have been shutdown and deleted, and the service has been shutdown.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><i>service-id</i> — The unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every SR OS on which this service is defined.</p> <p><b>Values</b> 1 to 2147483648</p> <p><b>customer</b> <i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>vpn</b> <i>vpn-id</i> — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>Default</b> null (0)</p> <p><b>m-vpls</b> — Specifies a management VPLS.</p> <p><b>b-vpls   i-vpls</b> — Creates a backbone-vpls or ISID-vpls for use with PBB.</p> <p><b>name</b> <i>name</i> — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.</p> <p>To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service. If a name is not specified at creation time, then SR OS assigns a string version of the <i>service-id</i> as the name.</p> <p>Service names may not begin with an integer (0 to 9).</p> <p><b>Values</b> <i>name</i>: 64 characters maximum</p> |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## site

|                    |                                                                                                                               |

| <b>Description</b> | <p>This command configures the time-period the system keeps the local sites in standby status, waiting for BGP updates from remote PEs before running the DF (designated-forwarder) election algorithm to decide whether the site should be unblocked. This timer is terminated if an update is received for which the remote PE has transitioned from DF to non-DF.</p> <p>The <b>no</b> form of the command removes the value from the configuration.</p> |
| <b>Default</b>     | 2                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the site activation timer in seconds.<br><b>Values</b> 0 to 100                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command configures the BGP multi-homing site minimum down time. When set to a non-zero value, if the site goes operationally down it will remain operationally down for at least the length of time configured for the <b>site-min-down-timer</b>, regardless of whether other state changes would have caused it to go operationally up. This timer is restarted every time that the site transitions from up to down. Setting this parameter to zero allows the minimum down timer to be disabled for this service.</p> <p>The above operation is optimized in the following circumstances:</p> <ul style="list-style-type: none"> <li>• If the site goes down on the designated forwarder but there are no BGP multi-homing peers with the same site in an operationally up state, then the <b>site-min-down-timer</b> is not started and is not used.</li> <li>• If the site goes down on the designated forwarder but there are no active BGP multi-homing peers, then the <b>site-min-down-timer</b> is not started and is not used.</li> <li>• If the <b>site-min-down-timer</b> is active and a BGP multi-homing update is received from the designated forwarder indicating its site has gone down, the <b>site-min-down-timer</b> is immediately terminated and this PE becomes the designated forwarder if the BGP multi-homing algorithm determines it should be the designated forwarder.</li> </ul> <p>The <b>no</b> form of this command reverts to the default value.</p> |
| <b>Default</b>     | Taken from the value of <b>site-min-down-timer</b> configured for Multi-Chassis BGP multi-homing under the <b>config&gt;redundancy&gt;bgp-multi-homing</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>min-down-time</i> — Specifies the time, in seconds, that a BGP multi-homing site remains operationally down after a transition from up to down.</p> <p><b>Values</b>      0 to 100 seconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## site-id

| <b>Description</b> | This command associates a BVPLS SAP with the global Ethernet tunnel object specified by <i>tunnel-id</i> . Only one-to-one mapping between SAP and Ethernet tunnel is supported in the initial implementation. The global eth-tunnel <i>tunnel-id</i> with at least a member port must be configured in advance for the command to be successful. A SAP will be instantiated using the active path components (member port and control-tag) for VPLS forwarding. The last member port in the Ethernet tunnel cannot be deleted if there is a SAP configured on that eth-tunnel. This command is only available in the BVPLS context.<br><br>The <b>no</b> form of this command removes the sap from the Ethernet tunnel object. |
| <b>Default</b>     | no sap is specified                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command binds a VPLS service to an existing Service Distribution Point (SDP). Mesh SDPs bound to a service are logically treated like a single bridge “port” for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke-SDPs and SAPs) and not transmitted on any mesh SDPs.</p> <p>This command creates a binding between a service and an SDP. The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate the SDP with a valid service. If the <b>sdp sdp-id</b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. After it is removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>sdp-id</i> — Specifies the SDP identifier</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — Specifies the virtual circuit identifier. This value is used to validate the VC ID portion of each mesh SDP binding defined in the service. The default value of this object is equal to the service ID. Any value may be used for the <i>vc-id</i> when there is no existing mesh SDP within the service; if a mesh SDP exists then all other mesh SDPs in the service must be configured with the same <i>vc-id</i>.</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>vc-type</b> — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the <b>vc-type</b> command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the bindings VC type causes the binding to signal the new VC type to the far end when signaling is enabled.</p> <p>VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i>.</p> <p>The VC type value for Ethernet is 0x0005.</p> <p>The VC type value for an Ethernet VLAN is 0x0004.</p>          |

**ether** — Defines the VC type as Ethernet. The **ether** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke-SDP binding. (hex 5)

**vlan** — Defines the VC type as VLAN. The top VLAN tag, if a VLAN tag is present, is stripped from traffic received on the pseudowire, and a vlan-tag is inserted when forwarding into the pseudowire. The **ether** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for mesh SDP bindings.

Note: The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

**root-leaf-tag** — Specifies a tagging mesh SDP under an E-Tree VPLS. When a tag SDP binding is required, it is created with a root-leaf-tag flag. Only VLAN tag SDP bindings are supported. The VLAN type must be set to VC VLAN type. The root-leaf-tag parameter indicates this SDP binding is a tag SDP that will use a default VID 1 for root and 2 for leaf. The SDP binding tags egress E-Tree traffic with root and leaf VIDs as appropriate. Root and leaf VIDs are only significant between peering VPLS but the values must be consistent on each end. On ingress a tag SDP binding removes the VID tag on the interface between VPLS in the same E-Tree service. The tag SDP receives root tagged traffic and marks the traffic with a root indication internally. This option is not available on BGP EVPN-enabled E-Tree services.

**leaf-ac** — Specifies an access (AC) mesh SDP binding under a E-Tree VPLS as a leaf access (AC) SDP. The default E-Tree SDP type is a root-ac if *leaf-ac* or *root-leaf-tag* is not specified at SDP binding creation. This option is only available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services support the **leaf-ac** option.

## spoke-sdp

|                    |                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | This command binds a service to an existing Service Distribution Point (SDP). A spoke-SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke-SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received. |

The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.

The SDP must already be defined in the **config>service>sdp** context in order to associate an SDP with a VPLS service. If the **sdp sdp-id** is not already configured, an error message is generated. If the sdp-id does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. After it is removed, no packets are forwarded to the far-end router.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b> | <p><i>sdp-id</i> — Specifies the SDP identifier</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — Specifies the virtual circuit identifier</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>vc-type</b> — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the <b>vc-type</b> command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the bindings VC type causes the binding to signal the new VC type to the far end when signaling is enabled.<br/>VC types are derived according to IETF <i>draft-martini-l2circuit-trans-mpls</i>.<br/>The VC type value for Ethernet is 0x0005.<br/>The VC type value for an Ethernet VLAN is 0x0004.</p> <p><b>Values</b> ether, vlan</p> <p><b>ether</b> — Defines the VC type as Ethernet. The <b>ethernet</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings. Defining Ethernet is the same as executing <b>no vc-type</b> and restores the default VC type for the spoke-SDP binding. (hex 5)</p> <p><b>vlan</b> — Defines the VC type as VLAN. The <b>ethernet</b> and <b>vlan</b> keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke-SDP bindings.<br/>The VLAN VC-type inserts one dot1q tag within each encapsulated Ethernet packet transmitted to the far end and strips one dotQ tag, if a tag is present, from traffic received on the pseudowire.</p> |

Note: The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

**group-name** — Specifies the name of the split horizon group to which the SDP belongs.

**endpoint** — Specifies the service endpoint to which this SDP bind is attached. The service ID of the SDP binding must match the service ID of the service endpoint.

**no endpoint** — Removes the association of a spoke-SDP with an explicit endpoint name.

**root-leaf-tag** — Specifies a tagging spoke-SDP under an E-Tree VPLS. When a tag SDP binding is required, it is created with a root-leaf-tag flag. Only VLAN tag SDP bindings are supported. The VLAN type must be set to VC VLAN type. The root-leaf-tag parameter indicates this SDP binding is a tag SDP that will use a default VID tag of 1 for root and 2 for leaf. The SDP binding tags egress E-Tree traffic with root and leaf VIDs as appropriate. Root and leaf VIDs are only significant between peering VPLS but the values must be consistent on each end. On ingress a tag SDP binding removes the VID tag on the interface between VPLS in the same E-Tree service. The tag SDP receives root tagged traffic and marks the traffic with a root indication internally. This option is not available on BGP EVPN-enabled E-Tree services.

**leaf-ac** — Specifies an access (AC) spoke-SDP binding under a E-Tree VPLS as a leaf access (AC) SDP. The default E-Tree SDP binding type is a root-ac if *leaf-ac* or *root-leaf-tag* is not specified at SDP creation. This option is only available when the VPLS is designated as an E-Tree VPLS. BGP EVPN-enabled E-Tree VPLS services support the **leaf-ac** option.

## spb

| <b>Description</b> | <p>This command enables Shortest Path Bridging (SPB) on a B-VPLS instance. SPB uses IS-IS that supports multiple instances, therefore an instance must be specified. The declaration of SPB in this context is the control configuration for the SPB. This is an SPB management interface and it manages the configuration for IS-IS. Various parameters that define this SPB instance are configured under this SPB instance. Several of the parameters are shared with other B-VPLS service instances using SPB.</p> <p>SPB enables an instance of IS-IS protocol with the no shutdown command. Alternatively, the IS-IS protocol instance under SPB is disabled with the shutdown command in the <b>config&gt;service&gt;vpls b-vpls&gt;spb</b> context.</p> |

A Forwarding Identifier (FID) is optionally specified which is an abstraction of the BVID used for forwarding in SPB. When no FID is configured the control VPLS is advertised with FID value 1. When a FID value is specified, the control VPLS is advertised and associated with the FID value specified. The default algorithm for any FID declared or implicit is low-path-id. When a FID is specified, the ect-algorithm can be specified for the FID and changed only when there are no VPLS, SAPs or SDP bindings associated with the FID. The FID for a control instance cannot be changed after it is created. To change a FID the SPB component would have to be shutdown, deleted and re-created with a new FID.

**Note:** SPB operates with disable-learning, disable aging and discard-unknown. The state of these commands is ignored when SPB is configured.

| Context     | config>service>vpls b-vpls>sap>spb<br>config>service>vpls b-vpls>spoke-sdp>spb                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Description | <p>This command enables Shortest Path Bridging (SPB) on SAP or Spoke SDP. The B-VPLS may be a control B-VPLS or user B-VPLS. Since SPB uses IS-IS that supports multiple instances, SPB inherits the instance from the control B-VPLS.</p> <p>SPB at this context level is enabled immediately. SPB enables an instance of IS-IS protocol with the no shutdown command. Alternatively, the IS-IS protocol instance under SPB is disabled with the shutdown command in the <b>config&gt;service&gt;vpls b-vpls&gt;spb</b> context.</p> |
| Default     | no spb                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.</p> <p>The operational state of the entity is disabled as well as the operational state of any entities contained within.</p> <p>The <b>no</b> form of this command administratively enables an entity.</p> <p>SPB Interface — In the config&gt;service&gt;vpls b-vpls&gt;spb&gt; context, the command disables the IS-IS interface. By default, the IS-IS interface is disabled (shutdown).</p> |

## lsp-lifetime

|                    |                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lsp-lifetime</b> <i>seconds</i><br><b>no lsp-lifetime</b>                                                                                                      |
| <b>Context</b>     | config>service>vpls b-vpls>spb                                                                                                                                    |
| <b>Description</b> | This command sets the time, in seconds, SPB wants the LSPs it originates to be considered valid by other routers in the domain. This is a control B-VPLS command. |

Each LSP received is maintained in an LSP database until the *lsp-lifetime* expires unless the originating router refreshes the LSP. By default, each router refreshes its LSPs every 20 minutes (1200 seconds) so other routers will not age out the LSP.

The LSP refresh timer is derived from this formula:  $\text{lsp-lifetime}/2$ .

The **no** form of the command reverts to the default value.

|                   |                                                                                                                                     |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | <i>lsp-lifetime</i> 1200 — LSPs originated by SPB should be valid for 1200 seconds (20 minutes).                                    |
| <b>Parameters</b> | <i>seconds</i> — The time, in seconds, that SPB wants the LSPs it originates to be considered valid by other routers in the domain. |
| <b>Values</b>     | 350 to 65535                                                                                                                        |

## timers

|                    |                                                           |
|--------------------|-----------------------------------------------------------|
| <b>Syntax</b>      | <b>timers</b>                                             |
| <b>Context</b>     | config>service>vpls b-vpls>spb                            |
| <b>Description</b> | This command enables the context to configure SPB timers. |

## lsp-wait

|                    |                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lsp-wait</b> <i>lsp-wait</i> [ <b>lsp-initial-wait</b> <i>lsp-initial-wait</i> ] [ <b>lsp-second-wait</b> <i>lsp-second-wait</i> ]                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpls b-vpls>spb>timers                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command is used to customize LSP generation throttling. Timers that determine when to generate the first, second and subsequent LSPs can be controlled with this command. Subsequent LSPs are generated at increasing intervals of the second <b>lsp-wait</b> timer until a maximum value is reached. |

**Note:** The IS-IS timer granularity is 100 ms. Timer values are rounded down to the nearest granularity, for example a configured value of 550 ms is internally rounded down to 500 ms.

|                   |                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>lsp-wait</i> — Specifies the maximum interval in milliseconds between two consecutive occurrences of an LSP being generated. |
| <b>Values</b>     | 10 to 120000                                                                                                                    |
| <b>Default</b>    | 5000                                                                                                                            |

*lsp-initial-wait* — Specifies the initial LSP generation delay in milliseconds. Values < 100 ms are internally rounded down to 0, so that there is no added initial LSP generation delay.

**Values** 10 to 100000

**Default** 10

*lsp-second-wait* — Specifies the hold time in milliseconds between the first and second LSP generation.

**Values** 10 to 100000

**Default** 1000

## overload

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Syntax</b>      | <b>overload [timeout seconds]</b><br><b>no overload</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls b-vpls>spb                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command administratively sets the SPB to operate in the overload state for a specific time period, in seconds, or indefinitely. During normal operation, the router may be forced to enter an overload state due to a lack of resources. When in the overload state, the router is only used if the destination is reachable by SPB and will not be used for other transit traffic.</p> <p>If a time period is specified, the overload state persists for the configured length of time. If no time is specified, the overload state operation is maintained indefinitely.</p> <p>The overload command can be useful in circumstances where SPB is overloaded or used prior to executing a shutdown command to divert traffic around the switch.</p> <p>The <b>no</b> form of the command causes the router to exit the overload state.</p> |
| <b>Default</b>     | no overload                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>seconds</i> — The time, in seconds, that this router must operate in overload state.</p> <p><b>Values</b> 60 to 1800</p> <p><b>Default</b> Infinity (overload state maintained indefinitely)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## overload-on-boot

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>overload-on-boot [timeout seconds]</b><br><b>no overload-on-boot</b> |
| <b>Context</b> | config>service>vpls b-vpls>spb>                                         |

**Description** When the router is in an overload state, SPB the B-VPLS is used only if there is no other SPB B-VPLS to reach the destination. This command configures the IGP upon boot up in the overload state until one of the following events occur:

- The timeout timer expires.
- A manual override of the current overload state is entered with the **config>service>vpls instance>b-vpls>spb>no overload** command.

The **no** form of the command does not affect the overload-on-boot function.

If no timeout is specified, SPB IS-IS goes into overload indefinitely after a reboot. After the reboot, the SPB IS-IS status displays a permanent overload state:

```
L1 LSDB Overload : Manual on boot (Indefinitely in overload)
```

This state can be cleared with the **config>service>vpls instance>b-vpls>spb>no overload** command.

When specifying a timeout value, SPB IS-IS goes into overload for the configured timeout after a reboot. After the reboot, SPB IS-IS status displays the remaining time the system stays in overload:

```
L1 LSDB Overload : Manual on boot (Overload Time Left : 17)
```

The overload state can be cleared before the timeout expires with **config>service>vpls instance>b-vpls>spb>no overload** command.

The **no** form of the command removes the overload-on-boot functionality from the configuration.

**Default** no overload-on-boot

**Parameters** *seconds* — The time, in seconds, that this router must operate in overload state.

**Values** 60 to 1800

**Default** Infinity (overload state maintained indefinitely)

## spf-wait

**Syntax** **[no] spf-wait** *spf-wait* [*spf-initial-wait* [*spf-second-wait*]]

**Context** config>service>vpls b-vpls>spb>timers

**Description** This command defines the maximum interval between two consecutive SPF calculations in milliseconds. Timers that determine when to initiate the first, second and subsequent SPF calculations after a topology change occurs can be controlled with this command.

Subsequent SPF runs (if required) will occur at exponentially increasing intervals of the *spf-second-wait* interval. For example, if the *spf-second-wait* interval is 1000, then the next SPF will run after 2000 milliseconds, and then next SPF will run after 4000 milliseconds, etc., until it reaches the *spf-wait* value. The SPF interval will stay at *spf-wait* value until there are no more SPF runs scheduled in that interval. After a full interval without any SPF runs, the SPF interval will drop back to *spf-initial-wait*.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no spf-wait                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b> | <p><i>spf-wait</i> — Specifies the maximum interval in milliseconds between two consecutive SPF calculations.</p> <p><b>Values</b> 10 to 120000</p> <p><b>Default</b> 10000</p> <p><i>spf-initial-wait</i> — Specifies the initial SPF calculation delay in milliseconds after a topology change.</p> <p><b>Values</b> 10 to 100000</p> <p><b>Default</b> 1000</p> <p><i>spf-second-wait</i> — Specifies the hold time in milliseconds between the first and second SPF calculation.</p> <p><b>Values</b> 10 to 100000</p> <p><b>Default</b> 1000</p> |

| <b>Description</b> | <p>This command configures the four bit bridge priority for Shortest Path Bridging. This value is added to the 6 byte bridge Identifier (which is the system-id) in the top four bits of a two byte field. Note the actual value will be bit shifted 12 bits left effective putting this in the high bits of the 16 bits added to system ID.</p> <p>The bridge priority is important in choosing the Root Bridge for the single tree algorithm (lowest value = best). Bridge priority also factors into the tie breaker for SPF algorithms as described in the SPB standard. The bridge-identifier (system-id) of the control B-VPLS determines the tiebreaker when the bridge-priorities are equal.</p> |
| <b>Default</b>     | bridge-priority 8                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vpls b-vpls>spb>level                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command configures the ect-algorithm associated with a FID. Names are:</p> <ul style="list-style-type: none"> <li>• low-path-id</li> <li>• high-path-id</li> </ul> <p>The algorithm for low-path-id chooses the path with the lowest metric and uses the sum of each Bridge-ID to break-ties (in this case preferring the lowest bridge identifiers).</p> <p>The algorithm for high-path-id choose the path with the lowest metric and the sum of each Bridge-ID (after each one is modified by the algorithm mask) to break-ties (in this case preferring the highest bridge identifiers).</p> <p>A Forwarding Identifier (FID) is an abstraction of the IEEE 802.1 SPB Base VID and represents the VLAN (B-VPLS) in IS-IS LSPs. B-VPLS services with the same FID share B-MACs and I-SIDs. (the SAP encapsulation VLAN tag may be set to the same value as the FID or to any other valid VLAN tag). One or more FIDs can be associated with an ECT-algorithm by using the FID range. User B-VPLS services may share the same FID as the control B-VPLS or use independent FIDs where each FID has an assigned ect-algorithm. B-VPLS services with i-vpls services must have an independent FID. B-VPLS services with only PBB Epipes may share FIDs with other B-VPLS services including the control B-VPLS service.</p> <p>The ect-algorithm is associated with the FID and can only be changed only when there are no VPLS, SAPs or SDP bindings associated with the FID. The FID must be independent from the FID assigned to other services.</p> |

| <b>Description</b> | <p>This command sets the unicast forwarding to follow the shortest path tree defined by the ECT algorithm shortest path forwarding (spf) or to follow a single tree. (st). Shortest path trees make use of more link resources.</p> <p>Multicast traffic is defaulted to follow the single tree topology. A single tree unicast would make Multicast and unicast follow the same path.</p> |

| <b>Description</b> | This command configures the interval in seconds between hello messages issued on this interface at this level. This command is valid only for interfaces on control B-VPLS. |

---

The no form of the command to reverts to the default value.

**Default** hello-interval 3 — Hello interval default for the designated inter-system.

hello-interval 9 — Hello interval default for non-designated inter-systems.

**Parameters** *seconds* — The hello interval in seconds expressed as a decimal integer.

**Values** 1 to 20000

## hello-multiplier

**Syntax** **hello-multiplier** *multiplier*  
**no hello-multiplier**

**Context** config>service>vpls b-vpls>sap>spb>level  
config>service>vpls b-vpls>spoke-sdp>spb>level

**Description** This command configures the number of missing hello PDUs from a neighbor SPB declares the adjacency down. This command is valid only for interfaces on control B-VPLS.

The no form of the command reverts to the default value.
