

**7450 ETHERNET SERVICE SWITCH  
7750 SERVICE ROUTER  
7950 EXTENSIBLE ROUTING SYSTEM  
VIRTUALIZED SERVICE ROUTER**

**LAYER 2 SERVICES AND EVPN GUIDE: VLL, VPLS,  
PBB, AND EVPN  
RELEASE 16.0.R4**

**3HE 14130 AAAB TQZZA 01**

**Issue: 01**

**November 2018**

|          |                                                              |           |
|----------|--------------------------------------------------------------|-----------|
| <b>1</b> | <b>Getting Started .....</b>                                 | <b>19</b> |
| 1.1      | About This Guide .....                                       | 19        |
| 1.2      | Layer 2 Services and EVPN Configuration Process .....        | 21        |
| <br>     |                                                              |           |
| <b>2</b> | <b>VLL Services .....</b>                                    | <b>23</b> |
| 2.1      | ATM VLL (Apipe) Services .....                               | 23        |
| 2.1.1    | Apipe For End-to-End ATM Service .....                       | 23        |
| 2.1.2    | ATM Virtual Trunk Over IP/MPLS Packet Switched Network ..... | 24        |
| 2.1.3    | Traffic Management Support .....                             | 25        |
| 2.1.3.1  | Ingress Network Classification .....                         | 25        |
| 2.1.3.2  | Ingress Queuing and Shaping on the IOM .....                 | 26        |
| 2.1.3.3  | Egress Queuing and Shaping on the IOM .....                  | 26        |
| 2.1.3.4  | Egress Shaping/Scheduling .....                              | 26        |
| 2.2      | Circuit Emulation (Cpipe) Services .....                     | 28        |
| 2.2.1    | Mobile Infrastructure .....                                  | 28        |
| 2.2.2    | Circuit Emulation Modes .....                                | 29        |
| 2.2.3    | Circuit Emulation Parameters .....                           | 31        |
| 2.2.3.1  | Circuit Emulation Modes .....                                | 31        |
| 2.2.3.2  | Absolute Mode Option .....                                   | 32        |
| 2.2.3.3  | Payload Size .....                                           | 32        |
| 2.2.3.4  | Jitter Buffer .....                                          | 34        |
| 2.2.3.5  | CES Circuit Operation .....                                  | 35        |
| 2.2.4    | Services for Transporting CES Circuits .....                 | 35        |
| 2.2.5    | Network Synchronization Considerations .....                 | 36        |
| 2.2.6    | Cpipe Payload .....                                          | 37        |
| 2.3      | Ethernet Pipe (Epipe) Services .....                         | 38        |
| 2.3.1    | Epipe Service Overview .....                                 | 38        |
| 2.3.2    | Epipe Service Pseudowire VLAN Tag Processing .....           | 39        |
| 2.3.3    | Epipe Up Operational State Configuration Option .....        | 45        |
| 2.3.4    | Epipe with PBB .....                                         | 46        |
| 2.3.5    | Epipe over L2TPv3 .....                                      | 46        |
| 2.3.6    | Ethernet Interworking VLL .....                              | 47        |
| 2.3.7    | VLL CAC .....                                                | 48        |
| 2.3.8    | MC-Ring and VLL .....                                        | 49        |
| 2.4      | Frame Relay VLL (Fpipe) Services .....                       | 51        |
| 2.4.1    | Frame Relay VLL .....                                        | 51        |
| 2.4.2    | Frame Relay-to-ATM Interworking (FRF.5) VLL .....            | 52        |
| 2.4.3    | Traffic Management Support .....                             | 53        |
| 2.4.3.1  | Frame Relay Traffic Management .....                         | 53        |
| 2.4.3.2  | Ingress SAP Classification and Marking .....                 | 53        |
| 2.4.3.3  | Egress Network EXP Marking .....                             | 53        |
| 2.4.3.4  | Ingress Network Classification .....                         | 53        |
| 2.5      | IP Interworking VLL (Ipipe) Services .....                   | 54        |
| 2.5.1    | Ipipe VLL .....                                              | 54        |
| 2.5.2    | IP Interworking VLL Datapath .....                           | 55        |

|          |                                                                                            |     |
|----------|--------------------------------------------------------------------------------------------|-----|
| 2.5.3    | Extension to IP VLL for Discovery of Ethernet CE IP Address.....                           | 56  |
| 2.5.3.1  | VLL Ethernet SAP Processes.....                                                            | 57  |
| 2.5.4    | IPv6 Support on IP Interworking VLL .....                                                  | 60  |
| 2.5.4.1  | IPv6 Datapath Operation .....                                                              | 60  |
| 2.5.4.2  | IPv6 Stack Capability Signaling.....                                                       | 62  |
| 2.6      | Services Configuration for MPLS-TP.....                                                    | 64  |
| 2.6.1    | MPLS-TP SDPs.....                                                                          | 64  |
| 2.6.2    | VLL Spoke SDP Configuration .....                                                          | 66  |
| 2.6.2.1  | Epipe VLL Spoke SDP Termination on IES, VPRN, and VPLS .....                               | 69  |
| 2.6.3    | Configuring MPLS-TP Lock Instruct and Loopback.....                                        | 69  |
| 2.6.3.1  | MPLS-TP PW Lock Instruct and Loopback Overview .....                                       | 69  |
| 2.6.3.2  | Lock PW Endpoint Model .....                                                               | 70  |
| 2.6.3.3  | PW Redundancy and Lock Instruct and Loopback .....                                         | 71  |
| 2.6.3.4  | Configuring a Test SAP for an MPLS-TP PW .....                                             | 71  |
| 2.6.3.5  | Configuring an Administrative Lock.....                                                    | 72  |
| 2.6.3.6  | Configuring a Loopback.....                                                                | 73  |
| 2.6.4    | Switching Static MPLS-TP to Dynamic T-LDP Signaled PWs.....                                | 74  |
| 2.7      | VCCV BFD support for VLL, Spoke-SDP Termination on IES and<br>VPRN, and VPLS Services..... | 76  |
| 2.7.1    | VCCV BFD Support.....                                                                      | 76  |
| 2.7.2    | VCCV BFD Encapsulation on a Pseudowire .....                                               | 77  |
| 2.7.3    | BFD Session Operation .....                                                                | 77  |
| 2.7.4    | Configuring VCCV BFD .....                                                                 | 78  |
| 2.8      | Pseudowire Switching .....                                                                 | 80  |
| 2.8.1    | Pseudowire Switching with Protection.....                                                  | 81  |
| 2.8.2    | Pseudowire Switching Behavior .....                                                        | 83  |
| 2.8.2.1  | Pseudowire Switching TLV.....                                                              | 83  |
| 2.8.2.2  | Pseudowire Switching Point Sub-TLVs .....                                                  | 84  |
| 2.8.3    | Static-to-Dynamic Pseudowire Switching .....                                               | 84  |
| 2.8.4    | Ingress VLAN Swapping.....                                                                 | 85  |
| 2.8.4.1  | Ingress VLAN Translation.....                                                              | 86  |
| 2.8.5    | Pseudowire Redundancy.....                                                                 | 87  |
| 2.8.6    | Dynamic Multi-Segment Pseudowire Routing .....                                             | 87  |
| 2.8.6.1  | Overview.....                                                                              | 87  |
| 2.8.6.2  | Pseudowire Routing .....                                                                   | 92  |
| 2.8.6.3  | Configuring VLLs using Dynamic MS-PWs .....                                                | 94  |
| 2.8.6.4  | Pseudowire Redundancy.....                                                                 | 96  |
| 2.8.6.5  | VCCV OAM for Dynamic MS-PWs .....                                                          | 98  |
| 2.8.6.6  | VCCV-Ping on Dynamic MS-PWs .....                                                          | 98  |
| 2.8.6.7  | VCCV-Trace on Dynamic MS-PWs.....                                                          | 99  |
| 2.8.7    | Example Dynamic MS-PW Configuration.....                                                   | 99  |
| 2.8.8    | VLL Resilience with Two Destination PE Nodes .....                                         | 103 |
| 2.8.8.1  | Master-Slave Operation.....                                                                | 105 |
| 2.8.9    | Pseudowire SAPs.....                                                                       | 111 |
| 2.8.10   | Epipe Using BGP-MH Site Support for Ethernet Tunnels .....                                 | 111 |
| 2.8.10.1 | Operational Overview .....                                                                 | 112 |
| 2.8.10.2 | Detailed Operation.....                                                                    | 114 |
| 2.8.10.3 | BGP-MH Site Support for Ethernet Tunnels Operational Group<br>Model.....                   | 118 |

|          |                                                                               |     |
|----------|-------------------------------------------------------------------------------|-----|
| 2.8.10.4 | BGP-MH Specifics for MH Site Support for Ethernet Tunnels.....                | 118 |
| 2.8.10.5 | PW Redundancy for BGP-MH Site Support for Ethernet Tunnels.....               | 119 |
| 2.8.10.6 | T-LDP Status Notification Handling Rules of BGP-MH Epipes .....               | 119 |
| 2.8.11   | Access Node Resilience Using MC-LAG and Pseudowire<br>Redundancy .....        | 130 |
| 2.8.12   | VLL Resilience for a Switched Pseudowire Path.....                            | 132 |
| 2.9      | Pseudowire Redundancy Service Models .....                                    | 135 |
| 2.9.1    | Redundant VLL Service Model.....                                              | 135 |
| 2.9.2    | T-LDP Status Notification Handling Rules.....                                 | 137 |
| 2.9.2.1  | Processing Endpoint SAP Active/Standby Status Bits .....                      | 137 |
| 2.9.2.2  | Processing and Merging.....                                                   | 137 |
| 2.10     | High-Speed Downlink Packet Access (HSDPA) Off Load Fallback<br>over ATM ..... | 140 |
| 2.10.1   | Primary Spoke SDP Fallback to Secondary SAP .....                             | 141 |
| 2.10.2   | Reversion to Primary Spoke SDP Path .....                                     | 141 |
| 2.10.3   | MC-APS and MC-LAG.....                                                        | 141 |
| 2.10.3.1 | Failure Scenario .....                                                        | 143 |
| 2.11     | VLL Using G.8031 Protected Ethernet Tunnels .....                             | 145 |
| 2.12     | MPLS Entropy Label and Hash Label .....                                       | 146 |
| 2.13     | BGP Virtual Private Wire Service (VPWS) .....                                 | 147 |
| 2.13.1   | Single-Homed BGP VPWS.....                                                    | 147 |

| 3.2.10.1 | Spoke SDP Redundancy for Metro Interconnection .....              | 515        |
| 3.2.10.2 | Spoke SDP Based Redundant Access .....                            | 516        |
| 3.2.10.3 | Inter-Domain VPLS Resiliency Using Multi-Chassis Endpoints .....  | 517        |

|           |                                                                                        |     |
|-----------|----------------------------------------------------------------------------------------|-----|
| 3.2.10.4  | Support for Single Chassis Endpoint Mechanisms.....                                    | 522 |
| 3.2.10.5  | Using B-VPLS for Increased Scalability and Reduced<br>Convergence Times .....          | 525 |
| 3.2.10.6  | MAC Flush Additions for PBB VPLS .....                                                 | 526 |
| 3.2.11    | VPLS Access Redundancy.....                                                            | 529 |
| 3.2.11.1  | STP-based Redundant Access to VPLS .....                                               | 530 |
| 3.2.11.2  | Redundant Access to VPLS Without STP .....                                             | 530 |
| 3.2.12    | Object Grouping and State Monitoring .....                                             | 531 |
| 3.2.12.1  | VPLS Applicability — Block on VPLS a Failure .....                                     | 531 |
| 3.2.13    | MAC Flush Message Processing .....                                                     | 533 |
| 3.2.13.1  | Dual Homing to a VPLS Service.....                                                     | 535 |
| 3.2.13.2  | MC-Ring and VPLS .....                                                                 | 536 |
| 3.2.14    | ACL Next-Hop for VPLS .....                                                            | 537 |
| 3.2.15    | SDP Statistics for VPLS and VLL Services .....                                         | 538 |
| 3.2.16    | BGP Auto-Discovery for LDP VPLS .....                                                  | 538 |
| 3.2.16.1  | BGP AD Overview .....                                                                  | 539 |
| 3.2.16.2  | Information Model.....                                                                 | 539 |
| 3.2.16.3  | FEC Element for T-LDP Signaling .....                                                  | 540 |
| 3.2.16.4  | BGP-AD and Target LDP (T-LDP) Interaction .....                                        | 542 |
| 3.2.16.5  | SDP Usage.....                                                                         | 543 |
| 3.2.16.6  | Automatic Creation of SDPs.....                                                        | 543 |
| 3.2.16.7  | Manually Provisioned SDP .....                                                         | 544 |
| 3.2.16.8  | Automatic Instantiation of Pseudowires (SDP Bindings) .....                            | 545 |
| 3.2.16.9  | Mixing Statically Configured and Auto-Discovered Pseudowires in<br>a VPLS .....        | 545 |
| 3.2.16.10 | Resiliency Schemes .....                                                               | 546 |
| 3.2.17    | BGP VPLS .....                                                                         | 546 |
| 3.2.17.1  | Pseudowire Signaling Details .....                                                     | 548 |
| 3.2.17.2  | Supported VPLS Features.....                                                           | 551 |
| 3.2.18    | VCCV BFD Support for VPLS Services.....                                                | 551 |
| 3.2.19    | BGP Multi-Homing for VPLS .....                                                        | 552 |
| 3.2.19.1  | Information Model and Required Extensions to L2VPN NLRI .....                          | 553 |
| 3.2.19.2  | Supported Services and Multi-Homing Objects .....                                      | 555 |
| 3.2.19.3  | Blackhole Avoidance .....                                                              | 555 |
| 3.2.19.4  | BGP Multi-Homing for VPLS Inter-Domain Resiliency .....                                | 556 |
| 3.2.20    | Multicast-Aware VPLS.....                                                              | 557 |
| 3.2.20.1  | IGMP Snooping for VPLS.....                                                            | 558 |
| 3.2.20.2  | MLD Snooping for VPLS .....                                                            | 559 |
| 3.2.20.3  | PIM Snooping for VPLS.....                                                             | 559 |
| 3.2.20.4  | IPv6 Multicast Forwarding .....                                                        | 561 |
| 3.2.20.5  | PIM and IGMP/MLD Snooping Interaction .....                                            | 565 |
| 3.2.20.6  | Multi-Chassis Synchronization for Layer 2 Snooping States .....                        | 565 |
| 3.2.20.7  | VPLS Multicast-Aware High Availability Features .....                                  | 568 |
| 3.2.21    | RSVP and LDP P2MP LSP for Forwarding VPLS/B-VPLS BUM<br>and IP Multicast Packets ..... | 569 |
| 3.2.22    | MPLS Entropy Label and Hash Label .....                                                | 570 |
| 3.3       | Routed VPLS and I-VPLS .....                                                           | 571 |
| 3.3.1     | IES or VPRN IP Interface Binding .....                                                 | 571 |
| 3.3.1.1   | Assigning a Service Name to a VPLS Service .....                                       | 571 |

|         |                                                                                 |     |
|---------|---------------------------------------------------------------------------------|-----|
| 3.3.1.2 | Service Binding Requirements .....                                              | 572 |
| 3.3.1.3 | Bound Service Name Assignment.....                                              | 572 |
| 3.3.1.4 | Binding a Service Name to an IP Interface.....                                  | 572 |
| 3.3.1.5 | Bound Service Deletion or Service Name Removal .....                            | 573 |
| 3.3.1.6 | IP Interface Attached VPLS Service Constraints.....                             | 573 |
| 3.3.1.7 | IP Interface and VPLS Operational State Coordination.....                       | 573 |
| 3.3.2   | IP Interface MTU and Fragmentation .....                                        | 574 |
| 3.3.2.1 | Unicast IP Routing into a VPLS Service.....                                     | 574 |
| 3.3.3   | ARP and VPLS FDB Interactions .....                                             | 575 |
| 3.3.3.1 | R-VPLS Specific ARP Cache Behavior .....                                        | 576 |
| 3.3.4   | The allow-ip-int-bind VPLS Flag .....                                           | 577 |
| 3.3.4.1 | R-VPLS SAPs Only Supported on Standard Ethernet Ports .....                     | 577 |
| 3.3.4.2 | LAG Port Membership Constraints.....                                            | 577 |
| 3.3.4.3 | R-VPLS Feature Restrictions .....                                               | 578 |
| 3.3.4.4 | Routed I-VPLS Feature Restrictions .....                                        | 578 |
| 3.3.5   | IPv4 and IPv6 Multicast Routing Support.....                                    | 579 |
| 3.3.6   | BGP Auto-Discovery (BGP-AD) for R-VPLS Support.....                             | 582 |
| 3.3.7   | R-VPLS Caveats .....                                                            | 582 |
| 3.3.7.1 | VPLS SAP Ingress IP Filter Override .....                                       | 582 |
| 3.3.7.2 | IP Interface Defined Egress QoS Reclassification .....                          | 583 |
| 3.3.7.3 | Remarking for VPLS and Routed Packets .....                                     | 583 |
| 3.3.7.4 | 7450 Mixed Mode Chassis .....                                                   | 583 |
| 3.3.7.5 | IPv4 Multicast Routing.....                                                     | 583 |
| 3.3.7.6 | R-VPLS Supported Routing-related Protocols .....                                | 584 |
| 3.3.7.7 | Spanning Tree and Split Horizon.....                                            | 584 |
| 3.4     | VPLS Service Considerations .....                                               | 585 |
| 3.4.1   | SAP Encapsulations .....                                                        | 585 |
| 3.4.2   | VLAN Processing .....                                                           | 585 |
| 3.4.3   | Ingress VLAN Swapping.....                                                      | 586 |
| 3.4.4   | Service Auto-Discovery using Multiple VLAN Registration Protocol<br>(MVRP)..... | 587 |
| 3.4.4.1 | Configure the MVRP Infrastructure using an M-VPLS Context .....                 | 588 |
| 3.4.4.2 | Instantiate Related VLAN FDBs and Trunks in MVRP Scope.....                     | 588 |
| 3.4.4.3 | MVRP Activation of Service Connectivity .....                                   | 590 |
| 3.4.4.4 | MVRP Control Plane .....                                                        | 593 |
| 3.4.4.5 | STP-MVRP Interaction .....                                                      | 593 |
| 3.4.5   | VPLS E-Tree Services.....                                                       | 595 |
| 3.4.5.1 | VPLS E-Tree Services Overview .....                                             | 595 |
| 3.4.5.2 | Leaf-ac and Root-ac SAPs.....                                                   | 596 |
| 3.4.5.3 | Leaf-ac and Root-ac SDP Binds .....                                             | 597 |
| 3.4.5.4 | Root-leaf-tag SAPs.....                                                         | 598 |
| 3.4.5.5 | Root-leaf-tag SDP Binds .....                                                   | 599 |
| 3.4.5.6 | Interaction between VPLS E-Tree Services and Other Features .....               | 599 |
| 3.5     | Configuring a VPLS Service with CLI .....                                       | 603 |
| 3.5.1   | Basic Configuration .....                                                       | 603 |
| 3.5.2   | Common Configuration Tasks .....                                                | 604 |
| 3.5.3   | Configuring VPLS Components.....                                                | 605 |
| 3.5.3.1 | Creating a VPLS Service.....                                                    | 605 |
| 3.5.3.2 | Enabling Multiple MAC Registration Protocol (MMRP) .....                        | 606 |

|          |                                                                                    |     |
|----------|------------------------------------------------------------------------------------|-----|
| 3.5.3.3  | Configuring GSMP Parameters .....                                                  | 614 |
| 3.5.3.4  | Configuring a VPLS SAP .....                                                       | 615 |
| 3.5.3.5  | Configuring SAP Subscriber Management Parameters .....                             | 625 |
| 3.5.3.6  | MSTP Control over Ethernet Tunnels .....                                           | 626 |
| 3.5.3.7  | Configuring SDP Bindings .....                                                     | 627 |
| 3.5.3.8  | Configuring Overrides on Service SAPs .....                                        | 628 |
| 3.5.4    | Configuring VPLS Redundancy .....                                                  | 639 |
| 3.5.4.1  | Creating a Management VPLS for SAP Protection .....                                | 640 |
| 3.5.4.2  | Creating a Management VPLS for Spoke-SDP Protection .....                          | 642 |
| 3.5.4.3  | Configuring Load Balancing with Management VPLS .....                              | 644 |
| 3.5.4.4  | Configuring Selective MAC Flush .....                                              | 649 |
| 3.5.4.5  | Configuring Multi-Chassis Endpoints .....                                          | 649 |
| 3.5.5    | ATM/Frame Relay PVC Access and Termination on a VPLS Service .....                 | 653 |
| 3.5.6    | Configuring BGP Auto-Discovery .....                                               | 655 |

# 1 Getting Started

## 1.1 About This Guide

This guide describes Layer 2 service and EVPN functionality provided by the Nokia family of routers and presents examples to configure and implement various protocols and services.

This guide is organized into functional chapters and provides concepts and descriptions of the implementation flow, as well as Command Line Interface (CLI) syntax and command usage.

The topics and commands described in this document apply to the:

- 7450 ESS
- 7750 SR
- 7950 XRS
- VSR

[Table 1](#) lists the available chassis types for each SR OS router.

**Table 1 Supported SR OS Router Chassis Types**

| 7450 ESS                                                                                                                             | 7750 SR                                                                                                                                                                                                                                                                                  | 7950 XRS                                                                                   |
|--------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>• 7450 ESS-6/6v</li> <li>• 7450 ESS-7/12 running in standard mode (not mixed-mode)</li> </ul> | <ul style="list-style-type: none"> <li>• 7450 ESS-7/12 running in mixed-mode (not standard mode)</li> <li>• 7750 SR-a4/a8</li> <li>• 7750 SR-c4/c12</li> <li>• 7750 SR-1e/2e/3e</li> <li>• 7750 SR-7/12</li> <li>• 7750 SR-12e</li> <li>• 7750 SR-7s/14s</li> <li>• 7750 SR-1</li> </ul> | <ul style="list-style-type: none"> <li>• 7950 XRS-16c</li> <li>• 7950 XRS-20/40</li> </ul> |

For a list of unsupported features by platform and chassis, refer to the SR OS 16.0.Rx Software Release Notes, part number 3HE 14220 000x TQZZA or the VSR Release Notes, part number 3HE 14204 000x TQZZA.

Command outputs shown in this guide are examples only; actual displays may differ depending on supported functionality and user configuration.

**Note:** This guide generically covers Release 16.0.Rx content and may contain some content that will be released in later maintenance loads. Refer to SR OS 16.0.Rx Software Release Notes, part number 3HE 14220 000x TQZZA or the *VSR Release Notes*, part number 3HE 14204 000x TQZZA, for information about features supported in each load of the Release 16.0.Rx software.

## 1.2 Layer 2 Services and EVPN Configuration Process

[Table 2](#) lists the tasks related to configuring and implementing Layer 2 Services and EVPN functionality.

This guide is presented in an overall logical configuration flow. Each section describes a software area and provides CLI syntax and command usage to configure parameters for a functional area.

**Table 2 Configuration Process**

| Area                                      | Task                                                        | Section                                                                                            |

## 2 VLL Services

### 2.1 ATM VLL (Apipe) Services

This section provides information about the ATM VLL (Apipe) services and implementation.

This feature is supported on the 7450 ESS platform in mixed-mode.

#### 2.1.1 Apipe For End-to-End ATM Service

An Apipe provides a point-to-point ATM service between users connected to 7450 ESS or 7750 SR nodes on an IP/MPLS network. Users are either directly connected to a PE or through an ATM access network. In both cases, an ATM PVC (for example, a virtual channel (VC) or a virtual path (VP)) is configured on the PE. This feature supports local cross-connecting when users are attached to the same PE node. VPI/VCI translation is supported in the Apipe.

PE1, PE2, and PE3 receive standard UNI/NNI cells on the ATM Service Access Point (SAP) that are then encapsulated into a pseudowire packet using the N:1 cell mode encapsulation or AAL5 SDU mode encapsulation according to RFC 4717, *Encapsulation Methods for Transport of ATM Over MPLS Networks*. When using N:1 cell mode encapsulation, cell concatenation into a pseudowire packet is supported. In this application, both VC- and VP-level connections are supported.

The ATM pseudowire is initiated using Targeted LDP (T-LDP) signaling as specified in RFC 4447, *Pseudo-wire Setup and Maintenance using LDP*. The SDP can be an MPLS or a GRE type.

[Figure 1](#) shows an example of Apipe for end-to-end ATM service.

**Figure 1**      **Apipe for End-to-End ATM Service**

### 2.1.2 ATM Virtual Trunk Over IP/MPLS Packet Switched Network

For 7450 ESS or 7750 SR OS, ATM virtual trunk (VT) implements a transparent trunking of user and control traffic between two ATM switches over an ATM pseudowire. [Figure 2](#) shows ATM 2 and ATM 3 switches that appear as if they are directly connected over an ATM link. Control traffic includes PNNI signaling and routing traffic.

**Figure 2 ATM VT Application**

The VT SAP on a PE is identified by a tuple (port, VPI-range) meaning that all cells arriving on the specified port within the specified VPI range are fed into a single ATM pseudowire for transport across the IP/MPLS network. A user can configure the whole ATM port as a VT and does not need to specify a VPI range. No VPI/VCI translation is performed on ingress or egress. Cell order is maintained within a VT. As a special case, the two ATM ports could be on the same PE node.

By carrying all cells from all VPIs making up the VT in one pseudowire, a solution is provided that is robust; for example, black holes on some VPIs but not others. The solution is also operationally efficient since the entire VT can be managed as a single entity from the Network Manager (single point for configuration, status, alarms, statistics, and so on).

ATM virtual trunks use PWE3 N:1 ATM cell mode encapsulation to provide a cell-mode transport, supporting all AAL types, over the MPLS network. Cell concatenation on a pseudowire packet is supported. The SDP can be an MPLS or a GRE type.

The ATM pseudowire is initiated using Targeted LDP (T-LDP) signaling (defined in RFC 4447, *Pseudowire Setup and Maintenance using LDP*). In this application, there is no ATM signaling on the gateway nodes since both endpoints of the MPLS network are configured by the network operator. ATM signaling between the ATM nodes is passed transparently over the VT (along with user traffic) from one ATM port on a PE to another ATM port on a remote (or the same) SR PE.

## 2.1.3 Traffic Management Support

Traffic management support is supported only on the 7750 SR.

### 2.1.3.1 Ingress Network Classification

Classification is based on the EXP value of the pseudowire label and EXP-to-FC mapping is determined by the network ingress QoS policy.

### 2.1.3.2 Ingress Queuing and Shaping on the IOM

Each SAP of an ATM VLL has an associated single ingress service queue on the IOM. The default QoS policy configures this queue to have CIR=0 and PIR=line rate. Other QoS policies can be applied if they specify a single service queue. Applying a non-default QoS policy allows the CIR/PIR of the incoming traffic to be controlled, regardless of whether ATM policing is configured, and provides queuing and shaping to smooth traffic flows on the ingress of the network.

### 2.1.3.3 Egress Queuing and Shaping on the IOM

Each SAP of an ATM VLL has an associated single egress service queue on the IOM. The default QoS policy configures this queue to have CIR=0 and PIR=line rate. Other QoS policies can be applied if they specify a single service queue. Applying a non-default QoS policy allows the CIR/PIR of the outgoing traffic to be controlled, regardless of whether ATM shaping is configured.

### 2.1.3.4 Egress Shaping/Scheduling

Each SAP of an ATM VLL has an associated egress ATM traffic descriptor. The default traffic descriptor has service category UBR with zero MIR, resulting in endpoints associated with this descriptor being scheduled at the lowest priority on the ATM MDA. Egress traffic may be shaped or scheduled, depending on the configuration of the egress ATM traffic descriptor associated with the SAP. [Table 3](#) describes how the different service categories, and shaping settings, and priorities affect egress transmission rates.

Shaping applies to CBR, rtVBR, and nrtVBR service categories and results in cells being transmitted in such a way as to satisfy a downstream ATM UPC function. For example, the transmission rate will be limited (in the case of CBR, there is a hard limit of PIR, while rtVBR/nrtVBR will transmit at SIR with short (constrained by MBS) bursts of up to PIR), and the inter-cell gap will also be controlled.

Service categories UBR and rtVBR are scheduled on the WRR scheduler with the configured rates (MIR for UBR+) determining the weight applied to the flow. Weights are between 1 and 255 and are determined by a formula applied to the configured rate. UBR flows (for example, those with no MIR) receive a weight of 1 and the maximum weight of 255 is reached by flows with configured rates of around 8 Mb/s. Scheduling does not apply a limit to the transmission rate; the available port bandwidth is shared out by the scheduler according to the weight, so if the other flows are quiescent, one flow may burst up to port bandwidth.

Shaping and scheduling of egress ATM VLL traffic is performed entirely at the ATM layer and is, therefore, not forwarding-class-aware. If the offered rate is greater than can be transmitted toward the customer (either because the shaping rate limits transmission or because the SAP does not receive sufficient servicing in the weighed round-robin used for scheduled SAPs), the per-VC queue will begin to discard traffic. These discards trigger the congestion control mechanisms in the MDA queues or in the IOM service egress queues associated with the SAP. For AAL5 SDU VLLs, these discards occur at the AAL5 SDU level. For N-to-1 VLLs, these discards occur at the level of the cell or a block of cells when cell concatenation is enabled.

**Table 3 Service Categories and Relative Priorities**

| Flow Type        | Transmission Rate                                                                                     | Priority                                     |
|------------------|-------------------------------------------------------------------------------------------------------|----------------------------------------------|
| shaped CBR       | Limited to configured PIR                                                                             | Strict priority over all other traffic       |
| shaped rtVBR     | Limited to configured SIR, but with bursts up to PIR within MBS                                       | Strict priority over all but shaped CBR      |
| shaped nrtVBR    | Limited to configured SIR, but with bursts up to PIR within MBS                                       | Strict priority over all scheduled traffic   |
| scheduled nrtVBR | Weighted share (according to SIR) of port bandwidth remaining after shaped traffic has been exhausted | In the same WRR scheduler as UBR+ and UBR    |
| scheduled UBR+   | Weighted share (according to MIR) of port bandwidth remaining after shaped traffic has been exhausted | In the same WRR scheduler as nrtVBR and UBR  |
| scheduled UBR    | Weighted share (with weight of 1) of port bandwidth remaining after shaped traffic has been exhausted | In the same WRR scheduler as nrtVBR and UBR+ |

## 2.2 Circuit Emulation (Cpipe) Services

This section provides information about Circuit Emulation (Cpipe) services. Cpipe is supported for the 7450 ESS and 7750 SR only.

**Note:** Cpipe VLL is not supported in System Profile B. To determine if Cpipes are currently provisioned, use the **show service service-using cpipe** command before configuring profile B.

### 2.2.1 Mobile Infrastructure

Packet infrastructure is required within 2G, 2.5G, and 3G mobile networks to handle SMS messaging, web browsing, and emerging applications such as streaming video, gaming, and video on demand. Within existing 2.5G and 3G mobile networks, ATM is defined as the transport protocol. Within existing 2G networks, TDM is defined as the transport protocol. Due to the relatively low bit rate of existing handsets, most cell sites use 2 to 10 DS1s or E1s to transport traffic. When using ATM over multiple DS1/E1 links, Inverse Multiplexing over ATM (IMA) is very effective for aggregating the available bandwidth for maximum statistical gain and providing automatic resilience in the case of a link failure. Also, multiple DS1s or E1s are required to transport the 2G voice traffic.

Typically, low-cost devices are used at the many cell sites to transport multiple DS1 or E1 using ATM/IMA and TDM over an Ethernet/MPLS infrastructure. In Nokia applications, the circuit emulation would currently be performed using the 7705 SAR. This could be performed by DMXplore at the cell site. However, a large number of cell sites aggregate into a single switching center. Book-ending 7705 SAR nodes would require a very large number of systems at the switching center (see [Figure 3](#)). Therefore, a channelized OC3/STM1 solution is much more efficient at the switching center. [Table 4](#) defines the cellsite backhaul types, CSR roles, and transport acronyms used in [Figure 3](#).

With a channelized OC3/STM1 CES CMA/MDA in the 7750 SR, Nokia can provide a converged, flexible solution for IP/MPLS infrastructures for 2G/2.5G/3G mobile networks supporting both the CES (by CES CMA/MDA) and ATM/IMA transported traffic (by the ASAP MDA).

**Figure 3**      **Mobile Infrastructure**

**Table 4**      **Mobile Infrastructure Definitions**

| Cellsite Backhaul Type | CSR Role                            | Transport Acronyms                  |
|------------------------|-------------------------------------|-------------------------------------|
| Microwave              | Circuit emulation                   | CSR: Cellsite Service Router        |
| xDSL                   | ATM IMA termination into pseudowire | MAR: Mobile Aggregation Router      |

## 2.2.2 Circuit Emulation Modes

Two modes of circuit emulation are supported: unstructured and structured. Unstructured mode is supported for DS1 and E1 channels per RFC 4553, *Structure-Agnostic Time Division Multiplexing (TDM) over Packet (SAToP)*. Structured mode is supported for N\*64 kb/s circuits as per RFC 5086, *Structure-Aware Time Division Multiplexed (TDM) Circuit Emulation Service over Packet Switched Network (CESoPSN)*. Also, DS1, E1, and N\*64 kb/s circuits are supported (per MEF8). TDM circuits are optionally encapsulated in MPLS or Ethernet as per the referenced standards in the following examples.

## RFC 4553 (SAToP) MPLS PSN Encapsulation:

### CESoPSN Packet Format for an MPLS PSN:

### MEF8 PSN Encapsulation:

### 2.2.3 Circuit Emulation Parameters

### 2.2.3.1 Circuit Emulation Modes

All channels on the CES CMA/MDA are supported as circuits to be emulated across the packet network. Structure-aware mode is supported for N\*64 kb/s channel groups in DS1 and E1 carriers. Fragmentation is not supported for circuit emulation packets (structured or unstructured).

For DS1 and E1 unstructured circuits, the framing can be set to unframed. When channel group 1 is created on an unframed DS1 or E1, it is automatically configured to contain all 24 or 32 channels, respectively.

N\*64 kb/s circuit emulation supports basic and Channel Associated Signaling (CAS) options for timeslots 1 to 31 (channels 2 to 32) on E1 carriers and channels 1 to 24 on DS1 carriers. CAS in-band is supported; therefore, no separate pseudowire support for CAS is provided. CAS option can be enabled or disabled for all channel groups on a specific DS1 or E1. If CAS operation is enabled, timeslot 16 (channel 17) cannot be included in the channel group on E1 carriers. Control channel signaling (CCS) operation is not supported.

### 2.2.3.2 Absolute Mode Option

For all circuit emulation channels except those with differential clock sources, RTP headers in absolute mode can be optionally enabled (disabled by default). For circuit emulation channels that use differential clock sources, this configuration is blocked. All channel groups on a specific DS1 or E1 can be configured for the same mode of operation.

When enabled for absolute mode operation, an RTP header will be inserted. On transmit, the CES IWF will insert an incrementing (by 1 for each packet) timestamp into the packets. All other fields will be set to zero. The RTP header will be ignored on receipt. This mode is enabled for interoperability purposes only for devices that require an RTP header to be present.

### 2.2.3.3 Payload Size

For DS3, E3, DS1, and E1 circuit emulation, the payload size can be configurable in number of octets. The default values for this parameter are shown in [Table 5](#). Unstructured payload sizes can be set to a multiple of 32 octets and minimally be 64 octets. TDM satellite supports only unstructured payloads.

**Table 5** Unstructured Payload Defaults

| TDM Circuit | Default Payload Size |
|-------------|----------------------|
| DS1         | 192 octets           |
| E1          | 256 octets           |

For N\*64 kb/s circuits, the number of octets or DS1/E1 frames to be included in the TDM payload needs to be configurable in the range 4 to 128 DS1/E1 frames in increments of 1 or the payload size in octets. The default number of frames is shown in [Table 6](#) with associated packet sizes. For the number of 64 kb/s channels included (N), the following number of default frames apply for no CAS: N=1, 64 frames; 2<=N<= 4, 32 frames; 5<=N<= 15, 16 frames; N>=16, 8 frames.

For CAS circuits, the number of frames can be 24 for DS1 and 16 for E1, which yields a payload size of N\*24 octets for T1 and N\*16 octets for E1. For CAS, the signaling portion is an additional ((N+1)/2) bytes, where N is the number of channels. The additional signaling bytes are not included in the TDM payload size, although they are included in the actual packet size shown in [Table 6](#).

The full ABCD signaling value can be derived before the packet is sent. This occurs for every 24 frames for DS1 ESF and every 16 frames for E1. For DS1 SF, ABAB signaling is actually sent because SF framing only supports AB signaling every 12 frames.

**Table 6 Structured Number of Default Frames**

| Num Timeslots | No CAS             |                 |                 | DS1 CAS             |             | E1 CAS              |             |
|---------------|--------------------|-----------------|-----------------|---------------------|-------------|---------------------|-------------|
|               | num-frames default | Default Payload | Minimum Payload | Payload (24 Frames) | Packet Size | Payload (16 Frames) | Packet Size |
| 1             | 64                 | 64              | 40              | 24                  | 25          | 16                  | 17          |
| 2             | 32                 | 64              | 64              | 48                  | 49          | 32                  | 33          |
| 3             | 32                 | 96              | 96              | 72                  | 74          | 48                  | 50          |
| 4             | 32                 | 128             | 128             | 96                  | 98          | 64                  | 66          |
| 5             | 16                 | 80              | 80              | 120                 | 123         | 80                  | 83          |
| 6             | 16                 | 96              | 96              | 144                 | 147         | 96                  | 99          |
| 7             | 16                 | 112             | 112             | 168                 | 172         | 112                 | 116         |
| 8             | 16                 | 128             | 128             | 192                 | 196         | 128                 | 132         |
| 9             | 16                 | 144             | 144             | 216                 | 221         | 144                 | 149         |

| 26            | 8                  | 208             | 208             | NA                  | NA          | 416                 | 429         |
| 27            | 8                  | 216             | 216             | NA                  | NA          | 432                 | 446         |
| 28            | 8                  | 224             | 224             | NA                  | NA          | 448                 | 462         |
| 29            | 8                  | 232             | 232             | NA                  | NA          | 464                 | 479         |
| 30            | 8                  | 240             | 240             | NA                  | NA          | 480                 | 495         |
| 31            | 8                  | 248             | 248             | NA                  | NA          | NA                  | NA          |

**Note:** num-frames DS1 CAS are multiples of 24; num-frames E1 is a multiple of 16.

### 2.2.3.4 Jitter Buffer

For each circuit, the maximum receive jitter buffer is configurable. Packet delay from this buffer starts when the buffer is 50% full, to give an operational packet delay variance (PDV) equal to 75% of the maximum buffer size. The default value for the jitter buffer is nominally 5 ms. However, for lower-speed N\*64 kb/s circuits and CAS circuits, the following default values are used to align with the default number of frames (and resulting packetization delay) to allow at least two frames to be received before starting to playout the buffer. The jitter buffer is at least four times the packetization delay. The following default jitter buffer values for structured circuits apply:

Basic CES (DS1 and E1):

N=1, 32 ms

2<=N<=4, 16 ms

5<=N<=15, 8 ms

N>=16, 5 ms

### 2.2.3.5 CES Circuit Operation

The circuit status can be tracked to be either up, loss of packets, or administratively down. Statistics are available for the number of in-service seconds and the number of out-of-service seconds when the circuit is administratively up.

Jitter buffer overrun and underrun counters are available by statistics and optionally logged while the circuit is up. On overruns, excess packets are discarded and counted. On underruns, all ones are sent for unstructured circuits. For structured circuits, all ones or a user-defined data pattern is sent based on configuration. Also, if CAS is enabled, all ones or a user-defined signaling pattern is sent based on configuration.

For each CES circuit, alarms can be optionally disabled/enabled for stray packets, malformed packets, packet loss, receive buffer overrun, and remote packet loss. An alarm is raised if the defect persists for 3 seconds, and cleared when the defect no longer persists for 10 seconds. These alarms are logged and trapped when enabled.

## 2.2.4 Services for Transporting CES Circuits

Each circuit can be optionally encapsulated in MPLS, Ethernet packets. Circuits encapsulated in MPLS use circuit pipes (Cpipes) to connect to the far-end circuit. Cpipes support either SAP spoke-SDP or SAP-SAP connections. Cpipes are supported over MPLS and GRE tunnels. The Cpipe default service MTU is set to 1514 bytes.

Circuits encapsulated in Ethernet can be selected as a SAP in Epipe. Circuits encapsulated in Ethernet can be SAP spoke-SDP connections or Ethernet CEM SAP-to-Ethernet SAP for all valid Epipe SAPs. Circuits requiring CEM SAP-to-CEM SAP connections use Cpipes. A local and remote EC-ID and far-end destination MAC address can be configurable for each circuit. The CMA/MDA MAC address will be used as the source MAC address for these circuits.

For all service types, there are deterministic PIR=CIR values with class=EF parameters based on the circuit emulation parameters.

All circuit emulation services support the display of status of up, loss of packet (LOP), or admin down. Also, any jitter buffer overruns or underruns are logged.

---

Non-stop services are supported for Cpipes and CES over Epipes.

## 2.2.5 Network Synchronization Considerations

Each OC-3/STM-1 port can be independently configured to be loop-timed or node-timed. Each OC-3/STM-1 port can be configured to be a timing source for the node. TDM satellites only support node-timed mode.

Each DS-1 or E-1 channel without CAS signaling enabled can be independently configured to be loop-timed, node-timed, adaptive-timed, or differential-timed. Each DS-1 or E-1 channel with CAS signaling enabled can be independently configured to be loop-timed or node-timed. Adaptive timing and differential timing are not supported on DS-1 or E-1 channels with CAS signaling enabled. For the TDM satellite, each DS1/E1 channel can be loop-timed, node-timed, or differential-timed.

The adaptive recovered clock of a CES circuit can be used as a timing reference source for the node (ref1 or ref2). This is required to distribute network timing to network elements that only have packet connectivity to the network. One timing source on the CMA/MDA can be monitored for timing integrity. Both timing sources can be monitored if they are configured on separate CMA/MDAs while respecting the timing subsystem slot requirements.

If a CES circuit is being used for adaptive clock recovery at the remote end (such that the local end is now an adaptive clock master), Nokia recommends setting the DS-1/E-1 to be node-timed to prevent potential jitter issues in the recovered adaptive clock at the remote device. This is not applicable to TDM satellites.

For differential-timed circuits, the following timestamp frequencies are supported: 103.68 MHz (for recommended >100 MHz operation), 77.76 MHz (for interoperability with SONET/SDH-based systems such as TSS-5) and 19.44 MHz (for Y.1413 compliance). TDM satellite supports only 77.76 MHz.

Adaptive and differential timing recovery must comply with published jitter and wander specifications (G.823, G.824, and G.8261) for traffic interfaces under typical network conditions and for synchronous interfaces under specified packet network delay, loss, and delay variance (jitter) conditions. The packet network requirements to meet the synchronous interface requirements are to be determined during the testing phase.

On the 7450 ESS and 7750 SR CES CMA, a BITS port is also provided. The BITS port can be used as one of the two timing reference sources in the system timing subsystem. The operation of BITS ports configured as ref1 or ref2 is the same as existing ports configured as ref1 and ref2 with all options supported. The operation of the 7450 ESS or 7750 SR BITS source is unchanged and the BITS ports are not available on the CES MDAs (only SF/CPM BITS are available).

## 2.2.6 Cpipe Payload

Figure 4 shows the format of the CESoPSN TDM payload (with and without CAS) for packets carrying trunk-specific 64 kb/s service. In CESoPSN, the payload size is dependent on the number of timeslots used. This is not applicable to TDM satellite since only unstructured DS1/E1 is supported.

**Figure 4 CESoPSN MPLS Payload Format**

## 2.3 Ethernet Pipe (Epipe) Services

This section provides information about the Epipe service and implementation.

### 2.3.1 Epipe Service Overview

An Epipe service is the Nokia implementation of an Ethernet VLL based on the IETF “Martini Drafts” (draft-martini-l2circuit-trans-mpls-08.txt and draft-martini-l2circuit-encapmpls-04.txt) and the IETF Ethernet Pseudowire Draft (draft-so-pwe3-ethernet-00.txt).

An Epipe service is a Layer 2 point-to-point service where the customer data is encapsulated and transported across a service provider IP, MPLS, or Provider Backbone Bridging (PBB) VPLS network. An Epipe service is completely transparent to the customer data and protocols. The Epipe service does not perform any MAC learning. A local Epipe service consists of two SAPs on the same node, whereas a distributed Epipe service consists of two SAPs on different nodes. SDPs are not used in local Epipe services.

Each SAP configuration includes a specific port or channel on which service traffic enters the router from the customer side (also called the access side). Each port is configured with an encapsulation type. If a port is configured with an IEEE 802.1Q (referred to as dot1q) encapsulation, a unique encapsulation value (ID) must be specified.

**Figure 5 Epipe/VLL Service**

OSSG021

## 2.3.2 Epipe Service Pseudowire VLAN Tag Processing

Distributed Epipe services are connected using a pseudowire, which can be provisioned statically or dynamically and is represented in the system as a spoke-SDP. The spoke-SDP can be configured to process zero, one, or two VLAN tags as traffic is transmitted and received; see [Table 7](#) and [Table 8](#) for the ingress and egress tag processing. In the transmit direction, VLAN tags are added to the frame being sent. In the received direction, VLAN tags are removed from the frame being received. This is analogous to the SAP operations on a null, dot1q, and QinQ SAP.

The system expects a symmetrical configuration with its peer; specifically, it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. When removing VLAN tags from a spoke-SDP, the system attempts to remove the configured number of VLAN tags. If fewer tags are found, the system removes the VLAN tags found and forwards the resulting packet.

Because some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. With an asymmetrical behavior, a protocol extraction will not necessarily function as it would with a symmetrical configuration, resulting in an unexpected operation.

The VLAN tag processing is configured as follows on a spoke-SDP in an Epipe service:

- Zero VLAN tags processed — This requires the configuration of **vc-type ether** under the spoke-SDP, or in the related PW template.
- One VLAN tag processed — This requires one of the following configurations:
  - **vc-type vlan** under the spoke-SDP or in the related PW template
  - **vc-type ether** and **force-vlan-vc-forwarding** under the spoke-SDP or in the related PW template
- Two VLAN tags processed — This requires the configuration of **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** under the spoke-SDP or in the related PW template.

The PW template configuration provides support for BGP VPWS services.

The following restrictions apply to VLAN tag processing:

- The configuration of **vc-type vlan** and **force-vlan-vc-forwarding** is mutually exclusive.
- **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** can be configured with the spoke-SDP signaled as either **vc-type ether** or **vc-type vlan**.

- The following are not supported with **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** configured under the spoke-SDP, or in the related PW template:
  - Multi-segment pseudowires.
  - PBB-Epipe services
  - force-vlan-vc-forwarding under the same spoke-SDP or PW template
  - Eth-CFM LM tests are NOT supported on UP MEPs when force-qinq-vc-forwarding is enabled.

[Table 7](#) and [Table 8](#) describe the VLAN tag processing with respect to the zero, one, and two VLAN tag configuration described for the VLAN identifiers, Ethertype, ingress QoS classification (dot1p/DE), and QoS propagation to the egress (which can be used for egress classification and/or to set the QoS information in the innermost egress VLAN tag).

**Table 7 Epipe Spoke-SDP VLAN Tag Processing: Ingress**

| Ingress (Received on Spoke-SDP)                     | Zero VLAN Tags | One VLAN Tag                                              | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                 |
|-----------------------------------------------------|----------------|-----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN identifiers                                    | N/A            | Ignored                                                   | Both inner and outer ignored                                                                                                                    |
| Ethertype (to determine the presence of a VLAN tag) | N/A            | 0x8100 or value configured under <b>sdp vlan-vc-etype</b> | Both inner and outer VLAN tags: 0x8100, or outer VLAN tag value configured under <b>sdp vlan-vc-etype</b> (inner VLAN tag value must be 0x8100) |
| Ingress QoS (dot1p/DE) classification               | N/A            | Ignored                                                   | Both inner and outer ignored                                                                                                                    |

**Table 7** Epipe Spoke-SDP VLAN Tag Processing: Ingress (Continued)

| Ingress (Received on Spoke-SDP)      | Zero VLAN Tags | One VLAN Tag                          | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------|----------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Qos (dot1p/DE) propagation to egress | Dot1p/DE=0     | Dot1p/DE taken from received VLAN tag | <p>Dot1p/DE taken as follows:</p> <ul style="list-style-type: none"> <li>• If the egress encapsulation is a Dot1q SAP, Dot1p/DE bits are taken from the outer received VLAN tag</li> <li>• If the egress encapsulation is QinQ SAP, the s-tag bits are taken from the outer received VLAN tag and the c-tag bits from the inner received VLAN tag</li> </ul> <p>The egress cannot be a spoke-sdp since <b>force-qinq-vc-forwarding</b> does not support multi-segment PWs.</p> |

**Table 8**      **Epipe-Spoke SDP VLAN Tag Processing: Egress**

| Egress (Sent on Mesh or Spoke-SDP)  | Zero VLAN Tags | One VLAN Tag                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

It can be one of the following:</p> <ul style="list-style-type: none"> <li>inner tag received on a QinQ SAP</li> <li>value from the VLAN tag received on a dot1q SAP</li> <li>value from the outer tag received on a qtag.* SAP</li> <li>value 0 if there is no service delimiting VLAN tag at the ingress SAP</li> </ul> |

**Table 8**      **Epipe-Spoke SDP VLAN Tag Processing: Egress (Continued)**

| Egress (Sent on Mesh or Spoke-SDP) | Zero VLAN Tags | One VLAN Tag                                                                                                                                                                                                   | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                    |                | <ul style="list-style-type: none"> <li>0 if there is no service delimiting VLAN tag at the ingress SAP or spoke-SDP</li> </ul> <p>Note: Neither the inner nor outer dot1p/DE values can be explicitly set.</p> | <p>If <b>s-tag-c-tag</b> is configured, the inner and outer dot1p/DE bits are taken from the inner and outer ingress service delimiting tag (respectively). They can be:</p> <ul style="list-style-type: none"> <li>inner and outer tags received on a QinQ SAP</li> <li>value from the VLAN tag received on a dot1q SAP for the outer tag and zero for the inner tag</li> <li>value from the outer tag received on a qtag.* SAP for the outer tag and zero for the inner tag</li> <li>value 0 if there is no service delimiting VLAN tag at the ingress SAP</li> </ul> <p>Note: Neither the inner nor outer dot1p/DE values can be explicitly set.</p> |

Any non-service delimiting VLAN tags are forwarded transparently through the Epipe service. SAP egress classification is possible on the outermost customer VLAN tag received on a spoke-SDP using the **ethernet-ctag** parameter in the associated SAP egress QoS policy.

---

### 2.3.3 Epipe Up Operational State Configuration Option

By default, the operational state of the Epipe is tied to the state of the two connections that comprise the Epipe. If either of the connections in the Epipe are operationally down, the Epipe service that contains that connection will also be operationally down. The operator can configure a single SAP within an Epipe that does not affect the operational state of that Epipe, using the optional **ignore-oper-state** command. Within an Epipe, if a SAP that includes this optional command becomes operationally down, the operational state of the Epipe will not transition to down. The operational state of the Epipe will remain up. This does not change that the SAP is down and no traffic can transit an operationally down SAP. Removing and adding this command on the fly will evaluate the operational state of the service, based on the SAPs and the addition or deletion of this command.

Service OAM (SOAM) designers may consider using this command if an operationally up MEP configured on the operationally down SAP within an Epipe is required to receive and process SOAM PDUs. When a service is operationally down, this is not possible. For SOAM PDUs to continue to arrive on an operationally up, MEP configured on the failed SAP, the service must be operationally up. Consider the case where an operationally up MEP is placed on a UNI-N or E-NNI and the UNI-C on E-NNI peer is shutdown in such a way that it causes the SAP to become operationally down.

Two connections must be configured within the Epipe; otherwise, the service will be operationally down regardless of this command. The **ignore-oper-state** functionality will only operate as intended when the Epipe has one ingress and one egress. This command is not to be used for Epipe services with redundant connections that provide alternate forwarding in case of failure, even though the CLI does not prevent this configuration.

Support is available on Ethernet SAPs configured on ports or Ethernet SAPs configured on LAG. However, it is not allowed on SAPs using LAG profiles or if the SAP is configured on a LAG that has no ports.

---

## 2.3.4 Epipe with PBB

A PBB tunnel may be linked to an Epipe to a B-VPLS. MAC switching and learning is not required for the point-to-point service. All packets ingressing the SAP are PBB encapsulated and forwarded to the PBB tunnel to the backbone destination MAC address. Likewise, all the packets ingressing the B-VPLS destined for the ISID are PBB de-encapsulated and forwarded to the Epipe SAP. A fully specified backbone destination address must be provisioned for each PBB Epipe instance to be used for each incoming frame on the related I-SAP. If the backbone destination address is not found in the B-VPLS FDB, packets may be flooded through the B-VPLSs.

All B-VPLS constructs may be used including B-VPLS resiliency and OAM. Not all generic Epipe commands are applicable when using a PBB tunnel.

## 2.3.5 Epipe over L2TPv3

The L2TPv3 feature provides a framework to transport Ethernet pseudowire services over an IPv6-only network without MPLS. This architecture relies on the abundance of address space in the IPv6 protocol to provide unique far-end and local-end addressing that uniquely identify each tunnel and service binding.

L2TPv3 provides the capability of transporting multiple Epipes (up to 16K per system), by binding multiple IPv6 addresses to each node and configuring one SDP per Epipe.

Because the IPv6 addressing uniqueness identifies the customer and service binding, the L2TPv3 control plane is disabled in this mode.

L2TPv3 is supported on non-12e 7750 SR and 7450 ESS (mixed mode) and 7950 XRS platforms.

ETH-CFM is supported for OAM services.

**Figure 6** L2TPv3 SDP

al\_0201

## 2.3.6 Ethernet Interworking VLL

Figure 7 provides an example of an Ethernet interworking VLL. The Ethernet interworking VLL provides a point-to-point Ethernet VLL service between Frame Relay (FR) attached users, ATM-attached users, and Ethernet-attached users across an IP/MPLS packet switched network. It effectively provides ATM and FR bridged encapsulation termination on the existing Epipe service of the 7750 SR.

**Figure 7** Application of Ethernet Interworking VLL

OSSG059

The following connectivity scenarios are supported:

- a Frame Relay or ATM user connected to a ATM network communicating with a Ethernet user connected to a 7750 SR PE node on a IP/MPLS network
- a Frame Relay or ATM user connected to 7750 SR PE node communicating with an Ethernet user connected to a 7750 SR PE node on a IP/MPLS network. This feature supports local cross-connecting when these users are attached to the same 7750 SR PE node.

Users attach over an ATM UNI with RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*, tagged/untagged bridged Ethernet PDUs, a FR UNI using RFC 2427, *Multiprotocol Interconnect over Frame Relay*, tagged/untagged bridged Ethernet PDUs, or an Ethernet tagged/untagged UNI interface. However, the VCI/VPI and the data-link connection identifier (DLCI) are the identifiers of the SAP in the case of ATM and FR, respectively, and the received tags are transparent to the service, so are preserved.

The Ethernet pseudowire is established using T-LDP signaling and can use the **ether** or **vlan** VC types on the SDP. The SDP can be either an MPLS or GRE type.

### 2.3.7 VLL CAC

The VLL Connection Admission Control (CAC) is supported for the 7750 SR only and provides a method to administratively account for the bandwidth used by VLL services inside an SDP that consists of RSVP LSPs.

The service manager keeps track of the available bandwidth for each SDP. The SDP available bandwidth is applied through a configured booking factor. An administrative bandwidth value is assigned to the spoke-SDP. When a VLL service is bound to an SDP, the amount of bandwidth is subtracted from the adjusted available SDP bandwidth. When the VLL service binding is deleted from the SDP, the amount of bandwidth is added back into the adjusted SDP available bandwidth. If the total adjusted SDP available bandwidth is overbooked when adding a VLL service, a warning is issued and the binding is rejected.

This feature does not guarantee bandwidth to a VLL service because there is no change to the datapath to enforce the bandwidth of an SDP by means such as shaping or policing of constituent RSVP LSPs.

---

## 2.3.8 MC-Ring and VLL

To support redundant VLL access in ring configurations, the multi-chassis ring (MC-Ring) feature is applicable to VLL SAPs. A conceptual drawing of the operation is shown in [Figure 8](#). The specific CPE that is connected behind the ring node has access to both BSAs through the same VLAN provisioned in all ring nodes. There are two SAPs (with the same VLAN) provisioned on both nodes.

If a closed ring status occurs, one of the BSAs becomes the master and will signal an active status bit on the corresponding VLL pseudowire. Similarly, the standby BSA will signal a standby status. With this information, the remote node can choose the correct path to reach the CPE. In case of a broken ring, the node that can reach the ring node, to which the CPE is connected by RNCV check, will become master and will signal corresponding status on its pseudowire.

The mapping of individual SAPs to the ring nodes is done statically through CLI provisioning. To keep the convergence time to a minimum, MAC learning must be disabled on the ring node so all CPE originated traffic is sent in both directions. If the status is operationally down on the SAP on the standby BSA, that part of the traffic will be blocked and not forwarded to the remote site.

**Figure 8** MC-Ring in a Combination with VLL Service

OSSG174

For further information about Multi-Chassis Ring Layer 2 (with ESM), refer to the *Advanced Configuration Guide*.

## 2.4 Frame Relay VLL (Fpipe) Services

This section provides information about the Frame Relay VLL (Fpipe) service and implementation. Fpipe is supported for the 7750 SR only.

### 2.4.1 Frame Relay VLL

Figure 9 shows an application of a Frame Relay VLL. The Fpipe provides a point-to-point Frame Relay service between users connected to 7750 SR nodes on the IP/MPLS network. Users are connected to the 7750 SR.

**Figure 9 Application of a Fpipe**

PE nodes using Frame Relay PVCs PE1, PE2, and PE3 receive a standard Q.922 Core frame on the Frame Relay SAP and encapsulate it into a pseudowire packet according to the 1-to-1 Frame Relay encapsulation mode in RFC 4619, *Encapsulation Methods for Transport of Frame Relay Over MPLS Networks*. The 7750 SR Fpipe feature supports local cross-connecting when the users are attached to the same 7750 SR PE node.

The FR pseudowire is initiated using T-LDP signaling as specified in RFC 4447, *Pseudo-wire Setup and Maintenance using LDP*. The SDP can be an MPLS or a GRE type.

## 2.4.2 Frame Relay-to-ATM Interworking (FRF.5) VLL

Figure 10 provides an example of a point-to-point Frame Relay service between users where one user is connected to an existing ATM network, the other to a 7750 SR PE node on an IP/MPLS network.

**Figure 10** Frame Relay-to-ATM Network Interworking (FRF.5) VLL

OSSG070

This VLL uses an ATM AAL5 SDU pseudowire between the 7750 SR PE nodes. It is configured by adding a FR SAP to an Apipe service using vc-type atm-sdu. The 7750 SR PE2 node performs an FRF.5 interworking function to interwork the ingress and egress data paths as well as the operations required in an FR and an ATM VLL.

The pseudowire is initiated using Targeted LDP signaling as specified in the IETF Draft *draft-ietf-pwe3-control-protocol-xx.txt*. The SDP can be an MPLS or a GRE type.

## **2.4.3 Traffic Management Support**

### **2.4.3.1 Frame Relay Traffic Management**

Traffic management of Fpipes is supported for the 7750 SR only and is achieved through the application of ingress and egress QoS policies to SAPs like other Frame Relay SAPs. No queuing occurs on the MDA; all queuing, policing, and shaping occurs on the IOM and, therefore, traffic management is forwarding-class-aware. Forwarding classes may be determined by inspecting the DSCP marking of contained IP packets (for example) and this will determine both the queuing and the EXP bit setting of packets on an Fpipe.

### **2.4.3.2 Ingress SAP Classification and Marking**

Ingress SAP classification and marking is supported for the 7450 ESS and 7750 SR only. DE=0 frames are subject to the CIR marking algorithm in the queue. Drop preference for these packets will follow the state of the CIR bucket associated with the ingress queue. The value is marked in the drop preference bit of the internal header and in the DE bit in the Q.922 frame header. DE=1 frames are classified in “out-of-profile” state and are not overwritten by the CIR marking in the ingress queue. The drop preference is set to high.

### **2.4.3.3 Egress Network EXP Marking**

FC-to-EXP mapping is supported for the 7450 ESS and 7750 SR only and is as per the Network Egress QoS policy. Marking of the EXP field in both label stacks is performed.

### **2.4.3.4 Ingress Network Classification**

Classification is supported for the 7450 ESS and 7750 SR only and is based on the EXP value of the pseudowire label and EXP-to-FC mapping is as per Network Ingress QoS policy.

## 2.5 IP Interworking VLL (Ipipe) Services

This section provides information about IP Interworking VLL (Ipipe) services.

### 2.5.1 Ipipe VLL

Figure 11 provides an example of IP connectivity between a host attached to a point-to-point access circuit (FR, ATM, PPP) with routed PDU IPv4 encapsulation and a host attached to an Ethernet interface. Both hosts appear to be on the same LAN segment. This feature is supported for the 7450 ESS and 7750 SR and enables service interworking between different link layer technologies. A typical use of this application is in a Layer 2 VPN when upgrading a hub site to Ethernet while keeping the spoke sites with their existing Frame Relay or ATM IPv4 (7750 SR only) routed encapsulation.

**Note:** Ipipe VLL is not supported in System Profile B. To determine if Ipipes are currently provisioned, use the **show service service-using ipipe** command before configuring profile B.

**Figure 11** IP Interworking VLL (Ipipe)

IPIPE\_001

The ATM SAP is supported by the 7750 SR only. It carries the IPv4 packet using RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5, VC-Mux or LLC/SNAP routed PDU encapsulation*.

The Frame Relay SAP uses RFC 2427, *Multiprotocol Interconnect over Frame Relay*, routed PDU encapsulation of an IPv4 packet. A PPP interface uses RFC 1332, *The PPP Internet Protocol Control Protocol (IPCP)*, PPP IPCP encapsulation of an IPv4 packet. A Cisco-HDLC SAP uses the routed IPv4 encapsulation. The pseudowire uses the IP Layer 2 transport pseudowire encapsulation type.

**Note:** The lpipe is a point-to-point Layer 2 service. All packets received on one SAP of the lpipe will be forwarded to the other SAP. No IP routing of customer packets occurs.

## 2.5.2 IP Interworking VLL Datapath

In [Figure 11](#), PE 2 is manually configured with both CE 1 and CE 2 IP addresses. These are host addresses and are entered in /32 format. PE 2 maintains an ARP cache context for each IP interworking VLL. PE 2 responds to ARP request messages received on the Ethernet SAP. PE 2 responds with the Ethernet SAP configured MAC address as a proxy for any ARP request for CE 1 IP address. PE 2 silently discards any ARP request message received on the Ethernet SAP for an address other than that of CE 1. Likewise, PE 2 silently discards any ARP request message with the source IP address other than that of CE 2. In all cases, PE 2 keeps track of the association of IP to MAC addresses for ARP requests it receives over the Ethernet SAP.

To forward unicast frames destined for CE 2, PE 2 needs to know the CE 2 MAC address. When the lpipe SAP is first configured and administratively enabled, PE2 sends an ARP request message for CE 2 MAC address over the Ethernet SAP. Until an ARP reply is received from CE2, providing the CE2 MAC address, unicast IP packets destined for CE2 will be discarded at PE2. IP broadcast and IP multicast packets are sent on the Ethernet SAP using the broadcast or direct-mapped multicast MAC address.

To forward unicast frames destined for CE 1, PE 2 validates the MAC destination address of the received Ethernet frame. The MAC address should match that of the Ethernet SAP. PE 2 then removes the Ethernet header and encapsulates the IP packet directly into a pseudowire without a control word. PE 1 removes the pseudowire encapsulation and forwards the IP packet over the Frame Relay SAP using RFC 2427, *Multiprotocol Interconnect over Frame Relay*, routed PDU encapsulation.

To forward unicast packets destined for CE1, PE2 validates the MAC destination address of the received Ethernet frame. If the IP packet is unicast, the MAC destination must match that of the Ethernet SAP. If the IP packet is multicast or broadcast, the MAC destination address must be an appropriate multicast or broadcast MAC address.

The other procedures are similar to the case of communication between CE 1 and CE 2, except that the ATM SAP and the Ethernet SAP are cross-connected locally and IP packets do not get sent over an SDP.

A PE does not flush the ARP cache unless the SAP goes administratively or operationally down. The PE with the Ethernet SAP sends unsolicited ARP requests to refresh the ARP cache every “T” seconds. ARP requests are staggered at an increasing rate if no reply is received to the first unsolicited ARP request. The value of T is configurable by the user through the mac-refresh CLI command.

### 2.5.3 Extension to IP VLL for Discovery of Ethernet CE IP Address

VLL services provide IP connectivity between a host attached to a point-to-point access circuit (FR, ATM, PPP) with routed PDU encapsulation and a host attached to an Ethernet interface. Both hosts appear to be on the same IP interface. This feature is supported only for IPv4 payload.

In deployments where it is not practical for operators to obtain and configure their customer CE address, the following behaviors apply:

- A service comes up without prior configuration of the CE address parameter under both the SAP and the spoke-SDP.
- Operators rely solely on received ARP messages from the Ethernet SAP-attached CE device to update the ARP cache with no further check of the validity of the source IP address of the ARP request message and the target IP address being resolved.
- The LDP address list TLV signaling the learned CE IP address to the remote PE is supported. This is to allow the PE with the FR SAP to respond to an invFR ARP request message received from the FR-attached CE device. Only Ethernet SAP and FR SAP can learn the CE address through ARP and invFR ARP, respectively. The 7450 ESS and 7750 SR OS do not support invATM ARP on an ATM interface.

---

### 2.5.3.1 VLL Ethernet SAP Processes

The operator can enable the following CE address discovery processes by configuring the **ce-address-discovery** in the **config>service>ipipe** context.

- The service is brought up without the CE address parameter configured at either the SAP or the spoke-SDP.
- The operator cannot configure the **ce-address** parameter under the **config>service>ipipe>sap** or **config>service>ipipe>spoke-sdp** context when the **ce-address-discovery** in the **config>service>ipipe** context is enabled. Conversely, the operator is not allowed to enable the **ce-address-discovery** option under the Ipipe service if it has a SAP and/or spoke-SDP with a user-entered **ce-address** parameter.
- While an ARP cache is empty, the PE does not forward unicast IP packets over the Ethernet SAP but forwards multicast/broadcast packets. target IP address being resolved.
- The PE waits for an ARP request from the CE to learn both IP and MAC addresses of the CE. Both entries are added into the ARP cache. The PE accepts any ARP request message received over Ethernet SAP and updates the ARP cache IP and MAC entries with no further check of the source IP address of the ARP request message or of the target IP address being resolved.
- The 7450 ESS, 7750 SR, and 7950 XRS routers will always reply to a received ARP request message from the Ethernet SAP with the SAP MAC address and a source IP address of the target IP address being resolved without any further check of the latter.
- If the router received an address list TLV from the remote PE node with a valid IP address of the CE attached to the remote PE, the router will not check the CE IP address against the target IP address being resolved when replying to an ARP request over the Ethernet SAP.
- The ARP cache is flushed when the SAP bounces or when the operator manually clears the ARP cache. This results in the clearing of the CE address discovered on this SAP. However, when the SAP comes up initially or comes back up from a failure, an unsolicited ARP request is not sent over the Ethernet SAP.
- If the Ipipe service uses a spoke-SDP, the router includes the address list TLV in the interface parameters field of the pseudowire Forwarding Equivalent Class (FEC) TLV in the label mapping message. The address list TLV contains the current value of the CE address in the ARP cache. If no address was learned, an address value of 0.0.0.0 must be used.

- If the remote PE included the address list TLV in the received label mapping message, the local router updates the remote PE node with the most current IP address of the Ethernet CE using a T-LDP notification message with the TLV status code set to 0x0000002C and containing an LDP address list. The notification message is sent each time an IP address different from the current value in the ARP cache is learned. This includes when the ARP is flushed and the CE address is reset to the value of 0.0.0.0.
- If the remote PE did not include the address list TLV in the received label mapping message, the local router will not send any notification messages containing the address list TLV during the lifetime of the IP pseudowire.
- If the operator disables the **ce-address-discovery** option under the VLL service, service manager instructs LDP to withdraw the service label and the service is shutdown. The pseudowire labels will only be signaled and the service will come up if the operator re-enters the option again or manually enters the **ce-address** parameter under SAP and spoke-SDP.

#### 2.5.3.1.1 VLL FR SAP Procedures

The operator enables the following CE address dynamic learning procedures by enabling the **ce-address-discovery** option under the VLL service on the 7450 ESS or 7750 SR.

- Allow the service to come up without the CE address parameter configured at both the SAP and spoke-SDP. If one or both parameters are configured, they are ignored.
- The operator cannot configure the **ce-address** parameter under SAP or spoke-SDP when the **ce-address-discovery** option under the VLL service is enabled. Conversely, the operator is not allowed to enable the **ce-address-discovery** option under the lpipe service if it has a SAP and/or spoke-SDP with a user-entered **ce-address** parameter.
- If the router receives an invFR ARP request message over the FR SAP, it updates the ARP cache with the FR CE address. It also replies with the IP address of the CE attached to the remote PE if a valid address was advertised in the address list TLV by this remote PE. Otherwise, the router updates the ARP cache but does not reply to the invFR ARP.
- If the lpipe service uses a spoke-SDP, the router includes the address list TLV in the interface parameters field of the pseudowire FEC TLV in the label mapping message. The address list TLV contains the current value of the CE address in the ARP cache. If no address was learned, then an address value of 0.0.0.0 is used.

- If the remote PE included the address list TLV in the received label mapping message, the local router updates the remote PE node with the most current IP address of the FR CE using a T-LDP status notification message containing an LDP address list. The notification message is sent each time an IP address different from the current value in the ARP cache is learned. This includes when the ARP is flushed and the CE address is reset to the value of 0.0.0.00.
- If the remote PE did not include the address list TLV in the received label mapping message, the local router does not send any notification messages containing the address list TLV during the lifetime of the IP pseudowire.

### 2.5.3.1.2 VLL ATM SAP Procedures

The operator enables the following CE address dynamic learning procedures by enabling the **ce-address-discovery** option under the VLL service on the 7750 SR.

- Allow the service to come up without the **ce-address** parameter configured at both the SAP and spoke-SDP. If one or both parameters are configured, they are ignored.
- The operator is not allowed to configure the **ce-address** parameter under the SAP or spoke-SDP when the **ce-address-discovery** option under the VLL service is enabled. Conversely, the operator is not allowed to enable the **ce-address-discovery** option under the lpipe service if it has a SAP and/or spoke-SDP with a user-entered **ce-address** parameter.
- If the router receives an invATM ARP request message over the ATM SAP, the router silently discards it. The router does not support receiving or sending of an invATM ARP message.
- If the lpipe service uses a spoke-SDP, the router includes the address list TLV in the interface parameters field of the pseudowire FEC TLV in the label mapping message. The address list TLV contains an address value of 0.0.0.0.
- If the remote PE included the address list TLV in the received label mapping message, the local router will not make further updates to the address list TLV to the remote PE node using a T-LDP status notification message since the learned IP address of the ATM-attached CE will never change away from the value of 0.0.0.0.
- If the remote PE did not include the address list TLV in the received label mapping message, the local router will not send any notification messages containing the address list TLV during the lifetime of the IP pseudowire.

### 2.5.3.1.3 VLL PPP/IPCP and Cisco-HDLC SAP Procedures

The procedures are similar to the case of an ATM SAP. The remote CE address can only be learned in the case of a PPP SAP but is not sent in the address list TLV to the remote PE in both PPP and Cisco-HDLC SAP cases.

## 2.5.4 IPv6 Support on IP Interworking VLL

The 7450 ESS, 7750 SR, and 7950 XRS nodes support both the transport of IPv6 packets and the interworking of IPv6 Neighbor discovery/solicitation messages on an IP Interworking VLL. IPv6 capability is enabled on an lpipe using the **ce-address-discovery ipv6** command in the CLI.

### 2.5.4.1 IPv6 Datapath Operation

The IPv6 Datapath operation uses ICMPv6 extensions to automatically resolve IP address and link address associations. These are IP packets, as compared to ARP and invARP in IPv4, which are separate protocols and not based on IP packets. Manual configuration of IPv6 addresses is not supported on the IP Interworking VLL.

Each PE device intercepts ICMPv6 Neighbor Discovery (RFC 2461) packets, whether received over the SAP or over the pseudowire. The device inspects the packets to learn IPv6 interface addresses and CE link-layer addresses, modifies these packets as required according to the SAP type, then forwards them toward the original destination. The PE is also capable of generating packets to interwork between CEs (by using IPv6 Neighbor Discovery) and CEs that use other neighbor discovery protocols to bring up the link; for example, IPv6CP for PPP.

The PE device learns the IPv6 interface addresses for its directly-attached CE and other IPv6 interface addresses for the far-end CE. The PE device also learns the link-layer address of the local CE and uses it when forwarding traffic between the local and far-end CEs.

As with IPv4, the SAP accepts both unicast and multicast packets. For unicast packets, the PE checks that the MAC address/IP addresses are consistent with that in the ARP cache before forwarding; otherwise, the packet is silently discarded. Multicast packets are validated and forwarded. If more than one IP address is received per MAC address in a neighbor discovery packet, or if multiple neighbor discovery packets are received for a specific MAC address, the currently cached address is overwritten with the most recent value.

Figure 12 shows the data path operation for IPv6 on an IP Interworking VLL between the Ethernet and PPP (IPv6CP) SAPs.

**Figure 12 Data Path for Ethernet CE to PPP Attached CE**

With reference to neighbor discovery between Ethernet and PPP CEs in Figure 12, the steps are as follows:

1. Ethernet-attached CE2 sends a Neighbor Solicitation message toward PE2 in order to begin the neighbor discovery process.
2. PE2 snoops this message, and the MAC address and IP address of CE2 is stored in the ARP cache of PE2 before forwarding the Neighbor Solicitation on the IP pseudowire to PE1.
3. PE1 snoops this message that arrives on the IP pseudowire and stores the IP address of the remote CE. Since CE3 is attached to a PPP SAP, which uses IPv6CP to bring up the link, PE1 generates a neighbor advertisement message and sends it on the lpipe toward PE2.
4. PE2 receives the neighbor advertisement on the lpipe from PE1. It must replace the Layer 2 address in the neighbor advertisement message with the MAC address of the SAP before forwarding to CE2.

### 2.5.4.2 IPv6 Stack Capability Signaling

The 7750 SR, 7450 ESS, and 7950 XRS support IPv6 capability negotiation between PEs at the ends of an IP interworking VLL. Stack capability negotiation is performed if stack-capability-signaling is enabled in the CLI. Stack capability negotiation is disabled by default. Therefore, it must be assumed that the remote PE supports both IPv4 and IPv6 transport over an lpipe.

A stack-capability sub-TLV is signaled by the two PEs using T-LDP so that they can agree on which stacks they should be using. By default, the IP pseudowire will always be capable of carrying IPv4 packets. Therefore, this capability sub-TLV is used to indicate if other stacks need to be supported concurrently with IPv4.

The stack-capability sub-TLV is a part of the interface parameters of the pseudowire FEC. This means that any change to the stack support requires that the pseudowire be torn down and re-signaled.

A PE that supports IPv6 on an IP pseudowire must signal the stack-capability sub-TLV in the initial label mapping message for the pseudowire. For the 7750 SR, 7450 ESS, and 7950 XRS, this means that the stack-capability sub-TLV must be included if both the **stack-capability-signaling** and **ce-address-discovery ipv6** options are enabled under the VLL service.

In Release 14.0, if one PE of an IP interworking VLL supports IPv6, while the far-end PE does not support IPv6 (or ce-address-discovery ipv6 is disabled), the pseudowire does not come up.

If a PE that supports IPv6 (that is, stack-capability-signaling ipv6 is enabled) has already sent an initial label mapping message for the pseudowire, but does not receive a stack-capability sub-TLV from the far-end PE in the initial label mapping message, or one is received but it is set to a reserved value, then the PE assumes that a configuration error has occurred. That is, if the remote PE did not include the stack-capability sub-TLV in the received label mapping message, or it does include the sub-TLV but with the IPv6 bit cleared, and if stack-capability-signaling is enabled, the local node with ce-address-discovery ipv6 enabled withdraws its pseudowire label with the LDP status code "IP Address type mismatch".

If a 7750 SR, 7450 ESS, and 7950 XRS PE that supports IPv6 (that is, stack-capability-signaling ipv6 is enabled) has not yet sent a label mapping message for the pseudowire and does not receive a stack-capability sub-TLV from the far-end PE in the initial label mapping message, or one is received but it is set to a reserved value, the PE assumes that a configuration error has occurred and does not send a label mapping message of its own.

If the IPv6 stack is not supported by both PEs, or at least one of the PEs does support IPv6 but does not have the **ce-address-discovery ipv6** option selected in the CLI, IPv6 packets received from the AC are discarded by the PE. IPv4 packets are always supported.

If IPv6 stack support is implemented by both PEs, but the **ce-address-discovery ipv6** command was not enabled on both so that the IP pseudowire came up with only IPv4 support, and one PE is later toggled to **ce-address-discovery ipv6**, then that PE sends a label withdraw with the LDP status code meaning “Wrong IP Address Type” (Status Code 0x0000004B9).

If the IPv6 stack is supported by both PEs and, therefore, the pseudowire is established with IPv6 capability at both PEs, but the **ce-address-discovery ipv6** command on one PE is later toggled to **no ce-address-discovery ipv6** so that a PE ceases to support the IPv6 stack, then that PE sends a label withdraw with the LDP status code meaning “Wrong IP Address Type”.

## 2.6 Services Configuration for MPLS-TP

MPLS-TP PWs are supported in Epipe, Apipe, and Cpipe VLLs and Epipe spoke termination on IES/VP RN and VPLS, I-VPLS, and B-VPLS on the 7450 ESS and 7750 SR only.

This section describes how SDPs and spoke-SDPs are used with MPLS-TP LSPs and static pseudowires with MPLS-TP OAM. It also describes how to conduct test service throughput for PWs, using lock instruct messages and loopback configuration.

### 2.6.1 MPLS-TP SDPs

Only MPLS SDPs are supported.

An SDP used for MPLS-TP supports the configuration of an MPLS-TP identifier as the far-end address as an alternative to an IP address. IP addresses are used if IP/MPLS LSPs are used by the SDP, or if MPLS-TP tunnels are identified by IPv4 source/destination addresses. MPLS-TP node identifiers are used if MPLS-TP tunnels are used.

Only static SDPs with signaling off support MPLS-TP spoke-SDPs.

The following CLI shows the MPLS-TP options:

```
config
service
  sdp 10 [mpls | GRE | [ldp-enabled] [create]
    signaling <off | on>
    [no] lsp <xyz>
    [no] accounting-policy <policy-id>
    [no] adv-mtu-override
    [no] booking-factor <percentage>
    [no] class-forwarding
    [no] collect-stats
    [no] description <description-string>
    [no] far-end <ip-address> | [node-id
      {<ip-address> | <0...4,294,967,295>} [global-id <global-id>]]
    [no] tunnel-far-end <ip-address>
    [no] keep-alive
    [no] mixed-lsp-mode
    [no] metric <metric>
    [no] network-domain <network-domain-name>
    [no] path-mtu <mtu>
    [no] pbb-etype <ethertype>
    [no] vlan-vc-etype <ethertype>
    [no] shutdown
```

The **far-end node-id** *ip-address* **global-id** *global-id* command is used to associate an SDP far end with an MPLS-TP tunnel whose far-end address is an MPLS-TP node ID. If the SDP is associated with an RSVP-TE LSP, the far end must be a routable IPv4 address.

The system accepts the node-id being entered in either 4-octet IP address format (a.b.c.d) or unsigned integer format.

The SDP far end refers to an MPLS-TP node-id/global-id only if:

- delivery type is MPLS
- signaling is off
- keep-alive is disabled
- mixed-lsp-mode is disabled
- adv-mtu-override is disabled

An LSP can only be allowed to be configured if the far-end information matches the lsp far end information (whether MPLS-TP or RSVP).

- Only one LSP is allowed if the far end is an MPLS-TP node-id/global-id.
- MPLS-TP or RSVP-TE LSPs are supported. However, LDP and BG LSPs are not blocked in CLI.

Signaling LDP or BGP is blocked if:

- far-end node-id/global-id is configured
- control-channel-status is enabled on any spoke (or mate vc-switched spoke)
- pw-path-id is configured on any spoke (or mate vc-switched spoke)
- IES/VP RN interface spoke control-word is enabled

The following commands are blocked if a far-end node-id/global-id is configured:

- class-forwarding
- tunnel-far-end
- mixed-lsp-mode
- keep-alive
- ldp or bgp-tunnel
- adv-mtu-override

## 2.6.2 VLL Spoke SDP Configuration

The system can be a T-PE or an S-PE for a pseudowire (a spoke-SDP) supporting MPLS-TP OAM. MPLS-TP related commands are applicable to spoke-SDPs configured under all services supported by MPLS-TP pseudowires. All commands and functions that are applicable to spoke-SDPs are supported, except for those that explicitly depend on T-LDP signaling of the pseudo-wire, or as stated following. Likewise, all existing functions on a specified service SAP are supported if the spoke-SDP that it is mated to is MPLS-TP.

vc-switching is supported.

The following describes how to configure MPLS-TP on an Epipe VLL. However, a similar configuration applies to other VLL types.

A spoke-SDP bound to an SDP with the **mpls-tp** keyword cannot be **no shutdown** unless the ingress label, the egress label, the control word, and the pw-path-id are configured, as follows:

```
config
  service
    epipe
      [no] spoke-sdp sdp-id[:vc-id]
        [no] hash-label
        [no] standby-signaling-slave

      [no] spoke-sdp sdp-id[:vc-id] [vc-type {ether | vlan}]
        [create] [vc-switching] [no-endpoint | {endpoint [icb]}]
      egress
        vc-label <out-label>
      ingress
        vc-label <in-label>
      control-word
      bandwidth <bandwidth>
      [no] pw-path-id
        agi <agi>
        saii-type2 <global-id:node-id:ac-id>
        taii-type2 <global-id:node-id:ac-id>
      exit
      [no] control-channel-status
    [no] refresh-timer <value>
  request-timer <request-timer-secs> retry-timer <retry-timer-secs> timeout-
multiplier <multiplier>
no request-timer
  [no] acknowledgment
  [no] shutdown
  exit
```

The **pw-path-id** context is used to configure the end-to-end identifiers for an MS-PW. These may not coincide with those for the local node if the configuration is at an S-PE. The SAI and TAI are consistent with the source and destination of a label mapping message for a signaled PW.

The **control-channel-status** command enables static pseudowire status signaling. This is valid for any spoke-SDP where **signaling none** is configured on the SDP (for example, where T-LDP signaling is not in use). The refresh timer is specified in seconds, from 10-65535, with a default of 0 (off). This value can only be changed if **control-channel-status** is **shutdown**.

Commands that rely on PW status signaling are allowed if control-channel-status is configured for a spoke-SDP bound to an SDP with signaling off, but the system will use control channel status signaling rather than T-LDP status signaling. The ability to configure control channel status signaling on a specified spoke-SDP is determined by the credit-based algorithm described earlier. Control channel status for a pseudowire only counts against the credit-based algorithm if the pseudowire is in a **no shutdown** state and has a non-zero refresh timer and a non-zero request timer.

A shutdown of a service will result in the static PW status bits for the corresponding PW being set.

The spoke-SDP is held down unless the **pw-path-id** is complete.

The system will accept the node-id of the pw-path-id saii or taii being entered in either 4-octet IP address format (a.b.c.d) or unsigned integer format.

The control-word must be enabled to use MPLS-TP on a spoke-SDP.

The optional acknowledgment to a static PW status message is enabled using the **acknowledgment** command. The default is **no acknowledgment**.

The **pw-path-id** is only configurable if all of the following are true:

- in network mode D
- sdp signaling is off
- control-word is enabled (control-word is disabled by default)
- on service type Epipe, VPLS, Cpipe, or IES/VP RN interface
- An MPLS-TP node-id/global-id is configured under the **config>router>mpls>mpls-tp** context. This is required for OAM to provide a reply address.

In the vc-switching case, if configured to make a static MPLS-TP spoke SDP to another static spoke SDP, the TAIL of the spoke-SDP must match the SAIL of its mate, and the SAIL of the spoke-SDP must match the TAIL of its mate.

A control-channel-status no shutdown is allowed only if all of the following are true:

- in network-mode D
- sdp signaling is off

- control-word is enabled (control-word by default is disabled)
- the service type is Epipe, Apipe, VPLS, Cpipe, or IES/VP RN interface
- pw-status-signaling is enabled (as follows)
- pw-path-id is configured for this spoke

The **hash-label** option is only configurable if SDP far end is not node-id/global-id.

The control channel status request mechanism is enabled when the **request-timer timer** parameter is non-zero. When enabled, this overrides the normal RFC-compliant refresh timer behavior. The refresh timer value in the status packet defined in RFC 6478 is always set to zero. The refresh-timer in the sending node is taken from the request-timer <timer1> timer. The two mechanisms are not compatible with each other. One node sends a request timer while the other is configured for refresh timer. In a specified node, the request timer can only be configured with both acknowledgment and refresh timers disabled.

When configured, the procedures following are used instead of the RFC 6478 procedures when a PW status changes.

The CLI commands to configure control channel status requests are as follows:

```
[no] control-channel-status
[no] refresh-timer <value> //0,10-65535, default:0
[no] request-timer <timer1> retry-timer <timer2>
      [timeout-multiplier <value>]
[no] shutdown
exit
```

**request-timer** <timer1>: 0, 10-65535, defaults: 0.

- This parameter determines the interval at which PW status messages are sent, including a reliable delivery TLV, with the “request” bit set (as follows). This cannot be enabled if refresh-timer is not equal to zero (0).

**retry-timer** <timer2>: 3-60s

- This parameter determines the timeout interval if no response to a PW status is received. This defaults to zero (0) when **no retry-timer**.

**timeout-multiplier** <value> - 3 to 15

- If a requesting node does not get a response after retry-timer × multiplier, the node must assume that the peer is down. This defaults to zero (0) when **no retry-timer**.

### 2.6.2.1 Epipe VLL Spoke SDP Termination on IES, VPRN, and VPLS

All existing commands (except for those explicitly specified following) are supported for spoke-SDP termination on IES, VPRN, and VPLS (VPLS, I-VPLS and B-VPLS and routed VPLS) services. Also, the MPLS-TP commands listed preceding are supported. The syntax, default values, and functional behavior of these commands is the same as for Epipe VLLs, as specified preceding.

Also, the PW Control Word is supported on spoke-SDP termination on IES/VPRN interfaces for pseudowires of type “Ether” with statically assigned labels (signaling off) for spoke-SDPs configured with MPLS-TP Identifiers.

The following CLI commands under spoke-SDP are blocked for spoke-SDPs with statically assigned labels (and the SDP has signaling off) and MPLS-TP identifiers:

- **no status-signaling** — This command causes the spoke-SDP to fall back to using PW label withdrawal as a status signaling method. However, T-LDP is not supported on MPLS-TP SDPs. Control channel status signaling should always be used for signaling PW status. Since active/standby dual-homing into a routed VPLS requires the use of T-LDP label withdrawal as the method for status signaling, active/standby dual-homing into routed VPLS is not supported if the spoke-SDPs are MPLS-TP.
- **propagate-mac-flush** — This command requires the ability to receive MAC Flush messages using T-LDP signaling and is blocked.

### 2.6.3 Configuring MPLS-TP Lock Instruct and Loopback

MPLS-TP supports lock instruct and loopback for PWs.

#### 2.6.3.1 MPLS-TP PW Lock Instruct and Loopback Overview

The lock instruct and loopback capability for MPLS-TP PWs includes the ability to:

- administratively lock a spoke-SDP with MPLS-TP identifiers
- divert traffic to and from an external device connected to a SAP
- create a data path loopback on the corresponding PW at a downstream S-PE or T-PE that was not originally bound to the spoke-SDP being tested
- forward test traffic from an external test generator into an administratively locked PW, while simultaneously blocking the forwarding of user service traffic

MPLS-TP provides the ability to conduct test service throughput for PWs, using lock instruct messages and loopback configuration. To conduct a service throughput test, you can apply an administrative lock at each end of the PW. This creates a test service that contains the SAP connected to the external device. Lock request messaging is not supported. You can also configure a MEP to send a lock instruct message to the far-end MEP. The lock instruct message is carried in a G-ACh on Channel 0x0026. A lock can be applied using the CLI or NMS. The forwarding state of the PW can be either active or standby.

After locking a PW, you can put it into loopback mode (for two-way tests) so the ingress data path in the forward direction is cross-connected to the egress data path in the reverse direction of the PW. This is accomplished by configuring the source MEP to send a loopback request to an intermediate MIP or MEP. A PW loopback is created at the PW level, so everything under the PW label is looped back. This distinguishes a PW loopback from a service loopback, where only the native service packets are looped back. The loopback is also configured through CLI or NMS.

The following MPLS-TP lock instruct and loopback functionality is supported:

- An MPLS-TP loopback can be created for an Epipe, Cpipe or Apipe VLL.
- Test traffic can be inserted at an Epipe, Cpipe or Apipe VLL endpoint or at an Epipe spoke-sdp termination on a VPLS interface.

### 2.6.3.2 Lock PW Endpoint Model

You can administratively lock a spoke-SDP by locking the host service using the **admin-lock** parameter of the **tools** command. The following conditions and constraints apply:

- Both ends of a PW or MS-PW represented by a spoke-SDP must be administratively locked.
- Test traffic can be injected into the spoke-SDP using a SAP defined within a test service. The test service must be identified in the **tools** command at one end of the locked PW.
- All traffic is forwarded to and from the test SAP defined in the test service, which must be of a type that is compatible with the spoke-SDP.
- Traffic to and from a non-test SAP is dropped. If no test SAP is defined, all traffic received on the spoke-SDP is dropped, and all traffic received on the paired SAP is also dropped.
- If a spoke-SDP is administratively locked, it is treated as operationally down. If a VLL SAP is paired with a spoke-SDP that is administratively locked, the SAP OAM treats this as if the spoke-SDP is operationally down.

- If a VPLS interface is paired to a spoke-SDP that is administratively locked, the L2 interface is taken down locally.
- Control-channel-status must be shutdown prior to administratively locking a spoke-SDP.

### 2.6.3.3 PW Redundancy and Lock Instruct and Loopback

It is possible to apply an administrative lock and loopback to one or more spoke-SDPs within a redundant set. That is, it is possible to move a spoke-SDP from an existing endpoint to a test service. When an administrative lock is applied to a spoke-SDP, it becomes operationally down and cannot send or receive traffic from the normal service SAP or spoke interface. If the lock is applied to all the spoke-SDPs in a service, all the spoke-SDPs will become operationally down.

### 2.6.3.4 Configuring a Test SAP for an MPLS-TP PW

A test SAP is configured under a unique test service type. This looks similar to a normal service context, but will normally only contain a SAP configuration:

```
config
service
  epipe <service-id> [test] [create]
    [no] sap <sap-id>
    [no] shutdown
  [no] shutdown
config
service
  apipe <service-id> [vc-type {atm-vcc | atm-sdu | atm-vpc | atm-cell}]
    [test] [create]
    [no] sap <sap-id>
    [no] shutdown
  [no] shutdown
config
service
  cpipe <service-id> [vc-type {satop-e1 | satop-t1 | cesopsn | cesopsncas}]
    [test] [create]
    [no] sap <sap-id>
    [no] shutdown
  [no] shutdown
```

You can define test SAPs appropriate to any service or PW type supported by MPLS-TP, including an Apipe, Cpipe or Epipe. The following test SAP types are supported:

- Ethernet NULL, 1q, Q-in-Q
- ATM VC, VP, VT, and so on

- TDM E1, E3, DS0, DS3, and so on

The following constraints and conditions apply:

- Up to a maximum of 16 test services can be configured per system.
- It is possible to configure access ingress and access egress QoS policies on a test SAP, as well as any other applicable SAP-specific commands and overrides.
- Vc-switching and spoke-SDP are blocked for services configured under the test context.
- The **test** keyword is mutually exclusive with vc-switching and customer.
- Valid commands under a compatible test service context do not need to be blocked just because the service is a test service.

### 2.6.3.5 Configuring an Administrative Lock

An administrative lock is configured on a spoke-SDP using the **admin-lock** option of the **tools perform** command, as follows:

```
tools
  perform
    service-id <svc-id>
      admin-lock
        pw
          sdp <sdp-id> admin-lock [test-svc-id <id>]
```

The following conditions and constraints apply for configuring an administrative lock:

- The lock can be configured either on a spoke-SDP that is bound to a SAP, another spoke-SDP or a VPLS interface.
- The lock is only allowed if a PW path ID is defined (for example, for static PWs with MPLS-TP identifiers).
- The lock cannot be configured on spoke-SDPs that are an Inter-Chassis Backup (ICB) or if the vc-switching keyword is present.
- The control-channel-status must be shutdown. The operator should also shutdown control-channel-status on spoke-SDPs belonging to an MS-PW at an S-PE whose far ends are administratively locked at its T-PEs. This should be enforced throughout the network management if using the 5620 SAM.
- When enabled, all traffic on the spoke-SDP is sent to and from a paired SAP that has the **test** keyword present, if such a SAP exists in the X endpoint (see [Pseudowire Redundancy Service Models](#)). Otherwise, all traffic to and from the paired SAP is dropped.

- The lock can be configured at a spoke-SDP that is bound to a VLL SAP or a VPLS interface.
- The **test-svc-id** parameter refers to the test service that should be used to inject test traffic into the service. The test service must be of a compatible type to the existing spoke-SDP under test (see [Table 9](#)).
- If the **test-svc-id** parameter is not configured on an admin-locked spoke-SDP, user traffic is blocked on the spoke-SDP.

The service manager should treat an administrative lock as a fault from the perspective of a paired SAP that is not a test SAP. This will cause the appropriate SAP OAM fault indication.

[Table 9](#) maps supported real services to their corresponding test services.

**Table 9 Mapping of Real Services to Test Service Types**

| Service  | Test Service |
|----------|--------------|
| CPIPE    | CPIPE        |
| EPIPE    | EPIPE        |
| APIPE    | APIPE        |
| VPLS     | EPIPE        |
| PBB VPLS | EPIPE        |

### 2.6.3.6 Configuring a Loopback

If a loopback is configured on a spoke-SDP, all traffic on the ingress direction of the spoke-sdp and associated with the ingress vc-label is forwarded to the egress direction of the spoke-SDP. A loopback may be configured at either a T-PE or an S-PE. It is recommended that an administrative lock is configured before configuring the loopback on a spoke-SDP. This is enforced by the NMS.

A data path loopback is configured using a **tools perform** command, as follows:

```
tools
  perform
    service-id <svc-id>
    loopback
      pw
        sdp <sdp-id>:<vc-id> {start | stop}
```

The following constraints and conditions apply for PW loopback configuration:

- The spoke-SDP cannot be an ICB or be bound to a VPLS interface.
- A PW path ID must be configured, that is, the spoke-SDP must be static and use MPLS-TP identifiers.
- The spoke-SDP must be bound to a VLL mate SAP or another spoke-SDP that is not an ICB.
- The control-channel-status must be shutdown.
- The following are disabled on a spoke-SDP for which a loopback is configured:
  - Filters
  - PW shaping
- Only network port QoS is supported.

## 2.6.4 Switching Static MPLS-TP to Dynamic T-LDP Signaled PWs

Some use cases for MPLS-TP require an MPLS-TP based aggregation network and an IP-based core network to interoperate, so providing the seamless transport of packet services across static MPLS-TP and dynamically signaled domains using an MS-PW. In this environment, end-to-end VCCV Ping and VCCV Trace may be used on the MS-PW, as illustrated in [Figure 13](#).

**Figure 13 Static - Dynamic PW Switching with MPLS-TP**

Services are backhauled from the static MPLS-TP network on the left to the dynamic IP/MPLS network on the right. The router acts as an S-PE interconnecting the static and dynamic domains.

The router implementation supports such use cases through the ability to mate a static MPLS-TP spoke SDP, with a defined *pw-path-id*, to a FEC128 spoke SDP. The dynamically signaled spoke SDP must be MPLS; GRE PWs are not supported, but the T-LDP signaled PW can use any supported MPLS tunnel type (for example, LDP, RSVP-TE, static, BGP). The control-word must be enabled on both mate spoke SDPs.

Mapping of control channel status signaling to and from T-LDP status signaling at the router S-PE is also supported.

The use of VCCV Ping and VCCV Trace on an MS-PW composed of a mix of static MPLS-TP and dynamic FEC128 segments is described in more detail in the 7450 ESS, 7750 SR, 7950 XRS, and VSR OAM and Diagnostics Guide.

---

## 2.7 VCCV BFD support for VLL, Spoke-SDP Termination on IES and VPRN, and VPLS Services

This section provides information about VCCV BFD support for VLL, spoke-SDP Termination on IES and VPRN, and VPLS Services. VCCV BFD is supported on the 7450 ESS and 7750 SR only.

### 2.7.1 VCCV BFD Support

The SR OS supports RFC 5885, which specifies a method for carrying BFD in a pseudowire-associated channel. This enables BFD to monitor the pseudowire between its terminating PEs, regardless of how many P routers or switching PEs the pseudowire may traverse. This makes it possible for faults that are local to individual pseudowires to be detected, whether or not they also affect forwarding for other pseudowires, LSPs, or IP packets. VCCV BFD is ideal for monitoring specific high-value services, where detecting forwarding failures (and potentially restoring from them) in the minimal amount of time is critical.

VCCV BFD is supported on VLL services using T-LDP spoke-SDPs or BGP VPWS. It is supported for Apipe, Cpipe, Epipe, Fpipe, and lpipe VLL services.

VCCV BFD is supported on IES/VPRN services with T-LDP spoke -SDP termination (for Epipes and lpipes).

VCCV BFD is supported on LDP- and BGP-signaled pseudowires, and on pseudowires with statically configured labels, whether signaling is off or on for the SDP. VCCV BFD is not supported on MPLS-TP pseudowires.

VCCV BFD is supported on VPLS services (both spoke-SDPs and mesh SDPs). VCCV BFD is configured by:

- configuring generic BFD session parameters in a BFD template
- applying the BFD template to a spoke-SDP or pseudowire-template binding, using the **bfd-template** *template\_name* command
- enabling the template on that spoke-SDP, mesh SDP, or pseudowire-template binding using the **bfd-enable** command

---

## 2.7.2 VCCV BFD Encapsulation on a Pseudowire

The SR OS supports IP/UDP encapsulation for BFD. With this encapsulation type, the UDP headers are included on the BFD packet. IP/UDP encapsulation is supported for pseudowires that use router alert (VCCV Type 2), and for pseudowires with a control word (VCCV Type 1). In the control word case, the IPv4 channel (channel type 0x0021) is used. On the node, the destination IPv4 address is fixed at 127.0.0.1 and the source address is 127.0.0.2.

VCCV BFD sessions run end-to-end on a switched pseudowire. They do not terminate on an intermediate S-PE; therefore, the TTL of the pseudowire label on VCCV BFD packets is always set to 255 to ensure that the packets reach the far-end T-PE of an MS-PW.

## 2.7.3 BFD Session Operation

BFD packets flow along the full length of a PW, from T-PE to T-PE. Since they are not intercepted at an S-PE, single-hop initialization procedures are used.

A single BFD session exists per pseudowire.

BFD runs in asynchronous mode.

BFD operates as a simple connectivity check on a pseudowire. The BFD session state is reflected in the MIBs and in the **show>service id>sdp>vccv-bfd session** command. Therefore, BFD operates in a similar manner to other proactive OAM tools, such as SAA with VCCV Ping. BFD is not used to change the operation state of the pseudowire or to modify pseudowire redundancy. Mapping the BFD state to SAP OAM is not supported.

VCCV BFD runs in software with a minimum supported timer interval of 1 s.

BFD is only used for fault detection. While RFC 5885 provides a mode in which VCCV BFD can be used to signal pseudowire status, this mode is only applicable for pseudowires that have no other status signaling mechanism in use. LDP status and static pseudowire status signaling always take precedence over BFD-signaled PW status, and BFD-signaled pseudowire status is not used on pseudowires that use LDP status or static pseudowire status signaling mechanisms.

## 2.7.4 Configuring VCCV BFD

Generic BFD session parameters are configured for VCCV using the **bfd-template** command, in the **config>router>bfd** context. However, there are some restrictions.

For VCCV, the BFD session cannot terminate on the CPM network processor. Therefore, an error is generated if the user tries to bind a BFD template using the **type cpm-np** command within the **config>router>bfd>bfd-template** context.

As well, the minimum supported value for the **transmit-interval** and **receive-interval** commands when BFD is used for VCCV-BFD is 1s. Attempting to bind a BFD template with any unsupported transmit or receive interval will generate an error.

Finally, attempting to commit changes to a BFD template that is already bound to a pseudowire where the new values are invalid for VCCV BFD will result in an error.

If the preceding BFD timer values are changed in a specified template, any BFD sessions on pseudowires to which that template is bound will try to renegotiate their timers to the new values.

Commands within the BFD-template use a **begin-commit** model. To edit any value within the BFD template, a **begin** command needs to be executed after the template context has been entered. However, a value will still be stored temporarily in the template-module until the **commit** command is issued. When the **commit** is issued, values will be used by other modules such as the MPLS-TP module and BFD module.

For pseudowires where the pseudowire template does not apply, a named BFD template is configured on the spoke-SDP using the **config service [epipe | cpipe | apipe | fpipe | ipipe] spoke-sdp bfd-template name** command, then enabled using the **config service [epipe | cpipe | apipe | fpipe | ipipe] spoke-sdp bfd-enable** command. For example, LDP-signaled spoke-SDPs for a VLL service that uses the pseudowire ID FEC (FEC128) or spoke-SDPs with static pseudowire labels with or without MPLS-TP identifiers.

Configuring and enabling a BFD template on a static pseudowire already configured with MPLS-TP identifiers (that is, with a pw-path-id) or on a spoke-SDP with a configured pw-path-id is not supported. Likewise, if a BFD template is configured and enabled on a spoke-SDP, a pw-path-id cannot be configured on the spoke-SDP.

The **bfd-enable** command is blocked on a spoke-SDP configured with VC-switching. This is because VCCV BFD always operates end-to-end on an MS-pseudowire. It is not possible to extract VCCV BFD packets at the S-PE.

For IES and VPRN spoke-SDP termination where the pseudowire template does not apply (that is, where the spoke-SDP is signaled with LDP and uses the pseudowire ID FEC (FEC128)), the BFD template is configured using the **config service ies | vprn if spoke-sdp bfd-template** *name* command, then enabled using the **config service ies | vprn if spoke-sdp bfd-enable** command.

For H-VPLS, where the pseudowire template does not apply (that is, LDP-VPLS spoke and mesh SDPs that use the pseudowire ID FEC(FEC128)) the BFD template is configured using the **config service vpls spoke-sdp bfd-name** *name* command or the **config service vpls mesh-sdp bfd-name** *name* command. VCCV BFD is then enabled with the bfd-enable command under the VPLS spoke-SDP or mesh-SDP context.

Pseudowires where the pseudowire template does apply and that support VCCV BFD are as follows:

- BGP-AD, which is signaled using the Generalized pseudowire ID FEC (FEC129) with Attachment Individual Identifier (All) type I
- BGP VPLS
- BGP VPWS

For these pseudowire types, a named BFD template is configured and enabled from the pseudowire template binding context.

For BGP VPWS, the BFD template is configured using the **config service epipe bgp pw-template-binding bfd-template** *name* command, then enabled using the **config service epipe bgp pw-template-binding bfd-enable** command.

## 2.8 Pseudowire Switching

The pseudowire switching feature provides the user with the ability to create a VLL service by cross-connecting two spoke-SDPs. This feature allows the scaling of VLL and VPLS services in a large network in which the otherwise full mesh of PE devices would require thousands of Targeted LDP (T-LDP) sessions per PE node.

Services with one SAP and one spoke-SDP are created normally on the PE; however, the target destination of the SDP is the pseudowire switching node instead of what is normally the remote PE. Also, the user configures a VLL service on the pseudowire switching node using the two SDPs.

The pseudowire switching node acts in a passive role with respect to signaling of the pseudowires. It waits until one or both of the PEs sends the label mapping message before relaying it to the other PE. This is because it needs to pass the interface parameters of each PE to the other.

A pseudowire switching point TLV is inserted by the switching pseudowire to record its system address when relaying the label mapping message. This TLV is useful in a few situations:

- It allows for troubleshooting of the path of the pseudowire especially if multiple pseudowire switching points exist between the two PEs.
- It helps in loop detection of the T-LDP signaling messages where a switching point would receive back a label mapping message it had already relayed.
- The switching point TLV is inserted in pseudowire status notification messages when they are sent end-to-end or from a pseudowire switching node toward a destination PE.

Pseudowire OAM is supported for the manual switching pseudowires and allows the pseudowire switching node to relay end-to-end pseudowire status notification messages between the two PEs. The pseudowire switching node can generate a pseudowire status and send it to one or both of the PEs by including its system address in the pseudowire switching point TLV. This allows a PE to identify the origin of the pseudowire status notification message.

In the following example, the user configures a regular Epipe VLL service PE1 and PE2. These services each consist of a SAP and a spoke-SDP. However, the target destination of the SDP is not the remote PE, but the pseudowire switching node. Also, the user configures an Epipe VLL service on the pseudowire switching node using the two SDPs.

```
|7450 ESS, 7750 SR, and 7950 XRS PE1 (Epipe)|---sdp 2:10---|7450 ESS, 7750 SR, and  
7950 XRS PW SW (Epipe)|---sdp 7:15---|7450 ESS, 7750 SR, and 7950 XRS PE2 (Epipe)|
```

---

Configuration examples are in [Configuring Two VLL Paths Terminating on T-PE2](#).

## 2.8.1 Pseudowire Switching with Protection

Pseudowire switching scales VLL and VPLS services over a multi-area network by removing the need for a full mesh of targeted LDP sessions between PE nodes.

[Figure 14](#) shows the use of pseudowire redundancy to provide a scalable and resilient VLL service across multiple IGP areas in a provider network.

In the network in [Figure 14](#), PE nodes act as masters and pseudowire switching nodes act as slaves for the purpose of pseudowire signaling. A switching node will need to pass the SAP interface parameters of each PE to the other PEs. T-PE1 sends a label mapping message for the Layer 2 FEC to the peer pseudowire switching node; for example, S-PE1. The label mapping message will include the SAP interface parameters, such as MTU, in the label mapping message. S-PE1 checks the FEC against the local information and, if a match exists, appends the optional pseudowire switching point TLV to the FEC TLV in which it records its system address. T-PE1 then relays the label mapping message to S-PE2. S-PE2 performs similar operations and forwards a label mapping message to T-PE2.

The same procedures are followed for the label mapping message in the reverse direction; for example, from T-PE2 to T-PE1. S-PE1 and S-PE2 will make the spoke-SDP cross-connect only when both directions of the pseudowire have been signaled and matched.

**Figure 14 VLL Resilience with Pseudowire Redundancy and Switching**

OSSG114

The pseudowire switching TLV is useful in a few situations. First, it allows for troubleshooting of the path of the pseudowire, especially if multiple pseudowire switching points exist between the two T-PE nodes. Second, it helps in loop detection of the T-LDP signaling messages where a switching point receives back a label mapping message that the point already relayed. Finally, it can be inserted in pseudowire status messages when they are sent from a pseudowire switching node toward a destination PE.

Pseudowire status messages can be generated by the T-PE nodes and/or the S-PE nodes. Pseudowire status messages received by a switching node are processed, and passed on to the next hop. An S-PE node appends the optional pseudowire switching TLV, with the S-PEs system address added to it, to the FEC in the pseudowire status notification message, only if that S-PE originated the message or the message was received with the TLV in it. Otherwise, the message was originated by a T-PE node and the S-PE should process and pass the message without changes, except for the VC-ID value in the FEC TLV.

## 2.8.2 Pseudowire Switching Behavior

In the network in [Figure 14](#), PE nodes act as masters and pseudowire switching nodes act as slaves for the purpose of pseudowire signaling. This is because a switching node will need to pass the SAP interface parameters of each PE to the other. T-PE1 sends a label mapping message for the Layer 2 FEC to the peer pseudowire switching node; for example, S-PE1. It will include the SAP interface parameters, such as MTU, in the label mapping message. S-PE1 checks the FEC against the local information and, if a match exists, appends the optional pseudowire switching point TLV to the FEC TLV in which it records its system address. T-PE1 then relays the label mapping message to S-PE2. S-PE2 performs similar operation and forwards a label mapping message to T-PE2.

The same procedures are followed for the label mapping message in the reverse direction; for example, from T-PE2 to T-PE1. S-PE1 and S-PE2 will affect the spoke-SDP cross-connect only when both directions of the pseudowire have been signaled and matched.

Pseudowire status messages can be generated by the T-PE nodes and/or the S-PE nodes. Pseudowire status messages received by a switching node are processed, then passed on to the next hop. An S-PE node appends the optional pseudowire switching TLV, with its system address added to it, to the FEC in the pseudowire status notification message, only if it originated the message or the message was received with the TLV in it. Otherwise, the message was originated by a T-PE node and the S-PE should process and pass the message without changes, except for the VC-ID value in the FEC TLV.

The merging of the received T-LDP status notification message and the local status for the spoke-SDPs from the service manager at a PE complies with the following rules:

- When the local status for both spoke-SDPs is up, the S-PE passes any received SAP or SDP binding generated status notification message unchanged; for example, the status notification TLV is unchanged but the VC-ID in the FEC TLV is set to value of the pseudowire segment to the next hop.
- When the local operational status for any of the spokes is down, the S-PE always sends an SDP-binding down status bits regardless of whether the received status bits from the remote node indicated SAP up or down or SDP-binding up or down.

### 2.8.2.1 Pseudowire Switching TLV

The format of the pseudowire switching TLV is as follows:

[illegible]

PW sw TLV Length — Specifies the total length of all the following pseudowire switching point TLV fields in octets

Type — Encodes how the Value field is to be interpreted

**Length** — Specifies the length of the Value field in octets

Value — Octet string of Length octets that encodes information to be interpreted as specified by the Type field

### 2.8.2.2 Pseudowire Switching Point Sub-TLVs

Following is information specific to pseudowire switching point sub-TLVs:

- Pseudowire ID of last pseudowire segment traversed — Sub-TLV type that contains a pseudowire ID in the format of the pseudowire ID
- Pseudowire switching point description string — An optional description text string of up to 80 characters
- IP address of pseudowire switching point — An options sub-TLV; IP V4 or V6 address of the pseudowire switching point.
- MH VCCV capability indication

### 2.8.3 Static-to-Dynamic Pseudowire Switching

When one segment of the pseudowire cross-connect at the S-PE is static while the other is signaled using T-LDP, the S-PE operates much like a T-PE from a signaling perspective and as an S-PE from a data plane perspective.

The S-PE signals a label mapping message as soon as the local configuration is complete. The control word C-bit field in the pseudowire FEC is set to the value configured on the static spoke-SDP.

When the label mapping for the egress direction is also received from the T-LDP peer, and the information in the FEC matches that of the local configuration, the static-to-dynamic cross-connect is created.

It is possible that end nodes of a static pseudowire segment can be misconfigured. In this case, an S-PE or T-PE node may be receiving packets with the wrong encapsulation, so that an invalid payload could be forwarded over the pseudowire or the SAP, respectively. Also, if the S-PE or T-PE node is expecting the control word in the packet encapsulation and the received packet comes with no control word, but the first nibble below the label stack is 0x0001, the packet may be mistaken for a VCCV OAM packet and may be forwarded to the CPM. In that case, the CPM will perform a check of the IP header fields such as version, IP header length, and checksum. If any of these fail the VCCV packet will be discarded.

## 2.8.4 Ingress VLAN Swapping

This feature is supported on VPLS and VLL services where the end-to-end solution is built using two node solutions (requiring SDP connections between the nodes).

In VLAN swapping, only the VLAN ID value is copied to the inner VLAN position. The Ethertype of the inner tag will be preserved and all consecutive nodes will work with that value. Similarly, the dot1p bits value of outer tag will not be preserved.

[Figure 15](#) describes a network where, at user-access side (DSLAM-facing SAPs), every subscriber is represented by several QinQ SAPs with inner-tag encoding service and outer tag encoding subscriber (DSL line). At the aggregation side (BRAS- or PE-facing SAPs) every subscriber is represented by DSL line number (inner VLAN tag) and DSLAM (outer VLAN tag). The effective operation on the VLAN tag is to drop the inner tag at the access side and push another tag at the aggregation side.

**Figure 15 Ingress VLAN Swapping**

Fig\_36

### 2.8.4.1 Ingress VLAN Translation

Figure 16 indicates an application where different circuits are aggregated in the VPLS-based network. The access side is represented by an explicit dot1q encapsulated SAP. Because the VLAN ID is port specific, those connected to different ports might have the same VLAN. The aggregation side is aggregated on the same port; therefore, a unique VLAN ID is required.

**Figure 16 Ingress VLAN Translation**

OSSG146

## 2.8.5 Pseudowire Redundancy

Pseudowire redundancy provides the ability to protect a pseudowire with a pre-provisioned secondary standby pseudowire and to switch traffic over to that secondary standby pseudowire in case of a SAP and/or network failure condition. Normally, pseudowires are redundant by the virtue of the SDP redundancy mechanism. For instance, if the SDP is an RSVP LSP and is protected by a secondary standby path and/or by Fast-Reroute paths (FRR), the pseudowire is also protected. However, there are two applications in which SDP redundancy does not protect the end-to-end pseudowire path:

- There are two different destination PE nodes for the same VLL service. The main use case is the provision of dual-homing of a CPE or access node to two PE nodes located in different POPs. The other use case is the provision of a pair of active and standby BRAS nodes, or active and standby links to the same BRAS node, to provide service resiliency to broadband service subscribers.
- The pseudowire path is switched in the middle of the network and the pseudowire switching node fails.

Pseudowire and VPLS link redundancy extends link-level resiliency for pseudowires and VPLS to protect critical network paths against physical link or node failures. These innovations enable the virtualization of redundant paths across the metro or core IP network to provide seamless and transparent fail-over for point-to-point and multi-point connections and services. When deployed with multi-chassis LAG, the path for return traffic is maintained through the pseudowire or VPLS switchover, which enables carriers to deliver “always on” services across their IP/MPLS networks.

## 2.8.6 Dynamic Multi-Segment Pseudowire Routing

### 2.8.6.1 Overview

Dynamic Multi-Segment Pseudowire Routing (Dynamic MS-PWs) enable a complete multi-segment pseudowire to be established, while only requiring per-pseudowire configuration on the T-PEs. No per-pseudowire configuration is required on the S-PEs. End-to-end signaling of the MS-PW is achieved using T-LDP, while multi-protocol BGP is used to advertise the T-PEs, allowing dynamic routing of the MS-PW through the intervening network of S-PEs. Dynamic multi-segment pseudowires are described in the IETF Draft *draft-ietf-pwe3-dynamic-ms-pw-13.txt*.

Figure 17 shows the operation of dynamic MS-PWs.

**Figure 17** Dynamic MS-PW Overview

OSSG572

The FEC 129 All Type 2 structure depicted in [Figure 18](#) is used to identify each individual pseudowire endpoint:

**Figure 18** MS-PW Addressing using FEC129 All Type 2

OSSG573

A 4-byte global-id followed by a 4-byte prefix and a 4-byte attachment circuit ID are used to provide for hierarchical, independent allocation of addresses on a per-service provider network basis. The first 8 bytes (global-id + prefix) may be used to identify each individual T-PE or S-PE as a loopback Layer 2 address.

The All type is mapped into the MS-PW BGP NLRI (a BGP AFI of L2VPN, and SAFI for network layer reachability information for dynamic MS-PWs). As soon as a new T- PE is configured with a local prefix address of global id: prefix, pseudowire routing will proceed to advertise this new address to all the other T- PEs and S-PEs in the network, as depicted in [Figure 19](#).

**Figure 19 Advertisement of PE Addresses by PW Routing**

In step 1 of [Figure 19](#), a new T-PE (T-PE2) is configured with a local prefix.

Next, in steps 2 to 5, MP-BGP will use the NLRI for the MS-PW routing SAFI to advertise the location of the new T-PE to all the other PEs in the network. Alternatively, static routes may be configured on a per T-PE/S-PE basis to accommodate non-BGP PEs in the solution.

As a result, pseudowire routing tables for all the S-PEs and remote T-PEs are populated with the next hop to be used to reach T-PE2.

VLL services can then be established, as illustrated in [Figure 20](#).

**Figure 20** Signaling of Dynamic MS-PWs using T-LDP

OSSG575

In step 1 and 1' of [Figure 20](#) the T-PEs are configured with the local and remote endpoint information: Source AII (SAII) and Target AII (TAII). On the router, the AIs are locally configured for each spoke-SDP, according to the model shown in [Figure 21](#). Therefore the router provides for a flexible mapping of the AII to SAP. That is, the values used for the AII are through local configuration, and it is the context of the spoke-SDP that binds it to a specific SAP.

**Figure 21** Mapping of AII to SAP

OSSG576

Before T-LDP signaling starts, the two T-PEs decide on an active and passive relationship using the highest All (comparing the configured SAll and TAll) or the configured precedence. Next, the active T-PE (in the IETF draft, this is referred to as the source T-PE or ST-PE) checks the PW routing table to determine the next signaling hop for the configured TAll using the longest match between the TAll and the entries in the PW routing table.

This signaling hop is then used to choose the T-LDP session to the chosen next-hop S-PE. Signaling proceeds through each subsequent S-PE using similar matching procedures to determine the next signaling hop. Otherwise, if a subsequent S-PE does not support dynamic MS-PW routing, so uses a statically configured PW segment, the signaling of individual segments follows the procedures already implemented in the PW Switching feature.

BGP can install a PW All route in the PW routing table with ECMP next-hops. However, when LDP needs to signal a PW with matching TAll, it will choose only one next-hop from the available ECMP next-hops. PW routing supports up to 4 ECMP paths for each destination.

The signaling of the forward path ends when the PE matches the TAll in the label mapping message with the SAll of a spoke-SDP bound to a local SAP. The signaling in the reverse direction can now be initiated, which follows the entries installed in the forward path. The PW routing tables are not consulted for the reverse path. This ensures that the reverse direction of the PW follows exactly the same set of S-PEs as the forward direction.

This solution can be used in either a MAN-WAN environment or in an Inter-AS/Inter-Provider environment as depicted in [Figure 22](#).

**Figure 22 VLL Using Dynamic MS-PWs, Inter-AS Scenario**

OSSG577

Data plane forwarding at the S-PEs uses pseudowire service label switching, as per the pseudowire switching feature.

## 2.8.6.2 Pseudowire Routing

Each S-PE and T-PE has a pseudowire routing table that contains a reference to the T-LDP session to use to signal to a set of next hop S-PEs to reach a specific T-PE (or the T-PE if that is the next hop). For VLLs, this table contains aggregated All Type 2 FECs and may be populated with routes that are learned through MP-BGP or that are statically configured.

MP-BGP is used to automatically distribute T-PE prefixes using the new MS-PW NLRI, or static routes can be used. The MS-PW NLRI is composed of a Length, an 8-byte route distinguisher (RD), a 4-byte global-id, a 4-byte local prefix, and (optionally) a 4-byte AC-ID. Support for the MS-PW address family is configured in CLI under the **config>router>bgp>family ms-pw** context.

MS-PW routing parameters are configured in the **config>service>pw-routing** context.

To enable support for dynamic MS-PWs on a 7750 SR, 7450 ESS, or 7950 XRS node to be used as a T-PE or S-PE, a single, globally unique, S-PE ID, known as the S-PE address, is first configured under **config>service>pw-routing** on each node to be used as a T-PE or S-PE. The S-PE address has the format global-id:prefix. It is not possible to configure any local prefixes used for pseudowire routing or to configure spoke-SDPs using dynamic MS-PWs at a T-PE unless an S-PE address has already been configured. The S-PE address is used as the address of a node used to populate the switching point TLV in the LDP label mapping message and the pseudowire status notification sent for faults at an S-PE.

Each T-PE is also configured with the following parameters:

- Global-id — This is a 4-byte identifier that uniquely identifies an operator or the local network.
- Local prefix — One or more local (Layer 2) prefixes (up to a maximum of 16), which are formatted in the style of a 4-octet IPv4 address. A local prefix identifies a T-PE or S-PE in the PW routing domain.
- For each local prefix, at least one 8-byte RD can be configured. It is also possible to configure an optional BGP community attribute.

For each local prefix, BGP then advertises each global-id/prefix tuple and unique RD and community pseudowire using the MS-PW NLRI, based on the aggregated FEC129 All Type 2 and the Layer 2 VPN/PW routing AFI/SAFI 25/6, to each T-PE/ S-PE that is a T-LDP neighbor, subject to local BGP policies.

The dynamic advertisement of each of these pseudowire routes is enabled for each prefix and RD using the **advertise-bgp** command.

An export policy is also required in order to export MS-PW routes in MP-BGP. This can be done using a default policy, such as the following:

```
*A:lin-123>config>router>policy-options# info
-----
    policy-statement "ms-pw"
      default-action accept
      exit
    exit
-----
```

However, this would export all routes. A recommended choice is to enable filtering per-family, as follows:

```
*A:lin-123>config>router>policy-options# info
-----
    policy-statement "to-mspw"
      entry 1
        from
          family ms-pw
        exit
        action accept
        exit
      exit
    exit
-----
```

The following command is then added in the **config>router>bgp** context:

```
export "to-mspw"
```

Local-preference for IBGP and BGP communities can be configured under such a policy.

### 2.8.6.2.1 Static Routing

As well as support for BGP routing, static MS-PW routes may also be configured using the **config services pw-routing static-route** command. Each static route comprises the target T-PE global-id and prefix, and the IP address of the T-LDP session to the next hop S-PE or T-PE that should be used.

If a static route is set to 0, this represents the default route. If a static route exists to a specified T-PE, this default route is used in preference to any BGP route that may exist.

### 2.8.6.2.2 Explicit Paths

A set of default explicit routes to a remote T-PE or S-PE prefix may be configured on a T-PE under **config>services>pw-routing** using the **path name** command. Explicit paths are used to populate the explicit route TLV used by MS-PW T-LDP signaling. Only strict (fully qualified) explicit paths are supported.

It is possible to configure explicit paths independently of the configuration of BGP or static routing.

### 2.8.6.3 Configuring VLLs using Dynamic MS-PWs

One or more spoke-SDPs may be configured for distributed Epipe VLL services. Dynamic MS-PWs use FEC129 (also known as the Generalized ID FEC) with Attachment Individual Identifier (All) Type 2 to identify the pseudowire, as opposed to FEC128 (also known as the PW ID FEC) used for traditional single segment pseudowires and for pseudowire switching. FEC129 spoke-SDPs are configured under the **spoke-sdp-fec** command in the CLI.

FEC129 All Type 2 uses a Source Attachment Individual Identifier (SAII) and a Target Attachment Individual Identifier (TAII) to identify the end of a pseudowire at the T-PE. The SAII identifies the local end, while the TAI identifies the remote end. The SAII and TAI are each structured as follows:

- Global-id — This is a 4-byte identifier that uniquely identifies an operator or the local network.
- Prefix — A 4-byte prefix, which should correspond to one of the local prefixes assigned under pw-routing.
- AC-ID — A 4-byte identifier for the local end of the pseudowire. This should be locally unique within the scope of the global-id:prefix.

#### 2.8.6.3.1 Active/Passive T-PE Selection

Dynamic MS-PWs use single-sided signaling procedures with double-sided configuration; a fully qualified FEC must be configured at both endpoints. That is, one T-PE (the source T-PE, ST-PE) of the MS-PW initiates signaling for the MS-PW, while the other end (the terminating T-PE, TT-PE) passively waits for the label mapping message from the far end. This termination end only responds with a label mapping message to set up the opposite direction of the MS-PW when it receives the label mapping from the ST-PE. By default, the router will determine which T-PE is the ST-PE (the active T-PE) and which is the TT-PE (the passive T-PE) automatically, based on comparing the SAII with the TAI as unsigned integers. The T-PE with

SAll>TAIl assumes the active role. However, it is possible to override this behavior using the signaling {**master** | **auto**} command under **spoke-sdp-fec**. If master is selected at a specified T-PE, that T-PE will assume the active role. If a T-PE is at the endpoint of a spoke-SDP that is bound to an VLL SAP and single-sided auto-configuration is used (see [2.8.6.3.2](#)), then that endpoint is always passive. Therefore, signaling master should only be used when it is known that the far end will assume a passive behavior.

### 2.8.6.3.2 Automatic Endpoint Configuration

Automatic endpoint configuration allows the configuration of an endpoint without specifying the TAIL associated with that **spoke-sdp-fec**. It allows a single-sided provisioning model where an incoming label mapping message with a TAIL that matches the SAll of that spoke-SDP is automatically bound to that endpoint. This is useful in scenarios where a service provider wants to separate service configuration from the service activation phase.

Automatic endpoint configuration is supported for Epipe VLL **spoke-sdp-fec** endpoints bound to a VLL SAP. It is configured using the **spoke-sdp-fec auto-config** command, and excluding the TAIL from the configuration. When auto-configuration is used, the node assumes passive behavior from a point of view of T-LDP signaling (see [2.8.6.3.1](#)). Therefore, the far-end T-PE must be configured as the signaling master for that **spoke-sdp-fec**.

### 2.8.6.3.3 Selecting a Path for an MS-PW

Path selection for signaling occurs in the outbound direction (ST-PE to TT-PE) for an MS-PW. In the TT-PE to ST-PE direction, a label mapping message follows the reverse of the path already taken by the outgoing label mapping.

A node can use explicit paths, static routes, or BGP routes to select the next hop S-PE or T-PE. The order of preference used in selecting these routes is:

1. Explicit Path
2. Static route
3. BGP route

To use an explicit path for an MS-PW, an explicit path must have been configured in the **config>services>pw-routing>path path-name** context. The user must then configure the corresponding **path path-name** under **spoke-sdp-fec**.

If an explicit path name is not configured, the TT-PE or S-PE will perform a longest match lookup for a route (static if it exists, and BGP if not) to the next hop S-PE or T-PE to reach the TAIL.

Pseudowire routing chooses the MS-PW path in terms of the sequence of S-PEs to use to reach a specified T-PE. It does not select the SDP to use on each hop, which is instead determined at signaling time. When a label mapping is sent for a specified pseudowire segment, an LDP SDP will be used to reach the next-hop S-PE/T-PE if such an SDP exists. If not, and an RFC 3107 labeled BGP SDP is available, then that will be used. Otherwise, the label mapping will fail and a label release will be sent.

#### 2.8.6.3.4 Pseudowire Templates

Dynamic MS-PWs support the use of the pseudowire template for specifying generic pseudowire parameters at the T-PE. The pseudowire template to use is configured in the **spoke-sdp-fec>pw-template-bind** *policy-id* context. Dynamic MS-PWs do not support the provisioned SDPs specified in the pseudowire template. Auto-created GRE SDPs are supported with dynamic MS-PWs by creating the PW template used within the **spoke-sdp-fec** with the parameter **auto-gre-sdp**.

#### 2.8.6.4 Pseudowire Redundancy

Pseudowire redundancy is supported on dynamic MS-PWs used for VLLs. It is configured in a similar manner to pseudowire redundancy on VLLs using FEC128, whereby each spoke-sdp-fec within an endpoint is configured with a unique SAIL/ TAIL.

[Figure 23](#) shows the use of pseudowire redundancy.

**Figure 23 Pseudowire Redundancy**

OSSG578

The following is a summary of the key points to consider in using pseudowire redundancy with dynamic MS-PWs:

- Each MS-PW in the redundant set must have a unique SAIL/TAI set and is signaled separately. The primary pseudowire is configured in the **spoke-sdp-fec>primary** context.
- Each MS-PW in the redundant set should use a diverse path (from the point of view of the S-PEs traversed) from every other MS-PW in that set if path diversity is possible in a specific network topology. There are a number of possible ways to achieve this:
  - Configure an explicit path for each MS-PW.
  - Allow BGP routing to automatically determine diverse paths using BGP policies applied to different local prefixes assigned to the primary and standby MS-PWs.
  - Path diversity can be further provided for each primary pseudowire through the use of a BGP RD.

If the primary MS-PW fails, fail-over to a standby MS-PW occurs, as per the normal pseudowire redundancy procedures. A configurable retry timer for the failed primary MS-PW is then started. When the timer expires, attempts to reestablish the primary MS-PW using its original path occur, up to a maximum number of attempts as per the retry count parameter. On successful reestablishment the T-PE may then optionally revert back to the primary MS-PW.

Since the SDP ID is determined dynamically at signaling time, it cannot be used as a tie breaker to choose the primary MS-PW between multiple MS-PWs of the same precedence. The user should, therefore, explicitly configure the precedence values to determine which MS-PW is active in the final selection.

### 2.8.6.5 VCCV OAM for Dynamic MS-PWs

The primary difference between dynamic MS-PWs and those using FEC128 is support for FEC129 All type 2. As in PW Switching, VCCV on dynamic MS-PWs requires the use of the VCCV control word on the pseudowire. Both the `vccv-ping` and `vccv-trace` commands support dynamic MS-PWs.

### 2.8.6.6 VCCV-Ping on Dynamic MS-PWs

VCCV-ping supports the use of FEC129 All type 2 in the target FEC stack of the ping echo request message. The FEC to use in the echo request message is derived in one of two ways: Either the user can specify only the *spoke-sdp-fec-id* of the MS-PW in the **vccv-ping** command, or the user can explicitly specify the SAll and TAll to use.

If the SAll:TAll is entered by the user in the `vccv-ping` command, those values are used for the `vccv-ping` echo request, but their order is reversed before being sent so that they match the order for the downstream FEC element for an S-PE, or the locally configured SAll:TAll for a remote T-PE of that MS-PW. If SAll:TAll is entered as well as the *spoke-sdp-fec-id*, the system will verify the entered values against the values stored in the context for that *spoke-sdp-fec-id*.

Otherwise, if the SAll:TAll to use in the target FEC stack of the `vccv-ping` message is not entered by the user, and if a switching point TLV was previously received in the initial label mapping message for the reverse direction of the MS-PW (with respect to the sending PE), then the SAll:TAll to use in the target FEC stack of the `vccv-ping` echo request message is derived by parsing that switching point TLV based on the user-specified TTL (or a TTL of 255 if none is specified). In this case, the order of the SAll:TAll in the switching point TLV is maintained for the `vccv-ping` echo request message.

If no pseudowire switching point TLV was received, then the SAll:TAll values to use for the `vccv-ping` echo request are derived from the MS-PW context, but their order is reversed before being sent so that they match the order for the downstream FEC element for an S-PE, or the locally configured SAll:TAll for a remote T-PE of that MS-PW.

The use of *spoke-sdp-fec-id* in vccv-ping is only applicable at T-PE nodes, since it is not configured for a specified MS-PW at S-PE nodes.

### 2.8.6.7 VCCV-Trace on Dynamic MS-PWs

The 7750 SR, 7450 ESS, and 7950 XRS support the MS-PW path trace mode of operation for VCCV trace, as per pseudowire switching, but using FEC129 All type 2. As in the case of vccv-ping, the SAll:TAIl used in the VCCV echo request message sent from the T-PE or S-PE from which the VCCV trace command is executed is specified by the user or derived from the context of the MS-PW. The use of *spoke-sdp-fec-id* in vccv-trace is only applicable at T-PE nodes, since it is not configured for a specified MS-PW at S-PE nodes.

## 2.8.7 Example Dynamic MS-PW Configuration

This section describes an example of how to configure Dynamic MS-PWs for a VLL service between a set of Nokia nodes. The network consists of two T-PEs and two nodes, in the role of S-PEs, as shown in the following figure. Each 7750 SR, 7450 ESS, or 7950 XRS peers with its neighbor using LDP and BGP.

**Figure 24** Dynamic MS-PW Example

The example uses BGP to route dynamic MS-PWs and T-LDP to signal them. Therefore, each node must be configured to support the MS-PW address family under BGP, and BGP and LDP peerings must be established between the T-PEs/S-PEs. The appropriate BGP export policies must also be configured.

Next, pseudowire routing must be configured on each node. This includes an S-PE address for every participating node, and one or more local prefixes on the T-PEs. MS-PW paths and static routes may also be configured.

When this routing and signaling infrastructure is established, spoke-sdp-fecs can be configured on each of the T-PEs, as follows:

```

config
  router
    ldp
      targeted-session
        peer 10.20.1.5
      exit
    exit

## 2.8.8 VLL Resilience with Two Destination PE Nodes

Figure 25 shows the application of pseudowire redundancy to provide Ethernet VLL service resilience for broadband service subscribers accessing the broadband service on the service provider BRAS.

**Figure 25 VLL Resilience**

OSSG115

If the Ethernet SAP on PE2 fails, PE2 notifies PE1 of the failure by either withdrawing the primary pseudowire label it advertised or by sending a pseudowire status notification with the code set to indicate a SAP defect. PE1 will receive it and will immediately switch its local SAP to forward over the secondary standby spoke-SDP. To avoid black holing of packets during the switching of the path, PE1 will accept packets received from PE2 on the primary pseudowire while transmitting over the

backup pseudowire. However, in other applications such as those described in [Access Node Resilience Using MC-LAG and Pseudowire Redundancy](#), it will be important to minimize service outage to end users.

When the SAP at PE2 is restored, PE2 updates the new status of the SAP by sending a new label mapping message for the same pseudowire FEC or by sending pseudowire status notification message indicating that the SAP is back up. PE1 then starts a timer and reverts back to the primary at the expiry of the timer. By default, the timer is set to 0, which means PE1 reverts immediately. A special value of the timer (infinity) will mean that PE1 should never revert back to the primary pseudowire.

The behavior of the pseudowire redundancy feature is the same if PE1 detects or is notified of a network failure that brought the spoke-SDP status to operationally down. The following are the events that will cause PE1 to trigger a switchover to the secondary standby pseudowire:

1. T-LDP peer (remote PE) node withdrew the pseudowire label.
2. T-LDP peer signaled a FEC status indicating a pseudowire failure or a remote SAP failure.
3. T-LDP session to peer node times out.
4. SDP binding and VLL service went down as a result of network failure condition such as the SDP to peer node going operationally down.

The SDP type for the primary and secondary pseudowires need not be the same. That is, the user can protect an RSVP-TE based spoke-SDP with an LDP or GRE based one. This provides the ability to route the path of the two pseudowires over different areas of the network. All VLL service types, for example, Apipe, Epipe, Fpipe, and Lpipe, are supported on the 7750 SR.

Nokia routers support the ability to configure multiple secondary standby pseudowire paths. For example, PE1 uses the value of the user-configurable precedence parameter associated with each spoke-SDP to select the next available pseudowire path after the failure of the current active pseudowire (whether it is the primary or one of the secondary pseudowires). The revertive operation always switches the path of the VLL back to the primary pseudowire though. There is no revertive operation between secondary paths, meaning that the path of the VLL will not be switched back to a secondary pseudowire of higher precedence when the latter comes back up again.

Nokia routers support the ability for a user-initiated manual switchover of the VLL path to the primary or any of the secondary, be supported to divert user traffic in case of a planned outage such as in node upgrade procedures.

On the 7750 SR, this application can make use of all types of VLL supported on SR-series routers. However, if a SAP is configured on an MC-LAG instance, only the Epipe service type is allowed.

### 2.8.8.1 Master-Slave Operation

This section describes master-slave pseudowire redundancy. It adds the ability for the remote peer to react to the pseudowire standby status notification, even if only one spoke-SDP terminates on the VLL endpoint on the remote peer, by blocking the transmit (Tx) direction of a VLL spoke-SDP when the far-end PE signals standby. This solution enables the blocking of the Tx direction of a VLL spoke-SDP at both master and slave endpoints when standby is signaled by the master endpoint. This approach satisfies a majority of deployments where bidirectional blocking of the forwarding on a standby spoke-SDP is required.

Figure 26 shows the operation of master-slave pseudowire redundancy. In this scenario, an Epipe service is provided between CE1 and CE2. CE2 is dual-homed to PE2 and PE3; therefore, PE1 is dual-homed to PE2 and PE3 using Epipe spoke-SDPs. The objective of this feature is to ensure that only one pseudowire is used for forwarding in both directions by PE1, PE2, and PE3 in the absence of a native dual homing protocol between CE2 and PE2/PE3, such as MC-LAG. In normal operating conditions (the SAPs on PE2 and PE3 toward CE2 are both up and there are no defects on the ACs to CE2), PE2 and PE3 cannot choose which spoke-SDP to forward on, based on the status of the AC redundancy protocol.

**Figure 26 Master-Slave Pseudowire Redundancy**

al\_0149

Master-slave pseudowire redundancy adds the ability for the remote peer to react to the pseudowire standby status notification, even if only one spoke-SDP terminates on the VLL endpoint on the remote peer. When the CLI command **standby-signaling-slave** is enabled at the spoke-SDP or explicit endpoint level in PE2 and PE3, then any spoke-SDP for which the remote peer signals PW FWD Standby will be blocked in the transmit direction.

This is achieved as follows. The **standby-signaling-master** state is activated on the VLL endpoint in PE1. In this case, a spoke-SDP is blocked in the transmit direction at this master endpoint if it is either in operDown state, or it has lower precedence than the highest precedence spoke-SDP, or the specific peer PE signals one of the following pseudowire status bits:

- Pseudowire not forwarding (0x01)
- SAP (ingress) receive fault (0x02)
- SAP (egress) transmit fault (0x04)
- SDP binding (ingress) receive fault (0x08)
- SDP binding (egress) transmit fault (0x10)

That the specified spoke-SDP has been blocked will be signaled to the LDP peer through the pseudowire status bit (PW FWD Standby (0x20)). This will prevent traffic being sent over this spoke-SDP by the remote peer, but only if that remote peer supports and reacts to pseudowire status notification. Previously, this applied only if the spoke-SDP terminates on an IES, VPRN, or VPLS. However, if standby-signaling-slave is enabled at the remote VLL endpoint, the Tx direction of the spoke-SDP will also be blocked, according to the rules in [Operation of Master-Slave Pseudowire Redundancy with Existing Scenarios](#).

Although master-slave operation provides bidirectional blocking of a standby spoke-SDP during steady-state conditions, it is possible that the Tx directions of more than one slave endpoint can be active for transient periods during a fail-over operation. This is due to slave endpoints transitioning a spoke-SDP from standby to active receiving and/or processing a pseudowire preferential forwarding status message before those endpoints transitioning a spoke-SDP to standby. This transient condition is most likely when a forced switchover is performed, or the relative preferences of the spoke-SDPs are changed, or the active spoke-SDP is shutdown at the master endpoint. During this period, loops of unknown traffic may be observed. Fail-overs due to common network faults that can occur during normal operation, or a failure of connectivity on the path of the spoke-SDP or the SAP, would not result in such loops in the data path.

### 2.8.8.1.1 Interaction with SAP-Specific OAM

If all of the spoke-SDPs bound to a SAP at a slave PE are selected as standby, then this should be treated from a SAP OAM perspective in the same manner as a fault on the service: an SDP binding down or remote SAP down. That is, a fault should be indicated to the service manager. If SAP-specific OAM is enabled toward the CE, such as Ethernet Continuity Check Message (CCM), Ethernet Link Management Interface (E-LMI), or FR LMI, then this should result in the appropriate OAM message being sent on the SAP. This can enable the remote CE to avoid forwarding traffic toward a SAP that will drop it.

Figure 27 shows an example for the case of Ethernet LMI.

**Figure 27 Example of SAP OAM Interaction with Master-Slave Pseudowire Redundancy**

### 2.8.8.1.2 Local Rules at Slave VLL PE

It is not possible to configure a standby-signaling-slave on endpoints or spoke-SDPs that are bound to an IES, VPRN, ICB, or MC-EP, or that are part of an MC-LAG or MC-APS.

If **standby-signaling-slave** is configured on a specific spoke-SDP or explicit endpoint, then the following rules apply. The rules describe the case of several spoke-SDPs in an explicit endpoint. The same rules apply to the case of a single spoke-SDP outside of an endpoint where no endpoint exists:

- Rules for processing endpoint SAP active/standby status bits:
  - Since the SAP in endpoint X is never a part of an MC-LAG/MC-APS instance, a forwarding status of active is always advertised.

- Rules for processing and merging local and received endpoint objects with an up or down operational status:
  1. Endpoint X is operationally up if at least one of its objects is operationally up. It is Down if all of its objects are operationally down.
  2. If all objects in endpoint X did any or all of the following, the node must send status bits of SAP down over all Y endpoint spoke-SDPs:
    - transitioned locally to down state
    - received a SAP down notification via remote T-LDP or via SAP-specific OAM signal
    - received status bits of SDP-binding down
    - received states bits of PW not forwarding
  3. Endpoint Y is operationally up if at least one of its objects is operationally up. It is down if all its objects are operationally down.
  4. If a spoke-SDP in endpoint Y, including the ICB spoke-SDP, transitions locally to down state, the node must send T-LDP SDP-binding down status bits on this spoke-SDP.
  5. If a spoke-SDP in endpoint Y received T-LDP SAP down status bits, and/or T-LDP SDP-binding down status bits, and/or status bits of PW not forwarding, the node saves this status and takes no further action. The saved status is used for selecting the active transmit endpoint object.
  6. If all objects in endpoint Y, or a single spoke-SDP that exists outside of an endpoint (and no endpoint exists), the node must send a SAP down notification on the X endpoint SAP via the SAP-specific OAM signal, if applicable:
    - transitioned locally to down state
    - received status bits of T-LDP SAP down
    - received status bits of T-LDP SDP-binding down
    - received status bits of PW not forwarding
    - received status bits of PW FWD standby
  7. If the peer PE for a specified object in endpoint Y signals PW FWD standby, the spoke-SDP must be blocked in the transmit direction and the spoke-SDP is not eligible for selection by the active transmit selection rules.
  8. If the peer PE for a specified object in endpoint Y does not signal PW FWD standby, then spoke-SDP is eligible for selection.

### 2.8.8.1.3 Operation of Master-Slave Pseudowire Redundancy with Existing Scenarios

This section discusses how master-slave pseudowire redundancy could operate.

## VLL Resilience Path Example

Figure 28 shows VLL resilience path example. An sample configuration follows.

**Figure 28** VLL Resilience

OSSG246

A **revert-time** value of zero (default) means that the VLL path will be switched back to the primary immediately after it comes back up.

```

PE-1
configure service epipe 1
endpoint X
exit
exit
endpoint Y
    revert-time 0
    standby-signaling-master
    exit
    sap 1/1/1:100 endpoint X
    spoke-sdp 1:100 endpoint Y
precedence primary
    spoke-sdp 2:200 endpoint Y
precedence 1
  
```

```

PE-2
configure service epipe 1
    endpoint X
    exit
    sap 2/2/2:200 endpoint X
    spoke-sdp 1:100
    standby-signaling-slave
  
```

```

PE-3
configure service epipe 1
    endpoint X
    exit
    sap 3/3/3:300 endpoint X
    spoke-sdp 2:200
    standby-signaling-slave
  
```

### 2.8.8.1.4 VLL Resilience for a Switched Pseudowire Path

Figure 29 displays VLL resilience for a switched pseudowire path example. A sample configuration follows.

**Figure 29 VLL Resilience with Pseudowire Switching**

```
T-PE-1
configure service epipe 1
  endpoint X
  exit
  endpoint Y
  revert-time 100
  standby-signaling-master
  exit
  sap 1/1/1:100 endpoint X
  spoke-sdp 1:100 endpoint Y
    precedence primary
  spoke-sdp 2:200 endpoint Y
    precedence 1
  spoke-sdp 3:300 endpoint Y
    precedence 1
```

```
T-PE-2
configure service epipe 1
  endpoint X
  exit
  endpoint Y
  revert-time 100
  standby-signaling-slave
  exit
  sap 2/2/2:200 endpoint X
  spoke-sdp 4:400 endpoint Y
    precedence primary
  spoke-sdp 5:500 endpoint Y
    precedence 1
  spoke-sdp 6:600 endpoint Y
    precedence 1
```

```
S-PE-1
```

VC switching indicates a VC cross-connect so that the service manager does not signal the VC label mapping immediately but will put S-PE-1 into passive mode, as follows:

```
configure service epipe 1 vc-switching
  spoke-sdp 1:100
  spoke-sdp 4:400
```

## 2.8.9 Pseudowire SAPs

Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Layer 3 Services Guide: IES and VPRN* for information about how to use pseudowire SAPs with Layer 2 services.

## 2.8.10 Epipe Using BGP-MH Site Support for Ethernet Tunnels

Using Epipe in combination with G.8031 and BGP multi-homing in the same manner as VPLS offers a multi-chassis resiliency option for Epipe services that is a non-learning and non-flooded service. MC-LAG (see [Access Node Resilience Using MC-LAG and Pseudowire Redundancy](#)) offers access node redundancy with active/stand-by links while Ethernet tunnels offer per service redundancy with all active links and active or standby services. G.8031 offers an end-to-end service resiliency for Epipe and VPLS services. BGP-MH site support for Ethernet tunnels offers Ethernet edge resiliency for Epipe services that integrates with MPLS pseudowire redundancy.

[Figure 30](#) shows the BGP-MH site support for Ethernet tunnels, where a G.8031 edge device (A) is configured with two provider edge switches (B and C). G.8031 is configured on the Access devices (A and F). An Epipe endpoint service is configured along with BGP Multi-homing and Pseudowire Redundancy on the provider edge nodes (B/C and D/E). This configuration offers a fully redundant Epipe service.

**Figure 30 BGP-MH Site Support for Ethernet Tunnels**

OSSG750

### 2.8.10.1 Operational Overview

G.8031 offers a number of redundant configurations. Normally, it offers the ability to control two independent paths for 1:1 protection. In the BGP-MH site support for Ethernet tunnels case, BGP drives G.8031 as a slave service. In this case, the provider edge operates using only standard 802.1ag MEPs with CCM to monitor the paths. [Figure 31](#) shows an Epipe service on a Customer Edge (CE) device that uses G.8031 with two paths and two MEPs. The paths can use a single VLAN of dot1q or QinQ encapsulation.

**Figure 31 G.8031 for Slave Operation**

OSSG749

In a single-service deployment, the control (CFM) and data will share the same port and VID. For multiple services for scaling, fate sharing is allowed between multiple SAPs, but all SAPs within a group must be on the same physical port.

To get fate sharing for multiple services with this feature, a dedicated G.8031 CE-based service (one VLAN) is connected to a Epipe SAP on a PE, which uses BGP-MH and operational groups to control other G.8031 tunnels. This dedicated G.8031 service still has data control capabilities, but the data Epipe service is not bearing user data packets. On the CE, this G.8031 is only used for group control. Making this a dedicated control (CFM) for a set of G.8031 tunnels is to simplify operation and allow individual disabling of services. Using a dedicated G.8031 service to both control and to carry data traffic is allowed.

Fate sharing from the PE side is achieved using BGP and operational groups. G.8031 Epipe services can be configured on the CE as regular non-fate shared G.8031 services, but due to the configuration on the PE side, these Ethernet tunnels will be treated as a group following the one designated control service. The G.8031 control logic on the CE is a slave to the BGP-MH control.

On the CE, G.8031 allows independent configuration of VIDs on each path. On the PE, the Epipe or endpoint that connects to the G.8031 service must have a SAP with the corresponding VID. If the G.8031 service has a Maintenance End Point (MEP) for that VID, the SAP should be configured with a MEP. The MEPs on the paths on the CE signal standard interface status TLV (ifStatusTLV), No Fault (Up), and Fault

(Down). The MEPs on the PE (Epipe or endpoint) also use signaling of ifStatusTLV No Fault (Up), and Fault (Down) to control the G.8031 SAP. However, in the 7750 SR, 7450 ESS, and 7950 XRS model, fate shared Ethernet tunnels with no MEP are allowed. In this case, it is up to the CE to manage these CE-based fate shared tunnels.

Interface status signaling (ifStatusTLV) is used to control the G.8031 tunnel from the PE side. Normally the CE will signal No Fault (Up) in the path SAP MEP ifStatusTLV before the BGP-MH will cause the SAP MEP to become active by signaling No Fault (Up).

## 2.8.10.2 Detailed Operation

For this feature, BGP-MH is used as the master control and the Ethernet tunnel is a slave. The G.8031 on the CE is unaware that it is being controlled. While a single Epipe service is configured and will serve as the control for the CE connection, allowing fate sharing, all signaling to the CE is based on the ifStatusTLV per G.8031 tunnel. By controlling G.8031 with BGP-MH, the G.8031 CE is forced to be a slave to the PE BGP-MH election. BGP-MH election is controlled by the received VPLS preference or BGP local-preference, or the PE ID (IP address of provider edge) if local-preference is equal to VPLS preference. There may be traps generated on the CE side for some G.8031 implementations, but these can be suppressed or filtered to allow this feature to operate.

There are two configuration options:

- Every G.8031 service SAP terminates on a single Epipe that has BGP-MH. These Epipes may use endpoints with or without ICBs.
- A control Epipe service monitors a single SAP that is used for group control of fate shared CE services. In this case, the Epipe service has a SAP that serves as the control termination for one Ethernet tunnel connection. The group fate sharing SAPs may or may not have MEPs if they use shared fate. In this case, the Epipe may have endpoints but will not support ICBs.

The MEP ifStatusTlv and CCM are used for monitoring the PE to CE SAP. MEP ifStatusTlv is used to signal that the Ethernet tunnel inactive and CCM is used as an aliveness mechanism. There is no G.8031 logic on the PE; the SAP is controlling the corresponding CE SAP.

**Table 10** SAP MEP Signaling (Continued)

|   | G.8031 ET on CE                                             | Path A MEP Facing Node B Local ifStatus | Path B MEP Facing Node C Local ifStatus | Path B PE MEP ifStatus | Path B PE MEP ifStatus |
|---|-------------------------------------------------------------|-----------------------------------------|-----------------------------------------|------------------------|------------------------|
| 6 | Partitioned Network<br>Use Path Precedence<br>Up use Path A | No Fault                                | No Fault                                | No Fault               | No Fault               |

**Notes:**

1. No Fault = no ifStatusTlv transmit | CCM transmit normally
2. Fault = ifStatusTlv transmit down | no CCM transmit

**Events in Sample Operation**

The following describes the events for switchover in [Figure 32](#). This configuration uses operational groups. The nodes of interest are A, B, and C listed in [Table 10](#).

1. A single G.8031 SAP that represents the control for a group of G.8031 SAPs is configured on the CE.
  - The Control SAP does not normally carry any data; however, it can if needed.
  - An Epipe service is provisioned on each PE node (B/C), only for control (no customer traffic flows over this service).
  - On CE A, there is an Epipe Ethernet tunnel (G.8031) control SAP.
  - The Ethernet tunnel has two paths:
    - one facing B
    - one facing C
  - PE B has an Epipe control SAP that is controlled by the BGP-MH site and PE C also has the corresponding SAP that is controlled by the same BGP-MH site.
2. At node A, there are MEPs configured under each path that check connectivity on the A-B and A-C links. At nodes B and C, there is a MEP configured under their respective SAPs with fault propagation enabled with the use of ifStatusTlv.
3. Initially, assume there is no link failure:
  - SAPs on node A have ifStatusTLV No Fault to B and C (no MEP fault detected at A); see [Table 10](#) row 1 (Fault is signaled in the other direction PE to CE).

- BGP-MH determines which is the master or Designated Forwarder (DF).
  - Assume SAP on node B is picked as the DF.
  - The MEP at Path A-B signals ifStatusTlv No Fault. Due to this signal, the MEP under the node A path facing node B detects the path to node B is usable by the path manager on A.
4. At the CE node A, Path A-C becomes standby and is brought down; see [Table 10](#) row 2.
- Since fault propagation is enabled under the SAP node C MEP, and ifStatusTLV is operationally Down, the Path remains in the present state.
  - Under these conditions, the MEP under the node A path facing node C detects the fault and informs Ethernet manager on node A.
  - Node A then considers bringing path A-C down.
  - ET port remains up since path A-B is operationally up. This is a stable state.
5. On nodes B and C, each Epipe-controlled SAP is the sole (controlling) member of an operational group.
- Other data SAPs may be configured for fate shared VLANs (Ethernet tunnels) and to monitor the control SAP.
  - The SAPs facing the CE node A share the fate of the control SAP and follow the operation.
6. If there is a break in path A-B connectivity (CCM timeout or LOS on the port for link A-B), then on node A the path MEP detects connectivity failure and informs Ethernet tunnel manager; see [Table 10](#) row 4.
7. At this point, the Ethernet tunnel is down since both path A-B and path A-C are down.
8. The CE node A Ethernet tunnel goes down.
9. At node B on the PE, the SAP also detects the failure and the propagation of fault status goes to BGP-MH; see [Table 10](#) row 4.
10. This in turn feeds into BGP-MH, which deems the site non-DF and makes the site standby.
11. Since the SAP at node B is standby, the service manager feeds this to CFM, which then propagates a Fault toward node A. This is a cyclic fault propagation. However, since path A-B is broken, the situation is stable; see [Table 10](#) row 5.
12. There is traffic loss during the BGP-MH convergence.
- Load sharing mode is recommended when using a 7450 as a CE node A device.
  - BGP-MH signals that node C is now the DF; see [Table 10](#) row 3.
13. BGP-MH on node C elects a SAP and brings it up.
14. ET port transitions to port A-C, and is operationally up. This is a stable state. The A-C SAPs monitoring the operational group on C transitions to operationally up.

Unidirectional failures: At point 6 the failure was detected at both ends. In the case of a unidirectional failure, CCM times out on one side.

1. In the case where the PE detects the failure, it propagates the failure to BGP-MH and the BGP-MH takes the site down causing the SAPs on the PE to signal a Fault to the CE.
2. In the case where G.8031 on the CE detects the failure, it takes the tunnel down and signals a fault to the PE, and then the SAP propagates that to BGP-MH.

### **2.8.10.3 BGP-MH Site Support for Ethernet Tunnels Operational Group Model**

For operational groups, one or more services follow the controlling service. On node A, there is an ET SAP facing nodes B/C, and on nodes B/C there are SAPs of the Epipe on physical ports facing node A. Each of the PE data SAPs monitor their respective operational groups, meaning they are operationally up or down based on the operational status of the control SAPs. On node A, since the data SAP is on the ET logical port, it goes operationally down whenever the ET port goes down and similarly for going operationally up.

Alternatively, an Epipe service may be provisioned on each node for each G.8031 data SAP (one-for-one service with no fate sharing). On CE node A, there will be a G.8031 Ethernet tunnel. The Ethernet tunnel has two paths: one facing node B and one facing node C. This option is the same as the control SAP, but there are no operational groups. However, now there is a BGP-MH site per service. For large sites, operational groups are more efficient.

### **2.8.10.4 BGP-MH Specifics for MH Site Support for Ethernet Tunnels**

[BGP Multi-Homing for VPLS](#) describes the procedures for using BGP to control resiliency for VPLS. These procedures are the same except that an Epipe service can be configured for BGP-MH.

### 2.8.10.5 PW Redundancy for BGP-MH Site Support for Ethernet Tunnels

[Pseudowire Redundancy Service Models](#) and [VLL Resilience with Pseudowire Redundancy and Switching](#) are used for the MPLS network resiliency. BGP MH site support for Ethernet tunnels reuses this model.

### 2.8.10.6 T-LDP Status Notification Handling Rules of BGP-MH Epipes

Using [Figure 35](#) as a reference, the following are the rules for generating, processing, and merging T-LDP status notifications in VLL service with endpoints.

#### 2.8.10.6.1 Rules for Processing Endpoint SAP Active/Standby Status Bits

1. The advertised admin forwarding status of active/standby reflects the status of the local Epipe SAP in BGP-MH instance. If the SAP is not part of an MC-LAG instance or a BGP-MH instance, the forwarding status of Active is always advertised.
2. When the SAP in endpoint X is part of a BGP-MH instance, a node must send T-LDP forwarding status bit of SAP active/standby over all Y endpoint spoke-SDPs, except the ICB spoke-SDP, whenever this (BGP-MH designated forwarder) status changes. The status bit sent over the ICB is always zero (Active by default).
3. When the SAP in endpoint X is not part of an MC-LAG instance or BGP-MH instance, then the forwarding status sent over all Y endpoint spoke-SDPs should always be set to zero (Active by default).
4. The received SAP active/standby status is saved and used for selecting the active transmit endpoint object Pseudowire Redundancy procedures.

#### 2.8.10.6.2 Rules for Processing, Merging Local, and Received Endpoint Operational Status

1. Endpoint X is operationally up if at least one of its objects is operationally Up. It is Down if all its objects are operationally down.

2. If the SAP in endpoint X transitions locally to the down state, or received a SAP Down notification via SAP-specific OAM signal (SAP MEP), the node must send T-LDP SAP down status bits on the Y endpoint ICB spoke-SDP only. BGP-MH SAPs support MEPs for ifStatusTLV signaling. All other SAP types cannot exist on the same endpoint as an ICB spoke-SDP since non Ethernet SAP cannot be part of an MC-LAG instance or a BGP-MH Instance.
3. If the ICB spoke-SDP in endpoint X transitions locally to Down state, the node must send T-LDP SDP-binding down status bits on this spoke-SDP.
4. If the ICB spoke-SDP in endpoint X received T-LDP SDP-binding down status bits or PW not forwarding status bits, the node saves this status and takes no further action. The saved status is used for selecting the active transmit endpoint object as per Pseudowire Redundancy procedures.
5. If all objects in endpoint X did any or all of the following, the node must send status bits of SAP Down over all Y endpoint spoke-SDPs, including the ICB:
  - transitioned locally to the down state due to operator or BGP-MH DF election
  - received a SAP down notification via remote T-LDP status bits or via SAP-specific OAM signal (SAP MEP)
  - received status bits of SDP-binding down
  - received status bits of PW not forwarding
6. Endpoint Y is operationally up if at least one of its objects is operationally Up. It is Down if all its objects are operationally down.
7. If a spoke-SDP in endpoint Y, including the ICB spoke-SDP, transitions locally to down state, the node must send T-LDP SDP-binding down status bits on this spoke-SDP.
8. If a spoke-SDP in endpoint Y, including the ICB spoke-SDP, did any or all of the following, the node saves this status and takes no further action:
  - received T-LDP SAP down status bits
  - received T-LDP SDP-binding down status bits
  - received PW not forwarding status bitsThe saved status is used for selecting the active transmit endpoint object as per Pseudowire Redundancy procedures.
9. If all objects in endpoint Y, except the ICB spoke-SDP, did any or all of the following, the node must send status bits of SDP-binding down over the X endpoint ICB spoke-SDP only:
  - transitioned locally to the down state
  - received T-LDP SAP down status bits
  - received T-LDP SDP-binding down status bits
  - received PW not forwarding status bits

10. If all objects in endpoint Y did any or all of the following, the node must send status bits of SDP-binding down over the X endpoint ICB spoke-SDP only, and must send a SAP down notification on the X endpoint SAP via the SAP-specific OAM signal:

- transitioned locally to down state
- received T-LDP SAP down status bits
- received T-LDP SDP-binding down status bits
- received PW not forwarding status bits

In this case the SAP MEP ifStatusTLV is operationally down and also signals the BGP-MH site, if this SAP is part of a BGP Site.

### 2.8.10.6.3 Operation for BGP-MH Site Support for Ethernet Tunnels

A multi-homed site can be configured on up to four PEs although two PEs are sufficient for most applications, with each PE having a single object SAP connecting to the multi-homed site. SR OS G.8031 implementation with load sharing allows multiple PEs as well. The designated forwarder election chooses a single connection to be operationally up, with the other placed in standby. Only revertive behavior is supported in release 14.0.

Fate sharing (the status of one site can be inherited from another site) is achievable using monitor-groups.

The following are supported:

- All Ethernet-tunnel G.8031 SAPs on CE:
  - 7750 SR, 7450 ESS, or 7950 XRS G.8031 in load sharing mode (recommended)
  - 7750 SR, 7450 ESS, or 7950 XRS G.8031 in non-load sharing mode
- Epipe and endpoint with SAPs on PE devices.
- Endpoints with PW.
- Endpoints with active/standby PWs.

There are the following constraints with this feature:

- Not supported with PBB Epipes.
- Spoke SDP (pseudowire).
  - BGP signaling is not supported.
  - Cannot use BGP MH for auto-discovered pseudowire. This is achieved in a VPLS service using SHGs, which are not available in Epipes.

- Other multi-chassis redundancy features are not supported on the multi-homed site object, as follows:
  - MC-LAG
  - MC-EP
  - MC-Ring
  - MC-APS
- Master and Slave pseudowire is not supported.

**Figure 33 Sample Topology Full Redundancy**

See the following [Configuration Examples](#) for configuration examples derived from Figure 33.

## Configuration Examples

### Node-1: Using operational groups and Ethernet CFM per SAP

```
#-----
echo "Eth-CFM Configuration"
#-----
eth-cfm
  domain 100 format none level 3
  association 2 format icc-based name "node-3-site-1-0"
  bridge-identifier 1
  exit
```

```

        remote-mepid 310
    exit
    association 2 format icc-based name "node-3-site-1-1"
        bridge-identifier 100
    exit
    remote-mepid 311
    exit
exit
exit
exit

#-----
echo "Service Configuration"
#-----

service
    customer 1 create

### Configuration with Fate Sharing on Node-3

In this example, the SAPs monitoring the operational groups do not need CFM if the corresponding SAP on the CE side is using fate sharing.

#### Node-1:

```

#-----
echo "Service Configuration" Oper-groups
#-----
    service
        customer 1 create
            description "Default customer"
        exit
        sdp 2 mpls create
        ...

    exit
    pw-template 1 create
        vc-type vlan
    exit
    oper-group "og-name-et" create
    exit
    epipe 1 customer 1 create
        service-mtu 500
        bgp
            route-distinguisher 65000:1
            route-target export target:65000:1 import target:65000:1
        exit
        site "site-1" create
            site-id 1
            sap 1/1/2:1.1
            boot-timer 100
            site-activation-timer 2
            no shutdown
        exit
        endpoint "x" create
        exit
        endpoint "y" create
        exit

```

```

        sap 1/1/2:1.1 endpoint "x" create
        eth-cfm
            mep 130 domain 100 association 1 direction down
            fault-propagation-enable use-if-tlv
            ccm-enable
            no shutdown
        exit
    exit
    oper-group "og-name-et"
exit

```

### 2.8.11 Access Node Resilience Using MC-LAG and Pseudowire Redundancy

[Figure 34](#) shows the use of both Multi-Chassis Link Aggregation (MC-LAG) in the access network and pseudowire redundancy in the core network to provide a resilient end-to-end VLL service to the customers.

**Figure 34 Access Node Resilience**

OSSG116

In this application, a new pseudowire status bit of active or standby indicates the status of the SAP in the MC-LAG instance in the SR-series aggregation node. All spoke-SDPs are of secondary type and there is no use of a primary pseudowire type in this mode of operation. Node A is in the active state according to its local MC-LAG instance and therefore advertises active status notification messages to both its peer pseudowire nodes; for example, nodes C and D. Node D performs the same operation. Node B is in the standby state according to the status of the SAP in its local MC-LAG instance, so advertises standby status notification messages to both nodes C and D. Node C performs the same operation.

An SR-series node selects a pseudowire as the active path for forwarding packets when both the local pseudowire status and the received remote pseudowire status indicate active status. However, an SR-series device in standby status according to the SAP in its local MC-LAG instance is capable of processing packets for a VLL service received over any of the pseudowires that are up. This is to avoid black holing of user traffic during transitions. The SR-series standby node forwards these packets to the active node by the Inter-Chassis Backup pseudowire (ICB pseudowire) for this VLL service. An ICB is a spoke-SDP used by an MC-LAG node to back up an MC-LAG SAP during transitions. The same ICB can also be used by the peer MC-LAG node to protect against network failures causing the active pseudowire to go down.

At configuration time, the user specifies a precedence parameter for each of the pseudowires that are part of the redundancy set, as described in the application in [VLL Resilience with Two Destination PE Nodes](#). An SR-series node uses this to select which pseudowire to forward packets to in case both pseudowires show active/active for the local/remote status during transitions.

Only VLL service of type Epipe is supported in this application. Also, ICB spoke-SDP can only be added to the SAP side of the VLL cross-connect if the SAP is configured on an MC-LAG instance.

## 2.8.12 VLL Resilience for a Switched Pseudowire Path

[Figure 35](#) shows the use of both pseudowire redundancy and pseudowire switching to provide a resilient VLL service across multiple IGP areas in a provider network.

**Figure 35 VLL Resilience with Pseudowire Redundancy and Switching**

OSSG114

Pseudowire switching is a method for scaling a large network of VLL or VPLS services by removing the need for a full mesh of T-LDP sessions between the PE nodes as the number of these nodes grows over time.

Like in the application in [VLL Resilience with Two Destination PE Nodes](#), the T-PE1 node switches the path of a VLL to a secondary standby pseudowire if a network side failure caused the VLL binding status to be operationally down or if T-PE2 notified it that the remote SAP went down. This application requires that pseudowire status notification messages generated by either a T-PE node or a S-PE node be processed and relayed by the S-PE nodes.

It is possible that the secondary pseudowire path terminates on the same target PE as the primary; for example, T-PE2. This provides protection against network side failures but not against a remote SAP failure. When the target destination PE for the primary and secondary pseudowires is the same, T-PE1 will normally not switch the VLL path onto the secondary pseudowire upon receipt of a pseudowire status notification indicating the remote SAP is down, because the status notification is sent over both the primary and secondary pseudowires. However, the status notification on the primary pseudowire may arrive earlier than the one on the secondary pseudowire due to the differential delay between the paths. This will cause T-PE1 to

---

switch the path of the VLL to the secondary standby pseudowire and remain there until the status notification is cleared. Then, the VLL path is switched back to the primary pseudowire due to the revertive behavior operation. The path will not switch back to a secondary path when it comes up, even if it has a higher precedence than the currently active secondary path.

For the 7750 SR, this application can make use of all types of VLL supported on the routers; for example, Apipe, Fpipe, Epipe, and Lpipe services. A SAP can be configured on a SONET/SDH port that is part of an APS group. However, if a SAP is configured on an MC-LAG instance, only the Epipe service type will be allowed.

## 2.9 Pseudowire Redundancy Service Models

This section describes the various MC-LAG and pseudowire redundancy scenarios as well as the algorithm used to select the active transmit object in a VLL endpoint.

The redundant VLL service model is described in the following section, [Redundant VLL Service Model](#).

### 2.9.1 Redundant VLL Service Model

To implement pseudowire redundancy, a VLL service accommodates more than a single object on the SAP side and on the spoke-SDP side. [Figure 36](#) shows the model for a redundant VLL service based on the concept of endpoints.

**Figure 36 Redundant VLL Endpoint Objects**

OSSG211

By default a VLL service supports two implicit endpoints managed internally by the system. Each endpoint can only have one object: a SAP or a spoke-SDP.

To add more objects, up to two explicitly named endpoints may be created per VLL service. The endpoint name is locally significant to the VLL service. They are referred to as endpoint X and endpoint Y as illustrated in [Figure 36](#).

Figure 36 is just an example; the Y endpoint can also have a SAP and/or an ICB spoke-SDP. The following describes the four types of endpoint objects supported and the rules used when associating them with an endpoint of a VLL service:

- SAP — There can only be a maximum of one SAP per VLL endpoint.
- Primary spoke-SDP — The VLL service always uses this pseudowire and only switches to a secondary pseudowire when this primary pseudowire is down; the VLL service switches the path to the primary pseudowire when it is back up. The user can configure a timer to delay reverting back to primary or to never revert. There can only be a maximum of one primary spoke-SDP per VLL endpoint.
- Secondary spoke-SDP — There can be a maximum of four secondary spoke-SDPs per endpoint. The user can configure the precedence of a secondary pseudowire to indicate the order in which a secondary pseudowire is activated.
- Inter-Chassis Backup (ICB) spoke-SDP — This special pseudowire is used for MC-LAG and pseudowire redundancy applications. Forwarding between ICBs is blocked on the same node. The user has to explicitly indicate that the spoke-SDP is an ICB, at creation time. However, following are a few scenarios where the user can configure the spoke-SDP as ICB or as a regular spoke-SDP on a specified node. The CLI for those cases will indicate both options.

A VLL service endpoint can only use a single active object to transmit at any specified time but can receive from all endpoint objects.

An explicitly named endpoint can have a maximum of one SAP and one ICB. When a SAP is added to the endpoint, only one more object of type ICB spoke-SDP is allowed. The ICB spoke-SDP cannot be added to the endpoint if the SAP is not part of an MC-LAG instance. Conversely, a SAP that is not part of an MC-LAG instance cannot be added to an endpoint that already has an ICB spoke-SDP.

An explicitly named endpoint that does not have a SAP object, can have a maximum of four spoke-SDPs and can include any of the following:

- a single primary spoke-SDP
- one or many secondary spoke-SDPs with precedence
- a single ICB spoke-SDP

## 2.9.2 T-LDP Status Notification Handling Rules

Using [Redundant VLL Endpoint Objects](#) as a reference, the following are the rules for generating, processing, and merging T-LDP status notifications in VLL service with endpoints. Any allowed combination of objects as specified in [Redundant VLL Service Model](#) can be used on endpoints X and Y. The following sections see the specific combination objects in [Figure 36](#) as an example to describe the more general rules.

### 2.9.2.1 Processing Endpoint SAP Active/Standby Status Bits

The advertised admin forwarding status of active/standby reflects the status of the local LAG SAP in MC-LAG application. If the SAP is not part of an MC-LAG instance, the forwarding status of active is always advertised.

When the SAP in endpoint X is part of an MC-LAG instance, a node must send a T-LDP forwarding status bit of SAP active/standby over all Y endpoint spoke-SDPs, except the ICB spoke-SDP, whenever this status changes. The status bit sent over the ICB is always zero (active by default).

When the SAP in endpoint X is not part of an MC-LAG instance, then the forwarding status sent over all Y endpoint spoke-SDPs should always be set to zero (active by default).

### 2.9.2.2 Processing and Merging

Endpoint X is operationally up if at least one of its objects is operationally up. It is down if all of its objects are operationally down.

If the SAP in endpoint X transitions locally to the down state, or received a SAP down notification by SAP-specific OAM signal, the node must send T-LDP SAP down status bits on the Y endpoint ICB spoke-SDP only. Ethernet SAP does not support SAP OAM protocol. All other SAP types cannot exist on the same endpoint as an ICB spoke-SDP because a non-Ethernet SAP cannot be part of an MC-LAG instance.

If the ICB spoke-SDP in endpoint X transitions locally to down state, the node must send T-LDP SDP-binding down status bits on this spoke-SDP.

If the ICB spoke-SDP in endpoint X received T-LDP SDP-binding down status bits or pseudowire not forwarding status bits, the node saves this status and takes no further action. The saved status is used for selecting the active transmit endpoint object.

If all objects in endpoint X did any or all of the following, the node must send status bits of SAP down over all “Y” endpoint spoke-SDPs, including the ICB:

- transitioned locally to down state
- received a SAP down notification by remote T-LDP status bits or by SAP-specific OAM signal
- received SDP-binding down status bits
- received PW not forwarding status bits

Endpoint Y is operationally up if at least one of its objects is operationally up. It is down if all its objects are operationally down.

If a spoke-SDP in endpoint Y, including the ICB spoke-SDP, transitions locally to down state, the node must send T-LDP SDP-binding down status bits on this spoke-SDP.

If a spoke-SDP in endpoint Y, including the ICB spoke-SDP, did any or all of the following, the node saves this status and takes no further action:

- received T-LDP SAP down status bits
- received T-LDP SDP-binding down status bits
- received PW not forwarding status bits

The saved status is used for selecting the active transmit endpoint object.

If all objects in endpoint Y, except the ICB spoke-SDP, did any or all of the following, the node must send status bits of SDP-binding down over the X endpoint ICB spoke-SDP only:

- transitioned locally to the down state
- received T-LDP SAP down status bits
- received T-LDP SDP-binding down status bits
- received PW not forwarding status bits

If all objects in endpoint Y did any or all of the following, the node must send status bits of SDP-binding down over the X endpoint ICB spoke-SDP, and must send a SAP down notification on the X endpoint SAP by the SAP-specific OAM signal if applicable:

- transitioned locally to down state

- received T-LDP SAP down status bits
- received T-LDP SDP-binding down status bits
- received PW not forwarding status bits

An Ethernet SAP does not support signaling status notifications.

## 2.10 High-Speed Downlink Packet Access (HSDPA) Off Load Fallback over ATM

For many Universal Mobile Telecommunications System (UMTS) networks planning to deploy High-Speed Downlink Packet Access (HSDPA), the existing mobile backhaul topology consists of a cell site that is partially backhauled over DSL (for the HSDPA portion) and partially over an existing TDM/ATM infrastructure (for UMTS voice traffic).

**Figure 37 HSDPA Off Load Fallback over ATM**

OSSG483

For example, the service pseudowires provider may use a 7705 SAR with one or two ATM E1 uplinks for real-time voice traffic and an Ethernet uplink connected to a DSL model for NRT data traffic. At the RNC site, a 7750 SR service router can be used, connected by ASAP (E1 IMA bundles) or STM-n ATM to the TDM/ATM network, and Ethernet to the DSL backhaul network.

On the MSC-located SR connected to the Radio Network Controller (RNC), there is a standard pseudowire (Ethernet or ATM) that has an active pseudowire by IP / MPLS, but the standby path is not IP/MPLS capable. Therefore, the active/standby pseudowire concept is extended to allow standby to be an access SAP to an ATM network for ATM pseudowire or Ethernet (bridged over ATM) for ETH pseudowire.

Normally, if the MPLS pseudowire path is active, this path is used. If a failure happens on the IP/MPLS path, detected through BFD-TLDP or local notification, traffic needs to switch to the SAP that is connected to the ATM/TDM backhaul network. As soon as the MPLS pseudowire path becomes available again, reversion back to the pseudowire path is supported.

## 2.10.1 Primary Spoke SDP Fallback to Secondary SAP

For HSDPA, Apipe and Epipe service termination on the SR where an endpoint-X SAP connects to the mobile RNC (by ATM or Ethernet) and an endpoint Y has a primary spoke-SDP and a secondary SAP on an SR ATM or ASAP MDA (with bridged PDU encapsulation for Epipes). The secondary SAP has the same restrictions as the SAP in endpoint-X for Apipe and Epipe, respectively.

It is sufficient to have a single secondary SAP (without any precedence), which implies that it cannot be mixed with any secondary spoke-SDPs; 1+1 APS and MC-APS is supported on the secondary SAP interface.

Similar to the current pseudowire redundancy implementation, receive should be enabled on both objects even though transmit is only enabled on one.

It is expected that BFD for T-LDP will be used in most applications to decrease the fault detection times and minimize the outage times upon failure.

## 2.10.2 Reversion to Primary Spoke SDP Path

The **endpoint revert-time** reversion from secondary to primary paths in the **config>service>apipe>endpoint** and **config>service>epipe>endpoint** contexts are consistent with standard pseudowire redundancy. Various network configurations and equipment require different reversion configurations. The default revert-time is 0.

## 2.10.3 MC-APS and MC-LAG

In many cases, 7750 SRs are deployed in redundant pairs at the MSC. In this case, MC-APS is typically used for all ATM connections. [Figure 38](#) shows this case, assuming that MC-APS is deployed on both the RNC connection and the ATM network connection. For MC-APS to be used, clear channel SONET or SDH connections should be used.

**Figure 38 HSDPA Off Load Fallback with MC-APS**

In this scenario, endpoint Y allows an ICB spoke-SDP as well as the primary spoke-SDP and secondary SAP. ICB operation is maintained as the current redundant pseudowire operation and the ICB spoke-SDP is always given an active status. The ICB spoke-SDP is only used if both the primary spoke-SDP and secondary SAP are not available. The secondary SAP is used if it is operationally up and the primary spoke-SDP pseudowire status is not active. Receive is enabled on all objects even though transmit is only enabled on one.

To allow correct operation in all failure scenarios, an ICB spoke-SDP must be added to endpoint X. The ICB spoke-SDP is only used if the SAP is operationally down.

The following is an example configuration of Epipes mapping to [Figure 38](#). A SAP can be added to an endpoint with a non-ICB spoke-SDP only if the precedence of the spoke is **primary**.

#### 7750 SR #1

```
*A:ALA-A>config>service# epipe 1
-----
    endpoint X
    exit
    endpoint Y
    exit
```

```

sap 1/1/2:0 endpoint X
exit
spoke-sdp 1:100 endpoint X icb
exit
spoke-sdp 10:500 endpoint Y
precedence primary
exit
sap 1/1/3:0 endpoint Y
exit
spoke-sdp 1:200 endpoint Y icb
exit
-----
*A:ALA-A>config>service#

```

## 7750 SR #2

```

*A:ALA-B>config>service# epipe 1
-----
endpoint X
exit
endpoint Y
exit
sap 2/3/4:0 endpoint X
exit
spoke-sdp 1:200 endpoint X icb
exit
spoke-sdp 20:600 endpoint Y
precedence primary
exit
sap 2/3/5:0 endpoint Y
exit
spoke-sdp 1:100 endpoint Y icb
exit
-----
*A:ALA-B>config>service#

```

### 2.10.3.1 Failure Scenario

Based on the previously mentioned rules, the following is an example of a failure scenario. Assuming both links are active on 7750 SR #1 and the Ethernet connection to the cell site fails (most likely failure scenario because the connection would not be protected), SDP1 would go down and the secondary SAP would be used in 7750 SR #1 and 7705 SAR, as shown in [Figure 39](#).

**Figure 39 Ethernet Failure At Cell Site**

If the active link to the Layer 2 switched network was on 7750 SR #2 at the time of the failure, SAP1 would be operationally down (because the link is in standby) and ICB1 would be used. Because the RNC SAP on 7750 SR #2 is on a standby APS link, ICB1 would be active and it would connect to SAP2 because SDP2 is operationally down as well.

All APS link failures would be handled through the standard pseudowire status messaging procedures for the RNC connection and through standard ICB usage for the Layer 2 switched network connection.

---

## 2.11 VLL Using G.8031 Protected Ethernet Tunnels

The use of MPLS tunnels provides the 7450 ESS and 7750 SR OS a way to scale the core while offering fast failover times using MPLS FRR. In environments where Ethernet services are deployed using native Ethernet backbones, Ethernet tunnels are provided to achieve the same fast failover times as in the MPLS FRR case.

The Nokia VLL implementation offers the capability to use core Ethernet tunnels compliant with ITU-T G.8031 specification to achieve 50 ms resiliency for backbone failures. This is required to comply with the stringent SLAs provided by service providers. Epipe and Ipipe services are supported.

When using Ethernet tunnels, the Ethernet tunnel logical interface is created first. The Ethernet tunnel has member ports, which are the physical ports supporting the links. The Ethernet tunnel control SAPs carry G.8031 and 802.1ag control traffic and user data traffic. Ethernet service SAPs are configured on the Ethernet tunnel. Optionally, when tunnels follow the same paths, end-to-end services may be configured with fate shared Ethernet tunnel SAPs, which carry only user data traffic and share the fate of the Ethernet tunnel port (if correctly configured).

Ethernet tunnels provide a logical interface that VLL SAPs may use just as regular interfaces. The Ethernet tunnel provides resiliency by providing end-to-end tunnels. The tunnels are stitched together by VPLS or Epipe services at intermediate points. Epipes offer a more scalable option.

For further information, refer to *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide*.

---

## 2.12 MPLS Entropy Label and Hash Label

The router supports the MPLS entropy label (RFC 6790) and the Flow Aware Transport label, known as the hash label (RFC 6391). These labels allow LSR nodes in a network to load-balance labeled packets in a much more granular fashion than allowed by just hashing on the standard label stack. See the *7450 ESS*, *7750 SR*, *7950 XRS*, and *VSR MPLS Guide* for further information.

## 2.13 BGP Virtual Private Wire Service (VPWS)

BGP Virtual Private Wire Service (VPWS) is a point-to-point L2 VPN service based on RFC 6624 *Layer 2 Virtual Private Networks using BGP for Auto-Discovery and Signaling* which in turn uses the BGP pseudowire signaling concepts from RFC 4761, *Virtual Private LAN Service Using BGP for Auto-Discovery and Signaling*.

The BGP signaled pseudowires created can use either automatic or pre-provisioned SDPs over LDP- or BGP-signaled tunnels (the choice of tunnel depends on the tunnel's preference in the tunnel table), or over GRE. Pre-provisioned SDPs must be configured when RSVP signaled transport tunnels are used.

The use of an automatically created GRE tunnel is enabled by creating the PW template used within the service with the parameter **auto-gre-sdp**. The GRE SDP and SDP binding is created after a matching BGP route is received.

Inter-AS model C and dual-homing are supported.

### 2.13.1 Single-Homed BGP VPWS

A single-homed BGP VPWS service is implemented as an Epipe connecting a SAP or static GRE tunnel (a spoke-SDP using a GRE SDP configured with static MPLS labels) and a BGP signaled pseudowire, maintaining the Epipe properties such as no MAC learning. The MPLS pseudowire data plane uses a two-label stack; the inner label is derived from the BGP signaling and identifies the Epipe service while the outer label is the tunnel label of an LSP transporting the traffic between the two end systems.

Figure 40 shows how this service would be used to provide a virtual leased line service (VLL) across an MPLS network between two sites: A and B.

**Figure 40 Single-Homed BGP-VPWS Example**

An Epipe is configured on PE1 and PE2 with BGP VPWS enabled. PE1 and PE2 are connected to site A and B, respectively, each using a SAP. The interconnection between the two PEs is achieved through a pseudowire that is signaled using BGP VPWS updates over a specific tunnel LSP.

## 2.13.2 Dual-Homed BGP VPWS

A BGP-VPWS service can benefit from dual-homing, as described in IETF Draft *draft-ietf-bess-vpls-multihoming-01*. When using dual-homing, two PEs connect to a site, with one PE being the designated forwarder for the site and the other blocking its connection to the site. On failure of the active PE, its pseudowire, or its connection to the site, the other PE becomes the designated forwarder and unblocks its connection to the site.

### 2.13.2.1 Single Pseudowire Example

A pseudowire is established between the designated forwarder of the dual-homed PEs and the remote PE. If a failure causes a change in the designated forwarder, the pseudowire is deleted and reestablished between the remote PE and the new designated forwarder. This topology requires that the VE IDs on the dual-homed PEs are set to the same value.

A dual-homed, single pseudowire topology example is shown in [Figure 41](#).

**Figure 41 Dual-Homed BGP VPWS with Single Pseudowire**

SR\_QPD\_0002

An Epipe with BGP VPWS enabled is configured on each PE. Site A is dual-homed to PE1 and PE2 with the remote PE (PE3) connecting to site B. An Epipe service is configured on each PE in which there is a SAP connecting to the local site.

The pair of dual-homed PEs perform a designated forwarder election, which is influenced by BGP route selection, the site state, and by configuring the site-preference. A site will only be eligible to be the designated forwarder if it is up (the site state will be down if there is no pseudowire established or if the pseudowire is in an oper down state). The winner, for example PE1, becomes the active switch for traffic sent to and from site A, while the loser blocks its connection to site A.

Pseudowires are signaled using BGP from PE1 and PE2 to PE3, but only from PE3 to the designated forwarder in the opposite direction (so only one bi-directional pseudowire is established). There is no pseudowire between PE1 and PE2; this is achieved by configuration.

Traffic is sent and received traffic on the pseudowire connected between PE3 and the designated forwarder, PE1.

If the site state is oper down, both the D and Circuit Status Vector (CSV) bits (see the following for more details) are set in the BGP-VPWS update which will cause the remote PE to use the pseudowire to the new designated forwarder.

### 2.13.2.2 Active/Standby Pseudowire Example

Pseudowires are established between the remote PE and each dual-homed PE. The remote PE can receive traffic on either pseudowire, but will only send on the one to the designated forwarder. This creates an active/standby pair of pseudowires. At most, one standby pseudowire will be established; this being determined using the tie-breaking rules defined in the multi-homing draft. This topology requires each PE to have a different VE ID.

A dual-homed, active/standby pseudowires topology example is shown in [Figure 42](#).

**Figure 42**      **Dual-homed BGP VPWS with Active/Standby Pseudowires**

SR\_QPD\_0003

An Epipe with BGP VPWS enabled is configured on each PE. Site A is dual-homed to PE1 and PE2 with the remote PE (PE3) connecting to site B. An Epipe service is configured on each PE in which there is a SAP connecting to the local site.

The pair of dual-homed PEs perform a designated forwarder election, which is influenced by configuring the site-preference. The winner, PE1 (based on its higher site-preference) becomes the active switch for traffic sent to and from site A, while the loser, PE2, blocks its connection to site A. Pseudowires are signaled using BGP between PE1 and PE3, and between PE2 and PE3. There is no pseudowire between PE1 and PE2; this is achieved by configuration. The active/standby pseudowires on PE3 are part of an endpoint automatically created in the Epipe service.

Traffic is sent and received on the pseudowire connected to the designated forwarder, PE1.

### 2.13.3 BGP VPWS Pseudowire Switching

Pseudowire switching is supported with a BGP VPWS service allowing the cross connection between a BGP VPWS signaled spoke-SDP and a static GRE tunnel, the latter being a spoke-SDP configured with static MPLS labels using a GRE SDP. No other spoke-SDP types are supported. Support is not included for BGP multi-homing using an active and a standby pseudowire to a pair of remote PEs.

Operational state changes to the GRE tunnel are reflected in the state of the Epipe and propagated accordingly in the BGP VPWS spoke-SDP status signaling, specifically using the BGP update D and CSV bits.

The following configuration is required:

1. The Epipe service must be created using the **vc-switching** parameter.
2. The GRE tunnel spoke-SDP must be configured using a GRE SDP with **signaling off**, and have the ingress and egress vc-labels statically configured.

An example configuration is as follows:

```
configure
  service
    sdp 1 create
      signaling off
      far-end 192.168.1.1
      keep-alive
      shutdown
    exit
    no shutdown
  exit
  pw-template 1 create
  exit
  epipe 1 customer 1 vc-switching create
    description "BGP VPWS service"
    bgp
      route-distinguisher 65536:1
      route-target export target:65536:1 import target:65536:1
      pw-template-binding 1
    exit
  exit
  bgp-vpws
    ve-name "PE1"
    ve-id 1
  exit
  remote-ve-name "PE2"
  ve-id 2
  exit
  no shutdown
  exit
  spoke-sdp 1:1 create
    ingress
      vc-label 1111
    exit
    egress
      vc-label 1122
    exit
    no shutdown
  exit
  no shutdown
  exit
```

### 2.13.3.1 Pseudowire Signaling

The BGP signaling mechanism used to establish the pseudowires is described in the BGP VPWS standards with the following differences:

- As stated in Section 3 of RFC 6624, there are two modifications of messages when compared to RFC 4761.
  - the Encaps Types supported in the associated extended community
  - the addition of a circuit status vector sub-TLV at the end of the VPWS NLRI
- The control flags and VPLS preference in the associated extended community are based on IETF Draft *draft-ietf-bess-vpls-multihoming-01*.

Figure 43 shows the format of the BGP VPWS update extended community.

**Figure 43 BGP VPWS Update Extended Community Format**

|                                    |
|------------------------------------|
| Extended Community Type (2 Octets) |
| Encaps Type (1 Octet)              |
| Control Flags (1 Octet)            |
| Layer-2 MTU (2 Octets)             |
| VPLS Preference (2 Octets)         |

*L2\_Guide\_42*

- Extended Community Type — The value allocated by IANA for this attribute is 0x800A.
- Encaps Type — Encapsulation type, identifies the type of pseudowire encapsulation. Ethernet VLAN (4) and Ethernet Raw mode (5), as described in RFC 4448, are the only values supported. If there is a mismatch between the Encaps Type signaled and the one received, the pseudowire is created but with the operationally down state.
- Control Flags — Control information regarding the pseudowires, see Figure 44 for more information.
- Layer 2 MTU — Maximum Transmission Unit to be used on the pseudowires. If the received Layer 2 MTU is zero, no MTU check is performed and the related pseudowire is established. If there is a mismatch between the local service-mtu and the received Layer 2 MTU, the pseudowire is created with the operationally down state and an MTU/Parameter mismatch indication.

- **VPLS Preference** – VPLS preference has a default value of zero for BGP-VPWS updates sent by the system, indicating that it is not in use. If the site-preference is configured, its value is used for the VPLS preference and is also used in the local designated forwarder election.

On receipt of a BGP VPWS update containing a non-zero value, it will be used to determine to which system the pseudowire is established, as part of the VPWS update process tie-breaking rules. The BGP local preference of the BGP VPWS update sent by the system is set to the same value as the VPLS preference if the latter is non-zero, as required by the draft (as long as the D bit in the extended community is not set to 1). Consequently, attempts to change the BGP local preference when exporting a BGP VPWS update with a non-zero VPLS preference will be ignored. This prevents the updates being treated as malformed by the receiver of the update.

For inter-AS, the preference information must be propagated between autonomous systems using the VPLS preference. Consequently, if the VPLS preference in a BGP-VPWS or BGP multi-homing update is zero, the local preference is copied by the egress ASBR into the VPLS preference field before sending the update to the eBGP peer. The adjacent ingress ASBR then copies the received VPLS preference into the local preference to prevent the update from being considered malformed.

The control flags are shown in [Figure 44](#).

**Figure 44 Control Flags**

The following bits in the Control Flags are defined:

**D** — Access circuit down indicator from IETF Draft *draft-kothari-l2vpn-auto-site-id-01*. D is 1 if all access circuits are down, otherwise D is 0.

**A** — Automatic site ID allocation, which is not supported. This is ignored on receipt and set to 0 on sending.

**F** — MAC flush indicator. This is not supported because it relates to a VPLS service. This is set to 0 and ignored on receipt.

**C** — Presence of a control word. Control word usage is supported. When this is set to 1, packets will be sent and are expected to be received, with a control word. When this is set to 0, packets will be sent and are expected to be received, without a control word (by default).

S — Sequenced delivery. Sequenced delivery is not supported. This is set to 0 on sending (no sequenced delivery) and, if a non-zero value is received (indicating sequenced delivery required), the pseudowire will not be created.

The BGP VPWS NLRI is based on that defined for BGP VPLS, but is extended with a circuit status vector, as shown in [Figure 45](#).

**Figure 45     BGP VPWS NLRI**

|                                  |
|----------------------------------|
| Length (2 Octets)                |
| Route Distinguisher (8 Octets)   |
| VE ID (2 Octets)                 |
| VE Block Offset (2 Octets)       |
| VE Block Size (2 Octets)         |
| Label Base (3 Octets)            |
| Circuit Status Vector (4 Octets) |

L2\_Guide\_43

The VE ID value is configured within each BGP VPWS service, the label base is chosen by the system, and the VE block offset corresponds to the remote VE ID because a VE block size of 1 is always used.

The circuit status vector is encoded as a TLV, as shown in [Figure 46](#) and [Figure 47](#).

**Figure 46     BGP VPWS NLRI TLV Extension Format**

|                                 |                     |                     |       |
|---------------------------------|---------------------|---------------------|-------|
| 0                               | 1                   | 2                   | 3     |
| 0 1 2 3 4 5 6 7 8 9             | 0 1 2 3 4 5 6 7 8 9 | 0 1 2 3 4 5 6 7 8 9 | 0 1 2 |
| Type                            | Length              | Value               |       |
| Value (Continued, if Needed)... |                     |                     |       |

L2\_Guide\_44

**Figure 47     Circuit Status Vector TLV Type**

|          |                       |
|----------|-----------------------|
| TLV Type | Description           |
| 1        | Circuit Status Vector |

L2\_Guide\_45

The circuit status vector is used to indicate the status of both the SAP/GRE tunnel and the status of the spoke-SDP within the local service. Because the VE block size used is 1, the most significant bit in the circuit status vector TLV value will be set to 1 if either the SAP/GRE tunnel or spoke-SDP is down, otherwise it will be set to 0. On receiving a circuit status vector, only the most significant byte of the CSV is examined for designated forwarder selection purposes.

If a circuit status vector length field of greater than 32 is received, the update will be ignored and not reflected to BGP neighbors. If the length field is greater than 800, a notification message will be sent and the BGP session will restart. Also, BGP VPWS services support a single access circuit, so only the most significant bit of the CSV is examined on receipt.

A pseudowire will be established when a BGP VPWS update is received that matches the service configuration, specifically the configured route-targets and remote VE ID. If multiple matching updates are received, the system to which the pseudowire is established is determined by the tie-breaking rules, as described in IETF Draft *draft-ietf-bess-vpls-multihoming-01*.

Traffic will be sent on the active pseudowire connected to the remote designated forwarder. Traffic can be received on either the active or standby pseudowire, although no traffic should be received on the standby pseudowire because the SAP/GRE tunnel on the non-designated forwarder should be blocked.

### 2.13.3.2 BGP-VPWS with Inter-AS Model C

BGP VPWS with inter-AS model C is supported both in a single-homed and dual-homed configuration.

When dual-homing is used, the dual-homed PEs must have different values configured for the **site-preference** (under the **site** within the Epipe service) to allow the PEs in a different AS to select the designated forwarder when all access circuits are up. The value configured for the **site-preference** is propagated between autonomous systems in the BGP VPWS and BGP multi-homing update extended community VPLS preference field. The receiving ingress ASBR copies the VPLS preference value into local preference of the update to ensure that the VPLS preference and local preference are equal, which prevents the update from being considered malformed.

### 2.13.3.3 BGP VPWS Configuration Procedure

In addition to configuring the associated BGP and MPLS infrastructure, the provisioning of a BGP VPWS service requires:

- Configuring the BGP Route Distinguisher, Route Target
  - Updates are accepted into the service only if they contain the configured import route-target
- Configuring a binding to the pseudowire template
  - Multiple pseudowire template bindings can be configured with their associated route-targets used to control which is applied
- Configuring the SAP or static GRE tunnel
- Configuring the name of the local VE and its associated VE ID
- Configuring the name of the remote VE and its associated VE ID
- For a dual-homed PE
  - Enabling the site
  - Configuring the site with non-zero site-preference
- For a remote PE
  - Configuring up to two remote VE names and associated VE IDs
- Enabling BGP VPWS

### 2.13.3.4 Use of Pseudowire Template for BGP VPWS

The pseudowire template concept used for BGP AD is re-used for BGP VPWS to dynamically instantiate pseudowires (SDP-bindings) and the related SDPs (provisioned or automatically instantiated).

The settings for the L2-Info extended community in the BGP update sent by the system are derived from the pseudowire-template attributes. The following rules apply:

- If multiple pseudowire-template-bindings (with or without import-rt) are specified for the VPWS instance, the first (numerically lowest ID) pseudowire-template entry will be used.
- Both Ethernet VLAN and Ethernet Raw Mode Encaps Types are supported; these are selected by configuring the vc-type in the pseudowire template to be either vlan or ether, respectively. The default is ether.
  - The same value must be used by the remote BGP VPWS instance to ensure that the related pseudowire will come up.

- Layer 2 MTU – derived from service VPLS **service-mtu** parameter.
  - The same value must be used by the remote BGP VPWS instance to ensure that the related pseudowire will come up.
- Control Flag C – can be 0 or 1, depending on the setting of the *controlword* parameter in the PW template 0.
- Control Flag S – always 0.

On reception, the values of the parameters in the L2-Info extended community of the BGP update are compared with the settings from the corresponding pseudowire-template. The following steps are used to determine the local pseudowire-template:

- The route-target values are matched to determine the pseudowire-template. The binding configured with the first matching route target is chosen.
- If a match is not found from the previous step, the lowest pw-template-binding (numerically) without any route-target configured is used[.
- If the values used for Encaps Type or Layer 2 MTU do not match, the pseudowire is created but with the operationally down state.
  - To interoperate with existing implementations, if the received MTU value = 0, then MTU negotiation does not take place; the related pseudowire is set up ignoring the MTU.
- If the value of the S flag is not zero, the pseudowire is not created.

The following pseudowire template parameters are supported when applied within a BGP VPWS service; the remainder are ignored:

```
configure service pw-template policy-id [use-provisioned-sdp |
    [prefer-provisioned-sdp] [auto-sdp]] [create] [name name]
accounting-policy acct-policy-id
no accounting-policy
[no] collect-stats
[no] controlword
egress
    filter ipv6 ipv6-filter-id
    filter ip ip-filter-id
    filter mac mac-filter-id
    no filter [ip ip-filter-id] [mac mac-filter-id] [ipv6 ipv6-filter-id]
    qos network-policy-id port-redirect-group queue-group-name instance instance-id
no qos [network-policy-id]
[no] force-vlan-vc-forwarding
hash-label [signal-capability]
no hash-label
ingress
    filter ipv6 ipv6-filter-id
    filter ip ip-filter-id
    filter mac mac-filter-id
    no filter [ip ip-filter-id] [mac mac-filter-id] [ipv6 ipv6-filter-id]
    qos network-policy-id fp-redirect-group queue-group-name instance instance-id
no qos [network-policy-id]
[no] sdp-exclude
```

```
[no] sdp-include
vc-type {ether | vlan}
vlan-vc-tag vlan-id
no vlan-vc-tag
```

For more information about this command, refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide*.

The **use-provisioned-sdp** option is permitted when creating the pseudowire template if a pre-provisioned SDP is to be used. Pre-provisioned SDPs must be configured whenever RSVP-signaled transport tunnels are used.

When the **prefer-provisioned-sdp** option is specified, if the system finds an existing matching SDP that conforms to any restrictions defined in the pseudowire template (for example, **sdp-include/sdp-exclude group**), it uses this matching SDP (even if the existing SDP is operationally down); otherwise, it automatically creates an SDP.

When the **auto-gre-sdp** option is specified, a GRE SDP is automatically created.

The **tools perform** command can be used in the same way as for BGP-AD to apply changes to the pseudowire template using the following format:

```
tools perform service [id service-id] eval-pw-template
policy-id [allow-service-impact]
```

If a user configures a service using a pseudowire template with the **prefer-provisioned-sdp** option, but without an applicable SDP being provisioned, and the system binds to an automatic SDP, and the user subsequently provisions an appropriate SDP, the system will not automatically switch to the new provisioned SDP. This will only occur if the pseudowire template is re-evaluated using the **tools perform service id service-id eval-pw-template** command.

### 2.13.3.5 Use of Endpoint for BGP VPWS

An endpoint is required on a remote PE connecting to two dual-homed PEs to associate the active/standby pseudowires with the Epipe service. An endpoint is automatically created within the Epipe service such that active/standby pseudowires are associated with that endpoint. The creation of the endpoint occurs when **bgp-vpws** is enabled (and deleted when it is disabled) and so will exist in both a single- and dual-homed scenario (this simplifies converting a single-homed service to a dual-homed service). The naming convention used is `_tmnx_BgpVpws-x`, where `x` is the service identifier. The automatically created endpoint has the default parameter values, although all are ignored in a BGP-VPWS service with the description field being defined by the system.

The command:

```
tools perform service id <service-id> endpoint <endpoint-name> force-switchover
```

will have no effect on an automatically created VPWS endpoint.

---

## 2.14 VLL Service Considerations

This section describes the general 7450 ESS, 7750 SR, and 7950 XRS service features and any special capabilities or considerations as they relate to VLL services.

### 2.14.1 SDPs

The most basic SDPs must have the following:

- A locally unique SDP identification (ID) number.
- The system IP address of the originating and far-end routers.
- An SDP encapsulation type, either GRE or MPLS.

The most basic Apipe and Fpipe SDP configurations for the 7750 SR must have the following:

- A locally unique SDP identification (ID) number and VC-ID.

#### 2.14.1.1 SDP Statistics for VPLS and VLL Services

The three-node network in [Figure 48](#) shows two MPLS SDPs and one GRE SDP defined between the nodes. These SDPs connect VPLS1 and VPLS2 instances that are defined in the three nodes. With this feature, the operator will have local CLI-based as well as SNMP-based statistics collection for each VC used in the SDPs. This will allow for traffic management of tunnel usage by the different services and with aggregation the total tunnel usage.

**Figure 48 SDP Statistics for VPLS and VLL Services**

OSSG208

## 2.14.2 SAP Encapsulations and Pseudowire Types

The Epipe service is designed to carry Ethernet frame payloads, so it can provide connectivity between any two SAPs that pass Ethernet frames. The following SAP encapsulations are supported on the 7450 ESS, 7750 SR, and 7950 XRS Epipe service:

- Ethernet null
- Ethernet dot1q
- QinQ
- SONET/SDH BCP-null for the 7450 ESS and 7750 SR
- SONET/SDH BCP-dot1q for the 7450 ESS and 7750 SR
- ATM VC with RFC 2684 Ethernet bridged encapsulation (see [Ethernet Interworking VLL](#)) for the 7750 SR
- FR VC with RFC 2427 Ethernet bridged encapsulation (see [Ethernet Interworking VLL](#)) for the 7450 ESS and 7750 SR

While different encapsulation types can be used, encapsulation mismatching can occur if the encapsulation behavior is not understood by connecting devices, which are unable to send and receive the expected traffic. For example, if the encapsulation type on one side of the Epipe is dot1q and the other is null, tagged traffic received on the null SAP will be double-tagged when it is transmitted out of the dot1q SAP.

ATM VLLs can be configured with both endpoints (SAPs) on the same router or with the two endpoints on different 7750 SRs. In the latter case, Pseudowire Emulation Edge-to-Edge (PWE3) signaling is used to establish a pseudowire between the devices, allowing ATM traffic to be tunneled through an MPLS or GRE network:

Two pseudowire encapsulation modes, that is, SDP vc-type, are available:

- PWE3 N-to-1 Cell Mode Encapsulation
- PWE3 AAL5 SDU Mode Encapsulation

The endpoints of Fpipes must be Data-Link Connection Identifiers (DLCIs) on any port that supports Frame Relay. The pseudowire encapsulation, or SDP vc-type, supported is the 1-to-1 Frame Relay encapsulation mode.

### 2.14.2.1 PWE3 N-to-1 Cell Mode

The endpoints of an N-to-1 mode VLL on a 7750 SR can be:

- ATM VCs — VPI/VCI translation is supported (that is, the VPI/VCI at each endpoint does not need to be the same).
- ATM VPs — VPI translation is supported (that is, the VPI at each endpoint need not be the same, but the original VCI will be maintained).
- ATM VTs (a VP range) — No VPI translation is supported (that is, the VPI/VCI of each cell is maintained across the network).
- ATM ports — No translation is supported (that is, the VPI/VCI of each cell is maintained across the network).

For N-to-1 mode VLLs, cell concatenation is supported. Cells will be packed on ingress to the VLL and unpacked on egress. As cells are being packed, the concatenation process may be terminated by:

- Reaching a maximum number of cells per packet.
- Expiry of a timer.
- (Optionally) change of the CLP bit.
- (Optionally) change of the PTI bits indicating the end of the AAL5 packet.

---

In N-to-1 mode, OAM cells are transported through the VLL as any other cell. The PTI and CLP bits are untouched, even if VPI/VCI translation is carried out.

### **2.14.2.2   PWE3 AAL5 SDU Mode**

The endpoints of an AAL5 SDU mode VLL on a 7750 SR must be ATM VCs specified by port/vpi/vci. VPI/ VCI translation is supported. The endpoint can also be a FR VC, specified by port/dlci. In this case, FRF.5 FR-ATM network interworking is performed between the ATM VC SAP or the SDP and the FR VC SAP.

In SDU mode, the mandatory PWE3 control word is supported. This allows the ATM VLL to transport OAM cells along with SDU frames, using the “T” bit to distinguish between them, to recover the original SDU length, and to carry CLP, EFCI, and UU information.

### **2.14.2.3   QoS Policies**

When applied to 7450 ESS, 7750 SR, or 7950 XRS Epipe, Apipe, and Fpipe services, service ingress QoS policies only create the unicast queues defined in the policy. The multipoint queues are not created on the service.

With Epipe, Apipe, and Fpipe services, egress QoS policies function as with other services where the class-based queues are created as defined in the policy. Both Layer 2 or Layer 3 criteria can be used in the QoS policies for traffic classification in a service. QoS policies on Apipes cannot perform any classification, and on Fpipes Layer 3 (IP), classification is performed.

### **2.14.2.4   Filter Policies**

7450 ESS, 7750 SR, and 7950 XRS Epipe, Fpipe, and Ipipe services can have a single filter policy associated on both ingress and egress. Both MAC and IP filter policies can be used on Epipe services.

Filters cannot be configured on 7750 SR Apipe service SAPs.

---

### **2.14.2.5 MAC Resources**

Epipe services are point-to-point Layer 2 VPNs capable of carrying any Ethernet payloads. Although an Epipe is a Layer 2 service, the 7450 ESS, 7750 SR, and 7950 XRS Epipe implementation does not perform any MAC learning on the service, so Epipe services do not consume any MAC hardware resources.

---

## 2.15 Configuring a VLL Service with CLI

This section provides information to configure Virtual Leased Line (VLL) services using the command line interface.

### 2.15.1 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed, and the CLI commands to configure the VLL services, as follows:

1. Associate the service with a customer ID.
2. Define SAP parameters:
  - Optionally - configure ATM parameters on the 7750 SR
  - Optionally - select egress and ingress QoS and/or scheduler policies (configured in the **config>qos** context).
  - Optionally - select accounting policy (configured in the **config>log** context).
3. Define spoke-SDP parameters.
4. Enable the service.

### 2.15.2 Configuring VLL Components

This section provides VLL configuration examples for the VLL services.

#### 2.15.2.1 Creating an Apipe Service

Use the following CLI syntax to create an Apipe service on a 7750 SR.

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[vpn vpn-id] [vc-type {atm-vcc|atm-sdu|atm-vpc|atm-
cell}] [vc-switching]
description description-string
interworking {frf-5}
service-mtu octets
no shutdown
```

The following example shows the command usage to create an Apipe service.

PE router 1 (A:ALA-41):

**Example:**     A:ALA-41>config>service# apipe 5 customer 1 create  
                  A:ALA-41config>service>apipe# description "apipe test"  
                  A:ALA-41config>service>apipe# service-mtu 1400  
                  A:ALA-41config>service>apipe# no shutdown  
                  A:ALA-41config>service>apipe#

PE router 2 (A:ALA-42):

**Example:**     A:ALA-42>config>service# apipe 5 customer 1 create  
                  A:ALA-42>config>service>apipe# description "apipe test"  
                  A:ALA-42>config>service>apipe# service-mtu 1400  
                  A:ALA-42>config>service>apipe# no shutdown  
                  A:ALA-42>config>service>apipe#

The following example shows the Apipe service creation output.

PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
      apipe 5 customer 1 create
      description "apipe test"
      service-mtu 1400
      no shutdown
      exit
...
-----
A:ALA-41>config>service#
```

PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
      apipe 5 customer 1 create
      description "apipe test"
      service-mtu 1400
      no shutdown
      exit
...
-----
A:ALA-42>config>service#
```

### 2.15.2.1.1 Configuring Basic Apipe SAP Parameters

Use the following CLI syntax to configure Apipe SAP parameters.

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[vpn vpn-id] [vc-type {atm-vcc|atm-sdu|atm-vpc|atm-
cell}][vc-switching]
    sap sap-id
        accounting-policy acct-policy-id
        atm
            egress
                traffic-desc traffic-desc-profile-id
            ingress
                traffic-desc traffic-desc-profile-id
        oam
            alarm-cells
            terminate
        collect-stats
        description description-string
        egress
            qos policy-id
            scheduler-policy scheduler-policy-name
        ingress
            qos policy-id [shared-queuing]
            scheduler-policy scheduler-policy-name
        multi-service-site customer-site-name
        no shutdown
```

The following example shows the command usage to create Apipe SAPs:

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# sap 1/1/1:0/32 create
A:ALA-41>config>service>apipe>sap# ingress
A:ALA-41>config>service>apipe>sap>ingress# qos 102
A:ALA-41>config>service>apipe>sap>ingress# exit
A:ALA-41>config>service>apipe>sap# egress
A:ALA-41>config>service>apipe>sap>egress# qos 103
A:ALA-41>config>service>apipe>sap>egress# exit
A:ALA-41>config>service>apipe>sap# no shutdown
A:ALA-41>config>service>apipe>sap# exit
A:ALA-41>config>service>apipe#
```

PE router 2 (A:ALA-42):

**Example:**

```
Example:A:ALA-42>config>service# apipe 5
A:ALA-42>config>service>apipe# sap 2/2/2:0/32 create
A:ALA-42>config>service>apipe>sap# ingress
A:ALA-42>config>service>apipe>sap>ingress# qos 102
A:ALA-42>config>service>apipe>sap>ingress# exit
A:ALA-42>config>service>apipe>sap# egress
A:ALA-42>config>service>apipe>sap>egress# qos 103
```

```
A:ALA-42>config>service>apipe>sap>egress# exit
A:ALA-42>config>service>apipe>sap# no shutdown
A:ALA-42>config>service>apipe>sap# exit
A:ALA-42>config>service>apipe#
```

The following output shows the Apipe SAP configuration.

#### PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 1/1/1:0/32 create
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

#### PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 2/2/2:0/32 create
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        no shutdown
    exit
...
-----
A:ALA-42>config>service#
```

### 2.15.2.1.2 Configuring an ATM SAP in the N-to-1 Mapping of ATM VPI/VCI to ATM Pseudowire

Users can configure an ATM-cell Apipe service with a new ATM SAP type. The SAP type refers to a preconfigured ATM connection profile name.

```
configure service apipe 100 vc-type atm-cell
    sap <port-id | aps-id>[:cp.<connection-profile-num>]
```

The ATM SAP connection profile is configured with the list of discrete VPI/VCI values, as follows:

```
configure connection-profile 2 {member vpi/vci...(up to 16)}
```

A connection profile can only be applied to a SAP that is part of an Apipe VLL service of vc-type atm-cell. The ATM SAP can be on a regular port or APS port. A connection profile can be applied to any number of ATM SAPs.

Up to a maximum of 16 discrete VPI/VCI values can be configured in a connection profile. After creation of the connection profile, the user can subsequently add, remove, or modify the VPI/VCI entries. This triggers a re-evaluation of all the ATM SAPs that are currently using that profile.

The user must also override the PW type signaled to type '0x0009 N:1 VCC cell' by using the following command:

```
config>service>apipe>signaled-vc-type-override atm-vcc
```

This command is not allowed in an Apipe VLL of vc-type value atm-cell if a configured ATM SAP is not using a connection profile. Conversely, if the signaling override command is enabled, only an ATM SAP with a connection profile assigned will be allowed.

The override command is not allowed on an Apipe VLL service of vc-type value other than atm-cell. It is also not allowed on a VLL service with the **vc-switching** option enabled because signaling of the pseudowire FEC in a Multi-Segment Pseudowire (MS-PW) is controlled by the T-PE nodes. Therefore, for this feature to be used on a MS-PW, configure an Apipe service of vc-type atm-cell at the T-PE nodes with the **signaled-vc-type-override** command enabled, and configure an Apipe VLL service of vc-type atm-vcc at the S-PE node with the **vc-switching** option enabled.

The following are the restrictions of this feature:

- A SAP-to-SAP VLL service is not supported using ATM SAP with a connection profile assigned. The user must configure each VPI/VCI into a separate SAP and create as many Apipe VLL services of type atm-vcc as required.

- An ATM SAP with a connection profile assigned cannot be configured on a port that is part of an MC-APS protection group.
- It is strongly recommended to not apply a VCI-based QoS Filter to the ingress of an ATM SAP with a connection profile. Because the filter matches the VCI value of the first cell of a concatenated packet, the entire packet will be treated the same way based on the action of the entry of the criteria; all cells of the concatenated packet will be mapped to the same FC and profile, based on the VCI value of the first cell.

This feature is supported on the 4-port OC-3/STM-1:OC-12/STM-4 ATM MDA and on the 16-port OC-3/STM-1 ATM MDA.

### 2.15.2.1.3 Configuring Apipe SDP Bindings

Use the following CLI syntax to create a spoke-SDP binding with an Apipe service.

**CLI Syntax:**

```
config>service# apipe service-id [customer customer-id]
[vpn vpn-id] [vc-type {atm-vcc|atm-sdu|atm-vpc|atm-
cell}] [vc-switching]
spoke-sdp sdp-id:vc-id
    cell-concatenation
    aal5-frame-aware
    clp-change
    max-cells cell-count
    max-delay delay-time
    egress
    vc-label egress-vc-label
    ingress
    vc-label ingress-vc-label
    no shutdown
```

The following example displays the command usage to create Apipe spoke-SDPs:

PE router 1 (A:ALA-41):

**Example:**

```
Example:A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# spoke-sdp 1:5 create
A:ALA-41>config>service>apipe>spoke-sdp# no shutdown
A:ALA-41>config>service>apipe>spoke-sdp# exit
```

PE router 2 (A:ALA-42):

**Example:**

```
Example:A:ALA-42>config>service# apipe 5
A:ALA-42>config>service>apipe# spoke-sdp 1:5 create
A:ALA-42>config>service>apipe>spoke-sdp# no shutdown
```

---

```
A:ALA-42>config>service>apipe>spoke-sdp# exit
```

The following output shows the Apipe spoke-SDP configurations.

**PE Router 1 (ALA-41):**

```
A:ALA-41>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 1/1/1:0/32 create
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        spoke-sdp 1:5 create
        exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

**PE Router 2 (ALA-42):**

```
A:ALA-42>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 2/2/2:0/32 create
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        spoke-sdp 1:5 create
        exit
        no shutdown
    exit
...
-----
A:ALA-42>config>service#
```

## 2.15.2.2 Creating a Cpipe Service

### 2.15.2.2.1 Basic Configuration

Use the following CLI syntax to create a Cpipe service on a 7750 SR. A route distinguisher must be defined in order for Cpipe to be operationally active.

**CLI Syntax:** `config>service# cpipe service-id [customer customer-id]  
[vpn vpn-id] [vc-type {satop-e1 | satop-t1 | cesopsn |  
cesopsn-cas}] [vc-switching] [create]`

For the 7450 ESS platforms, the vc-switching option must be configured for Cpipe functionality, as follows:

```
cpipe 1 name "XYZ Cpipe 1" customer 1 vc-switching vc-type cesopsn create
    spoke-sdp 20:1 create
        description "Description for Sdp Bind 20 for Svc ID 1"
        ingress
            vc-label 10002
        exit
    egress
        vc-label 10001
    exit
exit
spoke-sdp 50:1 create
    description "Description for Sdp Bind 50 for Svc ID 1"
exit
no shutdown
exit
```

The following displays a Cpipe service configuration example:

```
*A:ALA-1>config>service# info
-----
...
    cpipe 210 customer 1 vc-type cesopsn create
        service-mtu 1400
        sap 1/5/10.1.3.1 create
        exit
        spoke-sdp 1:210 create
        exit
        no shutdown
    exit
...
-----
*A:ALA-1>config>service#
```

## 2.15.2.2.2 Configuration Requirements

Before a Cpipe service can be provisioned, the following tasks must be completed:

- [Configuring a DS1 Port](#)
- [Configuring a Channel Group](#)

### Configuring a DS1 Port

The following example shows a DS1 port configured for CES:

```
A:sim216# show port 1/5/10.1.3.1
=====
TDM DS1 Interface
=====
Description          : DS1
Interface            : 1/5/10.1.3.1
Type                 : ds1                      Framing              : esf
Admin Status         : up                      Oper Status          : up
Physical Link        : yes                     Clock Source         : loop-timed
Signal Mode          : none
Last State Change    : 10/31/2006 14:23:12      Channel IfIndex      : 580943939
Loopback             : none                    Invert Data          : false
Remote Loop respond  : false                   In Remote Loop       : false
Load-balance-algo    : default                  Egr. Sched. Pol     : n/a
BERT Duration        : N/A                     BERT Pattern         : none
BERT Synched         : 00h00m00s               Err Insertion Rate   : 0
BERT Errors          : 0                       BERT Status          : idle
BERT Total Bits      : 0
Cfg Alarm            : ais los
Alarm Status         :
=====
A:sim216#
```

### Configuring a Channel Group

The following example shows a DS1 channel group configured for CES:

```
A:sim216# show port 1/5/10.1.3.1
=====
TDM DS0 Chan Group
=====
Description          : DS0GRP
Interface            : 1/5/10.1.3.1
TimeSlots           : 1-12
Speed               : 64                      CRC                  : 16
Admin Status        : up                      Oper Status          : up
Last State Change    : 10/31/2006 14:23:12      Chan-Grp IfIndex    : 580943940
Configured mode      : access                  Encap Type           : cem
Admin MTU            : 4112                    Oper MTU             : 4112
Physical Link        : Yes                     Bundle Number        : none
```

```

Idle Cycle Flags      : flags                      Load-balance-algo      : default
Egr. Sched. Pol      : n/a
=====
A:sim216#

```

### 2.15.2.2.3 Configuring Cpipe SAPs and Spoke-SDPs

The following examples show Cpipe SAP and spoke-SDP configurations:

```

*A:ALA-49>config>service# info
#-----
echo "Service Configuration"
#-----
...
    cpipe 100 customer 1 vc-type cesopnsn create
        service-mtu 1400
        sap 1/5/10.1.1.1 create
        exit
        spoke-sdp 1:100 create
        exit
        no shutdown
    exit
    cpipe 200 customer 1 vc-type cesopnsn-cas create
        sap 1/5/10.2.1.1 create
        exit
        sap 1/5/10.2.2.1 create
        exit
        no shutdown
    exit
    cpipe 210 customer 1 vc-type cesopnsn-cas create
        service-mtu 1400
        sap 1/5/10.1.3.1 create
        exit
        spoke-sdp 1:210 create
        exit
        no shutdown
    exit
    cpipe 300 customer 1 vc-type cesopnsn create
        sap 1/5/10.3.4.1 create
        exit
        sap 1/5/10.3.6.1 create
        exit
        no shutdown
    exit
    cpipe 400 customer 1 vc-type satop-el create
        sap 1/5/10.2.3.1 create
        exit
        spoke-sdp 1:400 create
        exit
        no shutdown
    exit
...
#-----
*A:ALA-49>config>service#

```

```
A:sim213>config>service>cpipe# info
-----
description "cpipe-100"
sap 1/5/10.1.1.1 create
cem
    packet jitter-buffer 16 payload-size 384
    report-alarm rpktloss
    no report-alarm stray
    rtp-header
exit
exit
spoke-sdp 1:100 create
exit
no shutdown
-----
A:sim213>config>service>cpipe#
```

### 2.15.2.3 Creating an Epipe Service

Use the following CLI syntax to create an Epipe service.

**CLI Syntax:**    config>service# epipe service-id [customer customer-id]  
                  [vpn vpn-id] [vc-switching]  
                  description description-string  
                  no shutdown

The following example shows an Epipe configuration:

```
A:ALA-1>config>service# info
-----
...
    epipe 500 customer 5 vpn 500 create
    description "Local epipe service"
    no shutdown
exit
-----
A:ALA-1>config>service#
```

#### 2.15.2.3.1 Configuring Epipe SAP Parameters

A default QoS policy is applied to each ingress and egress SAP. Additional QoS policies can be configured in the **config>qos** context. Filter policies are configured in the config>filter context and explicitly applied to a SAP. There are no default filter policies.

Use the following CLI syntax to create:

- [Local Epipe SAPs](#)

- [Distributed Epipe SAPs](#)

The following example shows a configuration for the 7950 XRS.

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
sap sap-id [endpoint endpoint-name]
sap sap-id [no-endpoint]
    accounting-policy policy-id
    collect-stats
    description description-string
    no shutdown
    egress
        filter {ip ip-filter-name | mac mac-filter-
            name}
        qos sap-egress-policy-id
        scheduler-policy scheduler-policy-name
    ingress
        filter {ip ip-filter-name | mac mac-filter-
            name}
        match-qinq-dot1p {top | bottom}
        qos policy-id
        scheduler-policy scheduler-policy-name
```

The following example shows a configuration for the 7450 ESS and 7750 SR.

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
sap sap-id [endpoint endpoint-name]
sap sap-id [no-endpoint]
    accounting-policy policy-id
    collect-stats
    description description-string
    no shutdown
    egress
        filter {ip ip-filter-name | mac mac-filter-
            name}
        qos sap-egress-policy-id
        scheduler-policy scheduler-policy-name
    ingress
        filter {ip ip-filter-name | mac mac-filter-
            name}
        match-qinq-dot1p {top | bottom}
        qos policy-id [shared-queuing]
        scheduler-policy scheduler-policy-name
```

## Local Epipe SAPs

To configure a basic local Epipe service, enter the **sap sap-id** command twice with different port IDs in the same service configuration.

By default, QoS policy ID 1 is applied to ingress and egress service SAPs. Existing filter policies or other existing QoS policies can be associated with service SAPs on ingress and egress ports. [Table 11](#) shows supported SAP types.

**Table 11 Supported SAP Types**

| Uplink Type | Svc SAP Type   | Cust. VID | Access SAPs       | Network SAPs         |
|-------------|----------------|-----------|-------------------|----------------------|
| L2          | Null-star      | N/A       | Null, dot1q *     | Q.*                  |
| L2          | Dot1q          | N/A       | Dot1q             | Q.*                  |
| L2          | Dot1q-preserve | X         | Dot1q (encap = X) | Q1.Q2 (where Q2 = X) |

An existing scheduler policy can be applied to ingress and egress SAPs to be used by the SAP queues and, at egress only, policers. The schedulers comprising the policy are created when the scheduler policy is applied to the SAP. If any policers or orphaned queues (with a non-existent local scheduler defined) exist on a SAP and the policy application creates the required scheduler, the status on the queue becomes non-orphaned at this time.

Ingress and egress SAP parameters can be applied to local and distributed Epipe service SAPs.

The following example shows the SAP configurations for local Epipe service 500 on SAP 1/1/2 and SAP 1/1/3 on ALA-1:

```
A:ALA-1>config>service# epipe 500 customer 5 create
config>service>epipe$ description "Local epipe service"
config>service>epipe# sap 1/1/2:0 create
config>service>epipe>sap? ingress
config>service>epipe>sap>ingress# qos 20
config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 20
config>service>epipe>sap>egress# scheduler-policy test1
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe>sap# exit

config>service>epipe# sap 1/1/3:0 create
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# qos 555
```

```

config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 627
config>service>epipe>sap>egress# scheduler-policy alpha
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe>sap# exit

```

The following example shows the local Epipe configuration:

```

A:ALA-1>config>service# info
-----
...
    epipe 500 customer 5 vpn 500 create
        description "Local epipe service"
        sap 1/1/2:0 create
            ingress
                qos 20
                filter ip 1
            exit
            egress
                scheduler-policy "test1"
                qos 20
            exit
        exit
        sap 1/1/3:0 create
            ingress
                qos 555
                filter ip 1
            exit
            egress
                scheduler-policy "alpha"
                qos 627
            exit
        exit
        no shutdown
    exit
-----
A:ALA-1>config>service#

```

### 2.15.2.3.2 Distributed Epipe SAPs

To configure a distributed Epipe service, you must configure service entities on the originating and far-end nodes. You should use the same service ID on both ends (for example, Epipe 5500 on ALA-1 and Epipe 5500 on ALA-2). The **spoke-sdp sdp-id:vc-id** must match on both sides. A distributed Epipe consists of two SAPs on different nodes.

By default, QoS policy ID 1 is applied to ingress and egress service SAPs. Existing filter policies or other existing QoS policies can be associated with service SAPs on ingress and egress.

An existing scheduler policy can be applied to ingress and egress SAPs to be used by the SAP queues and, at egress only, policers. The schedulers comprising the policy are created when the scheduler policy is applied to the SAP. If any policers or orphaned queues (with a non-existent local scheduler defined) exist on a SAP and the policy application creates the required scheduler, the status on the queue becomes non-orphaned at this time.

Ingress and egress SAP parameters can be applied to local and distributed Epipe service SAPs.

For SDP configuration information, refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide*. For SDP binding information, see [Configuring SDP Bindings](#).

The following example shows a configuration of a distributed service between ALA-1 and ALA-2:

```
A:ALA-1>epipe 5500 customer 5 create
config>service>epipe$ description "Distributed epipe service to east coast"
config>service>epipe# sap 221/1/3:21 create
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# qos 555
config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 627
config>service>epipe>sap>egress# scheduler-policy alpha
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe>sap# exit
config>service>epipe#

A:ALA-2>config>service# epipe 5500 customer 5 create
config>service>epipe$ description "Distributed epipe service to west coast"
config>service>epipe# sap 441/1/4:550 create
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# qos 654
config>service>epipe>sap>ingress# filter ip 1020
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 432
config>service>epipe>sap>egress# filter ip 6
config>service>epipe>sap>egress# scheduler-policy test1
config>service>epipe>sap>egress# exit
config>service>epipe>sap# no shutdown
config>service>epipe#
```

The following example shows the SAP configurations for ALA-1 and ALA-2:

```
A:ALA-1>config>service# info
-----
...
    epipe 5500 customer 5 vpn 5500 create
        description "Distributed epipe service to east coast"
```

```

        sap 221/1/3:21 create
        ingress
            qos 555
            filter ip 1
        exit
        egress
            scheduler-policy "alpha"
            qos 627
        exit
    exit
exit
...
-----
A:ALA-1>config>service#

A:ALA-2>config>service# info
-----
...
    epipe 5500 customer 5 vpn 5500 create
    description "Distributed epipe service to west coast"
    sap 441/1/4:550 create
    ingress
        qos 654
        filter ip 1020
    exit
    egress
        scheduler-policy "test1"
        qos 432
        filter ip 6
    exit
    exit
exit
...
-----
A:ALA-2>config>service#

```

## PBB Epipe Configuration

The following example shows the PBB Epipe configuration:

```

*A:Wales-1>config>service>epipe# info
-----
...
    description "Default epipe description for service id 20000"
    pbb-tunnel 200 backbone-dest-mac 00:03:fa:15:d3:a8 isid 20000
    sap 1/1/2:1.1 create
        description "Default sap description for service id 20000"
        ingress
            filter mac 1
        exit
    exit
    no shutdown
-----
*A:Wales-1>config>service>epipe#

```

**CLI Syntax:**    configure service vpls 200 customer 1 b-vpls create

```
*A:Wales-1>config>service>vpls# info
```

```
-----
...
  service-mtu 2000
  fdb-table-size 131071
  stp
  no shutdown
  exit
  sap 1/1/8 create
  exit
  sap 1/2/3:200 create
  exit
  mesh-sdp 1:200 create
  exit
  mesh-sdp 100:200 create
  exit
  mesh-sdp 150:200 create
  exit
  mesh-sdp 500:200 create
  exit
  no shutdown
-----
*A:Wales-1>config>service>vpls#
```

## Configuring Ingress and Egress SAP Parameters

By default, QoS policy ID 1 is applied to ingress and egress service SAPs. Existing filter policies or other existing QoS policies can be associated with service SAPs on ingress and egress ports.

An existing scheduler policy can be applied to ingress and egress SAPs to be used by the SAP queues and, at egress only, policers. The schedulers comprising the policy are created when the scheduler policy is applied to the SAP. If any policers or orphaned queues (with a non-existent local scheduler defined) exist on a SAP and the policy application creates the required scheduler, the status on the queue becomes non-orphaned at this time.

Ingress and egress SAP parameters can be applied to local and distributed Epipe service SAPs.

The following example shows the SAP ingress and egress parameters:

```
ALA-1>config>service# epipe 5500
config>service>epipe# sap 2/1/3:21
config>service>epipe>sap# ingress
config>service>epipe>sap>ingress# qos 555
config>service>epipe>sap>ingress# filter ip 1
config>service>epipe>sap>ingress# exit
config>service>epipe>sap# egress
config>service>epipe>sap>egress# qos 627
```

```

config>service>epipe>sap>egress# scheduler-policy alpha
config>service>epipe>sap>egress# exit
config>service>epipe>sap#

```

The following example shows the Epipe SAP ingress and egress configuration:

```

A:ALA-1>config>service#
-----
...
    epipe 5500 customer 5 vpn 5500 create
        description "Distributed epipe service to east coast"
        sap 2/1/3:21 create
            ingress
                qos 555
                filter ip 1
            exit
            egress
                scheduler-policy "alpha"
                qos 627
            exit
        exit
    spoke-sdp 2:123 create
        ingress
            vc-label 6600
        exit
        egress
            vc-label 5500
        exit
    exit
    no shutdown
    exit
-----
A:ALA-1>config>service#

```

### 2.15.2.3.3 Configuring SDP Bindings

[Figure 49](#) shows an example of a distributed Epipe service configuration between two routers, identifying the service and customer IDs, and the uni-directional SDPs required to communicate to the far-end routers.

A spoke-SDP is treated like the equivalent of a traditional bridge “port”, where flooded traffic received on the spoke-SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.

**Figure 49 SDPs — Uni-Directional Tunnels**

Use the following CLI syntax to create a spoke-SDP binding with an Epipe service.

**CLI Syntax:**

```
config>service# epipe service-id [customer customer-id]
spoke-sdp sdp-id:vc-id [vc-type {ether | vlan}]
vlan-vc-tag 0..4094
egress
    filter {ip ip-filter-id}
    vc-label egress-vc-label
ingress
    filter {ip ip-filter-id}
    vc-label ingress-vc-label
no shutdown
```

The following example shows the command usage to bind an Epipe service between ALA-1 and ALA-2. This example assumes the SAPs have already been configured (see [Distributed Epipe SAPs](#)).

```
A:ALA-1>config>service# epipe 5500
config>service>epipe# spoke-sdp 2:123
config>service>epipe>spoke-sdp# egress
config>service>epipe>spoke-sdp>egress# vc-label 5500
config>service>epipe>spoke-sdp>egress# exit
config>service>epipe>spoke-sdp# ingress
config>service>epipe>spoke-sdp>ingress# vc-label 6600
config>service>epipe>spoke-sdp>ingress# exit
config>service>epipe>spoke-sdp# no shutdown

ALA-2>config>service# epipe 5500
config>service>epipe# spoke-sdp 2:456
config>service>epipe>spoke-sdp# egress
config>service>epipe>spoke-sdp>egress# vc-label 6600
config>service>epipe>spoke-sdp>egress# exit
config>service>epipe>spoke-sdp# ingress
config>service>epipe>spoke-sdp>ingress# vc-label 5500
config>service>epipe>spoke-sdp>ingress# exit
config>service>epipe>spoke-sdp# no shutdown
```

The following example shows the SDP binding for the Epipe service between ALA-1 and ALA-2:

```
A:ALA-1>config>service# info
-----
...
    epipe 5500 customer 5 vpn 5500 create
        description "Distributed epipe service to east coast"
        sap 2/1/3:21 create
            ingress
                qos 555
                filter ip 1
            exit
        egress
            scheduler-policy "alpha"
            qos 627
        exit
    exit
    spoke-sdp 2:123 create
        ingress
            vc-label 6600
        exit
        egress
            vc-label 5500
        exit
    exit
    no shutdown
    exit
...
-----
A:ALA-1>config>service#

A:ALA-2>config>service# info
-----
...
exit
    epipe 5500 customer 5 vpn 5500 create
        description "Distributed epipe service to west coast"
        sap 441/1/4:550 create
            ingress
                qos 654
                filter ip 1020
            exit
        egress
            scheduler-policy "test1"
            qos 432
            filter ip 6
        exit
    exit
    spoke-sdp 2:456 create
        ingress
            vc-label 5500
        exit
        egress
            vc-label 6600
        exit
    exit
    no shutdown
    exit
...
-----
```

---

```
A:ALA-2>config>service#
```

## 2.15.2.4 Creating an Fpipe Service

Use the following CLI syntax to create an Fpipe service on a 7750 SR.

**CLI Syntax:**

```
config>service# fpipe service-id [customer customer-id]
[vpn vpn-id] [vc-type {fr-dlci}] [vc-switching]
description description-string
service-mtu octets
no shutdown
```

The following example shows the command usage to create an Fpipe service:

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# fpipe 1 customer 1 create
A:ALA-41config>service>fpipe# description "fpipe test"
A:ALA-41config>service>fpipe# service-mtu 1400
A:ALA-41config>service>fpipe# no shutdown
A:ALA-41config>service>fpipe#
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# fpipe 1 customer 1 create
A:ALA-42>config>service>fpipe# description "fpipe test"
A:ALA-42>config>service>fpipe# service-mtu 1400
A:ALA-42>config>service>fpipe# no shutdown
A:ALA-42>config>service>fpipe#
```

The following example shows the Fpipe service creation output:

PE router 1 (A:ALA-41):

A:ALA-41>config>service# info

```
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

PE router 2 (A:ALA-42):

A:ALA-42>config>service# info

```

-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        no shutdown
    exit
...
-----
A:ALA-42>config>service#

```

#### 2.15.2.4.1 Configuring Fpipe SAP Parameters

Use the following CLI syntax to configure Fpipe SAP parameters.

**CLI Syntax:**

```

config>service# fpipe service-id [customer customer-id]
                    [vpn vpn-id] [vc-type {fr-dlci}] [vc-switching]
                    sap sap-id
                        accounting-policy acct-policy-id
                        collect-stats
                        description description-string
                        egress
                            filter [ip ip-filter-id]
                            qos policy-id
                            scheduler-policy scheduler-policy-name
                        ingress
                            filter [ip ip-filter-id]
                            qos policy-id [shared-queuing]
                            scheduler-policy scheduler-policy-name
                    multi-service-site customer-site-name
                    no shutdown

```

The following example shows the command usage to create an Fpipe SAP:

PE router 1 (A:ALA-41):

**Example:**

```

A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# sap 1/2/1:16 create
A:ALA-41>config>service>fpipe>sap# ingress
A:ALA-41>config>service>fpipe>sap>ingress# qos 101
A:ALA-41>config>service>fpipe>sap>ingress# exit
A:ALA-41>config>service>fpipe>sap# egress
A:ALA-41>config>service>fpipe>sap>egress# qos 1020

```

```
A:ALA-41>config>service>fpipe>sap>egress# exit
A:ALA-41>config>service>fpipe>sap# no shutdown
A:ALA-41>config>service>fpipe>sap# exit
A:ALA-41>config>service>fpipe#
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# fpipe 1
A:ALA-42>config>service>fpipe# sap 2/1/1.1:16 create
A:ALA-42>config>service>fpipe>sap# ingress
A:ALA-42>config>service>fpipe>sap>ingress# qos 101
A:ALA-42>config>service>fpipe>sap>ingress# exit
A:ALA-42>config>service>fpipe>sap# egress
A:ALA-42>config>service>fpipe>sap>egress# qos 1020
A:ALA-42>config>service>fpipe>sap>egress# exit
A:ALA-42>config>service>fpipe>sap# no shutdown
A:ALA-42>config>service>fpipe>sap# exit
A:ALA-42>config>service>fpipe#
```

The following example shows the Fpipe SAP configuration:

PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 1/2/1:16 create
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 2/1/1.1:16 create
            ingress
...
-----
```

```

        qos 101
    exit
    egress
        qos 1020
    exit
    exit
    no shutdown
    exit
...
-----
A:ALA-42>config>service#

```

#### 2.15.2.4.2 Configuring Fpipe SDP Bindings

Use the following CLI syntax to create a spoke-SDP binding with an Fpipe service.

**CLI Syntax:**

```

config>service# fpipe service-id [customer customer-id]
[vpn vpn-id] [vc-type {fr-dlci}] [vc-switching]
spoke-sdp sdp-id:vc-id
    egress
        filter ip ip-filter-id
        vc-label egress-vc-label
    ingress
        filter ip ip-filter-id
        vc-label ingress-vc-label
    no shutdown

```

The following example shows the command usage to create an Fpipe spoke-SDP:

PE router 1 (A:ALA-41):

**Example:**

```

A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# spoke-sdp 1:1 create
A:ALA-41>config>service>spoke-sdp# no shutdown
A:ALA-41>config>service>spoke-sdp# exit

```

PE router 2 (A:ALA-42):

**Example:**

```

A:ALA-42>config>service# fpipe 1
A:ALA-42>config>service>fpipe# spoke-sdp 1:1 create
A:ALA-42>config>service>spoke-sdp# no shutdown
A:ALA-42>config>service>spoke-sdp# exit

```

The following example shows the Fpipe spoke-SDP configuration:

PE Router 1 (ALA-41):

```

A:ALA-41>config>service# info

```

```

-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 1/2/1:16 create
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
        exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#

```

#### PE Router 2 (ALA-42):

```

A:ALA-42>config>service# info
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 2/1/1.1:16 create
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
        exit
        no shutdown
    exit
...
-----
A:ALA-42>config>service#

```

### 2.15.2.5 Creating an Ipipe Service

Use the following CLI syntax to create an Ipipe service on a 7450 ESS or 7750 SR.

**CLI Syntax:**    config>service# ipipe service-id [customer customer-id]  
                     [vpn vpn-id] [vc-switching]  
                     description description-string  
                     no shutdown

The following example shows an Ipipe configuration:

```
A:ALA-1>config>service# info
-----
...
    ipipe 202 customer 1 create
        description "eth_ipipe"
        no shutdown
    exit
-----
A:ALA-1>config>service#
```

### 2.15.2.5.1 Configuring Ipipe SAP Parameters

The following example shows an Ipipe SAP configuration:

```
A:ALA-48>config>service# info
-----
...
    ipipe 202 customer 1 create
        sap 1/1/2:444 create
            description "eth_ipipe"
            ce-address 31.31.31.1
        exit
        sap 1/3/2:445 create
            description "eth_ipipe"
            ce-address 31.31.31.2
        exit
        no shutdown
    exit
...
-----
A:ALA-48>config>service#
```

The following example shows a Frame Relay to Ethernet local Ipipe configuration.

**Example:**

```
config>service# ipipe 204 customer 1 create
config>service>ipipe$ sap 1/1/2:446 create
config>service>ipipe>sap$ description "eth_fr_ipipe"
config>service>ipipe>sap$ ce-address 32.32.32.1
config>service>ipipe>sap$ no shutdown
config>service>ipipe>sap$ exit
config>service>ipipe# sap 2/2/2:16 create
config>service>ipipe>sap$ ce-address 32.32.32.2
config>service>ipipe>sap$ no shutdown
config>service>ipipe>sap$ exit
config>service>ipipe# no shutdown
config>service>ipipe# exit
config>service#
```

The following example shows the output:

```
A:ALA-48>config>service# info
-----
...
    ipipe 204 customer 1 create
        sap 1/1/2:446 create
            description "eth_fr_ipipe"
            ce-address 32.32.32.1
        exit
        sap 2/2/2:16 create
            ce-address 32.32.32.2
        exit
        no shutdown
    exit
...
-----
A:ALA-48>config>service#
```

The following example shows a PPP to Ethernet local Ipipe configuration.

**Example:**

```
config>service# ipipe 206 customer 1 create
config>service>ipipe$ sap 1/1/2:447 create
config>service>ipipe>sap$ description "eth_ppp_ipipe"
config>service>ipipe>sap$ ce-address 33.33.33.1
config>service>ipipe>sap$ no shutdown
config>service>ipipe>sap$ exit
config>service>ipipe# sap 2/2/2 create
config>service>ipipe>sap$ description "ppp_eth_ipipe"
config>service>ipipe>sap$ ce-address 33.33.33.2
config>service>ipipe>sap$ no shutdown
config>service>ipipe>sap$ exit
config>service>ipipe# no shutdown
config>service>ipipe# exit
config>service#
```

The following example shows the output:

```
A:ALA-48>config>service# info
-----
...
    ipipe 206 customer 1 create
        sap 1/1/2:447 create
            description "eth_ppp_ipipe"
            ce-address 33.33.33.1
        exit
        sap 2/2/2 create
            description "ppp_eth_ipipe"
            ce-address 33.33.33.2
        exit
        no shutdown
    exit
...
-----
A:ALA-48>config>service#
```

### 2.15.2.5.2 Configuring Ipipe SDP Bindings

The following example shows an Ipipe SDP configuration:

```
A:ALA-48>config>service# info
-----
...
    sdp 16 mpls create
        far-end 10.4.4.4
        ldp
        path-mtu 1600
        keep-alive
        shutdown
        exit
        no shutdown
    exit
...
    ipipe 207 customer 1 create
        shutdown
        sap 1/1/2:449 create
            description "Remote_Ipipe"
            ce-address 10.34.34.1
        exit
        spoke-sdp 16:516 create
            ce-address 10.31.31.2
        exit
    exit
...
-----
A:ALA-48>config>service#
```

## 2.15.3 Using Spoke-SDP Control Words

The control word command provides the option to add a control word as part of the packet encapsulation for PW types for which the control word is optional. These are Ethernet pseudowire (Epipe), ATM N:1 cell mode pseudowires (Apipe vc-types atm-vcc and atm-vpc), and VT pseudowire (Apipe vc-type atm-cell). The control word might be needed because when ECMP is enabled on the network, packets of a specific pseudowire may be spread over multiple ECMP paths if the hashing router mistakes the PW packet payload for an IPv4 or IPv6 packet. This occurs when the first nibble following the service label corresponds to a value of 4 or 6.

The control word negotiation procedures described in Section 6.2 of RFC 4447 are not supported and, therefore, the service will only come up if the same C-bit value is signaled in both directions. If a spoke-SDP is configured to use the control word, but the node receives a label mapping message with a C-bit clear, the node releases the label with an "Illegal C-bit" status code per Section 6.1 of RFC 4447. As soon as the user enables control of the remote peer, the remote peer withdraws its original label and sends a label mapping with the C-bit set to 1 and the VLL service is up in both nodes.

When the control word is enabled, VCCV packets also include the VCCV control word. In that case, the VCCV CC type 1 (OAM CW) is signaled in the VCCV parameter in the FEC. If the control word is disabled on the spoke-SDP, the Router Alert label is used. In that case, VCCV CC type 2 is signaled. For a multi-segment pseudowire (MS-PW), the CC type 1 is the only type supported; therefore, the control word must be enabled on the spoke-SDP to be able to use VCCV-ping and VCCV-trace.

The following example shows a spoke-SDP control word configuration:

```
-Dut-B>config>service>epipe# info
-----
description "Default epipe description for service id 2100"
sap 1/2/7:4 create
    description "Default sap description for service id 2100"
exit
spoke-sdp 1:2001 create
    control-word
exit
no shutdown
-----
*A:ALA-Dut-B>config>service>epipe#
To disable the control word on spoke-sdp 1:2001:
*A:ALA-Dut-B>config>service>epipe# info
-----
description "Default epipe description for service id 2100"
sap 1/2/7:4 create
    description "Default sap description for service id 2100"
exit
spoke-sdp 1:2001 create
exit
no shutdown
-----
*A:ALA-Dut-B>config>service>epipe#
```

## 2.15.4 Same-Fate Epipe VLANs Access Protection

The following example shows a G.8031 Ethernet tunnel for Epipe protection configuration for 7450 ESS or 7750 SR using same-fate SAPs for each Epipe access (two Ethernet member ports 1/1/1 and 2/1/1/1 are used):

```

*A:7750_ALU>config>eth-tunnel 1
-----
description "Protection is APS"
protection-type 8031_1to1
ethernet
    mac 00:11:11:11:11:12
    encap-type dot1q
exit
ccm-hold-time down 5 up 10 // 50 ms down, 1 second up
path 1
    member 1/1/1
    control-tag 5 // primary control vlan 5
    precedence primary
    eth-cfm
        mep 2 domain 1 association 1
        ccm-enable
        control-mep
        no shutdown
    exit
    exit
    no shutdown
exit
path 2
    member 2/1/1
    control-tag 105 //secondary control vlan 105
    eth-cfm
        mep 2 domain 1 association 2
        ccm-enable
        control-mep
        no shutdown
    exit
    exit
    no shutdown
exit
no shutdown
-----
# Configure Ethernet tunnel SAPs
-----
*A:7750_ALU>config>service epipe 10 customer 5 create
    sap eth-tunnel-1 create // Uses control tags from the Ethernet tunnel port
        description "g8031-protected access ctl/data SAP for eth-tunnel 1"

    exit
    no shutdown
-----
*A:7750_ALU>config>service epipe 11 customer 5 create
    sap eth-tunnel-1:1 create
        description "g8031-protected access same-fate SAP for eth-tunnel 1"

        // must specify tags for each corresponding path in Ethernet tunnel port
        eth-tunnel path 1 tag 6
        eth-tunnel path 2 tag 106
    exit
    ...
-----
*A:7750_ALU>config>service epipe 10 customer 5 create
    sap eth-tunnel-1:3 create
        description "g8031-protected access same-fate SAP for eth-tunnel 1"
        // must specify tags for each path for same-fate SAPs

```

```
eth-tunnel path 1 tag 10
eth-tunnel path 2 tag 110
exit
...
```

---

## 2.15.5 Pseudowire Configuration Notes

The **vc-switching** parameter must be specified when the VLL service is created. When the **vc-switching** parameter is specified, you are configuring an S-PE. This is a pseudowire switching point (switching from one pseudowire to another). Therefore, you cannot add a SAP to the configuration.

The following example shows the configuration when a SAP is added to a pseudowire. The CLI generates an error response if you attempt to create a SAP. VC switching is only needed on the pseudowire at the S-PE.

```
*A:ALA-701>config>service# epipe 28 customer 1 create vc-switching
*A:ALA-701>config>service>epipe$ sap 1/1/3 create
MINOR: SVCMDR #1311 SAP is not allowed under PW switching service
*A:ALA-701>config>service>epipe$
```

Use the following CLI syntax to create pseudowire switching VLL services. These are examples only. Different routers support different pseudowire switching VLL services.

**CLI Syntax:** config>service# apipe service-id [customer customer-id]  
[vpn vpn-id] [vc-type {atm-vcc|atm-sdu|atm-vpc|atm-cell}] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id

**CLI Syntax:** config>service# epipe service-id [customer customer-id]  
[vpn vpn-id] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id

**CLI Syntax:** config>service# fpipe service-id [customer customer-id]  
[vpn vpn-id] [vc-type {fr-dlci}] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id

**CLI Syntax:** config>service# ipipe service-id [customer customer-id]  
[vpn vpn-id] [vc-switching]  
description description-string  
spoke-sdp sdp-id:vc-id

The following example shows the command usage to configure VLL pseudowire switching services:

**Example:**

```
config>service# apipe 1 customer 1 vpn 1 vc-switching
create
config>service>apipe$ description "Default apipe
description for service id 100"
config>service>apipe# spoke-sdp 3:1 create
config>service>apipe>spoke-sdp# exit
config>service>apipe# spoke-sdp 6:200 create
config>service>apipe>spoke-sdp# exit
config>service>apipe# no shutdown
```

The following example shows configurations for each service:

```
*A:ALA-48>config>service# info
-----
...
    apipe 100 customer 1 vpn 1 vc-switching create
        description "Default apipe description for service id 100"
        spoke-sdp 3:1 create
        exit
        spoke-sdp 6:200 create
        exit
        no shutdown
    exit
...
    epipe 107 customer 1 vpn 107 vc-switching create
        description "Default epipe description for service id 107"
        spoke-sdp 3:8 create
        exit
        spoke-sdp 6:207 create
        exit
        no shutdown
    exit
...
    ipipe 108 customer 1 vpn 108 vc-switching create
        description "Default ipipe description for service id 108"
        spoke-sdp 3:9 create
        exit
        spoke-sdp 6:208 create
        exit
        no shutdown
    exit
...
    fpipe 109 customer 1 vpn 109 vc-switching create
        description "Default fpipe description for service id 109"
        spoke-sdp 3:5 create
        exit
        spoke-sdp 6:209 create
        exit
        no shutdown
    exit
...
-----
*A:ALA-48>config>service#
```

## 2.15.6 Configuring Two VLL Paths Terminating on T-PE2

**Figure 50 VLL Resilience with Pseudowire Redundancy and Switching**

OSSG114

### T-PE1

The following shows an example of the T-PE1 configuration:

```
*A:ALA-T-PE1>config>service>epipe# info
-----
endpoint "x" create
exit
endpoint "y" create
exit
spoke-sdp 1:100 endpoint "y" create
precedence primary
revert-time 0
exit
spoke-sdp 4:400 endpoint "y" create
precedence 0
exit
no shutdown
-----
*A:ALA-T-PE1>config>service>epipe#
```

The following shows an example of the T-PE2 configuration for 7950 XRS.

### T-PE2

```
*A:ALA-T-PE2>config>service>epipe# info
-----
      endpoint "x" create
      exit
      endpoint "y" create
      exit
      sap endpoint "x" create
      exit
      spoke-sdp 3:300 endpoint "y" create
          precedence primary
          revert-time 0
      exit
      spoke-sdp 6:600 endpoint "y" create
          precedence 0
      exit
      no shutdown
-----
*A:ALA-T-PE2>config>service>epipe#
```

The following shows an example of the T-PE2 configuration for 7450 ESS and 7750 SR.

### T-PE2

```
*A:ALA-T-PE2>config>service>epipe# info
-----
      endpoint "x" create
      exit
      endpoint "y" create
      exit
      sap 2/2/2:200 endpoint "x" create
      exit
      spoke-sdp 3:300 endpoint "y" create
          precedence primary
          revert-time 0
      exit
      spoke-sdp 6:600 endpoint "y" create
          precedence 0
      exit
      no shutdown
-----
*A:ALA-T-PE2>config>service>epipe#
```

**S-PE1:** Specifying the **vc-switching** parameter enables a VC cross-connect, so the service manager does not signal the VC label mapping immediately, but will put this into passive mode.

The following example shows the configuration:

```
*A:ALA-S-PE1>config>service>epipe# info
-----
```

```
...
    spoke-sdp 2:200 create
    exit
    spoke-sdp 3:300 create
    exit
    no shutdown
-----
*A:ALA-S-PE1>config>service>epipe#
```

**S-PE2:** Specifying the **vc-switching** parameter enables a VC cross-connect, so the service manager does not signal the VC label mapping immediately, but will put this into passive mode.

The following example shows the configuration:

```
*A:ALA-S-PE2>config>service>epipe# info
-----
...
    spoke-sdp 2:200 create
    exit
    spoke-sdp 3:300 create
    exit
    no shutdown
-----
*A:ALA-S-PE2>config>service>epipe#
```

## 2.15.7 Configuring VLL Resilience

[Figure 51](#) shows an example to create VLL resilience. The zero revert-time value means that the VLL path will be switched back to the primary immediately after it comes back up.

**Figure 51 VLL Resilience**

OSSG246

### PE-1:

The following example shows the configuration on PE-1:

```

*A:ALA-48>config>service>epipe# info
-----
    endpoint "x" create
    exit
    endpoint "y" create
    exit
    spoke-sdp 1:100 endpoint "y" create
        precedence primary
    exit
    spoke-sdp 2:200 endpoint "y" create
        precedence 1
    exit
    no shutdown
-----
*A:ALA-48>config>service>epipe#

```

## 2.15.8 Configuring VLL Resilience for a Switched Pseudowire Path

**Figure 52 VLL Resilience with Pseudowire Switching**

OSSG247

### T-PE-1

The following example shows the configuration on T-PE-1.

```

*A:ALA-48>config>service>epipe# info
-----
    endpoint "x" create
    exit
    endpoint "y" create
    exit
    sap 1/1/1:100 endpoint "x" create
    exit
    spoke-sdp 1:100 endpoint "y" create
        precedence primary
    exit
    spoke-sdp 2:200 endpoint "y" create
        precedence 1
    exit

```

```

        exit
        spoke-sdp 3:300 endpoint "y" create
            precedence 1
        exit
        no shutdown
-----
*A:ALA-48>config>service>epipe#

```

## T-PE-2

The following example shows the configuration on T-PE-2.

```

*A:ALA-49>config>service>epipe# info
-----
        endpoint "x" create
        exit
        endpoint "y" create
            revert-time 100
        exit
        spoke-sdp 4:400 endpoint "y" create
            precedence primary
        exit
        spoke-sdp 5:500 endpoint "y" create
            precedence 1
        exit
        spoke-sdp 6:600 endpoint "y" create
            precedence 1
        exit
        no shutdown
-----
*A:ALA-49>config>service>epipe#

```

## S-PE-1

The following example shows the configuration on S-PE-1.

```

*A:ALA-50>config>service>epipe# info
-----
...
        spoke-sdp 1:100 create
        exit
        spoke-sdp 4:400 create
        exit
        no shutdown
-----
*A:ALA-49>config>service>epipe#

```

## 2.15.9 Configuring BGP Virtual Private Wire Service (VPWS)

### 2.15.9.1 Single-Homed BGP VPWS

Figure 53 shows an example topology for a BGP VPWS service used to create a virtual lease-line across an MPLS network between two sites: A and B.

**Figure 53 Single-Homed BGP VPWS Configuration Example**

An Epipe is configured on PE1 and PE2 with BGP VPWS enabled. PE1 and PE2 are connected to site A and B, respectively, each using a SAP. The interconnection between the two PEs is achieved through a pseudowire, using Ethernet VLAN encapsulation, which is signaled using BGP VPWS over a tunnel LSP between PE1 and PE2. A MIP or MEP can be configured on a BGP VPWS SAP. However, fault propagation between a MEP and the BGP update state signaling is not supported. BGP VPWS routes are accepted only over an IBGP session.

The following example shows the BGP VPWS configuration on each PE:

```
PE1:
pw-template 1 create
  vc-type vlan
exit
epipe 1 customer 1 create
  bgp
    route-distinguisher 65536:1
    route-target export target:65536:1 import target:65536:1
    pw-template-binding 1
  exit
exit
bgp-vpws
  ve-name PE1
  ve-id 1
  exit
  remote-ve-name PE2
  ve-id 2
  exit
no shutdown
```

```

        exit
        sap 1/1/1:1 create
        exit
        no shutdown
    exit

PE2:

pw-template 1 create
    vc-type vlan
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:2
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
    exit
exit
bgp-vpws
    ve-name PE2
        ve-id 2
    exit
    remote-ve-name PE1
        ve-id 1
    exit
    no shutdown
exit
sap 1/1/1:1 create
exit
no shutdown
exit

```

The BGP-VPWS update can be shown using the following command:

```

A:PE1# show service l2-route-table bgp-vpws detail
=====
Services: L2 Bgp-Vpws Route Information - Summary
=====
Svc Id      : 1
VeId        : 2

```

## 2.15.9.2 Dual-Homed BGP VPWS

### Single Pseudowire Example:

Figure 54 shows an example topology for a dual-homed BGP VPWS service used to create a virtual lease-line across an MPLS network between two sites: A and B. A single pseudowire is established between the designated forwarder of the dual-homed PEs and the remote PE.

**Figure 54 Example of Dual-Homed BGP VPWS with Single Pseudowire**

SR\_QPD\_0002

An Epipe with BGP VPWS enabled is configured on each PE. Site A is dual-homed to PE1 and PE2 with a remote PE (PE3) connected to site B; each connection uses a SAP. A single pseudowire using Ethernet Raw Mode encaps connects PE3 to PE1. The pseudowire is signaled using BGP VPWS over a tunnel LSP between the PEs.

Site A is configured on PE1 and PE2 with the BGP route selection, the site state, and the site-preference used to ensure PE1 is the designated forwarder when the network is fully operational.

The following example shows the BGP VPWS configuration on each PE.

PE1:

```
pw-template 1 create
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:1
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
```

```
        exit
    exit
    bgp-vpws
        ve-name PE1
        ve-id 1
    exit
    remote-ve-name PE3
        ve-id 3
    exit
    no shutdown
exit
sap 1/1/1:1 create
exit
site "siteA" create
    site-id 1
    sap 1/1/1:1
    boot-timer 20
    site-activation-timer 5
    no shutdown
exit
no shutdown
exit
```

## PE2:

```
pw-template 1 create
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:2
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
    exit
exit
bgp-vpws
    ve-name PE2
    ve-id 1
    exit
    remote-ve-name PE3
        ve-id 3
    exit
    no shutdown
exit
sap 1/1/1:1 create
exit
site "siteA" create
    site-id 1
    sap 1/1/1:1
    boot-timer 20
    site-activation-timer 5
    no shutdown
exit
no shutdown
exit
```

**PE3:**

```
pw-template 1 create
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:3
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
    exit
exit
bgp-vpws
    ve-name PE3
    ve-id 3
    exit
    remote-ve-name PE1orPE2
    ve-id 1
    exit
    no shutdown
exit
sap 1/1/1:1 create
exit
no shutdown
exit
```

**Active/Standby Pseudowire Example:**

[Figure 55](#) shows an example topology for a dual-homed BGP VPWS service used to create a virtual lease-line across an MPLS network between two sites: A and B. Two pseudowires are established between the remote PE and the dual-homed PEs. The active pseudowire used for the traffic is the one connecting the remote PE to the designated forwarder of the dual-homed PEs.

**Figure 55 Example of Dual-homed BGP VPWS with Active/Standby Pseudowires**

An Epipe with BGP VPWS enabled is configured on each PE. Site A is dual-homed to PE1 and PE2 with a remote PE (PE3) connected to site B; each connection uses a SAP. Active/standby pseudowires using Ethernet Raw Mode encaps connects PE3 to PE1 and PE2, respectively. The pseudowires are signaled using BGP VPWS over a tunnel LSP between the PEs.

Site A is configured on PE1 and PE2 with the site-preference set to ensure that PE1 is the designated forwarder when the network is fully operational. An endpoint is automatically created on PE3 in which the active/standby pseudowires are created.

The following example shows the BGP VPWS configuration on each PE.

PE1:

```

pw-template 1 create
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:1
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
    exit
exit
bgp-vpws
    ve-name PE1
        ve-id 1
    exit
    remote-ve-name PE3

```

```
        ve-id 3
        exit
        no shutdown
    exit
    sap 1/1/1:1 create
    exit
    site "siteA" create
        site-id 1
        sap 1/1/1:1
        boot-timer 20
        site-activation-timer 5
        site-preference 200
        no shutdown
    exit
    no shutdown
exit
```

**PE2:**

```
pw-template 1 create
exit
epipe 1 customer 1 create
    bgp
        route-distinguisher 65536:2
        route-target export target:65536:1 import target:65536:1
        pw-template-binding 1
    exit
exit
bgp-vpws
    ve-name PE2
        ve-id 2
    exit
    remote-ve-name PE3
        ve-id 3
    exit
    no shutdown
exit
sap 1/1/1:1 create
exit
site "siteA" create
    site-id 1
    sap 1/1/1:1
    boot-timer 20
    site-activation-timer 5
    site-preference 10
    no shutdown
exit
no shutdown
exit
```

**PE3:**

```
pw-template 1 create
exit
epipe 1 customer 1 create
```

```
    bgp
      route-distinguisher 65536:3
      route-target export target:65536:1 import target:65536:1
      pw-template-binding 1
      exit
    exit
  bgp-vpws
    ve-name PE3
    ve-id 3
    exit
    remote-ve-name PE1
    ve-id 1
    exit
    remote-ve-name PE2
    ve-id 2
    exit
    no shutdown
  exit
  sap 1/1/1:1 create
  exit
  no shutdown
exit
```

## 2.16 Service Management Tasks

This section discusses VLL service management tasks.

### 2.16.1 Modifying Apipe Service Parameters

The following example shows the command usage to modify Apipe parameters, supported on the 7750 SR only:

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# sap 1/1/1:0/32 create
A:ALA-41>config>service>apipe>sap# accounting-policy 2
A:ALA-41>config>service>apipe>sap# exit
A:ALA-41>config>service>apipe# spoke-sdp 1:4
A:ALA-41>config>service>apipe>spoke-sdp# egress
A:ALA-41>config>service>apipe>spoke-sdp>egress# vc-
label 16
A:ALA-41>config>service>apipe>spoke-sdp>egress# exit
A:ALA-41>config>service>apipe>spoke-sdp# exit
A:ALA-41>config>service>apipe#
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# apipe 5
A:ALA-42>config>service>apipe# sap 2/2/2:0/32 create
A:ALA-42>config>service>apipe>sap# accounting-policy 2
A:ALA-42>config>service>apipe>sap# exit
A:ALA-42>config>service>apipe# spoke-sdp 1:4
A:ALA-42>config>service>apipe>spoke-sdp# egress
A:ALA-42>config>service>apipe>spoke-sdp>egress# vc-
label 16
A:ALA-42>config>service>apipe>spoke-sdp>egress# exit
A:ALA-42>config>service>apipe>spoke-sdp# exit
A:ALA-42>config>service>apipe#
```

```
PE Router 1 (ALA-41):
A:ALA-41>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 1/1/1:0/32 create
            accounting-policy 2
```

```

        ingress
            qos 102
        exit
        egress
            qos 103
        exit
    exit
    spoke-sdp 1:4 create
        egress
            vc-label 16
        exit
    no shutdown
    exit
...
-----
A:ALA-41>config>service#

PE Router 2 (ALA-42):
A:ALA-42>config>service# info
-----
...
    apipe 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 2/2/2:0/32 create
            accounting-policy 2
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        spoke-sdp 1:4 create
            egress
                vc-label 16
            exit
        no shutdown
    exit
...
-----
A:ALA-42>config>service#

```

## 2.16.2 Disabling an Apipe Service

An Apipe service can be shut down without deleting any service parameters.

**CLI Syntax:**    config>service#  
                  apipe service-id  
                  shutdown

PE router 1 (A:ALA-41):

---

**Example:**     A:ALA-41>config>service# apipe 5  
                  A:ALA-41>config>service>apipe# shutdown  
                  A:ALA-41>config>service>apipe# exit

PE router 2 (A:ALA-42):

**Example:**     A:ALA-42>config>service# apipe 5  
                  A:ALA-42>config>service>apipe# shutdown  
                  A:ALA-42>config>service>apipe# exit

PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    apipe 5 customer 1 create
        shutdown
        description "apipe test"
        service-mtu 1400
        sap 1/1/1:0/32 create
            accounting-policy 2
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        spoke-sdp 1:4 create
            egress
                vc-label 16
            exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
    apipe 5 customer 1 create
        shutdown
        description "apipe test"
        service-mtu 1400
        sap 2/2/2:0/32 create
            accounting-policy 2
            ingress
                qos 102
            exit
            egress
                qos 103
```

```

        exit
    exit
    spoke-sdp 1:4 create
        egress
        vc-label 16
    exit
exit
...
-----
A:ALA-42>config>service#

```

## 2.16.3 Re-enabling an Apipe Service

Use the following CLI syntax to re-enable an Apipe service that was shut down.

**CLI Syntax:**

```

config>service#
  apipe service-id
    no shutdown

```

PE router 1 (A:ALA-41):

**Example:**

```

A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# no shutdown
A:ALA-41>config>service>apipe# exit

```

PE router 2 (A:ALA-42):

**Example:**

```

A:ALA-42>config>service# apipe 5
A:ALA-42>config>service>apipe# no shutdown
A:ALA-42>config>service>apipe# exit

```

## 2.16.4 Deleting an Apipe Service

An Apipe service cannot be deleted until the SAP is shut down. If protocols and/or a spoke-SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete Apipe services.

**CLI Syntax:**

```

config>service#
  no apipe service-id
    shutdown
  no sap sap-id
    shutdown

```

```
no spoke-sdp [sdp-id:vc-id]
shutdown
```

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# sap 1/1/1:0/32
A:ALA-41>config>service>apipe>sap# shutdown
A:ALA-41>config>service>apipe>sap# exit
A:ALA-41>config>service>apipe# no sap 1/1/1:0/32
A:ALA-41>config>service>apipe# spoke-sdp 1:4
A:ALA-41>config>service>apipe>spoke-sdp# shutdown
A:ALA-41>config>service>apipe>spoke-sdp# exit
A:ALA-41>config>service>apipe# no spoke-sdp 1:4
A:ALA-41>config>service>apipe# shutdown
A:ALA-41>config>service>apipe# exit
A:ALA-41>config>service# no apipe 5
```

PE router 2 (A:ALA-42):

**Example:**

```
Example:A:ALA-41>config>service# apipe 5
A:ALA-41>config>service>apipe# sap 2/2/2:0/32
A:ALA-41>config>service>apipe>sap# shutdown
A:ALA-41>config>service>apipe>sap# exit
A:ALA-41>config>service>apipe# no sap 2/2/2:0/32
A:ALA-41>config>service>apipe# spoke-sdp 1:4
A:ALA-41>config>service>apipe>spoke-sdp# shutdown
A:ALA-41>config>service>apipe>spoke-sdp# exit
A:ALA-41>config>service>apipe# no spoke-sdp 1:4
A:ALA-41>config>service>apipe# shutdown
A:ALA-41>config>service>apipe# exit
A:ALA-41>config>service# no apipe 5
```

## 2.16.5 Modifying a Cpipe Service

The following example shows the Cpipe service configuration, supported on the 7750 SR only:

```
*A:ALA-1>config>service# info
-----
...
  cpipe 94002 customer 1 vc-type cesopsn create
    endpoint "to7705" create
    exit
    endpoint "toMC-APS" create
    exit
    sap aps-4.10.1.2.1 endpoint "toMC-APS" create
```

```

        ingress
        qos 20
        exit
    exit
    spoke-sdp 14004:94002 endpoint "to7705" create
    exit
    spoke-sdp 100:294002 endpoint "toMC-APS" icb create
    exit
    spoke-sdp 100:194002 endpoint "to7705" icb create
    exit
    no shutdown
    exit
...
-----
*A:ALA-1>config>service> Cpipe#

```

## 2.16.6 Deleting a Cpipe Service

A Cpipe service cannot be deleted until SAPs are shut down and deleted. If a spoke-SDP is defined, it must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete a Cpipe service.

**CLI Syntax:**

```

config>service#
[no] cpipe service-id [customer customer-id]
[no] spoke-sdp sdp-id
[no] shutdown
shutdown

```

## 2.16.7 Modifying Epipe Service Parameters

The following example shows how to add an accounting policy to an existing SAP:

**Example:**

```

config>service# epipe 2
config>service>epipe# sap 2/1/3:21
config>service>epipe>sap# accounting-policy 14
config>service>epipe>sap# exit

```

The following example shows the SAP configuration:

```

ALA-1>config>service# info
-----
    epipe 2 customer 6 vpn 2 create
    description "Distributed Epipe service to east coast"
    sap 2/1/3:21 create
    accounting-policy 14
    exit

```

```
spoke-sdp 2:6000 create
exit
no shutdown
exit
-----
ALA-1>config>service#
```

## 2.16.8 Disabling an Epipe Service

You can shut down an Epipe service without deleting the service parameters.

**CLI Syntax:**    config>service> epipe *service-id*  
                 shutdown

**Example:**       config>service# epipe 2  
                 config>service>epipe# shutdown  
                 config>service>epipe# exit

## 2.16.9 Re-enabling an Epipe Service

Use the following CLI syntax to re-enable an Epipe service that was shut down.

**CLI Syntax:**    config>service# epipe *service-id*  
                 no shutdown

**Example:**       config>service# epipe 2  
                 config>service>epipe# no shutdown  
                 config>service>epipe# exit

## 2.16.10 Deleting an Epipe Service

Perform the following steps prior to deleting an Epipe service:

**Step 1.** Shut down the SAP and SDP.

**Step 2.** Delete the SAP and SDP.

**Step 3.** Shut down the service.

Use the following CLI syntax to delete an Epipe service.

**CLI Syntax:**    config>service

```
[no] epipe service-id
shutdown
[no] sap sap-id
shutdown
[no] spoke-sdp sdp-id:vc-id
shutdown
```

**Example:**

```
config>service# epipe 2
config>service>epipe# sap 2/1/3:21
config>service>epipe>sap# shutdown
config>service>epipe>sap# exit
config>service>epipe# no sap 2/1/3:21
config>service>epipe# spoke-sdp 2:6000
config>service>epipe>spoke-sdp# shutdown
config>service>epipe>spoke-sdp# exit
config>service>epipe# no spoke-sdp 2:6000
config>service>epipe# epipe 2
config>service>epipe# shutdown
config>service>epipe# exit
config>service# no epipe 2
```

## 2.16.11 Modifying Fpipe Service Parameters

The following example shows the command usage to modify Fpipe parameters, supported on the 7750 SR only:

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# sap 1/2/1:16 create
A:ALA-41>config>service>fpipe>sap# accounting-policy 2
A:ALA-41>config>service>fpipe>sap# exit
A:ALA-41>config>service>fpipe# spoke-sdp 1:4
A:ALA-41>config>service>fpipe>spoke-sdp# ingress
A:ALA-41>config>service>fpipe>spoke-sdp>filter ip 10
A:ALA-41>config>service>fpipe>spoke-sdp# exit
A:ALA-41>config>service>fpipe#
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# fpipe 1
A:ALA-42>config>service>fpipe# sap 2/1/1.1:16 create
A:ALA-42>config>service>fpipe>sap# accounting-policy 2
A:ALA-42>config>service>fpipe>sap# exit
A:ALA-42>config>service>fpipe# spoke-sdp 1:1
A:ALA-42>config>service>fpipe>spoke-sdp# egress
```

```
A:ALA-42>config>service>fpipe>spoke-sdp>egress# filter
ip 10
A:ALA-42>config>service>fpipe>spoke-sdp>egress# exit
A:ALA-42>config>service>fpipe>spoke-sdp# exit
A:ALA-42>config>service>fpipe#
```

### PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 1/2/1:16 create
            accounting-policy 2
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
            ingress
                filter ip 10
            exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

### PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
    fpipe 1 customer 1 create
        description "fpipe test"
        service-mtu 1400
        sap 2/1/1.1:16 create
            accounting-policy 2
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
            egress
                filter ip 10
            exit
        no shutdown
    exit
...
-----
```

```
...
-----
A:ALA-42>config>service#
```

## 2.16.12 Disabling an Fpipe Service

An Fpipe service can be shut down without deleting any service parameters.

**CLI Syntax:**

```
config>service#
fpipe service-id
shutdown
```

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# shutdown
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# fpipe 1
A:ALA-42>config>service>fpipe# shutdown
```

PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    fpipe 1 customer 1 create
        shutdown
        description "fpipe test"
        service-mtu 1400
        sap 1/2/1:16 create
            accounting-policy 2
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
            ingress
                filter ip 10
        exit
    exit
...
-----
A:ALA-41>config>service#
```

PE Router 2 (ALA-42):

```
A:ALA-42>config>service# info
-----
...
    fpipe 1 customer 1 create
        shutdown
        description "fpipe test"
        service-mtu 1400
        sap 2/1/1.1:16 create
            accounting-policy 2
            ingress
                qos 101
            exit
            egress
                qos 1020
            exit
        exit
        spoke-sdp 1:1 create
            egress
                filter ip 10
            exit
        exit
    ...
-----
A:ALA-42>config>service#
```

## 2.16.13 Re-enabling an Fpipe Service

Use the following CLI syntax to re-enable an Fpipe service that was shut down.

**CLI Syntax:**

```
config>service#
    fpipe service-id
        no shutdown
```

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# no shutdown
A:ALA-41>config>service>fpipe# exit
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-42>config>service# fpipe 1
A:ALA-42>config>service>fpipe# no shutdown
A:ALA-42>config>service>fpipe# exit
```

## 2.16.14 Deleting an Fpipe Service

An Fpipe service cannot be deleted until the SAP is shut down. If protocols and/or a spoke-SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete a Fpipe service.

**CLI Syntax:**

```
config>service#
no fpipe service-id
shutdown
no sap sap-id
shutdown
no spoke-sdp [sdp-id:vc-id]
shutdown
```

PE router 1 (A:ALA-41):

**Example:**

```
A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# sap 1/1/1:0/32
A:ALA-41>config>service>fpipe>sap# shutdown
A:ALA-41>config>service>fpipe>sap# exit
A:ALA-41>config>service>fpipe# no sap 1/1/1:0/32
A:ALA-41>config>service>fpipe# spoke-sdp 1:1
A:ALA-41>config>service>fpipe>spoke-sdp# shutdown
A:ALA-41>config>service>fpipe>spoke-sdp# exit
A:ALA-41>config>service>fpipe# no spoke-sdp 1:1
A:ALA-41>config>service>fpipe# shutdown
A:ALA-41>config>service>fpipe# exit
A:ALA-41>config>service# no fpipe 1
```

PE router 2 (A:ALA-42):

**Example:**

```
A:ALA-41>config>service# fpipe 1
A:ALA-41>config>service>fpipe# sap 2/1/1.1:16
A:ALA-41>config>service>fpipe>sap# shutdown
A:ALA-41>config>service>fpipe>sap# exit
A:ALA-41>config>service>fpipe# no sap 2/1/1.1:16
A:ALA-41>config>service>fpipe# spoke-sdp 1:1
A:ALA-41>config>service>fpipe>spoke-sdp# shutdown
A:ALA-41>config>service>fpipe>spoke-sdp# exit
A:ALA-41>config>service>fpipe# no spoke-sdp 1:1
A:ALA-41>config>service>fpipe# shutdown
A:ALA-41>config>service>fpipe# exit
A:ALA-41>config>service# no fpipe 1
```

## 2.16.15 Modifying Ipipe Service Parameters

The following example shows the command usage to modify Ipipe parameters, supported on the 7450 ESS and 7750 SR only:

**Example:**

```
config>service# ipipe 202
config>service>ipipe# sap 1/1/2:444
config>service>ipipe>sap# shutdown
config>service>ipipe>sap# exit
config>service>ipipe# no sap 1/1/2:444
config>service>ipipe# sap 1/1/2:555 create
config>service>ipipe>sap$ description "eth_ipipe"
config>service>ipipe>sap$ ce-address 10.31.31.1
config>service>ipipe>sap$ no shutdown
config>service>ipipe>sap$ exit
config>service>ipipe# info
```

```
A:ALA-48>config>service# info
-----
...
    ipipe 202 customer 1 create
        sap 1/1/2:445 create
            description "eth_ipipe"
            ce-address 10.31.31.2
        exit
        sap 1/1/2:555 create
            description "eth_ipipe"
            ce-address 10.31.31.1
        exit
        no shutdown
    exit
...
-----
A:ALA-48>config>service#
```

## 2.16.16 Disabling an Ipipe Service

An Ipipe service can be shut down without deleting any service parameters.

**CLI Syntax:**

```
config>service#
ipipe service-id
shutdown
```

**Example:**

```
A:ALA-41>config>service# ipipe 202
A:ALA-41>config>service>ipipe# shutdown
```

```
A:ALA-48>config>service# info
-----
```

```
...
    ipipe 202 customer 1 create
        shutdown
        sap 1/1/2:445 create
            description "eth_ipipe"
            ce-address 10.31.31.2
        exit
        sap 1/1/2:555 create
            description "eth_ipipe"
            ce-address 10.31.31.1
        exit
    exit
...
-----
A:ALA-48>config>service#
```

## 2.16.17 Re-enabling an Ipipe Service

Use the following CLI syntax to re-enable an Ipipe service that was shut down.

**CLI Syntax:**

```
config>service#
    ipipe service-id
        no shutdown
```

**Example:**

```
A:ALA-41>config>service# ipipe 202
A:ALA-41>config>service>ipipe# no shutdown
```

## 2.16.18 Deleting an Ipipe Service

An Ipipe service cannot be deleted until the SAP is shut down. If protocols and/or a spoke-SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete an Ipipe service.

**CLI Syntax:**

```
config>service#
    no ipipe service-id
        shutdown
        no sap sap-id
            shutdown
        no spoke-sdp [sdp-id:vc-id]
            shutdown
```

**Example:**

```
config>service# ipipe 207
config>service>ipipe# sap 1/1/2:449
```

---

```
config>service>ipipe>sap# shutdown
config>service>ipipe>sap# exit
config>service>ipipe# no sap 1/1/2:449
config>service>ipipe# spoke-sdp 16:516
config>service>ipipe>spoke-sdp# shutdown
config>service>ipipe>spoke-sdp# exit
config>service>ipipe# no spoke-sdp 16:516
config>service>ipipe# exit
config>service# no ipipe 207
config>service#
```

## 2.17 VLL Service Configuration Command Reference

This chapter describes the VLL service configuration command reference.

### 2.17.1 Command Hierarchies

- [Apipe Service Configuration Commands](#)
- [Cpipe Service Configuration Commands](#)
- [Epipe Service Configuration Commands](#)
- [Fpipe Service Configuration Commands](#)
- [Ipipe Service Configuration Commands](#)

#### 2.17.1.1 Apipe Service Configuration Commands

- [Apipe Global Commands](#)
- [Apipe SAP Commands](#)
- [Apipe Spoke-SDP Commands](#)
- [Related Apipe Commands](#)

##### 2.17.1.1.1 Apipe Global Commands

```

config
  — service
    — apipe service-id [customer customer-id] [create] [vpn vpn-id] [vc-type {atm-vcc |
      atm-sdu | atm-vpc | atm-cell}] [vc-switching] [test] [name name]
    — no apipe service-id
      — description description-string
      — no description
      — endpoint endpoint-name [create]
      — no endpoint endpoint-name
        — active-hold-delay active-hold-delay
        — no active-hold-delay
        — description description-string
        — no description
        — revert-time {revert-time | infinite}
        — no revert-time
      — interworking frf-5

```

- no interworking
- service-mtu *octets*
- no service-mtu
- [no] shutdown
- signaled-vc-type-override *atm-vcc*
- no signaled-vc-type-override

### 2.17.1.1.2 Apipe SAP Commands

- ```

config
  — service
    — apipe
      — sap {port-id | aps-id}:[vpi/vci | vpi | vpi1.vpi2 | cp.conn-prof-id]
      — sap sap-id [create] [no-endpoint]
      — sap sap-id [create] endpoint endpoint-name
      — no sap sap-id
        — accounting-policy acct-policy-id
        — no accounting-policy [acct-policy-id]
        — atm
          — egress
            — traffic-desc traffic-desc-profile-id
            — no traffic-desc
          — ingress
            — traffic-desc traffic-desc-profile-id
            — no traffic-desc
          — [no] llf
          — oam
            — [no] alarm-cells
            — [no] terminate
        — bandwidth bandwidth
        — no bandwidth
        — [no] collect-stats

```

**Description** This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.

The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described as follows in Special Cases.

The **no** form of this command places the entity into an administratively enabled state.

**Special Cases** **Service Admin State** — Bindings to an SDP within the service will be put into the out-of-service state when the service is shutdown. While the service is shutdown, all customer packets are dropped and counted as discards for billing and debugging purposes.

**Service Operational State** — A service is regarded as operational providing that at least one SAP and one SDP are operational or if two SAPs are operational.

**SDP (global)** — When an SDP is shutdown at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.

**SDP (service level)** — Shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.

## description

| <b>Context</b>     | config>service>apipe<br>config>service>apipe>endpoint<br>config>service>cpipe<br>config>service>cpipe>endpoint<br>config>service>epipe<br>config>service>epipe>spoke-sdp<br>config>service>epipe>endpoint<br>config>service>fpipe<br>config>service>fpipe>endpoint<br>config>service>ipipe<br>config>service>ipipe>endpoint<br>config>service>ipipe>spoke-sdp<br>config>connection-profile |
| <b>Description</b> | <p>This command creates a text description stored in the configuration file for a configuration context. The <b>description</b> command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The <b>no</b> form of this command removes the string from the configuration.</p>                                             |
| <b>Default</b>     | No description associated with the configuration context.                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>description-string</i> — The description character string. Allowed values are any string up to 80 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.                                                                                              |

## description

| <b>Description</b> | <p>This command creates a text description stored in the configuration file for a configuration context. The <b>description</b> command associates a text string with a configuration context to help identify the content in the configuration file.</p> <p>The <b>no</b> form of this command removes the string from the configuration.</p> |
| <b>Default</b>     | No description associated with the configuration context.                                                                                                                                                                                                                                                                                      |

---

**Parameters**    *description-string* — The description character string. Allowed values are any string up to 160 characters composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.

## 2.17.2.2 VLL Global Service Commands

### apipe

**Syntax**    **apipe** *service-id* [**customer** *customer-id*] [**vpn** *vpn-id*] [**vc-type** {**atm-vcc** | **atm-sdu** | **atm-vpc** | **atm-cell**}] [**vc-switching**] [**test**] [**create**] [**name** *name*]  
**no apipe** *service-id*

**Context**    config>service

**Description**    The Apipe service provides a point-to-point Layer 2 VPN connection to a remote SAP or to another local SAP. An Apipe can connect an ATM or Frame Relay endpoint either locally or over a PSN to a remote endpoint of the same type or of a different type and perform interworking between the two access technologies.

**Parameters**    *service-id* — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The *service-id* must be the same number used for every 7450 ESS or 7750 SR on which this service is defined.

**Values**        *service-id*: 1 to 2147483647  
                                  *svc-name*: up to 64 characters

*customer-id* — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

**Values**        1 to 2147483647

*vpn vpn-id* — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.

**Values**        1 to 2147483647

**Default**        null (0)

**vc-type** — Keyword that specifies a 15 bit value that defines the type of the VC signaled to the peer. Its values are defined in IETF Draft *draft-ietf-pwe3-iana-allocation* and it defines both the signaled VC type as well as the resulting datapath encapsulation over the Apipe.

**Values**        atm-vcc, atm-sdu, atm-vpc, atm-cell

**Default**        atm-sdu

**vc-switching** — Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.

**test** — Specifies a unique test service type for the service context which will contain only a SAP configuration. The test service can be used to test the throughput and performance of a path for MPLS-TP PWs. This parameter is not supported on the 7950 XRS.

**name** *name* — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service. If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values**     *name*: up to 64 characters

## cpipe

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures a Circuit Emulation Services instance.</p> <p>When creating a service, you must enter the <b>customer</b> keyword and specify a <i>customer-id</i> to associate the service with a customer. The <i>customer-id</i> must already exist, having been created using the <b>customer</b> command in the <b>service</b> context. After a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>After a service is created, the use of the <b>customer</b> <i>customer-id</i> parameter is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>By default, no services exist until they are explicitly created with this command.</p> <p>The <b>no</b> form of this command deletes the service instance with the specified <i>service-id</i>. The service cannot be deleted until the service has been shutdown.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every router on which this service is defined.</p> <p><b>Values</b>     <i>service-id</i>: 1 to 2147483647<br/> <i>svc-name</i>: Specifies an existing service name up to 64 characters in length.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**customer-id** — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

**Values** 1 to 2147483647

**vpn vpn-id** — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN ID. If this parameter is not specified, the VPN ID uses the same service ID number.

**Values** 1 to 2147483647

**Default** null (0)

**vc-type** — The vc-type defines the type of unstructured or structured circuit emulation service to be configured.

**Values** **satop-e1**: Unstructured E1 circuit emulation service.  
**satop-t1**: Unstructured DS1 circuit emulation service.  
**cesopsn**: Basic structured N\*64 kb/s circuit emulation service.  
**cesopsn-cas**: Structured N\*64 kb/s circuit emulation service with signaling.

**Default** satop-e1

**vc-switching** — Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.

**test** — Specifies a unique test service type for the service context which will contain only a SAP configuration. The test service can be used to test the throughput and performance of a path for MPLS-TP PWs. This parameter applies to the 7450 ESS and 7750 SR only.

**create** — Keyword used to create the service. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

**name name** — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service. If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values** *name*: up to 64 characters

## epipe

**Syntax** **epipe** *service-id* **customer** *customer-id* [**vpn** *vpn-id*] [**vc-switching**] [**create**] [**name** *name*]  
**epipe** *service-id* [**test**] [**create**] [**name** *name*]  
**no epipe** *service-id*

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command configures an Epipe service instance. This command is used to configure a point-to-point epipe service. An Epipe connects two endpoints defined as Service Access Points (SAPs). Both SAPs may be defined in one 7450 ESS, 7750 SR, or 7950 XRS or they may be defined in separate devices connected over the service provider network. When the endpoint SAPs are separated by the service provider network, the far end SAP is generalized into a Service Distribution Point (SDP). This SDP describes a destination and the encapsulation method used to reach it.</p> <p>No MAC learning or filtering is provided on an Epipe.</p> <p>When creating a service, you must enter the <b>customer</b> keyword and specify a <i>customer-id</i> to associate the service with a customer. The <i>customer-id</i> must already exist, having been created using the <b>customer</b> command in the <b>service</b> context. After a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>After a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>By default, no epipe services exist until they are explicitly created with this command.</p> <p>The <b>no</b> form of this command deletes the epipe service instance with the specified <i>service-id</i>. The service cannot be deleted until the service has been shutdown.</p> <p>Cpipe services are enabled on the 7450 ESS in mixed mode.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every 7450 ESS, 7750 SR, or 7950 XRS on which this service is defined.</p> <p><b>Values</b>      <i>service-id</i>: 1 to 2147483647<br/>                  <i>svc-name</i>: up to 64 characters</p> <p><i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b>      1 to 2147483647</p> <p><i>vpn vpn-id</i> — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN ID. If this parameter is not specified, the VPN ID uses the same service ID number.</p> <p><b>Values</b>      1 to 2147483647</p> <p><b>Default</b>      null (0)</p> <p><b>vc-switching</b> — Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**test** — Specifies a unique test service type for the service context which will contain only a SAP configuration. The test service can be used to test the throughput and performance of a path for MPLS-TP PWs. This parameter applies to the 7450 ESS and 7750 SR only.

**create** — Keyword used to create the service instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

**name** *name* — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service. If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values**     *name*: up to 64 characters

| <b>Description</b> | This command configures an Fpipe service. An Fpipe provides a point-to-point L2 VPN connection to a remote SAP or to another local SAP. An Fpipe connects only Frame Relay endpoints either locally or over a PSN to a remote endpoint of the same type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p><i>service-id</i> — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every 7750 SR on which this service is defined.</p> <p><b>Values</b>     <i>service-id</i>: 1 to 2147483647<br/>                       <i>svc-name</i>: up to 64 characters</p> <p><i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b>     1 to 2147483647</p> <p><i>vpn</i> <i>vpn-id</i> — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.</p> <p><b>Values</b>     1 to 2147483647</p> <p><b>Default</b>    null (0)</p> |

**vc-type** — Specifies a 15 bit value that defines the type of the VC signaled to the peer. Its values are defined in *draft-ietf-pwe3-iana-allocation* and it defines both the signaled VC type as well as the resulting datapath encapsulation over the Apipe.

**Values** fr-dlci

**vc-switching** — Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.

**name** *name* — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values** *name*: up to 64 characters

## ipipe

| <b>Context</b>     | config>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command configures an IP-Pipe service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>service-id</i> — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every 7450 ESS or 7750 SR on which this service is defined.</p> <p><b>Values</b> <i>service-id</i>: 1 to 2147483647<br/><i>svc-name</i>: up to 64 characters</p> <p><i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b> 1 to 2147483647</p> <p><i>vpn</i> <i>vpn-id</i> — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number.</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>Default</b> null (0)</p> <p><b>vc-switching</b> — Specifies if the pseudowire switching signaling is used for the spoke SDPs configured in this service.</p> |

**create** — Keyword used to create the lpipe service instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

**name** *name* — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values**     *name*: up to 64 characters

### 2.17.2.3 Service Configuration Commands

Commands listed in this section may apply to multiple Apipe, Cpipe, Epipe, Fpipe, and lpipe contexts.

#### endpoint

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>endpoint</b> <i>endpoint-name</i> [ <b>create</b> ]<br><b>no endpoint</b> <i>endpoint-name</i>                    |
| <b>Context</b>     | config>service>apipe<br>config>service>cpipe<br>config>service>epipe<br>config>service>fpipe<br>config>service>ipipe |
| <b>Description</b> | This command configures a service endpoint.                                                                          |
| <b>Parameters</b>  | <i>endpoint-name</i> — Specifies an endpoint name.                                                                   |

#### active-hold-delay

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command specifies that the node will delay sending the change in the T-LDP status bits for the VLL endpoint when the MC-LAG transitions the LAG subgroup which hosts the SAP for this VLL endpoint from <b>active</b> to <b>standby</b> or when any object in the endpoint. For example, SAP, ICB, or regular spoke SDP, transitions from up to down operational state.</p> <p>By default, when the MC-LAG transitioned the LAG subgroup which hosts the SAP for this VLL endpoint from <b>active</b> to <b>standby</b>, the node sends immediately new T-LDP status bits indicating the new value of “standby” over the spoke SDPs which are on the mate-endpoint of the VLL. The same applies when any object in the endpoint changes an operational state from up to down.</p> <p>There is no delay applied to the VLL endpoint status bit advertisement when the MC-LAG transitions the LAG subgroup which hosts the SAP from <b>standby</b> to <b>active</b> or when any object in the endpoint transitions to an operationally up state.</p> |
| <b>Default</b>     | <p>0 — A value of zero means that when the MC-LAG transitioned the LAG subgroup which hosts the SAP for this VLL endpoint from <b>active</b> to <b>standby</b>, the node sends immediately new T-LDP status bits indicating the new value of <b>standby</b> over the spoke SDPs which are on the mate-endpoint of the VLL. The same applies when any object in the endpoint changes an operational state from up to down.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>active-hold-delay</i> — Specifies the active hold delay in 100s of milliseconds.</p> <p><b>Values</b>      0 to 60</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## revert-time

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <p><b>revert-time</b> [<i>revert-time</i>   <b>infinite</b>]<br/><b>no revert-time</b></p>                                                                                                                                                 |
| <b>Context</b>     | <p>config&gt;service&gt;apipe&gt;endpoint<br/>config&gt;service&gt;cpipe&gt;endpoint<br/>config&gt;service&gt;epipe&gt;endpoint<br/>config&gt;service&gt;fpipe&gt;endpoint<br/>config&gt;service&gt;ipipe&gt;endpoint</p>                  |
| <b>Description</b> | <p>This command configures the time to wait before reverting back to the primary spoke SDP defined on this service endpoint, after having failed over to a backup spoke SDP.</p>                                                           |
| <b>Parameters</b>  | <p><i>revert-time</i> — Specifies the time, in seconds, to wait before reverting to the primary SDP.</p> <p><b>Values</b>      0 to 600</p> <p><b>Default</b>      0</p> <p><b>infinite</b> — Causes the endpoint to be non-revertive.</p> |

## standby-signaling-master

|                    |                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] standby-signaling-master</b>                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>epipe>endpoint<br>config>service>ipipe>endpoint                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>When this command is enabled, the pseudowire standby bit (value 0x00000020) will be sent to T-LDP peer for each spoke SDP of the endpoint that is selected as a standby.</p> <p>This command is mutually exclusive with a VLL mate SAP created on a mc-lag/mc-aps or ICB. It is also mutually exclusive with vc-switching.</p> |
| <b>Default</b>     | standby-signaling-master                                                                                                                                                                                                                                                                                                          |

## interworking

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>apipe                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies the interworking function that should be applied for packets that ingress or egress SAPs that are part of an Apipe service.</p> <p>Interworking is applicable only when the two endpoints (i.e., the two SAPs or the SAP and the spoke SDP) are of different types. Also, there are limitations on the combinations of SAP type, vc-type, and interworking values as shown in <a href="#">Table 12</a>.</p> |

**Table 12 SAP types, VC-types and Interworking Values**

| SAP Type | Allowed VC-Type Value | Allowed Interworking Value |
|----------|-----------------------|----------------------------|
| ATM VC   | atm-vcc, atm-sdu      | None                       |
|          | fr-dlci               | Not Supported              |
| FR DLCI  | fr-dlci               | None                       |
|          | atm-sdu               | frf-5                      |

|                   |                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------|
| <b>Default</b>    | none (Interworking must be configured before adding a Frame-Relay SAP to an Apipe service.) |
| <b>Parameters</b> | <i>frf-5</i> — Specifies Frame Relay to ATM Network Interworking (FRF.5).                   |

## service-mtu

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command configures the service payload (Maximum Transmission Unit – MTU), in bytes, for the service. This MTU value overrides the service-type default MTU. The <b>service-mtu</b> defines the payload capabilities of the service. It is used by the system to validate the SAP and SDP binding's operational state within the service.</p> <p>The service MTU and a SAP's service delineation encapsulation overhead (4 bytes for a dot1q tag) is used to derive the required MTU of the physical port or channel on which the SAP was created. If the required payload is larger than the port or channel MTU, then the SAP will be placed in an inoperative state. If the required MTU is equal to or less than the port or channel MTU, the SAP will be able to transition to the operative state.</p> <p>When binding an SDP to a service, the service MTU is compared to the path MTU associated with the SDP. The path MTU can be administratively defined in the context of the SDP. The default or administrative path MTU can be dynamically reduced due to the MTU capabilities discovered by the tunneling mechanism of the SDP or the egress interface MTU capabilities based on the next hop in the tunnel path. If the service MTU is larger than the path MTU, the SDP binding for the service will be placed in an inoperative state. If the service MTU is equal to or less than the path MTU, then the SDP binding will be placed in an operational state.</p> <p>If a service MTU, port or channel MTU, or path MTU is dynamically or administratively modified, then all associated SAP and SDP binding operational states are automatically re-evaluated.</p> <p>Binding operational states are automatically re-evaluated.</p> <p>For i-VPLS and Epipes bound to a b-VPLS, the service-mtu must be at least 18 bytes smaller than the b-VPLS service MTU to accommodate the PBB header.</p> <p>Because this connects a Layer 2 to a Layer 3 service, adjust either the service-mtu under the Epipe service. The MTU that is advertised from the Epipe side is service-mtu minus EtherHeaderSize.</p> <p>The <b>no</b> form of this command returns the default <b>service-mtu</b> for the indicated service type to the default value.</p> <p>By default if no service-mtu is configured it is <math>(1514 - 14) = 1500</math>.</p> |
| <b>Default</b>     | apipe, fpipe: 1508<br><br>ipipe: 1500                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

epipe: 1514

Table 13 shows MTU values for specific VC types.

**Table 13** MTU Values

| SAP VC-Type                              | Example: Service MTU | Advertised MTU |
|------------------------------------------|----------------------|----------------|
| Ethernet                                 | 1514                 | 1500           |
| Ethernet (with preserved dot1q)          | 1518                 | 1504           |
| VPLS                                     | 1514                 | 1500           |
| VPLS (with preserved dot1q)              | 1518                 | 1504           |
| VLAN (dot1p transparent to MTU value)    | 1514                 | 1500           |
| VLAN (Q-in-Q with preserved bottom Qtag) | 1518                 | 1504           |

**Parameters** *octets* — The size of the MTU in octets, expressed as a decimal integer.

**Values** 1 to 9194

## signaled-vc-type-override

**Syntax** **signaled-vc-type-override** *atm-vcc*  
**no signaled-vc-type-override**

**Context** config>service>apipe

**Description** This command overrides the pseudowire type signaled to type 0x0009 N:1 VCC cell within an Apipe VLL service of vc-type atm-cell. Normally, this service vc-type signals a pseudowire of type 0x0003 ATM Transparent Cell.

This command is not allowed in an Apipe VLL of vc-type value atm-cell if a configured ATM SAP is not using a connection profile. Conversely, if the signaling override command is enabled, only an ATM SAP with a connection profile assigned will be allowed.

The **override** command is not allowed on Apipe VLL service of vc-type value other than atm-cell. It is also not allowed on a VLL service with the vc-switching option enabled since signaling of the PW FEC in a Multi-Segment PW (MS-PW) is controlled by the T-PE nodes. Therefore, for this feature to be used on a MS-PW, it is required to configure an Apipe service of vc-type atm-cell at the T-PE nodes with the signaled-vc-type-override enabled, and to configure a Apipe VLL service of vc-type atm-vcc at the S-PE node with the vc-switching option enabled.

The **no** form of this command returns the Apipe VLL service to signal its default pseudowire type

---

|                   |                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------|
| <b>Default</b>    | none                                                                                           |
| <b>Parameters</b> | <i>atm-vcc</i> — Specifies the pseudowire type to be signaled in the pseudowire establishment. |

## 2.17.2.4 Service SAP Commands

Commands listed in this section may apply to multiple Apipe, Cpipe, Epipe, Fpipe, and Ipipe contexts.

### sap

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the device. Each SAP must be unique.</p> <p>All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port. Channelized TDM ports are always access ports.</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded.</p> <p>The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>The following are supported on the 7750 SR only:</p> <ul style="list-style-type: none"> <li>• ATM VPI/VCI on an ATM port for vc-type atm-vcc and atm-sdu</li> <li>• ATM VPI on an ATM port for vc-type atm-vpc</li> </ul> |

- ATM virtual trunk - a range of VPIs on an ATM port for vc-type atm-cell
- ATM port for vc-type atm-cell
- ATM connection profile for vc-type atm-cell
- Frame Relay DLCI on a port for vc-type atm-sdu
- ATM SAP carries the IPv4 packet using RFC 2684, VC-Mux or LLC/SNAP routed PDU encapsulation for an lpipe service
- Frame Relay SAP RFC 2427, routed PDU encapsulation for an lpipe service
- Ethernet SAP RFC 1332, PPP IPCP encapsulation of an IPv4 packet for an lpipe service
- Ethernet SAP HDLC SAP uses the routed IPv4 encapsulation for an lpipe service
- ATM - Frame Relay, PPP/IPCP - PPP/IPCP
- Frame Relay-Frame Relay, ATM - ATM
- Ethernet-Ethernet
- cHDLC-cHDLC
- An ATM SAP can be part of an IMA bundle.
- A PPP SAP can be part of an MLPPP bundle.
- A FR SAP can be part of a MLFR bundle.

Ethernet SAPs support null, dot1q, and qinq is supported for all routers.

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Enhanced Service (IES), the IP interface must be shutdown before the SAP on that interface may be removed.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Default</b>       | No SAPs are defined                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Special Cases</b> | <p><b>Special Cases</b> — A SAP can be defined with Ethernet ports, SONET/SDH or TDM channels. At most, only one sdp-id can be bound to an VLL service. Since a VLL is a point-to-point service, it can have, at most, two end points. The two end points can be one SAP and one SDP or two SAPs. Up to 49 SDPs can be associated with a service in a single router. Each SDP must have a unique router destination or an error will be generated.</p> <p>A default SAP has the following format: port-id:*. This type of SAP is supported only on Ethernet MDAs and its creation is allowed only in the scope of Layer 2 services (Epipe and VPLS). This type of SAP is mutually exclusive with a SAP defined by explicit null encapsulation (for example, 1/1/1:0).</p> <p>Two Frame Relay SAPs cannot be configured on an Apipe service on the 7750 SR. The limitation is for an Apipe service in local mode, which has two SAPs associated with the service, as opposed to a configuration with a SAP and a SDP in remote case, the only combination of the type of SAPs allowed is either two ATM SAPs or an ATM SAP and a Frame Relay SAP. The CLI prevents adding two Frame Relay SAPs under an Apipe service.</p> |
| <b>Parameters</b>    | <p><i>sap-id</i> — Specifies the physical port identifier portion of the SAP.</p> <p><i>port-id</i> — Specifies the physical port ID.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

If the card in the slot has Media Dependent Adapters (MDAs) installed, the *port-id* must be in the *slot\_number/MDA\_number/port\_number* format. For example 6/2/3 specifies port 3 on MDA 2 in slot 6.

The *port-id* must reference a valid port type. When the *port-id* parameter represents SONET/SDH and TDM channels, the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

If the SONET/SDH port is configured as clear-channel then only the port is specified.

|                |                                 | <i>sub-port</i>          | a, b    |

**endpoint** — Adds a SAP endpoint association.

**no endpoint** — Removes the association of a SAP or a spoke SDP with an explicit endpoint name.

**create** — Keyword used to create a SAP instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

**Output** The following is an example of Apipe SAP information.

### Sample Output

```

| <b>Syntax</b>      | <b>atm</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | <pre> config&gt;service&gt;apipe&gt;sap config&gt;service&gt;epipe&gt;sap config&gt;service&gt;ipipe&gt;sap </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables access to the context to configure ATM-related attributes. This command can only be used when a specified context (for example, a channel or SAP) supports ATM functionality such as:</p> <ul style="list-style-type: none"> <li>• Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality</li> <li>• Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality.</li> </ul> <p>If ATM functionality is not supported for a specified context, the command returns an error.</p> |

## egress

|                |                                                                                                |
|----------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>egress</b>                                                                                  |
| <b>Context</b> | <pre> config&gt;service&gt;apipe&gt;sap&gt;atm config&gt;service&gt;epipe&gt;sap&gt;atm </pre> |

---

**Description** This command configures egress ATM attributes for the SAP.

## ingress

**Syntax** **ingress**

**Context** config>service>apipe>sap>atm  
config>service>epipe>sap>atm

**Description** This command configures ingress ATM attributes for the SAP.

## traffic-desc

**Syntax** **traffic-desc** *traffic-desc-profile-id*  
**no traffic-desc**

**Context** config>service>apipe>sap>atm>egress  
config>service>apipe>sap>atm>ingress  
config>service>epipe>sap>atm>egress  
config>service>epipe>sap>atm>ingress

**Description** This command assigns an ATM traffic descriptor profile to a specified context (for example, a SAP).

When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction. When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.

The **no** form of the command reverts the traffic descriptor to the default traffic descriptor profile.

**Default** The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.

**Parameters** *traffic-desc-profile-id* — Specifies a defined traffic descriptor profile (see the QoS atm-td-profile command).

## llf

**Syntax** [**no**] **llf**

**Context** config>service>apipe>sap>atm  
config>service>epipe>sap>ethernet

**Description** This command enables Link Loss Forwarding (LLF) on an Ethernet port or an ATM port. This feature provides an end-to-end OAM fault notification for Ethernet VLL service and for ATM VLL service of vc-type atm-cell. It brings down the Ethernet port (Ethernet LLF) or sends a SONET/SDH Path AIS (ATM LLF) toward the attached CE when there is a local fault on the Pseudowire or service, or a remote fault on the SAP or pseudowire, signaled with label withdrawal or T-LDP status bits. It ceases when the fault disappears.

The Ethernet port must be configured for null encapsulation.

For the 7750 SR, the ATM port must be configured as a SAP on an Apipe service of vc-type atm-cell. The ATM port must also be configured on the following MDAs:

- 1-port OC12/STM4 ASAP MDA. At OC3/STM1 port level
- 4-port ATM MDA at OC12/STM4 or OC3/STM1 port level

The ATM port must be configured as a SAP on an Apipe service of vc-type atm-cell. The ATM port must also be configured on the following MDAs:

- 1-port OC12/STM4 ASAP MDA. At OC3/STM1 port level
- 4-port ATM MDA at OC12/STM4 or OC3/STM1 port level

## oam

**Syntax** `oam`

**Context** `config>service>apipe>sap>atm`  
`config>service>epipe>sap>atm`  
`config>service>ipipe>sap>atm`

**Description** This command enables the context to configure OAM functionality for a PVCC delimiting a SAP.

- The ATM-capable MDAs support end-to-end and segment OAM functionality (AIS, RDI, Loopback) over both F5 (VC) and end-to-end F4 (VP) OAM:
- ITU-T Recommendation I.610 - B-ISDN Operation and Maintenance version 11/95
- GR-1248-CORE - Generic Requirements for Operations of ATM N3 June 1996
- GR-1113-CORE - Bellcore, Asynchronous Transfer Mode (ATM) (AAL) Protocols Generic Requirements, Issue 1, July 1994

## alarm-cells

**Syntax** `[no] alarm-cells`

**Context** `config>service>apipe>sap>atm>oam`  
`config>service>epipe>sap>atm>oam`  
`config>service>ipipe>sap>atm>oam`

**Description** This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC terminations to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.

When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes operationally down, or enters a fault state and becomes operationally up, or exits that fault state). RDI cells are generated when PVCC is operationally down. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).

The **no** command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, a PVCC's operational status is no longer affected by a PVCC's OAM state changes due to AIS/RDI processing (when **alarm-cells** is disabled, a PVCC will change operational status to operationally up due to alarm-cell processing) and RDI cells are not generated as result of the PVCC going into AIS or RDI state. The PVCC's OAM status, however, will record OAM faults as previously described.

**Default** Enabled for PVCCs delimiting IES SAPs

## terminate

**Syntax** [no] terminate

**Context** config>service>apipe>sap>atm>oam

**Description** This command specifies whether this SAP will act as an OAM termination point. ATM SAPs can be configured to tunnel or terminate OAM cells.

When configured to not terminate (the default is **no terminate**), the SAP will pass OAM cells through the VLL without inspecting them. The SAP will respond to OAM loopback requests that are directed to the local node by transmitting a loopback reply. Other loopback requests are transparently tunneled through the pseudowire. In this mode, it is possible to launch a loopback request toward the directly-attached ATM equipment and see the results of the reply.

When configured to terminate, the SAP will respond to AIS by transmitting RDI and will signal the change of operational status to the other endpoint (for example, through LDP status notifications). The SAP will respond to OAM loopback requests by transmitting a loopback reply. In this mode, it is possible to launch a loopback request toward the directly-attached ATM equipment and see the results of the reply.

For Apipe services, the user has the option of enabling or disabling this option for VC types atm-vcc and atm-sdu since these service types maintain the ATM layer and/or the AAL5 layer across the VLL. It is not supported on atm-vpc and atm-cell apipe vc types since the VLL must pass the VC level (F5) OAM cells.

The **terminate** option for OAM is the only and default mode of operation supported for an ATM SAP which is part of Epipe, lpipe, VPLS, and IES/VRN. This is because the ATM and AAL5 layers are terminated.

For Apipe services, the user has the option of enabling or disabling this option for vc types atm-vcc and atm-sdu since these service types maintain the ATM layer and/or the AAL5 layer across the VLL. It is not supported on atm-vpc and atm-cell Apipe vc types since the VLL must pass the VC level (F5).

The **terminate** option for OAM is the only and default mode of operation supported for an ATM SAP which is part of Epipe, lpipe, VPLS, and IES/VRN. This is because the ATM and AAL5 layers are terminated.

**Default** no terminate

## bandwidth

**Syntax** **bandwidth** *bandwidth*  
**no bandwidth**

**Context** config>service>apipe>sap  
config>service>cpipe>sap  
config>service>epipe>sap  
config>service>fpipe>sap  
config>service>ipipe>sap

**Description** This command specifies the admin bandwidth assigned to SAPs, ports and LAGs which is used by SAP bandwidth CAC.

SAP: Attempts to increase the SAP admin bandwidth will fail if there is insufficient available admin bandwidth on its port or LAG, otherwise the port or LAG available admin bandwidth will be reduced by the incremental SAP admin bandwidth. Reducing the SAP admin bandwidth will increase the available admin bandwidth on its port or LAG. This is not supported for PW-SAPs, Ethernet tunnels or subscriber group interface SAPs.

The **no** version of the command reverts to the default value.

**Default** no bandwidth

**Parameters** *bandwidth* — Specifies the admin bandwidth assigned to the SAP, port or LAG, in kb/s.

**Values** 1 to 3200000000

## collect-stats

**Syntax** [**no**] **collect-stats**

**Context** config>service>apipe>sap

```
config>service>cpipe>sap
config>service>cpipe>spoke-sdp
config>service>epipe>sap
config>service>epipe>spoke-sdp
config>service>fpipe>sap
config>service>ipipe>sap
```

**Description** This command enables accounting and statistical data collection for either the SAP, network port, or IP interface. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.

When the **no collect-stats** command is issued the statistics are still accumulated by the cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent **collect-stats** command is issued then the counters written to the billing file include all the traffic while the **no collect-stats** command was in effect.

**Default** no collect-stats

## dist-cpu-protection

**Syntax** **dist-cpu-protection** *policy-name*  
**no dist-cpu-protection**

**Context** config>service>apipe>sap  
config>service>cpipe>sap  
config>service>epipe>sap  
config>service>fpipe>sap  
config>service>ipipe>sap

**Description** This command assigns a Distributed CPU Protection (DCP) policy to the SAP. Only a valid existing DCP policy can be assigned to a SAP or a network interface (this rule does not apply to templates, such as an **msap-policy** template).

If no dist-cpu-protection policy is assigned to a SAP, then the default access DCP policy (\_default-access-policy) is used.

If no DCP functionality is required on the SAP then an empty DCP policy can be created and explicitly assigned to the SAP

**Parameters** *policy-name* — Specifies the name of the DCP policy up to 32 characters in length

## egress

**Syntax** **egress**

**Context** config>service>apipe>sap  
config>service>cpipe>sap  
config>service>epipe>sap

```
config>service>fpipe>sap
config>service>ipipe>sap
```

**Description** This command enables the context to configure egress SAP parameters.

If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing.

## ingress

**Syntax** **ingress**

**Context** config>service>apipe>sap  
config>service>cpipe>sap  
config>service>epipe>sap  
config>service>fpipe>sap  
config>service>ipipe>sap

**Description** This command enables the context to configure ingress SAP Quality of Service (QoS) policies.

If no sap-ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing.

## agg-rate

**Syntax** **[no] agg-rate**

**Context** config>service>apipe>sap>egress  
config>service>cpipe>sap>egress  
config>service>epipe>sap>egress  
config>service>fpipe>sap>egress  
config>service>ipipe>sap>egress

**Description** This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: **rate**, **limit-unused-bandwidth**, and **queue-frame-based-accounting**.

## limit-unused-bandwidth

**Syntax** **[no] limit-unused-bandwidth**

**Context** config>service>apipe>sap>egress>agg-rate  
config>service>cpipe>sap>egress>agg-rate  
config>service>epipe>sap>egress>agg-rate  
config>service>fpipe>sap>egress>agg-rate  
config>service>ipipe>sap>egress>agg-rate

**Description** This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

## rate

**Syntax** **rate** *kilobits-per-second*  
**no rate**

**Context** config>service>apipe>sap>egress>agg-rate  
config>service>cpipe>sap>egress>agg-rate  
config>service>epipe>sap>egress>agg-rate  
config>service>fpipe>sap>egress>agg-rate  
config>service>ipipe>sap>egress>agg-rate

**Description** This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, Vport, and so on).

**Parameters** *kilobits-per-second* — The enforced aggregate rate for all queues associated with the agg-rate context, in kilobits per second.

**Values** 1 to 3200000000 | max

## policer-control-override

**Syntax** **policer-control-override** [create]  
**no policer-control-override**

**Context** config>service>apipe>sap>egress  
config>service>apipe>sap>ingress  
config>service>cpipe>sap>egress  
config>service>cpipe>sap>ingress  
config>service>epipe>sap>egress  
config>service>epipe>sap>ingress  
config>service>fpipe>sap>egress  
config>service>fpipe>sap>ingress  
config>service>ipipe>sap>egress  
config>service>ipipe>sap>ingress

**Description** This command, within the SAP ingress or egress contexts, creates a CLI node for specific overrides to the applied policer-control-policy. A policy must be applied for a policer-control-overrides node to be created. If the policer-control-policy is removed or changed, the policer-control-overrides node is automatically deleted from the SAP.

The **no** form of the command removes any existing policer-control-policy overrides and the policer-control-overrides node from the SAP.

**Default** no policer-control-override

---

**Parameters**    **create** — The create keyword is required when the policer-control-overrides node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit confirmation, the create keyword is not required.

## max-rate

**Syntax**    **max-rate** {*rate* | **max**}

**Context**    config>service>apipe>sap>egress>policer-control-override  
                  config>service>apipe>sap>ingress>policer-control-override  
                  config>service>cpipe>sap>egress>policer-control-override  
                  config>service>cpipe>sap>ingress>policer-control-override  
                  config>service>epipe>sap>egress>policer-control-override  
                  config>service>epipe>sap>ingress>policer-control-override  
                  config>service>fpipe>sap>egress>policer-control-override  
                  config>service>fpipe>sap>ingress>policer-control-override  
                  config>service>ipipe>sap>egress>policer-control-override  
                  config>service>ipipe>sap>ingress>policer-control-override

**Description**    This command, within the SAP ingress and egress contexts, overrides the root arbiter parent policer max-rate that is defined within the policer-control-policy applied to the SAP.

When the override is defined, modifications to the policer-control-policy max-rate parameter have no effect on the SAP's parent policer until the override is removed using the **no max-rate** command within the SAP.

**Parameters**    *rate* — Specifies the rate override in kilobits per second.

**Values**    1 to 2000000000

**max** — Specifies the maximum rate override.

## priority-mbs-thresholds

**Syntax**    **priority-mbs-thresholds**

**Context**    config>service>apipe>sap>egress>policer-control-override  
                  config>service>apipe>sap>ingress>policer-control-override  
                  config>service>cpipe>sap>egress>policer-control-override  
                  config>service>cpipe>sap>ingress>policer-control-override  
                  config>service>epipe>sap>egress>policer-control-override  
                  config>service>epipe>sap>ingress>policer-control-override  
                  config>service>fpipe>sap>egress>policer-control-override  
                  config>service>fpipe>sap>ingress>policer-control-override  
                  config>service>ipipe>sap>egress>policer-control-override  
                  config>service>ipipe>sap>ingress>policer-control-override

**Description** This command overrides the CLI node contains the configured min-thresh-separation and the various priority level mbs-contribution override commands.

## min-thresh-separation

**Syntax** `min-thresh-separation size [bytes | kilobytes]`

**Context** `config>service>apipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>apipe>sap>ingress>policer-control-override>priority-mbs-threshold`  
`config>service>cpipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>cpipe>sap>ingress>policer-control-override>priority-mbs-threshold`  
`config>service>epipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>epipe>sap>ingress>policer-control-override>priority-mbs-threshold`  
`config>service>fpipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>fpipe>sap>ingress>policer-control-override>priority-mbs-threshold`  
`config>service>ipipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>ipipe>sap>ingress>policer-control-override>priority-mbs-threshold`

**Description** This command, within the SAP ingress and egress contexts, is used to override the root arbiter's parent policer min-thresh-separation parameter that is defined within the policer-control-policy applied to the SAP.

When the override is defined, modifications to the policer-control-policy min-thresh-separation parameter have no effect on the SAP's parent policer until the override is removed using the no min-thresh-separation command within the SAP.

The no form of the command removes the override and allows the min-thresh-separation setting from the policer-control-policy to control the root arbiter's parent policer's minimum discard threshold separation size.

**Default** no min-thresh-separation

**Parameters** `size` — The minimum discard threshold separation override value.

**Values** 1 to 16777216 | default

**bytes** — Signifies that `size` is expressed in bytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

**kilobytes** — Signifies that `size` is expressed in kilobytes. The bytes and kilobytes keywords are mutually exclusive and optional. The default is kilobytes.

## priority

**Syntax** `[no] priority level`

**Context** `config>service>apipe>sap>egress>policer-control-override>priority-mbs-threshold`  
`config>service>apipe>sap>ingress>policer-control-override>priority-mbs-threshold`  
`config>service>cpipe>sap>egress>policer-control-override>priority-mbs-threshold`

```

config>service>cpipe>sap>ingress>policer-control-override>priority-mbs-threshold
config>service>epipe>sap>egress>policer-control-override>priority-mbs-thresholds
config>service>epipe>sap>ingress>policer-control-override>priority-mbs-thresholds
config>service>fpipe>sap>egress>policer-control-override>priority-mbs-threshold
config>service>fpipe>sap>ingress>policer-control-override>priority-mbs-threshold
config>service>ipipe>sap>egress>policer-control-override>priority-mbs-threshold
config>service>ipipe>sap>ingress>policer-control-override>priority-mbs-threshold

```

|                    |                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>The priority-level level override CLI node contains the specified priority level's mbs-contribution override value.</p> <p>This node does not need to be created and will not be output in show or save configurations unless an mbs-contribution override exist for level.</p> |
| <b>Parameters</b>  | <p><i>level</i> — The level parameter is required when specifying priority-level and identifies which of the parent policer instances priority level's the mbs-contribution is overriding.</p> <p><b>Values</b> 1 to 8</p>                                                         |

## mbs-contribution

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | This command, within the QoS CLI node, is used to create, delete or modify policer control policies. A policer control policy is very similar to the scheduler-policy which is used to manage a set of queues by defining a hierarchy of virtual schedulers and specifying how the virtual schedulers interact to provide an aggregate SLA. In a similar fashion, the policer-control-policy controls the aggregate bandwidth available to a set of child policers. Once created, the policy can be applied to ingress or egress SAPs. |

### Policer Control Policy Instances

On the SAP side, an instance of a policy is created each time a policy is applied.

When applied to a sub-profile on a 7450 ESS and 7750 SR, an instance of the policy is created each time a subscriber successfully maps one or more hosts to the profile per ingress SAP.

Each instance of the policer-control-policy manages the policers associated with the object that owns the policy instance (SAP or subscriber). If a policer on the object is parented to an appropriate arbiter name that exists within the policy, the policer will be managed by the instance. If a policer is not parented or is parented to a non-existent arbiter, the policer will be orphaned and will not be subject to bandwidth control by the policy instance.

### Maximum Rate and Root Arbiter

The policer-control-policy supports an overall maximum rate (max-rate) that defines the total amount of bandwidth that may be distributed to all associated child policers. By default, that rate is set to max which provides an unlimited amount of bandwidth to the policers. Once the policy is created, an actual rate should be configured in order for the policy instances to be effective. At the SAP level, the maximum rate may be overridden on a per instance basis.

For subscribers, the maximum rate may only be overridden on the subscriber profile which will then be applied to all instances associated with the profile.

The maximum rate is defined within the context of the root arbiter which is always present in a policer-control-policy. The system creates a parent policer which polices the output of all child policers attached to the policy instance to the configured rate. Child policers may be parented directly to the root arbiter (parent root) or parented to one of the tiered arbiters (parent arbiter-name). Since each tiered arbiter must be parented to either another tiered arbiter or the root arbiter (default), every parented child policer is associated with the root arbiter and therefore the root arbiter's parent policer.

### **Parent Policer PIR Leaky Bucket Operation**

The parent policer is a single leaky bucket that monitors the aggregate throughput rate of the associated child policers. Forwarded packets increment the bucket by the size of each packet. The rate of the parent policer is implemented as a bucket decrement function which attempts to drain the bucket. If the rate of the packets flowing through the bucket is less than the decrement rate, the bucket does not accumulate depth. Each packet that flows through the bucket is accompanied by a derived discard threshold. If the current depth of the bucket is less than the discard threshold, the packet is allowed to pass through, retaining the colors derived from the packet's child policer. If the current depth is equal to or greater than the threshold value, the packet is colored red and the bucket depth is not incremented by the packet size. Also, any increased bucket depths in the child policer are canceled making any discard event an atomic function between the child and the parent.

Due to the fact that multiple thresholds are supported by the parent policer, the policer control policy is able to protect the throughput of higher priority child policers from the throughput of the lower priority child policers within the aggregate rate.

### **Tier 1 and Tier 2 Arbiters**

As previously stated, each child is attached either to the always available root arbiter or to an explicitly created tier 1 or tier 2 arbiter. Unlike the hardware parent policer based root arbiter, the arbiters at tier 1 and tier 2 are only represented in software and are meant to provide an arbitrary hierarchical bandwidth distribution capability. An arbiter created on tier 2 must parent to either to an arbiter on tier 1 or to the root arbiter. Arbiters created on tier 1 always parent to the root arbiter. In this manner, every arbiter ultimately is parented or grand-parented by the root arbiter.

Each tiered arbiter supports an optional rate parameter that defines a rate limit for all child arbiters or child policers associated with the arbiter. Child arbiters and policers attached to the arbiter have a level attribute that defines the strict level at which the child is given bandwidth by the arbiter. Level 8 is the highest and 1 is the lowest. Also a weight attribute defines each child's weight at that strict level in order to determine how bandwidth is distributed to multiple children at that level when insufficient bandwidth is available to meet each child's required bandwidth.

### **Fair and Unfair Bandwidth Control**

Each child policer supports three leaky buckets. The PIR bucket manages the policer's peak rate and maximum burst size, the CIR leaky bucket manages the policer's committed rate and committed burst size. The third leaky bucket is used by the policer control policy instance to manage the child policer's fair rate (FIR). When multiple child policers are attached to the root arbiter at the same priority level, the policy instance uses each child's FIR bucket rate to control how much of the traffic forwarded by the policer is fair and how much is unfair.

In the simplest case where all the child policers in the same priority level are directly attached to the root arbiter, each child's FIR rate is set according to the child's weight divided by the sum of the active children's weights multiplied by the available bandwidth at the priority level. The result is that the FIR bucket will mark the appropriate amount of traffic for each child as fair-based on the weighted fair output of the policy instance.

The fair/unfair forwarding control in the root parent policer is accomplished by implementing two different discard thresholds for the priority. The first threshold is discard-unfair and the second is discard-all for packet associated with the priority level. As the parent policer PIR bucket fills (due the aggregate forwarded rate being greater than the parent policers PIR decrement rate) and the bucket depth reaches the first threshold, all unfair packets within the priority are discarded. This leaves room in the bucket for the fair packets to be forwarded.

In the more complex case where one or more tiered arbiters are attached at the priority level, the policer control policy instance must consider more than just the child policer weights associated with the attached arbiter. If the arbiter is configured with an aggregate rate limit that its children cannot exceed, the policer control policy instance will switch to calculating the rate each child serviced by the arbiter should receive and enforces that rate using each child policers PIR leaky bucket.

When the child policer PIR leaky bucket is used to limit the bandwidth for the child policer and the child's PIR bucket discard threshold is reached, packets associated with the child policer are discarded. The child policer's discarded packets do not consume depth in the child policer's CIR or FIR buckets. The child policers discarded packets are also prevented from impacting the parent policer and will not consume the aggregate bandwidth managed by the parent policer.

### **Parent Policer Priority Level Thresholds**

As stated in the Tier 1 and Tier 2 Arbiter subsection, each child policer is attached either to the root arbiter or explicitly to one of the tier 1 or tier 2 arbiters. When attached directly to the root arbiter, its priority relative to all other child policers is indicated by the parenting level parameter. When attached through one of the tiered arbiters, the parenting hierarchy of the arbiters must be traced through to the ultimate attachment to the root arbiter. The parenting level parameter of the arbiter parented to the root arbiter defines the child policer's priority level within the parent policer.

The priority level is important since it defines the parent policer discard thresholds that will be applied at the parent policer. The parent policer has 8 levels of strict priority and each priority level has its own discard-unfair and discard-all thresholds. Each priority's thresholds are larger than the thresholds of the lower priority levels. This ensures that when the parent policer is discarding, it will be priority sensitive.

To visualize the behavior of the parent policer, picture that when the aggregate forwarding rate of all child policers is currently above the decrement rate of the parent PIR leaky bucket, the bucket depth will increase over time. As the bucket depth increases, it will eventually cross the lowest priority's discard-unfair threshold. If this amount of discard sufficiently lowers the remaining aggregate child policer rate, the parent PIR bucket will hover around this bucket depth. If however, the remaining aggregate child rate is still greater than the decrement rate, the bucket will continue to rise and eventually reach the lowest priority's discard-all threshold which will cause all packets associated with the priority level to be discarded (fair and unfair). Again, if the remaining aggregate child rate is less than or equal to the bucket decrement rate, the parent PIR bucket will hover around this higher bucket depth. If the remaining aggregate child rate is still higher than the decrement rate, the bucket will continue to rise through the remaining priority level discards until equilibrium is achieved.

Each child's rate feeding into the parent policer is governed by the child policer's PIR bucket decrement rate. The amount of bandwidth the child policer offers to the parent policer will not exceed the child policer's configured maximum rate.

### **Root Arbiter's Parent Policers' Priority Aggregate Thresholds**

Each policer-control-policy root arbiter supports configurable aggregate priority thresholds which are used to control burst tolerance within each priority level. Two values are maintained per priority level; the shared-portion and the fair-portion. The shared-portion represents the amount of parent PIR bucket depth that is allowed to be consumed by both fair and unfair child packets at the priority level. The fair-portion represents the amount of parent PIR bucket depth that only the fair child policer packets may consume within the priority level. It should be noted that the fair and unfair child packets associated with a higher parent policer priority level may also consume the bucket depth set aside for this priority.

While the policy maintains a parent policer default or explicit configurable values for shared-portion and fair-portion within each priority level, it is possible that some priority levels will not be used within the parent policer. Most parent policer use cases require fewer than eight strict priority levels.

To derive the actual priority level discard-unfair and discard-all thresholds while only accounting for the actual in-use priority levels, the system maintains a child policer to parent policer association counter per priority level for each policer control policy instance. As a child policer is parented to either the root or a tiered arbiter, the system determines the parent policer priority level for the child policer and increments the association counter for that priority level on the parent policer instance.

The shared-portion for each priority level is affected by the parent policer global min-thresh-separation parameter that defines the minimum separation between any in-use discard thresholds. When more than one child policer is associated with a parent policer priority level, the shared-portion for that priority level will be the current value of min-thresh-separation. When only a single child policer is associated, the priority level's shared-portion is zero since all packets from the child will be marked fair and the discard-unfair threshold is meaningless. When the association counter is zero, both the shared-portion and the fair-portion for that priority level are zero since neither discard thresholds will be used. Whenever the association counter is greater than 0, the fair-portion for that priority level will be derived from the current value of the priority's mbs-contribution parameter and the global min-thresh-separation parameter.

Each priority level's discard-unfair and discard-all thresholds are calculated based on an accumulation of lower priorities shared-portions and fair-portions and the priority level's own shared-portion and fair-portion. The base threshold value for each priority level is equal to the sum of all lower priority level's shared-portions and fair-portions. The discard-unfair threshold is the priority level's base threshold plus the priority level's shared-portion. The discard-all threshold for the priority level is the priority level's base threshold plus both the shared-portion and fair-portion values of the priority. As can be seen, an in-use priority level's thresholds are always greater than the thresholds of lower priority levels.

### Policer Control Policy Application

A policer-control-policy may be applied on any Ethernet ingress or egress SAP that is associated with a port (or ports in the case of LAG).

The **no** form of the command removes a non-associated policer control policy from the system. The command will not execute when policer-name is currently associated with any SAP context.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b> | <p><i>policy-name</i> — Each policer-control-policy must be created with a unique policy name. The name given as policy-name must adhere to the system policy ASCII naming requirements. If the defined policy-name already exists, the system will enter that policy's context for editing purposes. If policy-name does not exist, the system will attempt to create a policy with the specified name. Creating a policy may require use of the create parameter when the system is configured for explicit object creation mode.</p> <p><b>create</b> — The keyword is required when a new policy is being created and the system is configured for explicit object creation mode.</p> |

---

| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to a specific policer created on the SAP through a sap-ingress or sap-egress QoS policy.</p> <p>The <b>no</b> form of the command is used to remove any existing overrides for the specified policer-id.</p>                                                                                                                                                                                                                                                                                     |

- Parameters** *policer-id* — The *policer-id* parameter is required when executing the *policer* command within the *policer-overrides* context. The specified *policer-id* must exist within the *sap-ingress* or *sap-egress* QoS policy applied to the SAP. If the *policer* is not currently used by any forwarding class or forwarding type mappings, the *policer* will not actually exist on the SAP. This does not preclude creating an override context for the *policer-id*.
- create** — The *create* keyword is required when a *policer* *policer-id* override node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit confirmation, the *create* keyword is not required.

## cbs

- Syntax** **cbs** *size* [**bytes** | **kilobytes**]  
**no cbs**
- Context** config>service>apipe>sap>egress>policer-override>policer  
config>service>apipe>sap>ingress>policer-override>policer  
config>service>cpipe>sap>egress>policer-override>policer  
config>service>cpipe>sap>ingress>policer-override>policer  
config>service>epipe>sap>egress>policer-override>policer  
config>service>epipe>sap>ingress>policer-override>policer  
config>service>fpipe>sap>egress>policer-override>policer  
config>service>fpipe>sap>ingress>policer-override>policer  
config>service>ipipe>sap>egress>policer-override>policer  
config>service>ipipe>sap>ingress>policer-override>policer
- Description** This command, within the SAP ingress and egress *policer-overrides* contexts, is used to override the *sap-ingress* and *sap-egress* QoS policy configured CBS parameter for the specified *policer-id*.
- The **no** form of this command returns the CBS size to the default value.
- Default** no cbs
- Parameters** *size* — The *size* parameter is required when specifying *cbs* override and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional **byte** and **kilobyte** keywords are mutually exclusive and are used to explicitly define whether *size* represents bytes or kilobytes.
- Values** 0 to 16777216 | default
- bytes** — When bytes is defined, the value given for *size* is interpreted as the *policer's* MBS value in bytes.
- kilobytes** — When kilobytes is defined, the value given for *size* is interpreted as the *policer's* MBS value in kilobytes.

| <b>Description</b> | <p>This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured mbs parameter for the specified policer-id.</p> <p>The <b>no</b> form of the command is used to restore the policer's mbs setting to the policy defined value.</p>                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default</b>     | no mbs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><b>size</b> — The size parameter is required when specifying mbs override and is expressed as an integer representing the required size in either bytes or kilobytes. The default is kilobytes. The optional <b>byte</b> and <b>kilobyte</b> keywords are mutually exclusive and are used to explicitly define whether size represents bytes or kilobytes.</p> <p><b>Values</b> 0 to 16777216   default</p> <p><b>bytes</b> — When <b>bytes</b> is defined, the value given for <i>size</i> is interpreted as the policer's MBS value in bytes.</p> <p><b>kilobytes</b> — When <b>kilobytes</b> is defined, the value given for <i>size</i> is interpreted as the policer's MBS value in kilobytes.</p> |

## packet-byte-offset

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

```
config>service>ipipe>sap>ingress>policer-override>policer
```

**Description** This command, within the SAP ingress and egress policer-overrides contexts, is used to override the sap-ingress and sap-egress QoS policy configured packet-byte-offset parameter for the specified policer-id. Packet byte offset settings are not included in the applied rate when (queue) frame based accounting is configured; however, the offsets are applied to the statistics.

The **no** packet-byte-offset command is used to restore the policer's packet-byte-offset setting to the policy defined value.

**Default** no packet-byte-offset

**Parameters** *add-bytes* — Specifies the number of bytes that are added to the size each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is increased by the amount being added to the size of each packet.

**Values** 1 to 31

*sub-bytes* — Specifies the number of bytes that are subtracted from the size of each packet associated with the policer for rate metering, profiling and accounting purposes. From the policer's perspective, the maximum packet size is reduced by the amount being subtracted from the size of each packet.

**Values** 1 to 64

## percent-rate

**Syntax** **percent-rate** *pir-percent* [*cir cir-percent*]  
**no percent-rate**

**Context** config>service>apipe>sap>egress>policer-override>policer  
config>service>apipe>sap>ingress>policer-override>policer  
config>service>cpipe>sap>egress>policer-override>policer  
config>service>cpipe>sap>ingress>policer-override>policer  
config>service>ipipe>sap>egress>policer-override>policer  
config>service>ipipe>sap>ingress>policer-override>policer  
config>service>epipe>sap>egress>policer-override>policer

**Description** This command configures the percent rates (CIR and PIR) override.

**Parameters** *pir-percent* — Specifies the policer's PIR as a percentage of the policers's parent arbiter rate.

**Values** 0.01 to 100.00

**Default** 100.00

*cir-percent* — Specifies the policer's CIR as a percentage of the policers's parent arbiter rate.

**Values** 0.00 to 100.00

---

| <b>Description</b> | <p>The percent-rate command within the SAP ingress and egress QoS policy enables supports for a queue's PIR and CIR rate to be configured as a percentage of the egress port's line rate or of its parent scheduler's rate.</p> <p>When the rates are expressed as a port-limit, the actual rates used per instance of the queue will vary based on the port speed. For example, when the same QoS policy is used on a 1-Gb and a 10-Gb Ethernet port, the queue's rates will be 10 times greater on the 10 Gb port due to the difference in port speeds. This enables the same QOS policy to be used on SAPs on different ports without needing to use SAP based queue overrides to modify a queue's rate to get the same relative performance from the queue.</p> <p>If the port's speed changes after the queue is created, the queue's PIR and CIR rates will be recalculated based on the defined percentage value.</p> <p>When the rates are expressed as a local-limit, the actual rates used per instance of the queue are relative to the queue's parent scheduler rate. This enables the same QOS policy to be used on SAPs with different parent scheduler rates without needing to use SAP based queue overrides to modify a queue's rate to get the same relative performance from the queue.</p> <p>If the parent scheduler rate changes after the queue is created, the queue's PIR and CIR rates will be recalculated based on the defined percentage value.</p> <p>Queue rate overrides can only be specified in the form as configured in the QoS policy (a SAP override can only be specified as a percent-rate if the associated QoS policy was also defined as percent-rate). Likewise, a SAP override can only be specified as a rate (kb/s) if the associated QoS policy was also defined as a rate. Queue-overrides are relative to the limit type specified in the QOS policy.</p> <p>When no percent-rate is defined within a SAP ingress or egress queue-override, the queue reverts to the defined shaping and CIR rates within the SAP ingress and egress QOS policy associated with the queue.</p> |
| <b>Parameters</b>  | <i>percent-of-line-rate</i> — The percent-of-line-rate parameter is used to express the queue's shaping rate as a percentage of line rate. The line rate associated with the queue's port may dynamically change due to configuration or auto-negotiation. The line rate may also be affected by an egress port scheduler defined max-rate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*pir-percent* — Specifies the queue's PIR as a percentage dependent on the use of the port-limit or local-limit.

**Values** 0.01 to 100.00

**Default** 100.00

*cir-percent* — Specifies the queue's CIR as a percentage dependent on the use of the port-limit or local-limit.

**Values** 0.00 to 100.00

**Default** 100.00

## rate

**Syntax** `rate {rate | max} [cir {rate | max}]`

**Context** config>service>apipe>sap>egress>policer-override>policer  
config>service>apipe>sap>ingress>policer-override>policer  
config>service>cpipe>sap>egress>policer-override>policer  
config>service>cpipe>sap>ingress>policer-override>policer  
config>service>epipe>sap>egress>policer-override>policer  
config>service>epipe>sap>ingress>policer-override>policer  
config>service>ipipe>sap>egress>policer-override>policer  
config>service>ipipe>sap>ingress>policer-override>policer

**Description** This command within the SAP ingress and egress policer-overrides contexts is used to override the sap-ingress and sap-egress QoS policy configured rate parameters for the specified policer-id.

The **no** rate command is used to restore the policy defined metering and profiling rate to a policer.

**Parameters** **rate** *rate* — Specifies the policer instance metering rate for the PIR leaky bucket, in kilobits per second. The integer value is multiplied by 1000 to derive the actual rate in bits per second.

**Values** 1 to 2000000000

**cir** *rate* — Specifies the overriding value for the policy-derived profiling rate of the policer, in kilobits per second. The integer value is multiplied by 1000 to derive the actual rate in bits per second.

**Values** 0 to 2000000000

**max** — Uses the maximum policer rate, equal to the maximum capacity of the card on which the policer is configured. If the policer rate is set to a value larger than the maximum rate possible for the card, then the PIR or CIR used is equivalent to **max**.

| <b>Description</b> | <p>The SAP QoS policy's <b>policer stat-mode</b> command is used to configure the forwarding plane counters that allow offered, output, and discard accounting to occur for the policer. A policer has multiple types of offered packets (for example, soft in-profile and out-of-profile from ingress and hard in-profile and out-of-profile due to egress profile overrides) and each of these offered types is interacting with the policers metering and profiling functions resulting in colored output packets (green, yellow, and red). Due to the potentially large number of egress policers, it is not economical to allocate counters in the forwarding plane for all possible offered packet types and output conditions. Many policers will not be configured with a CIR profiling rate and not all policers will receive explicitly re-profiled offered packets. The <b>stat-mode</b> command allows provisioning of the number of counters each policer requires and indicates how the offered packet types and output conditions should be mapped to the counters.</p> <p>While a <b>no-stats</b> mode is supported that prevents any packet accounting, the use of the policer's parent command requires that the policer's <b>stat-mode</b> to be set at least to the minimal setting so that offered statistics are available for the policer's Fair Information Rate (FIR) to be calculated.</p> <p>Each time the policer's stat mode is changed, any previous counter values are lost and any new counters are set to zero.</p> <p>Each mode uses a certain number of counters per policer instance that are allocated from the forwarding plane's policer counter resources. The total/allocated/free statistics can be viewed by using the <b>tools dump resource-usage card fp</b> command. If insufficient counters exist to implement a mode on any policer instance, the stat-mode change will fail and the previous mode will continue unaffected for all instances of the policer.</p> <p>The <b>stat-mode</b> setting defined for the policer in the QoS policy may be overridden on a SAP where the policy is applied. If insufficient policer counter resources exist to implement the override, the stat-mode override command will fail. The current active stat mode setting will continue to be used by the policer.</p> |

The **no stat-mode** command attempts to return the policer's stat-mode setting to **minimal**. The command will fail if insufficient policer counter resources exist to implement **minimal** where the QoS policer is currently applied and has a forwarding class mapping.

Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Quality of Service Guide* for detailed information about the supported parameters for the **policer stat-mode** command.

## qinq-mark-top-only

|                    |                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | This command associates a Quality of Service (QoS) policy with an egress Service Access Point (SAP).<br><br>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the <i>policy-id</i> does not exist, an error will be returned.<br><br>The <b>qos</b> command, when used under the egress context, is used to associate egress QoS policies. |

The **qos** command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a specified type will return an error.

By default, if no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.

| <b>Context</b>     | config>service>apipe>sap>ingress<br>config>service>cpipe>sap>ingress<br>config>service>epipe>sap>ingress<br>config>service>fpipe>sap>ingress<br>config>service>ipipe>sap>ingress |
| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP).</p>                                                                     |

QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the policy-id does not exist, an error will be returned.

The **qos** command, when used under the ingress context, is used to associate ingress QoS policies. The **qos** command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.

Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a specified type will return an error.

By default, if no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.

The **no** form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.

| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b> | <p><i>policy-id</i> — The ingress policy ID to associate with SAP or IP interface on ingress. The policy ID must already exist.</p> <p><b>Values</b> 1 to 65535</p> <p><b>shared-queuing</b> — This keyword can only be specified on SAP ingress. The shared-queuing keyword specifies the shared queue policy will be used by this SAP. When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.</p> <p><b>fp-redirect-group</b> — This keyword can only be used on SAP ingress and associates a SAP ingress with an instance of a named queue group template on the ingress forwarding plane of a specified IOM/IMM/XMA. The queue-group-name and <b>instance</b> <i>instance-id</i> are mandatory parameters when executing the command.</p> <p><i>queue-group-name</i> — Specifies the name of the queue group to be instance on the forwarding plane of the IOM/IMM/XMA, up to 32 characters in length. The <i>queue-group-name</i> must correspond to a valid ingress forwarding plane queue group, created under <b>config&gt;card&gt;fp&gt;ingress&gt;access</b>.</p> <p><i>instance-id</i> — Specifies the instance of the named queue group on the IOM/IMM/XMA ingress forwarding plane.</p> |

## queue-override

|                |                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] queue-override</b>                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b> | <pre> config&gt;service&gt;apipe&gt;sap&gt;egress config&gt;service&gt;apipe&gt;sap&gt;ingress config&gt;service&gt;cpipe&gt;sap&gt;egress config&gt;service&gt;cpipe&gt;sap&gt;ingress config&gt;service&gt;epipe&gt;sap&gt;egress config&gt;service&gt;epipe&gt;sap&gt;ingress config&gt;service&gt;fpipe&gt;sap&gt;egress config&gt;service&gt;fpipe&gt;sap&gt;ingress </pre> |

```
config>service>ipipe>sap>egress
config>service>ipipe>sap>ingress
```

**Description** This command enables the context to configure override values for the specified SAP egress or ingress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy. If the policy was created as a template policy, this command overrides the parameter and its description and queue parameters in the policy.

## hs-secondary-shaper

**Syntax** **hs-secondary-shaper** *policy-name*  
**no hs-secondary-shaper**

**Context** config>service>epipe>sap>egress>queue-override  
config>service>ipipe>sap>egress>queue-override

**Description** This command configures the HS secondary shaper to be used to apply an aggregate rate and per-scheduling class rates to the SAP egress HSQ queue group.

The **no** form of the command removes the HS secondary shaper override from the configuration, reverting the SAP egress HSQ queue group to the default HS secondary shaper on that port.

**Parameters** *policy-name* — Specifies the secondary shaper name, up to 32 characters.

## hs-wrr-group

**Syntax** **hs-wrr-group** *group-id* [**create**]  
**no hs-wrr-group** *group-id*

**Context** config>service>epipe>sap>egress>queue-override  
config>service>ipipe>sap>egress>queue-override

**Description** This command configures the egress HS WRR group override parameters.

The **no** form of the command removes the group ID from the configuration.

**Parameters** *group-id* — Specifies the HS WRR group ID to override.

**Values** 1, 2

**create** — Keyword used to create an HSS WRR group. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## class-weight

|                    |                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | This command overrides the scheduling rate applied to the HS WRR group as a percentage of the port rate, including both the port's egress rate and port's HS scheduler policy maximum rate, if configured. The override rate type must match the corresponding rate type within the applied QoS policy.<br><br>The <b>no</b> form of this command removes the percent rate override value from the configuration. |
| <b>Parameters</b>  | <i>percent</i> — Specifies the percent rate of the HS WRR group.<br><br><b>Values</b> 0.01 to 100.00                                                                                                                                                                                                                                                                                                              |

## rate

|                    |                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rate</b> <i>rate</i><br><b>no rate</b>                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>epipe>sap>egress>queue-override>hs-wrr-group<br>config>service>ipipe>sap>egress>queue-override>hs-wrr-group                                                                                                                                                                                 |
| <b>Description</b> | This command overrides the scheduling rate applied to the HS WRR group in Kb/s. A rate can be specified in Kb/s or the keyword <b>max</b> can be used to remove the bandwidth limitation on the HS WRR group. The override rate type must match the corresponding rate type within the applied QoS policy. |

The **no** form of this command removes the rate override value from the configuration.

**Parameters** *rate* — Specifies the scheduling rate of the HS WRR group in Kb/s.

**Values** 1 to 2000000000, max

## hs-class-weight

**Syntax** **hs-class-weight** *weight*  
**no hs-class-weight**

**Context** config>service>epipe>sap>egress>queue-override>queue  
config>service>ipipe>sap>egress>queue-override>queue

**Description** This command overrides the class weight of this queue at its parent primary shaper, relative to the other queues and WRR groups in different HSQ queue groups in the same scheduling class.

The **no** form of this command removes the class weight override value from the configuration.

**Parameters** *weight* — Specifies the weight of the queue.

**Values** 1, 2, 4, 8

## hs-wred-queue

**Syntax** **hs-wred-queue policy** *slope-policy-name*  
**no hs-wred-queue**

**Context** config>service>epipe>sap>egress>queue-override>queue  
config>service>ipipe>sap>egress>queue-override>queue

**Description** This command overrides the slope policy applied to the HSQ queue group queue.

The **no** form of this command removes the WRED queue policy override value from the configuration.

**Parameters** *slope-policy-name* — Specifies an existing slope policy name to apply to this HSQ queue group queue, up to 32 characters.

## hs-wrr-weight

**Syntax** **hs-wrr-weight** *weight*  
**no hs-wrr-weight**

**Context** config>service>epipe>sap>egress>queue-override>queue  
config>service>ipipe>sap>egress>queue-override>queue

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> <p>This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case the configuration of the adaptation rule is performed under the <code>hs-wrr-group</code> within the SAP egress QoS policy.</p> <p>The <b>no</b> form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific <b>adaptation-rule</b> is removed, the default constraints for <b>rate</b> and <b>cir</b> apply.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Default</b>     | no adaptation-rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><b>pir</b> — The <b>pir</b> parameter defines the constraints enforced when adapting the PIR rate defined within the <b>queue queue-id rate</b> command. The <b>pir</b> parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the <b>rate</b> command is not specified, the default applies.</p> <p><b>cir</b> — The <b>cir</b> parameter defines the constraints enforced when adapting the CIR rate defined within the <b>queue queue-id rate</b> command. The <b>cir</b> parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the <b>cir</b> parameter is not specified, the default constraint applies.</p> <p><b>adaptation-rule</b> — Specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset.</p> <p><b>Values</b></p> <p><b>max</b> — The <b>max</b> (maximum) keyword is mutually exclusive with the <b>min</b> and <b>closest</b> options. When <b>max</b> is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the <b>rate</b> command.</p> <p><b>min</b> — The <b>min</b> (minimum) keyword is mutually exclusive with the <b>max</b> and <b>closest</b> options. When <b>min</b> is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the <b>rate</b> command.</p> <p><b>closest</b> — The <b>closest</b> parameter is mutually exclusive with the <b>min</b> and <b>max</b> parameter. When <b>closest</b> is defined, the operational PIR for the queue will be the rate closest to the rate specified using the <b>rate</b> command.</p> |

## avg-frame-overhead

## Description

This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a SONET or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap).

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be  $10000 \times 0.1$  or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be  $50 \times 20$  or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.

- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be  $7500 \times 1.1$  or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to figure the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

**On the 7450 ESS and 7750 SR, SAP and subscriber SLA-profile average frame overhead override** — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

|                   |                                                                                                                                                                                            |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>percent</i> — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues. |
| <b>Values</b>     | 0.00 to 100.00                                                                                                                                                                             |

| <b>Description</b> | <p>The queue <b>burst-limit</b> command defines an explicit shaping burst size for a queue. The configured size defines the shaping leaky bucket threshold level that indicates the maximum burst over the queue's shaping rate.</p> <p>The <b>no</b> form of this command restores the default burst limit to the specified queue. This is equivalent to specifying burst-limit default within the QoS policies. When specified within a queue-override queue context, any current burst limit override for the queue is removed and the queue's burst limit is controlled by its defining policy.</p>                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>     | no burst-limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><b>default</b> — Reverts the queue's burst limit to the system default value.</p> <p><i>size</i> — When a numeric value is specified (<i>size</i>), the system interprets the value as an explicit burst limit size. The value is expressed as an integer and, by default, is interpreted as the burst limit in kilobytes. If the value is intended to be interpreted in bytes, the <b>bytes</b> qualifier must be added following <i>size</i>.</p> <p><b>Values</b>      1 to 13671 kilobytes<br/>                 14000000 bytes</p> <p><b>Default</b>      No default for <i>size</i>; use the <b>default</b> keyword to specify default burst limit.</p> <p><b>bytes</b> — Specifies that the value given for <i>size</i> must be interpreted as the burst limit in bytes.</p> <p><b>kilobytes</b> — Specifies that the value given for <i>size</i> must be interpreted as the burst limit in kilobytes. If neither bytes nor kilobytes is specified, the default qualifier is <b>kilobytes</b>.</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's CBS parameters.</p> <p>It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a specific access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.</p> <p>When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly to drop packets.</p> <p>The <b>no</b> form of this command returns the CBS size to the default value.</p> |
| <b>Default</b>     | no cbs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is wanted, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).</p> <p><b>Values</b>      0 to 131072, default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**drop-tail**

|                |                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>drop-tail</b>                                                                                              |
| <b>Context</b> | config>service>apipe>sap>egress>queue-override>queue<br>config>service>apipe>sap>ingress>queue-override>queue |

```
config>service>cpipe>sap>egress>queue-override>queue
config>service>cpipe>sap>ingress>queue-override>queue
config>service>epipe>sap>egress>queue-override>queue
config>service>epipe>sap>ingress>queue-override>queue
config>service>fpipe>sap>egress>queue-override>queue
config>service>fpipe>sap>ingress>queue-override>queue
config>service>ipipe>sap>egress>queue-override>queue
config>service>ipipe>sap>ingress>queue-override>queue
```

**Description** This command enables the context to configure queue drop tail parameters.

## low

**Syntax** **low**

**Context**

```
config>service>apipe>sap>egress>queue-override>queue>drop-tail
config>service>apipe>sap>ingress>queue-override>queue>drop-tail
config>service>cpipe>sap>egress>queue-override>queue>drop-tail
config>service>cpipe>sap>ingress>queue-override>queue>drop-tail
config>service>fpipe>sap>egress>queue-override>queue>drop-tail
config>service>fpipe>sap>ingress>queue-override>queue>drop-tail
config>service>ipipe>sap>egress>queue-override>queue>drop-tail
config>service>ipipe>sap>ingress>queue-override>queue>drop-tail
config>service>epipe>sap>egress>queue-override>queue>drop-tail
config>service>epipe>sap>ingress>queue-override>queue>drop-tail
```

**Description** This command enables the context to configure the queue low drop-tail parameters. The low drop tail defines the queue depth beyond which out-of-profile packets are not accepted into the queue and will be discarded.

## percent-reduction-from-mbs

**Syntax** **percent-reduction-from-mbs** *percent*  
**no percent-reduction-from-mbs**

**Context**

```
config>service>apipe>sap>egress>queue-override>queue>drop-tail>low
config>service>apipe>sap>ingress>queue-override>queue>drop-tail>low
config>service>cpipe>sap>egress>queue-override>queue>drop-tail>low
config>service>cpipe>sap>ingress>queue-override>queue>drop-tail>low
config>service>fpipe>sap>egress>queue-override>queue>drop-tail>low
config>service>fpipe>sap>ingress>queue-override>queue>drop-tail>low
config>service>ipipe>sap>egress>queue-override>queue>drop-tail>low
config>service>ipipe>sap>ingress>queue-override>queue>drop-tail>low
config>service>epipe>sap>egress>queue-override>queue>drop-tail>low
config>service>epipe>sap>ingress>queue-override>queue>drop-tail>low
```

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command overrides the low queue drop tail as a percentage reduction from the MBS of the queue. For example, if a queue has an MBS of 600 kbytes and the percentage reduction is configured to be 30% for the low drop tail, then the low drop tail will be at 420 kbytes. Any out-of-profile packets will not be accepted into the queue if its depth is greater than this value, and so will be discarded. |
| <b>Parameters</b>  | <i>percent</i> — Specifies the percentage reduction from the MBS for a queue drop tail.                                                                                                                                                                                                                                                                                                                          |
| <b>Values</b>      | 0 to 100, default                                                                                                                                                                                                                                                                                                                                                                                                |

## mbs

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command overrides specific attributes of the specified queue's MBS parameters. A queue uses its MBS value to determine whether it has exhausted all of its buffers while enqueueing packets. Once the queue has exceeded the number of buffers allowed by the MBS, all packets are discarded until packets have been drained from the queue.</p> <p>The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope associated with a packet. A queue that has not exceeded its MBS is not guaranteed to have buffer available when needed or that the packet's RED slope will not force the discard of the packet. Setting correct CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>The <b>no</b> form of this command returns the MBS assigned to the queue to the default value.</p> |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>size</i> — The size parameter is an integer expression of the maximum number of kilobytes or bytes of buffering allowed for the queue. A value of 0 causes the queue to discard all packets.</p> <p><b>Values</b> 0 to 1073741824, default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**bytes** — Indicates that the *size* parameter value is expressed in bytes.

**kilobytes** — Indicates that the *size* parameter is expressed in kilobytes.

| <b>Description</b> | <p>This command defines an optional parent scheduler that further governs the available bandwidth given the queue aside from the queue's PIR setting. When multiple schedulers and/or queues share a child status with the parent scheduler, the <b>weight</b> or <b>level</b> parameters define how this queue contends with the other children for the parent's bandwidth.</p>                                                                                                                                                                                                                                                                                                                                                                      |

Checks are not performed to see if a *scheduler-name* exists when the parent command is defined on the queue. Scheduler names are configured in the **config>qos>scheduler-policy>tier level** context. Multiple schedulers can exist with the *scheduler-name* and the association pertains to a scheduler that should exist on the egress SAP as the policy is applied and the queue created. When the queue is created on the egress SAP, the existence of the *scheduler-name* is dependent on a scheduler policy containing the *scheduler-name* being directly or indirectly applied (through a multi-service customer site) to the egress SAP. If the *scheduler-name* does not exist, the queue is placed in the orphaned operational state. The queue will accept packets but will not be bandwidth limited by a virtual scheduler or the scheduler hierarchy applied to the SAP. The orphaned state must generate a log entry and a trap message. The SAP which the queue belongs to must also depict an orphan queue status. The orphaned state of the queue is automatically cleared when the *scheduler-name* becomes available on the egress SAP.

The parent scheduler can be made unavailable due to the removal of a scheduler policy or scheduler. When an existing parent scheduler is removed or inoperative, the queue enters the orphaned state and automatically returns to normal operation when the parent scheduler is available again.

When a parent scheduler is defined without specifying weight or strict parameters, the default bandwidth access method is weight with a value of 1.

The **no** form of the command removes a child association with a parent scheduler. If a parent association does not currently exist, the command has no effect and returns without an error. Once a parent association has been removed, the former child queue attempts to operate based on its configured rate parameter. Removing the parent association on the queue within the policy takes effect immediately on all queues using the SAP egress QoS policy.

#### Parameters

**weight** — These optional keywords are mutually exclusive to the **level** keyword. The weight defines the relative weight of this queue in comparison to other child schedulers, policers, and queues while vying for bandwidth on the parent *scheduler-name*. Any policers, queues, or schedulers defined as weighted receive no parental bandwidth until all policers, queues, and schedulers with a higher (numerically larger) priority on the parent have reached their maximum bandwidth or are idle.

All **weight** values from all weighted active policers, queues, and schedulers with a common parent scheduler are added together. Then, each individual active weight is divided by the total, deriving the percentage of remaining bandwidth provided to the policer, queue, or scheduler. A weight is considered to be active when the pertaining policer, queue, or scheduler has not reached its maximum rate and still has packets to transmit. All child policers, queues, and schedulers with a weight of 0 are considered to have the lowest priority level and are not serviced until all non-zero weighted policers, queues, and schedulers at that level are operating at the maximum bandwidth or are idle.

**Values**      0 to 100

**Default**     1

*cir-weight* — Defines the weight the queue or scheduler will use at the within-cir port priority level (defined by the cir-level parameter). The weight is specified as an integer value from 0 to 100 with 100 being the highest weight. When the cir-weight parameter is set to a value of 0 (the default value), the policer, queue, or scheduler does not receive bandwidth during the port schedulers within-cir pass and the cir-level parameter is ignored. If the cir-weight parameter is 1 or greater, the cir-level parameter comes into play.

**Values** 0 to 100

## percent-rate

| <b>Description</b> | <p>The <b>percent-rate</b> command supports a queue's shaping rate and CIR rate as a percentage of the egress port's line rate. When the rates are expressed as a percentage within the template, the actual rate used per instance of the queue group queue-id will vary based on the port speed. For example, when the same template is used to create a queue group on a 1-Gb and a 10-Gb Ethernet port, the queue's rates will be 10 times greater on the 10 Gb port due to the difference in port speeds. This enables the same template to be used on multiple ports without needing to use port based queue overrides to modify a queue's rate to get the same relative performance from the queue.</p> <p>If the port's speed changes after the queue is created, the queue's shaping and CIR rates will be recalculated based on the defined percentage value.</p> <p>The rate and percent-rate commands override one another. If the current rate for a queue is defined using the percent-rate command and the rate command is executed, the percent-rate values are deleted. In a similar fashion, the percent-rate command causes any rate command values to be deleted. A queue's rate may dynamically be changed back and forth from a percentage to an explicit rate at any time.</p> <p>An egress port queue group queue rate override may be expressed as either a percentage or an explicit rate independent on how the queue's template rate is expressed.</p> <p>The <b>no</b> form of this command returns the queue to its default shaping rate and cir rate. When <b>no percent-rate</b> is defined within a port egress queue group queue override, the queue reverts to the defined shaping and CIR rates within the egress queue group template associated with the queue.</p> |

| <b>Parameters</b> | <p><i>pir-percent</i> — Specifies the queue's shaping rate as a percentage of line rate. The line rate associated with the queue's port may dynamically change due to configuration or auto-negotiation. The line rate may also be affected by an egress port scheduler defined max-rate.</p> <p><b>Values</b>      0.01 to 100.00</p> <p><b>Default</b>      100.00</p> <p><i>cir-percent</i> — Specifies the queue's committed scheduling rate as a percentage of line rate. The line rate associated with the queue's port may dynamically change due to configuration or auto-negotiation. The line rate may also be affected by an egress port scheduler defined max-rate.</p> <p><b>Values</b>      0.00 to 100.00</p> <p><b>Default</b>      100.00</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.</p> <p>The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile and then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue's parent commands <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> |

The **rate** command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

This command is ignored for egress HSQ queue group queues which are attached to an HS WRR group within an associated HS attachment policy. In this case, the configuration of the **rate** is performed under the **hs-wrr-group** within the SAP egress QoS policy.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Parameters</b> | <p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits per second, for the queue. When the <b>rate</b> command is executed, a valid PIR setting must be explicitly defined. When the <b>rate</b> command has not been executed, the default PIR of <b>max</b> is assumed. Fractional values are not allowed and must be given as a positive integer. The actual PIR rate is dependent on the queue's <b>adaptation-rule</b> parameters and the actual hardware where the queue is provisioned.</p> <p><b>Values</b> 1 to 3200000000, <b>max</b></p> <p><b>Default</b> max</p> <p><i>cir-rate</i> — The <b>cir</b> parameter overrides the default administrative CIR used by the queue. When the <b>rate</b> command is executed, a CIR setting is optional. When the <b>rate</b> command has not been executed or the <b>cir</b> parameter is not explicitly specified, the default CIR (0) is assumed. Fractional values are not allowed and must be given as a positive integer. The <b>sum</b> keyword specifies that the CIR be used as the summed CIR values of the children schedulers, policers, or queues.</p> <p><b>Values</b> 0 to 3200000000, <b>max</b>, <b>sum</b></p> <p><b>Default</b> 0</p> |

## scheduler-override

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

---

**Description** This command specifies the set of attributes whose values have been overridden by management on this virtual scheduler. Clearing a given flag will return the corresponding overridden attribute to the value defined on the SAP's ingress scheduler policy.

## scheduler

**Syntax** **scheduler** *scheduler-name* [**create**]  
**no scheduler** *scheduler-name*

**Context** config>service>apipe>sap>egress>sched-override  
config>service>apipe>sap>ingress>sched-override  
config>service>cpipe>sap>egress>sched-override  
config>service>cpipe>sap>ingress>sched-override  
config>service>epipe>sap>egress>sched-override  
config>service>epipe>sap>ingress>sched-override  
config>service>fpipe>sap>egress>sched-override  
config>service>fpipe>sap>ingress>sched-override  
config>service>ipipe>sap>egress>sched-override  
config>service>ipipe>sap>ingress>sched-override

**Description** This command can be used to override specific attributes of the specified scheduler name. A scheduler defines bandwidth controls that limit each child (other schedulers, policers, and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have policers, queues or other schedulers defined as child associations. The scheduler can be a child which takes bandwidth from a scheduler in a higher tier. A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.

Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If *scheduler-name* already exists within the policy tier level (regardless of the inclusion of the keyword **create**), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause policers, queues, or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).

If the *scheduler-name* exists within the policy on a different tier (regardless of the inclusion of the keyword **create**), an error occurs and the current CLI context will not change.

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

1. The maximum number of schedulers has not been configured.
2. The provided *scheduler-name* is valid.
3. The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the following criteria, a name syntax error will occur, the command will not execute, and the CLI context will not change.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>scheduler-name</i> — The name of the scheduler.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Values</b>     | Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes.                                                                                                                                                                                                                                                       |
| <b>Default</b>    | None. Each scheduler must be explicitly created.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>create</b>     | — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given <i>scheduler-name</i> . If the <b>create</b> keyword is omitted, <b>scheduler-name</b> is not created when the system environment variable create is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists. |

| <b>Syntax</b>      | <b>parent</b> [ <b>weight</b> <i>weight</i> ] [ <b>cir-weight</b> <i>cir-weight</i> ]<br><b>no parent</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>apipe>sap>ingress>sched-override>scheduler<br>config>service>apipe>sap>egress>sched-override>scheduler<br>config>service>cpipe>sap>ingress>sched-override>scheduler<br>config>service>cpipe>sap>egress>sched-override>scheduler<br>config>service>epipe>sap>ingress>sched-override>scheduler<br>config>service>epipe>sap>egress>sched-override>scheduler<br>config>service>fpipe>sap>ingress>sched-override>scheduler<br>config>service>fpipe>sap>egress>sched-override>scheduler<br>config>service>ipipe>sap>ingress>sched-override>scheduler<br>config>service>ipipe>sap>egress>sched-override>scheduler                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.</p> <p>The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non-default weightings for fostered schedulers.</p> |

The **no** form of the command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

**Default** no parent

**Parameters** *weight* — **Weight** defines the relative weight of this scheduler in comparison to other child schedulers, policers, and queues at the same strict **level** defined by the **level** parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue, or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

**Values** 0 to 100

*cir-weight* — The **cir-weight** keyword defines the relative weight of this scheduler in comparison to other child schedulers, policers, and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

**Values** 0 to 100

## rate

**Syntax** **rate** *pir-rate* [**cir** *cir-rate*]  
**no rate**

**Context** config>service>apipe>sap>egress>sched-override>scheduler  
config>service>apipe>sap>ingress>sched-override>scheduler  
config>service>cpipe>sap>egress>sched-override>scheduler  
config>service>cpipe>sap>ingress>sched-override>scheduler  
config>service>fpipe>sap>egress>sched-override>scheduler  
config>service>fpipe>sap>ingress>sched-override>scheduler  
config>service>ipipe>sap>egress>sched-override>scheduler  
config>service>ipipe>sap>ingress>sched-override>scheduler  
config>service>epipe>sap>egress>sched-override>scheduler  
config>service>epipe>sap>ingress>sched-override>scheduler

**Description** This command can be used to override specific attributes of the specified scheduler rate. The **rate** command defines the maximum bandwidth that the scheduler can offer its child policers, queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase.

The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child policers or queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child policers, queues, and schedulers to operate at their maximum rates.

The **no** form of this command returns the scheduler's PIR and CIR parameters to the values configured in the applied scheduler policy.

**Parameters** *pir-rate* — The **pir** parameter accepts the **max** keyword or a value of 1 to 3200000000. Any other value will result in an error without modifying the current PIR rate.

**Values** 1 to 3200000000, **max**

*cir cir-rate* — The **cir** parameter accepts a value of 0 to 3200000000 or the **max** keyword. Any other value will result in an error without modifying the current CIR rate. If the **cir** parameter is set to **max**, then the CIR rate is set to infinity but bounded by the PIR rate.

The **sum** keyword specifies that the CIR will be used as the summed CIR values of the children schedulers, policers, or queues.

**Values** 0 to 3200000000, **max**, **sum**

## scheduler-policy

**Syntax** **scheduler-policy** *scheduler-policy-name*  
**no scheduler-policy**

**Context** config>service>apipe>sap>ingress  
config>service>apipe>sap>egress  
config>service>cpipe>sap>ingress  
config>service>cpipe>sap>egress  
config>service>epipe>sap>ingress  
config>service>epipe>sap>egress

```

config>service>fpipe>sap>ingress
config>service>fpipe>sap>egress
config>service>ipipe>sap>ingress
config>service>ipipe>sap>egress

```

**Description** This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created when the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the **config>qos>scheduler-policy scheduler-policy-name** context.

The **no** form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the ingress SAP queues associated with the customer site. Policers or queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have policers or queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more policers or queues. When the **no scheduler-policy** command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.

**Parameters** *scheduler-policy-name* — The *scheduler-policy-name* parameter applies an existing scheduler policy that was created in the **config>qos>scheduler-policy scheduler-policy-name** context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues and to egress policers managed by HQoS created on associated SAPs.

## multi-service-site

**Syntax** **multi-service-site customer-site-name**  
**no multi-service-site**

**Context** config>service>apipe>sap  
config>service>cpipe>sap  
config>service>epipe>sap  
config>service>fpipe>sap  
config>service>ipipe>sap

**Description** This command associates the SAP with a *customer-site-name*. If the specified *customer-site-name* does not exist in the context of the service customer ID an error occurs and the command will not execute. If *customer-site-name* exists, the current and future defined queues on the SAP (ingress and egress) will attempt to use the scheduler hierarchies created within *customer-site-name* as parent schedulers.

The **no** form of the command removes the SAP from any multi-service customer site the SAP belongs to. Removing the site can cause existing or future queues to enter an orphaned state.

**Default** None

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>customer-site-name</i> — The customer-site-name must exist in the context of the customer-id defined as the service owner. If customer-site-name exists and local scheduler policies have not been applied to the SAP, the current and future queues defined on the SAP will look for their parent schedulers within the scheduler hierarchies defined on customer-site-name. |
| <b>Values</b>     | Any valid customer-site-name created within the context of the customer-id.                                                                                                                                                                                                                                                                                                      |

## ce-address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>ipipe>sap<br>config>service>ipipe>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command specifies the IP address of the CE device associated with an Ipipe SAP or spoke SDP. In the case of a SAP, it is the address of the CE device directly attached to the SAP. For a spoke SDP, it is the address of the CE device reachable through that spoke SDP (for example, attached to the SAP on the remote node). The address must be a host address (no subnet addresses are accepted) as there must be only one CE device attached to an Ipipe SAP. The CE address specified at one end of an Ipipe will be used in processing ARP messages at the other endpoint, as the router acts as a proxy for ARP messages.</p> <p>On a 7450 ESS, this command specifies the IP address of the CE device associated with an Ipipe SAP. In the case of a SAP, it is the address of the CE device directly attached to the SAP. The address must be a host address (no subnet addresses are accepted) as there must be only one CE device attached to an Ipipe SAP. The CE address specified at one end of an Ipipe will be used in processing ARP messages at the other endpoint, as the router acts as a proxy for ARP messages.</p> |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address of the CE device associated with an Ipipe SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>ipipe>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies the interval between ARP requests sent on this Ipipe SAP. When the SAP is first enabled, an ARP request will be sent to the attached CE device and the received MAC address will be used in addressing unicast traffic to the CE. Although this MAC address will not expire while the Ipipe SAP is enabled and operational, it is verified by sending periodic ARP requests at the specified interval.</p> <p>The <b>no</b> form of this command restores mac-refresh to the default value.</p> |
| <b>Default</b>     | 14400                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

---

**Parameters**    *refresh interval* — Specifies the interval, in seconds, between ARP requests sent on this lpipe SAP.

**Values**        0 to 65535

## app-profile

**Syntax**        **app-profile** *app-profile-name*  
**no app-profile**

**Context**        config>service>epipe>sap  
config>service>epipe>spoke-sdp  
config>service>ipipe>sap  
config>service>ipipe>spoke-sdp

**Description**    This command configures the application profile name.

**Parameters**    *app-profile-name* — Specifies an existing application profile name configured in the **config>app-assure>group>policy** context.

## cflowd

**Syntax**        **[no] cflowd**

**Context**        config>service>epipe>sap

**Description**    This command enables cflowd to collect traffic flow samples through a service interface (SAP) for analysis. When cflowd is enabled on an Ethernet service SAP, the Ethernet traffic can be sampled and processed by the system's cflowd engine and exported to IPFIX collectors with the l2-ip template enabled.

cflowd is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement. When cflowd is enabled at the SAP level, all packets forwarded by the interface are subjected to analysis according to the cflowd configuration.

For L2 services, only ingress sampling is supported.

**Default**        no cflowd

## cpu-protection

**Syntax**        **cpu-protection** *policy-id* [**mac-monitoring**] | [**eth-cfm-monitoring** [**aggregate**] [**car**]]  
**no cpu-protection**

**Context**        config>service>epipe>spoke-sdp  
config>service>epipe>sap

| <b>Description</b> | This command enables the context to configure Ethernet properties in this SAP. |

## sap

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>sap</b> <i>eth-tunnel-tunnel-id[:eth-tunnel-sap-id]</i> [ <b>create</b> ] |
| <b>Context</b>     | config>service>epipe<br>config>service>ipipe<br>config>service>vpls               |
| <b>Description</b> | This command configures an Ethernet tunnel SAP.                                   |

An Ethernet tunnel control SAP has the format `eth-tunnel-tunnel-id` and is not configured with an Ethernet tunnel SAP ID. No Ethernet tunnel tags can be configured under a control SAP since the control SAP uses the control tags configured under the Ethernet tunnel port. This means that at least one member port and control tag must be configured under the Ethernet tunnel port before this command is executed. The control SAP is needed for carrying G.8031 and 802.1ag protocol traffic. This SAP can also carry user data traffic.

An Ethernet tunnel same-fate SAP has the format `eth-tunnel-tunnel-id:eth-tunnel-sap-id`. Same-fate SAPs carry only user data traffic. Multiple same-fate SAPs can be configured on one Ethernet tunnel port and share the fate of that port, provided the SAPs are properly configured with corresponding tags.

Ethernet tunnel SAPs are supported under VPLS, Epipe and Lpipe services only.

|                   |                                                                   |
|-------------------|-------------------------------------------------------------------|
| <b>Default</b>    | no sap                                                            |
| <b>Parameters</b> | <i>tunnel-id</i> — Specifies the tunnel ID.                       |
| <b>Values</b>     | 1 to 1024                                                         |
|                   | <i>eth-tunnel-sap-id</i> — Specifies a SAP ID of a same-fate SAP. |
| <b>Values</b>     | 0 to 4094                                                         |

| <b>Description</b> | <p>This command associates an AARP instance with a multi-homed SAP or spoke SDP. This instance uses the same AARP ID in the same node to provide traffic flow and packet asymmetry removal for a multi-homed SAP or spoke SDP.</p> <p>The type specifies the role of this service point in the AARP: either, primary (dual-homed) or secondary (dual-homed-secondary). The AA service attributes (app-profile and transit-policy) of the primary are inherited by the secondary endpoints. All endpoints within an AARP must be of the same type (SAP or spoke), and all endpoints with an AARP must be within the same service.</p> <p>The no form of the command removes the association between an AARP instance and a multi-homed SAP or spoke SDP.</p> |
| <b>Default</b>     | no aarp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>aarpld</i> — Specifies the AARP instance associated with this SAP. If not configured, no AARP instance is associated with this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Values</b>      | 1 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

*type* — Specifies the role of the SAP referenced by the AARP instance.

**Values**     **dual-homed** — The primary dual-homed AA subscriber side service-point of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.  
**dual-homed-secondary** — One of the secondary dual-homed AA subscriber side service-points of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.

| <b>Context</b>     | config>service>ipipe>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command associates an AARP instance to an Ipipe spoke SDP. This instance is paired with the same <i>aarp-id</i> in a peer node as part of a configuration to provide flow and packet asymmetry removal for traffic for a multi-homed SAP or spoke SDP. The <b>type</b> parameter specifies the role of this service point in the AARP instance.<br><br>The <b>no</b> form of the command removes the association. |
| <b>Default</b>     | no aarp                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>aarp-id</i> — An integer that identifies an AARP instance.<br><b>Values</b> 1 to 65535<br><b>subscriber-side-shunt</b> — Specifies that the AARP type is an inter-chassis shunt service for subscriber-side traffic.<br><b>network-side-shunt</b> — Specifies that the AARP type is an inter-chassis shunt service for network-side traffic.                                                                        |

## lag-link-map-profile

|                    |                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lag-link-map-profile</b> <i>link-map-profile-id</i><br><b>no lag-link-map-profile</b>                                                                                                                                                                                              |
| <b>Context</b>     | config>service>epipe>sap<br>config>service>ipipe>sap                                                                                                                                                                                                                                  |
| <b>Description</b> | This command assigns a pre-configured lag link map profile to a SAP/network interface configured on a LAG or a PW port that exists on a LAG. Once assigned/de-assigned, the SAP's/network interface's egress traffic will be re-hashed over LAG as required by the new configuration. |

The **no** form of this command reverts the SAP/network interface to use per-flow, service or link hash as configured for the service/LAG.

|                   |                                                                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no lag-link-map-profile                                                                                                                         |
| <b>Parameters</b> | <i>link-map-profile-id</i> — An integer from 1 to 64 that defines a unique lag link map profile on the LAG the SAP/network interface exists on. |

## lag-per-link-hash

|                    |                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lag-per-link-hash class {1   2   3} weight [weight]</b><br><b>no lag-per-link-hash</b>                                                                                                         |
| <b>Context</b>     | config>service>epipe>sap<br>config>service>ipipe>sap<br>config>service>vpls>sap                                                                                                                   |
| <b>Description</b> | This command configures weight and class to this SAP to be used on LAG egress when the LAG uses weighted per-link-hash.<br><br>The <b>no</b> form of this command restores default configuration. |
| <b>Default</b>     | no lag-per-link-hash (equivalent to weight 1 class 1)                                                                                                                                             |

## queue-frame-based-accounting

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] queue-frame-based-accounting</b>                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>epipe>sap>egress>agg-rate                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command is used to enable (or disable) frame based accounting on all policers and queues associated with the agg-rate context.<br><br>The command is supported on Ethernet ports only; it is not supported on HSMDA Ethernet ports.<br><br>Packet byte offset settings are not included in the applied rate when queue frame based accounting is configured; however the offsets are applied to the statistics. |

### 2.17.2.5 Service Spoke-SDP Commands

Commands listed in this section may apply to multiple Apipe, Cpipe, Epipe, Fpipe, and Ipipe contexts.

## spoke-sdp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command binds a service to an existing Service Distribution Point (SDP). A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with a service. If the <b>sdp sdp-id</b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end SR/ESS devices can participate in the service.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>     | No <i>sdp-id</i> is bound to a service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b>   | <p>This command binds a service to an existing Service Distribution Point (SDP). A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>The SDP must already be defined in the <b>config&gt;service&gt;sdp</b> context in order to associate an SDP with an Epipe, VPLS, VPRN, VPRN service. If the <b>sdp <i>sdp-id</i></b> is not already configured, an error message is generated. If the <i>sdp-id</i> does exist, a binding between that <i>sdp-id</i> and the service is created.</p> <p>SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.</p> <p>This command can also be used to associate a GRE tunnel carrying Ethernet payload with an Epipe and terminate it on a PW port referenced within the same Epipe service. The spoke SDP represents a L2oGRE tunnel with SDP delivery type set to <b>eth-gre-bridged</b>. With this configuration, the <b>vc-id</b> is unused since there is no multiplexing of Ethernet payload within the same tunnel. The <b>vc-id</b> value is included only to maintain the expected spoke SDP structure within an EPIPE service. For L2oGRE tunnels, the <b>vc-id</b> can be set to any arbitrary value within its configurable range.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>       | No <i>sdp-id</i> is bound to a service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Special Cases</b> | <p><b>Epipe</b> — At most, only one <i>sdp-id</i> can be bound to an Epipe service. Since an Epipe is a point-to-point service, it can have, at most, two end points. The two end points can be one SAP and one SDP or two SAPs. Vc-switching VLLs are an exception. If the VLL is a “vc-switching” VLL, then the two endpoints must both be SDPs.</p> <p>L2TPv3 SDP types are only supported on Epipe services and not other xpipe services.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The VC-ID is not used with L2TPv3 SDPs or L2oGRE tunnels, however it must be configured.</p> <p><b>Values</b> 1 to 4294967295</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**vc-type** — This command overrides the default VC type signaled for the spoke or mesh binding to the far end of the SDP. The VC type is a 15 bit-quantity containing a value which represents the type of VC. The actual signaling of the VC type depends on the signaling parameter defined for the SDP. If signaling is disabled, the **vc-type** command can still be used to define the dot1q value expected by the far-end provider equipment. A change of the bindings VC type causes the binding to signal the new VC type to the far end when signaling is enabled.

VC types are derived according to IETF *draft-martini-l2circuit-trans-mpls*.

The VC type value for Ethernet is 0x0005.

The VC type value for an Ethernet VLAN is 0x0004.

**Values** ethernet

**ether** — Defines the VC type as Ethernet. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings. Defining Ethernet is the same as executing **no vc-type** and restores the default VC type for the spoke SDP binding.

**vlan** — Defines the VC type as VLAN. The top VLAN tag, if a VLAN tag is present, is stripped from traffic received on the pseudowire, and a VLAN tag is inserted when forwarding into the pseudowire. The **ethernet** and **vlan** keywords are mutually exclusive. When the VC type is not defined then the default is Ethernet for spoke SDP bindings.

The VLAN VC-type requires at least one dot1q tag within each encapsulated Ethernet packet transmitted to the far end.

Note: The system expects a symmetrical configuration with its peer, specifically it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. Consequently, protocol extractions will not necessarily function for asymmetrical configurations as they would with a symmetrical configurations resulting in an unexpected operation.

**no-endpoint** — Removes the association of a spoke SDP with an explicit endpoint name.

**endpoint-name** — Specifies the name of the service endpoint.

**icb** — Configures the spoke SDP as an inter-chassis backup SDP binding.

## bandwidth

**Syntax** **bandwidth** *bw-value*  
**bandwidth max**  
**no bandwidth**

**Context** config>service>apipe>spoke-sdp  
config>service>cpipe>spoke-sdp  
config>service>epipe>spoke-sdp

```
config>service>fpipe>spoke-sdp  
config>service>ipipe>spoke-sdp
```

**Description** This command specifies the bandwidth to be used for VLL bandwidth accounting by the VLL CAC feature.

The service manager keeps track of the available bandwidth for each SDP. The maximum value is the sum of the bandwidths of all constituent LSPs in the SDP. The SDP available bandwidth is adjusted by the user configured booking factor.

If an LSP consists of a primary and many secondary standby LSPs, then the bandwidth used in the maximum SDP available bandwidth is that of the active path. Any change to an LSP active path bandwidth will update the maximum SDP available bandwidth. Note however that a change to any constituent LSP bandwidth due to re-signaling of the primary LSP path or the activation of a secondary path which causes overbooking of the maximum SDP available bandwidth causes a warning and a trap to be issued but no further action is taken. The activation of a bypass or detour LSP in the path of the primary LSP does not change the maximum SDP available bandwidth.

When the user binds a VLL service to this SDP, an amount of bandwidth equal to bandwidth is subtracted from the SDP available bandwidth adjusted by the booking factor. When the user deletes this VLL service binding from this SDP, an amount of bandwidth equal to bandwidth is added back into the SDP available bandwidth.

If the total SDP available bandwidth when adding this VLL service is about to overbook, a warning is issued and the binding is rejected. This means that the spoke SDP bandwidth does not update the maximum SDP available bandwidth. In this case, the spoke SDP is put in operational down state and a status message of "pseudowire not forwarding" is sent to the remote SR-series PE node. A trap is also generated. The service manager will not put the spoke SDP into an operationally up state until the user executes a **shutdown** command and then a **no-shutdown** command of the spoke SDP and the bandwidth check succeeds. Therefore, the service manager will not automatically audit spoke SDPs subsequently to their creation to check if bandwidth is available.

If the VLL service contains an endpoint with multiple redundant spoke SDPs, each spoke SDP will have its bandwidth checked against the available bandwidth of the corresponding SDP.

If the VLL service performs a pseudowire switching (VC switching) function, each spoke SDP is separately checked for bandwidth against the corresponding SDP.

This feature does not alter the way service packets are sprayed over multiple RSVP LSPs, which are part of the same SDP. That is, by default load balancing of service packets occurs over the SDP LSPs based on service-id, or based on a hash of the packet header if ingress SAP shared queuing is enabled. In both cases, the VLL bandwidth is not checked against the available bandwidth of the selected LSPs but on the total SDP available bandwidth. Therefore, if there is a single LSP per SDP, these two match.

If class-forwarding is enabled on the SDP, VLL service packets are forwarded to the SDP LSP which the packet forwarding class maps to, or if this is down to the default LSP. However, the VLL bandwidth is not checked against the selected LSP available bandwidth but on the total SDP available bandwidth. If there is a single LSP per SDP, these two match.

If a non-zero bandwidth is specified for a VLL service and attempts to bind the service to an LDP or a GRE SDP, a warning is issued that CAC failed but the VLL is established. A trap is also generated.

The **no** form of the command reverts to the default value.

| <b>Context</b>     | config>service>apipe>spoke-sdp<br>config>service>cpipe>spoke-sdp<br>config>service>epipe>spoke-sdp<br>config>service>epipe>bgp>pw-template-binding<br>config>service>fpipe>spoke-sdp<br>config>service>ipipe>spoke-sdp                                                                                                                                      |
| <b>Description</b> | This command configures a named BFD template to be used by VCCV BFD on PWs belonging to the VLL, BGP VPWS, or VPLS service. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Template parameters are configured under the <b>config&gt;router&gt;bfd</b> context. |
| <b>Default</b>     | no bfd-template                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>name</i> — A text string name for the template of up to 32 characters in printable 7-bit ASCII, enclosed in double quotes.                                                                                                                                                                                                                               |

## cell-concatenation

|                    |                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>apipe>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command enables the context to provide access to the various options that control the termination of ATM cell concatenation into an MPLS frame. Several options can be configured simultaneously. The concatenation process for a specified MPLS packet ends when the first concatenation termination condition is met. The concatenation parameters apply only to ATM N:1 cell mode VLL. |

| <b>Context</b>     | config>service>apipe>spoke-sdp>cell-concat                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables the configuration of the maximum number of ATM cells to accumulate into an MPLS packet. The remote peer will also signal the maximum number of concatenated cells it is willing to accept in an MPLS packet. When the lesser of (the configured value and the signaled value) number of cells is reached, the MPLS packet is queued for transmission onto the pseudowire. It is ensured that the MPLS packet MTU conforms to the configured service MTU.</p> <p>The <b>no</b> form of this command sets max-cells to the value '1' indicating that no concatenation will be performed.</p> |
| <b>Parameters</b>  | <p><i>cell-count</i> — Specifies the maximum number of ATM cells to be accumulated into an MPLS packet before queuing the packet for transmission onto the pseudowire.</p> <p><b>Values</b>      1 to 128</p> <p><b>Default</b>      1</p>                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>apipe>spoke-sdp>cell-concat                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command enables the configuration of the maximum amount of time to wait while performing ATM cell concatenation into an MPLS packet before transmitting the MPLS packet. This places an upper bound on the amount of delay introduced by the concatenation process. When this amount of time is reached from when the first ATM cell for this MPLS packet was received, the MPLS packet is queued for transmission onto the pseudowire.<br><br>The <b>no</b> form of this command resets max-delay to its default value. |
| <b>Parameters</b>  | <i>delay-time</i> — Specifies the maximum amount of time, in hundreds of microseconds, to wait before transmitting the MPLS packet with whatever ATM cells have been received. For example, to bound the delay to 1 ms the user would configure 10 (hundreds of microseconds). The delay-time is rounded up to one of the following values 1, 5, 10, 50, 100, 200, 300 and 400.<br><br><b>Values</b> 1 to 400<br><b>Default</b> 400                                                                                           |

## request-timer

|                    |                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>request-timer</b> <i>timer1</i> <b>retry-timer</b> <i>timer2</i> <b>timeout-multiplier</b> <i>multiplier</i><br><b>no request-timer</b>                                                                                                                                                         |
| <b>Context</b>     | config>service>apipe>spoke-sdp>control-channel-status<br>config>service>cpipe>spoke-sdp>control-channel-status<br>config>service>epipe>spoke-sdp>control-channel-status<br>config>service>vpls>spoke-sdp>control-channel-status                                                                    |
| <b>Description</b> | This command configures the control channel status request mechanism. When it is configured, control channel status request procedures are used. These augment the procedures for control channel status messaging from RFC 6478. This command cannot be used with a non-zero refresh-timer value. |

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><i>timer1</i> — Specifies the interval, in seconds, at which pseudowire status messages, including a reliable delivery TLV with the “request” bit set, are sent.</p> <p><b>Values</b> 10 to 65535</p> <p><i>timer2</i> — specifies the timeout interval, in seconds, if no response to a pseudowire status request is received. This parameter must be configured. A value of zero (0) disables retries.</p> <p><b>Values</b> 0, 3 to 60</p> <p><i>multiplier</i> — If a requesting node does not receive a valid response to a pseudowire status request within a number of seconds equal to the retry timer multiplied by this multiplier, then it will assume the pseudowire is down. This parameter is optional.</p> <p><b>Values</b> 3 to 20</p> |

| <b>Context</b>     | <pre>config&gt;service&gt;apipe&gt;spoke-sdp config&gt;service&gt;cpipe&gt;spoke-sdp config&gt;service&gt;epipe&gt;spoke-sdp config&gt;service&gt;fpipe&gt;spoke-sdp config&gt;service&gt;ipipe&gt;spoke-sdp</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>The control word command provides the option to add a control word as part of the packet encapsulation for pseudowire types for which the control word is optional. These are Ethernet pseudowires (Epipe). For the 7750 SR only, ATM N:1 cell mode pseudowires (apipe vc-types atm-vcc and atm-vpc) and VT pseudowire (apipe vc-type atm-cell).</p> <p>The configuration for the two directions of the pseudowire must match because the control word negotiation procedures described in Section 6.2 of RFC 4447 are not supported. The C-bit in the pseudowire FEC sent in the label mapping message is set to 1 when the control word is enabled. Otherwise, it is set to 0.</p> <p>The service will only come up if the same C-bit value is signaled in both directions. If a spoke-sdp is configured to use the control word but the node receives a label mapping message with a C-bit clear, the node releases the label with the an “Illegal C-bit” status code as per Section 6.1 of RFC 4447. As soon as the user also enabled the control the remote peer, the remote peer will withdraw its original label and will send a label mapping with the C-bit set to 1 and the VLL service will be up in both nodes. The control word must be enabled to allow MPLS-TP OAM to be used on a static spoke-sdp in a Apipe, Epipe and Cpipe service.</p> |

## egress

|                |                                                    |
|----------------|----------------------------------------------------|
| <b>Syntax</b>  | <b>egress</b>                                      |
| <b>Context</b> | <pre>config&gt;service&gt;apipe&gt;spoke-sdp</pre> |

```
config>service>cpipe>spoke-sdp
config>service>epipe>spoke-sdp
config>service>fpipe>spoke-sdp
config>service>ipipe>spoke-sdp
```

**Description** This command configures the egress SDP context.

## qos

**Syntax** **qos** *network-policy-id* **port-redirect-group** *queue-group-name* [**instance** *instance-id*]  
**no qos**

**Context** config>service>apipe>spoke-sdp>egress  
config>service>cpipe>spoke-sdp>egress  
config>service>epipe>spoke-sdp>egress  
config>service>fpipe>spoke-sdp>egress  
config>service>ipipe>spoke-sdp>egress  
config>service>vpls>spoke-sdp>egress  
config>service>vpls>mesh-sdp>egress  
config>service>pw-template>egress

**Description** This command is used to redirect PW packets to an egress port queue-group for the purpose of shaping.

The egress PW shaping provisioning model allows the mapping of one or more PWs to the same instance of queues, or policers and queues, that are defined in the queue-group template.

Operationally, the provisioning model consists of the following steps:

1. Create an egress queue-group template and configure queues only, or policers and queues for each FC that needs to be redirected.
2. Apply the queue-group template to the network egress context of all ports where there exists a network IP interface that the PW packets can be forwarded on. This creates one instance of the template on the egress of the port. One or more instances of the same template can be created.
3. Configure FC-to-policer or FC-to-queue mappings together with the redirect to a queue-group in the egress context of a network QoS policy. No queue-group name is specified in this step, which means the same network QoS policy can redirect different PWs to different queue-group templates.
4. Apply this network QoS policy to the egress context of a spoke-sdp inside a service, or to the egress context of a PW template and specify the redirect queue-group name.

One or more spoke-sdps can have their FCs redirected to use queues only, or queues and policers in the same queue-group instance.

The following are the constraints and rules of this provisioning model:

1. When a PW FC is redirected to use a queue or a policer and a queue in a queue-group and the queue-group name does not exist, the association is failed at the time the user associates the egress context of a spoke-sdp to the named queue-group. In such a case, the PW packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface the PW packet is forwarded on. This queue can be a queue-group queue or the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port. This is the existing implementation and default behavior for a PW packet.
2. When a PW FC is redirected to use a queue or a policer and a queue in a queue-group and the queue-group name exists but the policer-id and/or the queue-id is not defined in the queue-group template, the association is failed at the time the user associates the egress context of a spoke-sdp to the named queue-group. In such a case, the PW packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface the PW packet is forwarded on.
3. When a PW FC is redirected to use a queue or a policer and a queue in a queue-group and the queue-group name exists and the policer-id or policer-id plus queue-id exist, it is not required to check that an instance of that queue-group exists in all egress network ports that have network IP interfaces. The handling of this is dealt with in the data path as follows:
  - When a PW packet for that FC is forwarded and an instance of the referenced queue-group name exists on that egress port, the packet is processed by the queue-group policer and will then be fed to the queue-group queue.
  - When a PW packet for that FC is forwarded and an instance of the referenced queue-group name does not exist on that egress port, the PW packet will be fed directly to the corresponding egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.
4. If a network QoS policy is applied to the egress context of a PW, any PW FC that is not explicitly redirected in the network QoS policy will have the corresponding packets feed directly the corresponding the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.

When the queue-group name the PW is redirected to exists and the redirection succeeds, the marking of the packet's DEI/dot1p/DSCP and the tunnel's DEI/dot1p/DSCP/EXP is performed according to the relevant mappings of the {FC, profile} in the egress context of the network QoS policy applied to the PW. This is true regardless of whether an instance of the queue-group exists or not on the egress port the PW packet is forwarded to. If the packet's profile value changed due to egress child policer CIR profiling, the new profile value is used to mark the packet's DEI/dot1p and the tunnel's DEI/dot1p/EXP, and the DSCP/prec will be remarked if **enable-dscp-prec-marking** is enabled under the policer.

When the queue-group name the PW is redirected does not exist, the redirection command is failed. In this case, the marking of the packet's DEI/dot1p/DSCP and the tunnel's DEI/dot1p/DSCP/EXP fields is performed according to the relevant commands in the egress context of the network QoS policy applied to the network IP interface the PW packet is forwarded to.

The **no** version of this command removes the redirection of the PW to the queue-group.

---

|                   |                                                                                                                                 |

---

## qos

**Syntax** `qos network-policy-id fp-redirect-group queue-group-name instance instance-id`  
`no qos [network-policy-id]`

**Context** `config>service>apipe>spoke-sdp>ingress`  
`config>service>cpipe>spoke-sdp>ingress`  
`config>service>epipe>spoke-sdp>ingress`  
`config>service>fpipe>spoke-sdp>ingress`  
`config>service>ipipe>spoke-sdp>ingress`  
`config>service>vpls>spoke-sdp>ingress`  
`config>service>vpls>mesh-sdp>ingress`  
`config>service>pw-template>ingress`

**Description** This command is used to redirect PW packets to an ingress forwarding plane queue-group for the purpose of rate-limiting.

The ingress PW rate-limiting feature uses a policer in queue-group provisioning model. This model allows the mapping of one or more PWs to the same instance of policers that are defined in a queue-group template.

Operationally, the provisioning model in the case of the ingress PW shaping feature consists of the following steps:

1. Create an ingress queue-group template and configure policers for each FC that needs to be redirected and optionally for each traffic type (unicast or multicast).
2. Apply the queue-group template to the network ingress forwarding plane where there exists a network IP interface that the PW packets can be received on. This creates one instance of the template on the ingress of the FP. One or more instances of the same template can be created.
3. Configure FC-to-policer mappings together with the policer redirect to a queue-group in the ingress context of a network QoS policy. No queue-group name is specified in this step which means the same network QoS policy can redirect different PWs to different queue-group templates.
4. Apply this network QoS policy to the ingress context of a spoke-sdp inside a service, or to the ingress context of a PW template and specify the redirect queue-group name.

One or more spoke-sdps can have their FCs redirected to use policers in the same policer queue-group instance.

The following are the constraints and rules of this provisioning model when used in the ingress PW rate-limiting feature:

1. When a PW FC is redirected to use a policer in a named policer queue-group and the queue-group name does not exist, the association is failed at the time the user associates the ingress context of a spoke-sdp to the named queue-group. In such a case, the PW packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.

2. When a PW FC is redirected to use a policer in a named policer queue-group and the queue-group name exists but the policer-id is not defined in the queue-group template, the association is failed at the time the user associates the ingress context of a spoke-sdp to the named queue-group. In such a case, the PW packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
3. When a PW FC is redirected to use a policer in a named policer queue-group and the queue-group name exists and the policer-id is defined in the queue-group template, it is not required to check that an instance of that queue-group exists in all ingress FPs that have network IP interfaces. The handling of this is dealt within the data path as follows:
  - When a PW packet for that FC is received and an instance of the referenced queue-group name exists on that FP, the packet is processed by the policer and will then feed the per-FP ingress shared queues referred to as “policer-output-queues”.
  - When a PW packet for that FC is received and an instance of the referenced queue-group name does not exist on that FP, the PW packets will be fed directly into the corresponding ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
4. If a network QoS policy is applied to the ingress context of a PW, any PW FC that is not explicitly redirected in the network QoS policy will have the corresponding packets feed directly into the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
5. If no network QoS policy is applied to the ingress context of the PW, then all packets of the PW will feed:
  - the ingress network shared queue for the packet’s FC defined in the network-queue policy applied to the ingress of the MDA/FP. This is the default behavior.
  - a queue-group policer followed by the per-FP ingress shared queues, referred to as “policer-output-queues”, if the ingress context of the network IP interface from which the packet is received is redirected to a queue-group. The only exceptions to this behavior are for packets received from an IES/VP RN spoke interface and from an R-VPLS spoke-sdp that is forwarded to the R-VPLS IP interface. In these two cases, the ingress network shared queue for the packet’s FC defined in the network-queue policy applied to the ingress of the MDA/FP is used.

When a PW is redirected to use a policer queue-group, the classification of the packet for the purpose of FC and profile determination is performed according to the default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the PW. This is true regardless of whether an instance of the named policer queue-group exists on the ingress FP the pseudowire packet is received on. The user can apply a QoS filter matching the dot1-p in the VLAN tag corresponding to the Ethernet port encapsulation, the EXP in the outer label when the tunnel is an LSP, the DSCP in the IP header if the tunnel encapsulation is GRE, and the DSCP in the payload’s IP header if the user enabled the l3-use-dscp option and the pseudowire terminates in IES or VP RN service (spoke-interface).

When the policer queue-group name the pseudowire is redirected does not exist, the redirection command is failed. In this case, the packet classification is performed according to the default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the network IP interface the pseudowire packet is received on.

The **no** version of this command removes the redirection of the pseudowire to the queue-group.

- Parameters** *network-policy-id* — Specifies the network policy identification on the system.
- Values** 1 to 65535
- queue-group-name* — Specifies the name of the queue group template up to 32 characters in length.
- instance-id* — Specifies the identification of a specific instance of the queue-group.
- Values** 1 to 16384

## precedence

- Syntax** **precedence** [*precedence-value* | **primary**]  
**no precedence**
- Context** config>service>apipe>spoke-sdp  
config>service>cpipe>spoke-sdp  
config>service>epipe>spoke-sdp  
config>service>fpipe>spoke-sdp  
config>service>ipipe>spoke-sdp
- Description** This command specifies the precedence of the SDP binding when there are multiple SDP bindings attached to one service endpoint. The value of zero can only be assigned to one SDP bind making it the primary SDP bind. When an SDP binding goes down, the next highest precedence SDP binding will begin to forward traffic.
- The **no** form of the command returns the precedence value to the default.
- Default** 4
- Parameters** *precedence-value* — Specifies the spoke SDP precedence.
- Values** 1 to 4
- primary** — Assigns primary precedence to the spoke SDP.

## pw-path-id

- Syntax** [**no**] **pw-path-id**
- Context** config>service>apipe>spoke-sdp  
config>service>cpipe>spoke-sdp  
config>service>epipe>spoke-sdp  
config>service>vpls>spoke-sdp

**Description** This command enables the context to configure an MPLS-TP Pseudowire Path Identifier for a spoke-sdp. All elements of the PW path ID must be configured in order to enable a spoke-sdp with a PW path ID.

For an IES or VPRN spoke-sdp, the pw-path-id is only valid for ethernet spoke-sdps.

The **pw-path-id** is only configurable if all of the following is true:

- SDP signaling is off
- control-word is enabled (control-word is disabled by default)
- the service type is Epipe, VPLS, Cpipe, Apipe, or IES/VPRN interface
- mate SDP signaling is off for vc-switched services

The **no** form of the command deletes the PW path ID.

**Default** no pw-path-id

## agi

**Syntax** **agi** *agi*  
**no agi**

**Context** config>service>apipe>spoke-sdp>pw-path-id  
config>service>cpipe>spoke-sdp>pw-path-id  
config>service>epipe>spoke-sdp>pw-path-id  
config>service>vpls>spoke-sdp>pw-path-id

**Description** This command configures the attachment group identifier for an MPLS-TP PW.

**Parameters** *agi* — Specifies the attachment group identifier.

**Values** 0 to 4294967295

## saii-type2

**Syntax** **saii-type2** *global-id:node-id:ac-id*  
**no saii-type2**

**Context** config>service>epipe>spoke-sdp>pw-path-id  
config>service>cpipe>spoke-sdp>pw-path-id  
config>service>apipe>spoke-sdp>pw-path-id  
config>service>vpls>spoke-sdp>pw-path-id

**Description** This command configures the Source Individual Attachment Identifier (SAII) for an MPLS-TP spoke-sdp. If this is configured on a spoke-sdp for which vc-switching is also configured (for example, it is at an S-PE), then the values must match those of the taii-type2 of the mate spoke-sdp.

| <b>Context</b>     | config>service>apipe>spoke-sdp>pw-path-id<br>config>service>cpipe>spoke-sdp>pw-path-id<br>config>service>epipe>spoke-sdp>pw-path-id<br>config>service>vpls>spoke-sdp>pw-path-id                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command configures the Target Individual Attachment Identifier (TAII) for an MPLS-TP spoke SDP. If this is configured on a spoke SDP for which vc-switching is also configured (for example, it is at an S-PE), then the values must match those of the saii-type2 of the mate spoke SDP.                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>global-id</i> — Specifies the global ID at the target PE or T-PE for the MPLS-TP PW for a spoke SDP.</p> <p><b>Values</b> 0 to 4294967295</p> <p><i>node-id</i> — Specifies the node ID at the target PE or T-PE for the MPLS-TP PW for a spoke SDP.</p> <p><b>Values</b> a.b.c.d or 0 to 4294967295</p> <p><i>ac-id</i> — Specifies the attachment circuit ID at the target PE or T-PE for the MPLS-TP PW for a spoke SDP. If this node is the source of the PW, then the AC ID must be set to a locally unique value.</p> <p><b>Values</b> 1 to 4294967295</p> |

## entropy-label

|                |                                |
|----------------|--------------------------------|
| <b>Syntax</b>  | <b>[no] entropy-label</b>      |
| <b>Context</b> | config>service>epipe>spoke-sdp |

```
config>service>ipipe>spoke-sdp
config>service>fpipe>spoke-sdp
config>service>vpls>spoke-sdp
config>service>vpls>mesh-sdp
config>service>pw-template
config>service>vpls>bgp-evpn>mpls
config>service>epipe>bgp-evpn>mpls
```

**Description** This command enables or disables the use of entropy labels for spoke SDPs.

If **entropy-label** is configured, the entropy label and ELI are inserted in packets for which at least one LSP in the stack for the far-end of the tunnel used by the service has advertised entropy-label-capability. If the tunnel is RSVP type, **entropy-label** can also be controlled under the **config>router>mpls** or **config>router>mpls>lsp** contexts.

The entropy label and hash label features are mutually exclusive. The entropy label cannot be configured on a spoke SDP or service where the hash label feature has already been configured.

**Default** no entropy-label

## hash-label

**Syntax** **hash-label**  
**hash-label [signal-capability]**  
**no hash-label**

**Context** config>service>epipe>spoke-sdp  
config>service>fpipe>spoke-sdp  
config>service>ipipe>spoke-sdp  
config>service>pw-template

**Description** This command enables the use of the hash label on a VLL, VPRN or VPLS service bound to any MPLS type encapsulated SDP, as well as to a VPRN service that is using the **auto-bind-tunnel** with the **resolution-filter** set to any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option. This feature is also not supported on multicast packets forwarded using RSVP P2MP LSP or mLDP LSP in both the base router instance and in the multicast VPN (mVPN) instance. It is, however, supported when forwarding multicast packets using an IES/VPRN spoke-interface.

When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to one (1).

To allow applications where the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the Hash Label. This means that the value of the hash label will always be in the range [524,288 - 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.

The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. Note, however, that for VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL PW packets.

Packets generated in CPM and that are forwarded labeled within the context of a service (for example, OAM packets) must also include a Hash Label at the BoS and set the S-bit accordingly.

The TTL of the hash label is set to a value of 0.

The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh SDP, or an IES/VP RN spoke interface by adding the **signal-capability** option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:

- The 7450 ESS or 7750 SR local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke SDP or mesh SDP.
- If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.
- If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the **hash-label** option or the **signal-capability** option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke SDP or mesh SDP. If the remote PE does not support the **signal-capability** option, then there are a couple of possible outcomes:
  - If the **hash-label** option was enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
  - If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke SDP or mesh SDP at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the 7450 ESS or 7750 SR must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

|                   |                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no hash-label                                                                                                                                                                                                  |
| <b>Parameters</b> | <b>signal-capability</b> — Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The <b>signal-capability</b> option is not supported on a VPRN spoke-sdp. |

## ignore-oper-down

|                    |                                                                                                                                                                                                                        |

|                    |                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>filter [ip ip-filter-id]</b><br><b>no filter</b>                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>fpipe>spoke-sdp>egress<br>config>service>fpipe>spoke-sdp>ingress                                                                                                                                                                                |
| <b>Description</b> | This command associates an IP filter policy with an ingress or egress Service Distribution Point (SDP). Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a spoke SDP at a time. |

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress spoke SDP. The *ip-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.

The **no** form of this command removes any configured filter ID association with the SDP. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use the **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

The <b>oper-group</b> <i>name</i> must be already configured under the <b>config&gt;service</b> context before its name is referenced in this command.<br><br>The <b>no</b> form of the command removes the association. |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>group-name</i> — Specifies an oper group name.                                                                                                                                                                                                                                                                                 |

## oper-group

|                    |                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>oper-group</b> <i>group-name</i><br><b>no oper-group</b>                                                                                |
| <b>Context</b>     | config>service>epipe>sap                                                                                                                   |
| <b>Description</b> | This command configures the operational group identifier.<br><br>The no form of the command removes the group name from the configuration. |
| <b>Default</b>     | none                                                                                                                                       |
| <b>Parameters</b>  | <i>group-name</i> — Specifies the Operational-Group identifier up to 32 characters in length.                                              |

## pw-status-signaling

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] pw-status-signaling</b>                                              |
| <b>Context</b>     | config>service>epipe>spoke-sdp                                               |
| <b>Description</b> | This command enables pseudowire status signaling for this spoke SDP binding. |

The **no** form of the command disables the status signaling.

**Default** pw-status-signaling

## use-sdp-bmac

**Syntax** [no] **use-sdp-bmac**

**Context** config>service>epipe>spoke-sdp

**Description** This command indicates that this spoke SDP is expected to be part of a redundant pseudowire connected to a PBB Epipe service. Enabling this parameter will cause traffic forwarded from this spoke SDP into the B-VPLS domain to use a virtual backbone MAC as its source MAC address when both this, and the control pseudowire, are in the active state on this BEB. This virtual backbone MAC is derived from the SDP source-bmac-lsb configuration.

This command will fail when configuring it under a spoke SDP within a PBB-Epipe that is connected to a B-VPLS with mac-notification enabled.

**Default** no use-sdp-bmac

## vlan-vc-tag

**Syntax** **vlan-vc-tag tag**  
**no vlan-vc-tag tag**

**Context** config>service>epipe>spoke-sdp

**Description** This command specifies an explicit dot1q value used when encapsulating to the SDP far end. When signaling is enabled between the near and far end, the configured dot1q tag can be overridden by a received TLV specifying the dot1q value expected by the far end. This signaled value must be stored as the remote signaled dot1q value for the binding. The provisioned local dot1q tag must be stored as the administrative dot1q value for the binding.

When the dot1q tag is not defined, the default value of zero is stored as the administrative dot1q value. Setting the value to zero is equivalent to not specifying the value.

The **no** form of this command disables the command.

**Default** no vlan-vc-tag

**Parameters** *tag* — Specifies a valid VLAN identifier to bind an 802.1Q VLAN tag ID.

**Values** 0 to 4094

---

## spoke-sdp-fec

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command binds a service to an existing Service Distribution Point (SDP), using a dynamic MS-PW.</p> <p>A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.</p> <p>The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.</p> <p>When using dynamic MS-PWs, the particular SDP to bind-to is automatically selected based on the Target Attachment Individual Identifier (TAII) and the path to use, specified under spoke SDP FEC. The selected SDP will terminate on the first hop S-PE of the MS-PW. Therefore, an SDP must already be defined in the config&gt;service&gt;sdp context that reaches the first hop router of the MS-PW. The router will in order to associate an SDP with a service. If an SDP to that is not already configured, an error message is generated. If the sdp-id does exist, a binding between that sdp-id and the service is created.</p> <p>It differs from the spoke-sdp command in that the spoke-sdp command creates a spoke SDP binding that uses a pseudowire with the PW ID FEC. However, the spoke-sdp-fec command enables pseudowires with other FEC types to be used. Only the Generalized ID FEC (FEC129) may be specified using this command.</p> <p>The <b>no</b> form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

*endpoint-name* — Specifies the name of the service endpoint.  
**no endpoint** — Adds or removes a spoke SDP association.  
**icb** — Configures the spoke SDP as an inter-chassis backup SDP binding.

## auto-config

| <b>Description</b> | <p>This command enables single sided automatic endpoint configuration of the spoke SDP. The router acts as the passive T-PE for signaling this MS-PW.</p> <p>Automatic Endpoint Configuration allows the configuration of a spoke SDP endpoint without specifying the TAIL associated with that spoke SDP. It allows a single-sided provisioning model where an incoming label mapping message with a TAIL that matches the SAIL of that spoke SDP to be automatically bound to that endpoint. In this mode, the far end T-PE actively initiates MS-PW signaling and will send the initial label mapping message using T-LDP, while the router T-PE for which auto-config is specified will act as the passive T-PE.</p> <p>The <b>auto-config</b> command is blocked in CLI if signaling active has been enabled for this spoke SDP. It is only applicable to spoke SDPs configured under the Epipe, IES and VPRN interface context.</p> <p>The <b>no</b> form of the command means that the router T-PE either acts as the active T-PE (if signaling active is configured) or automatically determines which router will initiate MS-PW signaling based on the prefix values configured in the SAIL and TAIL of the spoke SDP. If the SAIL has the greater prefix value, then the router will initiate MS-PW signaling without waiting for a label mapping message from the far end. However, if the TAIL has the greater value prefix, then the router will assume that the far end T-PE will initiate MS-PW signaling and will wait for that label mapping message before responding with a T-LDP label mapping message for the MS-PW in the reverse direction.</p> |
| <b>Default</b>     | no auto-config                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command specifies the explicit path, containing a list of S-PE hops, that should be used for this spoke SDP. The path-name should correspond to the name of an explicit path configured in the <b>config&gt;service&gt;pw-routing</b> context.</p> |

If no path is configured, then each next-hop of the MS-PW used by the spoke SDP will be chosen locally at each T-PE and S-PE.

| <b>Description</b> | This command specifies the precedence of the SDP binding when there are multiple SDP bindings attached to one service endpoint. The value of zero can only be assigned to one SDP bind making it the primary SDP bind. When an SDP binding goes down, the next highest precedence SDP binding will begin to forward traffic.<br><br>The <b>no</b> form of the command returns the precedence value to the default. |
| <b>Default</b>     | 42                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>prec-value</i> — Specifies the spoke SDP precedence.<br><b>Values</b> 1 to 4<br><b>primary</b> — Assigns primary precedence to this spoke SDP.                                                                                                                                                                                                                                                                  |

## pw-template-bind

| <b>Context</b>     | config>service>epipe>spoke-sdp-fec                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command enables a user to configure this router as the active or passive T-PE for signaling this MS-PW, or to automatically select whether this T-PE is active or passive based on the prefix. In an active role, this endpoint initiates MS-PW signaling without waiting for a T-LDP label mapping message to arrive from the far end T-PE. In a passive role, it will wait for the initial label mapping message from the far end before sending a label mapping for this end of the PW. In auto mode, if the SAIL has the greater prefix value, then the router will initiate MS-PW signaling without waiting for a label mapping message from the far end. However, if the TAIL has the greater value prefix, then the router will assume that the far end T-PE will initiate MS-PW signaling and will wait for that label mapping message before responding with a T-LDP label mapping message for the MS-PW in the reverse direction.</p> <p>The <b>no</b> form of the command means that the router T-PE automatically selects the which router will initiate MS-PW signaling based on the prefix values configured in the SAIL and TAIL of the spoke SDP, as previously described.</p> |
| <b>Default</b>     | auto                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## standby-signaling-slave

|                |                                     |
|----------------|-------------------------------------|
| <b>Syntax</b>  | <b>[no] standby-signaling-slave</b> |
| <b>Context</b> | config>service>epipe>spoke-sdp-fec  |

---

**Description** This command enables standby-signaling-slave for an Epipe.

## taii-type2

**Syntax** **taii-type2** *global-id:prefix:ac-id*  
**no taii-type2**

**Context** config>service>epipe>spoke-sdp-fec

**Description** taii-type2 configures the target attachment individual identifier for the spoke-sdp. This is only applicable to FEC129 All type 2.

This command is blocked in CLI if this end of the spoke SDP is configured for single-sided auto configuration (using the **auto-config** command).

**Parameters** *global-id* — A Global ID of this router T-PE. This value must correspond to one of the *global\_id* values configured for a local-prefix under **config>service>pw-routing>local-prefix** context.

**Values** 1 to 4294967295

*prefix* — The prefix on this router T-PE that the spoke-sdp SDP is associated with. This value must correspond to one of the prefixes configured under **config>service>pw-routing>local-prefix** context.

**Values** an IPv4-formatted address a.b.c.d or 1 to 4294967295

*ac-id* — An unsigned integer representing a locally unique identifier for the spoke SDP.

**Values** 1 to 4294967295

## 2.17.2.6 Related Apipe Commands

### 2.17.2.6.1 Connection Profile Commands

## connection-profile

**Syntax** **connection-profile** *conn-prof-id* [create]  
**no connection-profile** *conn-prof-id*

**Context** config

**Description** This command creates a profile for the user to configure the list of discrete VPI/VCI values to be assigned to an ATM SAP of an Apipe VLL of **vc-type atm-cell**.

A connection profile can only be applied to a SAP which is part of an Apipe VLL service of **vc-type atm-cell**. The ATM SAP can be on a regular port or APS port.

A maximum of 8000 connection profiles can be created on the system.

The **no** form of this command deletes the profile from the configuration.

|                   |                                                     |
|-------------------|-----------------------------------------------------|
| <b>Default</b>    | none                                                |
| <b>Parameters</b> | <i>conn-prof-id</i> — Specifies the profile number. |
| <b>Values</b>     | 1 to 8000                                           |

### 2.17.2.7 Epipe Global Commands

## bgp

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [ <b>no</b> ] <b>bgp</b>                                                                                         |
| <b>Context</b>     | config>service>epipe                                                                                             |
| <b>Description</b> | This command enables the context to configure the BGP related parameters BGP used for multi-homing and BGP VPWS. |

The **no** form of this command removes the string from the configuration.

## pw-template-binding

|                    |                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pw-template-binding</b> <i>policy-id</i> [ <b>import-rt</b> { <i>ext-community</i> ,.(upto 5 max)}}]<br><b>no pw-template-binding</b> <i>policy-id</i>                                                                                                                                      |
| <b>Context</b>     | config>service>epipe>bgp                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command binds the advertisements received with the route targets (RT) that match the configured list (either the generic or the specified import) to a specific pw-template. If the RT list is not present, or if multiple matches are found, the numerically lowest pw-template is used. |

The pw-template-binding applies to BGP-VPWS when enabled in the Epipe.

For BGP VPWS, the following additional rules govern the use of pseudowire-template:

- On transmission, the settings for the L2-Info extended community in the BGP updates are derived from the pseudowire template attributes. If multiple pseudowire template bindings (with or without import-rt) are specified for the same VPWS instance the first pw-template entry will be used for the information in the BGP update sent.
- On reception, the values of the parameters in the L2-Info extended community of the BGP updates are compared with the settings from the corresponding pseudowire template bindings. The following steps are used to determine the local pw-template:
  - The RT values are matched to determine the pw-template. The route targets configured for each pw-template-binding are compared to the route targets within the BGP update. The PW template corresponding to **pw-template-binding** with the first matching route target is used to for the SDP. The matching is performed from the lowest PW template binding identifier to the highest.
  - If no pw-template-binding matches are found from the previous step, the first (numerically lowest) configured pw-template entry without any route-target configured will be used.

If the value used for Layer 2 MTU (unless the value zero is received), or control word does not match, the pseudowire is created but with the operationally down state.

If the value used for the S (sequenced delivery) flags is not zero the pseudowire is not created.

The **tools perform** commands can be used to control the application of changes in pw-template for BGP-VPWS.

The **no** form of the command removes the values from the configuration.

|                   |                                                     |
|-------------------|-----------------------------------------------------|
| <b>Parameters</b> | <i>policy-id</i> — Specifies an existing policy ID. |
| <b>Values</b>     | 1 to 2147483647                                     |

*import-rt ext-comm* — Specifies the communities allowed to be accepted from remote PE neighbors. An extended BGP community in the type:x:y format. The value x can be an integer or IP address. The type can be the target or origin.

**Values**

target:{ip-addr:comm-val | 2byte-asnumber:ext-comm-val| 4byte-  
snumber:comm-val}

|                |                 |
|----------------|-----------------|
| ip-addr        | a.b.c.d         |
| comm-val       | 0 to 65535      |
| 2byte-asnumber | 0 to 65535      |
| ext-comm-val   | 0 to 4294967295 |
| 4byte-asnumber | 0 to 4294967295 |

route-distinguisher

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                    | <b>no route-target</b>                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>epipe>bgp                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command configures the route target (RT) component that is signaled in the related MPBGP attribute to be used for BGP multi-homing and BGP-VPWS when configured in the Epipe service. The ext-comm can have two formats: <ul style="list-style-type: none"> <li>• A two-octet AS-specific extended community, IPv4 specific extended community.</li> <li>• An RT value must be configured under BGP node when BGP Epipe is configured.</li> </ul> |
| <b>Parameters</b>  | <i>export ext-community</i> — Specifies communities allowed to be sent to remote PE neighbors.<br><br><i>import ext-community</i> — Specifies communities allowed to be accepted from remote PE neighbors.                                                                                                                                                                                                                                             |

## bgp-vpws

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>bgp-vpws</b>                                                              |
| <b>Context</b>     | config>service>epipe                                                              |
| <b>Description</b> | This command enables the context to configure BGP-VPWS parameters and addressing. |
| <b>Default</b>     | no bgp-vpws                                                                       |

## remote-ve-name

|                |                                        |
|----------------|----------------------------------------|
| <b>Syntax</b>  | [no] <b>remote-ve-name</b> <i>name</i> |
| <b>Context</b> | config>service>epipe>bgp-vpws          |

**Description** This command creates or edits a remote-ve-name. A single remote-ve-name can be created per BGP VPWS instance if the service is single-homed or uses a single pseudowire to connect to a pair of dual-homed systems. When the service requires active/standby pseudowires to be created to remote dual-homed systems then two remote-ve-names must be configured.

This context defines the remote PE to which a pseudowire will be signaled.

**remote-ve-name** commands can be added even if bgp-vpws is not shutdown.

The **no** form of the command removes the configured remote-ve-name from the bgp vpws node. It can be used when the BGP VPWS status is either shutdown or “no shutdown”.

**Parameters** *name* — Specifies a site name up to 32 characters in length.

## ve-name

**Syntax** [no] **ve-name** *name*

**Context** config>service>epipe>bgp-vpws

**Description** This command configures the name of the local VPWS instance in this service.

The **no** form of the command removes the ve-name.

**Parameters** *name* — Specifies a site name up to 32 characters in length.

## ve-id

**Syntax** **ve-id** *value*  
**no ve-id**

**Context** config>service>epipe>bgp-vpws>ve-name  
config>service>epipe>bgp-vpws>remote-ve-name

**Description** This command configures a ve-id for either the local VPWS instance when configured under the ve-name, or for the remote VPWS instance when configured under the remote-ve-name.

A single ve-id can be configured per ve-name or remote-ve-name. The ve-id can be changed without shutting down the VPWS instance. When the ve-name ve-id changes, BGP withdraws the previously advertised route and sends a route-refresh to all the peers which would result in reception of all the remote routes again. The old PWs are removed and new ones are instantiated for the new ve-id value.

When the remote-ve-name ve-id changes, BGP withdraws the previously advertised route and send a new update matching the new ve-id. The old pseudowires are removed and new ones are instantiated for the new ve-id value.

NLRIs received whose advertised ve-id does not match the list of ve-ids configured under the remote ve-id will not have a spoke SDP binding auto-created but will remain in the BGP routing table but not in the Layer 2 route table. A change in the locally configured ve-ids may result in auto-sdp-bindings either being deleted or created, based on the new matching results.

Each ve-id configured within a service must be unique.

The **no** form of the command removes the configured ve-id. It can be used just when the BGP VPWS status is shutdown. The **no shutdown** command cannot be used if there is no ve-id configured.

|                   |                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no ve-id                                                                                                                        |
| <b>Parameters</b> | <i>value</i> — A two bytes identifier that represents the local or remote VPWS instance and is advertised through the BGP NLRI. |
| <b>Values</b>     | 1 to 65535                                                                                                                      |

## shutdown

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] shutdown                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>epipe>bgp-vpws                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command administratively enables/disables the local BGP VPWS instance. On de-activation an MP-UNREACH-NLRI is sent for the local NLRI.</p> <p>The <b>no</b> form of the command enables the BGP VPWS addressing and the related BGP advertisement. The associated BGP VPWS MP-REACH-NLRI will be advertised in an update message and the corresponding received NLRIs must be considered to instantiate the data plane.</p> |
| <b>Default</b>     | shutdown                                                                                                                                                                                                                                                                                                                                                                                                                            |

## load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | load-balancing                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>epipe                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables the load-balancing context to configure interface per-flow load balancing options that will apply to traffic entering this interface and egressing over a LAG/ECMP on system-egress. This is a per interface setting. For load-balancing options that can also be enabled on the system level, the options enabled on the interface level overwrite system level configurations.</p> |
| <b>Default</b>     | not applicable                                                                                                                                                                                                                                                                                                                                                                                               |

## per-service-hashing

|                    |                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] per-service-hashing</b>                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>epipe>load-balancing                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command enables on a per service basis, consistent per-service hashing for Ethernet services over LAG, over Ethernet tunnel (eth-tunnel) using loadsharing protection-type or over CCAG. Specifically, it enables the new hashing procedures for Epipe, VPLS, regular or PBB services. |

The following algorithm describes the hash-key used for hashing when the new option is enabled:

- If the packet is PBB encapsulated (contains an I-TAG ethertype) at the ingress side, use the ISID value from the I-TAG
- If the packet is not PBB encapsulated at the ingress side
  - For regular (non-PBB) VPLS and Epipe services, use the related service ID
  - If the packet is originated from an ingress IVPLS or PBB Epipe SAP
  - If there is an ISID configured use the related ISID value
  - If there is no ISID yet configured use the related service ID
  - For BVPLS transit traffic use the related flood list id
  - Transit traffic is the traffic going between BVPLS endpoints
  - An example of non-PBB transit traffic in BVPLS is the OAM traffic
  - The preceding rules apply regardless of traffic type
  - Unicast, BUM flooded without MMRP or with MMRP, IGMP snooped

The **no** form of this command implies the use of existing hashing options.

| <b>Context</b>     | config>service>vpls<br>config>service>epipe    |
| <b>Description</b> | This command configures global PBB parameters. |

## force-qtag-forwarding

|                |                                   |
|----------------|-----------------------------------|
| <b>Syntax</b>  | <b>[no] force-qtag-forwarding</b> |
| <b>Context</b> | config>service>epipe>pbb          |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command forces the addition of a IEEE 802.1q tag after the Customer MAC (CMAC) addresses when the PBB header is built, as it egresses a related BVPLS.</p> <p>It is used to preserve the dot1q and DE bits from the customer domain when the service delimiting qtags are stripped when the packet is ingressing a PBB Epipe or an IVPLS. The VLAN value of the service delimiting QTAG if one exists is used for the corresponding inserted dot1q field. If a service delimiting QTAG does not exist, then the value of zero is used for all the inserted QTAG bits.</p> <p>The <b>no</b> form of this command sets default behavior.</p> |
| <b>Default</b>     | no force-qtag-forwarding                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b> | config>service>epipe                                                                                      |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command is used to associate the PW-port with the PXC ports or PXC based LAGs referenced in the FPE. That is, the PW-port becomes anchored by the PXC. This enables an external PW that is mapped to the anchored PW-port to be seamlessly rerouted between the I/O ports without interruption of service on the PW-port.</p> <p>This mapping between the external PW (spoke SDP) and the PXC based PXC-port is performed via an Epipe operating in vc-switching mode (creation time parameter).</p> |
| <b>Default</b>     | no pw-port                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>pw-port-id</i> — Specifies the PW-port associated with this service.</p> <p><b>Values</b> 1 to 10239</p> <p><b>fpe</b> <i>fpe-id</i> — Specifies the FPE object which contains the PXC-based ports or PXC-based LAGs.</p> <p><b>Values</b> 1 to 64</p>                                                                                                                                                                                                                                                 |

## egress

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                                |
| <b>Context</b>     | config>service>epipe>pw-port                                                 |
| <b>Description</b> | This command enables the context to configure PW-port egress-side parameters |
| <b>Default</b>     | N/A                                                                          |

## shaper

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shaper</b>                                                       |
| <b>Context</b>     | config>service>epipe>pw-port>egress                                      |
| <b>Description</b> | This command enables the context to configure PW-port shaper parameters. |
| <b>Default</b>     | N/A                                                                      |

## int-dest-id

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>int-dest-id</b> <i>name</i><br><b>no int-dest-id</b>                                   |
| <b>Context</b>     | config>service>epipe>pw-port>egress>shaper                                                |
| <b>Description</b> | This command configures an intermediate destination identifier applicable to ESM PW SAPs. |
| <b>Default</b>     | N/A                                                                                       |

---

|                   |                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>name</i> — Specifies the default intermediate destination identifier, up to 32 characters in length, on the egress side for this PW-port entry. |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|

## vport

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vport</b> <i>vport</i><br><b>no vport</b>                                                                     |
| <b>Context</b>     | config>service>epipe>pw-port>egress>shaper                                                                       |
| <b>Description</b> | This command configures specifies the virtual port name of the shaper on the egress side for this PW-port entry. |
| <b>Default</b>     | N/A                                                                                                              |
| <b>Parameters</b>  | <i>vport</i> — Specifies a virtual port applicable to all PW SAPs.                                               |

## monitor-oper-group

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>monitor-oper-group</b> <i>group-name</i><br><b>no monitor-oper-group</b>                                                       |
| <b>Context</b>     | config>service>epipe>pw-port                                                                                                      |
| <b>Description</b> | This command configures the monitoring operational group name, up to 32 characters in length, associated with this PW-port entry. |
| <b>Default</b>     | N/A                                                                                                                               |
| <b>Parameters</b>  | <i>group-name</i> — Specifies an operational group to monitor.                                                                    |

## site

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|

## boot-timer

|                    |                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>boot-timer</b> <i>seconds</i><br><b>no boot-timer</b>                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>epipe>site                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command configures for how long the service manager waits after a node reboot before running the DF election algorithm. The boot-timer value should be configured to allow for the BGP sessions to come up and for the NLRI information to be refreshed/exchanged.</p> <p>The <b>no</b> form of the command reverts the default.</p> |
| <b>Default</b>     | 10                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the site boot-timer in seconds.<br><b>Values</b> 0 to 600                                                                                                                                                                                                                                                         |

## sap

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap</b> <i>sap-id</i><br><b>no sap</b>                                                                                              |
| <b>Context</b>     | config>service>epipe>site                                                                                                              |
| <b>Description</b> | <p>This command configures a SAP for the site.</p> <p>The <b>no</b> form of the command removes the SAP ID from the configuration.</p> |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.                                                  |

## site-activation-timer

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>site-activation-timer</b> <i>seconds</i><br><b>no site-activation-timer</b>                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>epipe>site                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command configures the time-period the system keeps the local sites in standby status, waiting for BGP updates from remote PEs before running the DF (designated-forwarder) election algorithm to decide whether the site should be unblocked. This timer is terminated if an update is received for which the remote PE has transitioned from DF to non-DF.</p> <p>The <b>no</b> form of the command removes the value from the configuration.</p> |
| <b>Default</b>     | 2                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

---

**Parameters**    *seconds* — Specifies the site activation timer in seconds.  
**Values**        0 to 100

## site-id

**Syntax**        **site-id** *value*  
**no site-id**

**Context**       config>service>epipe>site

**Description**   This command configures the identifier for the site in this service. It must match between services but it is local to the service.

**Parameters**    *value* — Specifies the site identifier.  
**Values**        1 to 65535

## site-min-down-timer

**Syntax**        **site-min-down-timer** *min-down-time*  
**no site-min-down-timer**

**Context**       config>service>epipe>site

**Description**   This command configures the BGP multi-homing site minimum down time. When set to a non-zero value, if the site goes operationally down it will remain operationally down for at least the length of time configured for the **site-min-down-timer**, regardless of whether other state changes would have caused it to go operationally up. This timer is restarted every time that the site transitions from up to down. Setting this parameter to zero allows the minimum down timer to be disabled for this service.

The preceding operation is optimized in the following circumstances:

- If the site goes down on the designated forwarder but there are no BGP multi-homing peers with the same site in an operationally up state, then the **site-min-down-timer** is not started and is not used.
- If the site goes down on the designated forwarder but there are no active BGP multi-homing peers, then the **site-min-down-timer** is not started and is not used.
- If the **site-min-down-timer** is active and a BGP multi-homing update is received from the designated forwarder indicating its site has gone down, the **site-min-down-timer** is immediately terminated and this PE becomes the designated forwarder if the BGP multi-homing algorithm determines it should be the designated forwarder.

The **no** form of the command reverts to default value.

**Default**        Taken from the value of **site-min-down-timer** configured for Multi-Chassis BGP multi-homing under the **config>redundancy>bgp-multi-homing** context.

---

**Parameters** *min-down-time* — Specifies the time, in seconds, that a BGP multi-homing site remains operationally down after a transition from up to down.

**Values** 0 to 100

## site-preference

**Syntax** **site-preference** *preference-value*  
**no site-preference**

**Context** config>service>epipe>site

**Description** This command defines the value to advertise in the VPLS preference field of the BGP VPWS and BGP Multi-homing NLRI extended community. This value can be changed without having to shutdown the site itself. The site-preference is only applicable to VPWS services.

When not configured, the default is zero, indicating that the VPLS preference is not in use.

**Default** no site-preference, value=0

**Parameters** *preference-value* — Specifies the preference value to advertise in the NLRI L2 extended community for this site.

**Values** 1 to 65535

**primary** — Sets the site-preference to 65535.

**backup** — Sets the site-preference to 1.

## recovery-timer

**Syntax** **recovery-timer** *timer-value*  
**no recovery-timer**

**Context** config>service>ipipe>eth-legacy-fault-notification

**Description** This timer provides the legacy protocols PPP, MLPPP and HDLC time to establish after the Ethernet fault condition has cleared. The legacy protocol is afforded this amount of time to establish the connection before a fault is declared on the legacy side and propagated to the Ethernet segment. This timer is started as a result of a clearing Ethernet failure. Faults that may exist on the legacy side will not be detected until the expiration of this timer. Until the legacy side connection is established or the timer expires the traffic arriving on the Ethernet SAP from a peer will be discarded. The default value is unlikely to be a representative of all operator requirements and must be evaluated on a case by case basis.

**Parameters** *timer-value* — The value of the wait time in tenths of a second (100 ms). Granularity is in 500 ms increments, starting from 1 s and up to 30 s.

**Values** 10 to 300

**Default** 100

## shutdown

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>ipipe>eth-legacy-fault-notification                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables or disables the propagation of fault from the Ethernet segment to the legacy connection using PPP, MLPPP and HDLC for an iPipe service. Issuing a “no shutdown” will activate the feature. Issuing a “shutdown” will deactivate the feature and stop fault notification from the Ethernet to PPP, MLPPP and HDLC protocols.</p> <p>The <b>no</b> form of the command activates the ethernet legacy fault propagation.</p> |
| <b>Default</b>     | shutdown                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## standby-signaling-slave

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Context</b>     | config>service>epipe>endpoint<br>config>service>epipe>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>When this command is enabled, the node will block the transmit forwarding direction of a spoke SDP based on the pseudowire standby bit received from a T-LDP peer.</p> <p>This command is present at the endpoint level as well as the spoke SDP level. If the spoke SDP is part of an explicit-endpoint, it will not be possible to change this setting at the spoke SDP level. An existing spoke SDP can be made part of the explicit endpoint only if the settings do not conflict. A newly created spoke SDP, which is part of a specific explicit-endpoint, will inherit this setting from the endpoint configuration.</p> <p>This command is mutually exclusive with an endpoint that is part of an mc-lag, mc-aps or an ICB.</p> <p>If the command is disabled, the node assumes the existing independent mode of behavior for the forwarding on the spoke SDP.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                    |                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egr-vtep</b> { <i>ip-address</i>   <i>ipv6-address</i> }<br><b>no egr-vtep</b>                                                                                                                                                                                       |
| <b>Context</b>     | config>service>epipe>vxlan                                                                                                                                                                                                                                              |
| <b>Description</b> | This command configures the static destination VTEP IP used when originating VXLAN packets for the service.                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies the IPv4 address used as the destination VTEP when originating VXLAN packets for the service.</p> <p><i>ipv6-address</i> — Specifies the IPv6 address used as the destination VTEP when originating VXLAN packets for the service.</p> |

## oper-group

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>oper-group</b> <i>name</i><br><b>no oper-group</b>                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>epipe>vxlan>egr-vtep                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command associates an operational group to the VXLAN static egress VTEP. If the egress VTEP IP disappears from the routing table, the oper-group status will become operationally down.</p> <p>The operational group must be monitored in a different service and not in the service where it is defined.</p> |
| <b>Parameters</b>  | <i>name</i> — Specifies the name of the <b>oper-group</b> , up to a maximum of 32 characters.                                                                                                                                                                                                                         |

## vxlan-src-vtep

|                    |                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vxlan-src-vtep</b> { <i>ip-address</i>   <i>ipv6-address</i> }<br><b>no vxlan-src-vtep</b>                                                                                                                                                                                       |
| <b>Context</b>     | config>service>epipe                                                                                                                                                                                                                                                                |
| <b>Description</b> | This command enables the router to use the configured IP address as the tunnel source IP address (source VTEP) when originating VXLAN-encapsulated frames for this service. This IP address is also used to set the BGP NLRI next-hop in EVPN route advertisements for the service. |
| <b>Default</b>     | no vxlan-src-vtep                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the non-system IPv4 address that terminates VXLAN for a service.<br><i>ipv6-address</i> — Specifies the IPv6 address that terminates VXLAN for a service.                                                                                             |

## 2.17.2.8 Epipe SAP Template Commands

### template

|                    |                                         |
|--------------------|-----------------------------------------|
| <b>Syntax</b>      | <b>template</b>                         |
| <b>Context</b>     | config>service                          |
| <b>Description</b> | This is the node for service templates. |

### epipe-sap-template

|                    |                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>epipe-sap-template</b> <i>name</i> [create]<br><b>no epipe-sap-template</b> <i>name</i>                                                                                                                                                |
| <b>Context</b>     | config>service>template                                                                                                                                                                                                                   |
| <b>Description</b> | This command specifies which SAP parameter template should be applied to the I2-ap SAP. This can only be changed when the I2-ap is shutdown.<br><br>The no form of the command removes the template, the SAP will use default parameters. |
| <b>Default</b>     | None                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>name</i> — Specifies the SAP template name associated with this template.                                                                                                                                                              |

---

## egress

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                         |
| <b>Context</b>     | config>service>template>epipe-sap-template                            |
| <b>Description</b> | This command enables the context to configure egress filter policies. |

## ingress

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                                   |
| <b>Context</b>     | config>service>template>epipe-sap-template                                                                       |
| <b>Description</b> | This command enables the context to configure ingress SAP Quality of Service (QoS) policies and filter policies. |

## filter

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] filter</b>                                                                                      |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress<br>config>service>template>epipe-sap-template>ingress |
| <b>Description</b> | This command enables the context to configure filter parameters.                                        |

## ip

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip <i>ip-filter-id</i></b><br><b>no ip</b>                                                                                                                                                                              |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter<br>config>service>template>epipe-sap-template>ingress>filter                                                                                                      |
| <b>Description</b> | This command associates an existing IP filter policy with the template.<br><br>This command is only supported in 'classic' configuration-mode ( <b>configure system management-interface configuration-mode classic</b> ). |
| <b>Parameters</b>  | <i>ip-filter-id</i> — Specifies the IP filter policy ID. The filter ID must already exist within the created IP filters.<br><br><b>Values</b> 1 to 65535                                                                   |

## ipv6

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipv6</b> <i>ipv6-filter-id</i><br><b>no ipv6</b>                                                                                                                                                                          |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter<br>config>service>template>epipe-sap-template>ingress>filter                                                                                                        |
| <b>Description</b> | This command associates an existing IPv6 filter policy with the template.<br><br>This command is only supported in 'classic' configuration-mode ( <b>configure system management-interface configuration-mode classic</b> ). |
| <b>Parameters</b>  | <i>ipv6-filter-id</i> — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.<br><br><b>Values</b> 1 to 65535                                                                  |

## mac

|                    |                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mac</b> <i>mac-filter-id</i><br><b>no mac</b>                                                                                                                                                                                        |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter<br>config>service>template>epipe-sap-template>ingress>filter                                                                                                                   |
| <b>Description</b> | This command associates an existing MAC filter policy with the template.<br><br>This command is only supported in 'classic' configuration-mode ( <b>configure system management-interface configuration-mode classic</b> ).             |
| <b>Parameters</b>  | <i>mac-filter-id</i> — Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.<br><br><b>Values</b> 1 to 65535 |

## filter-name

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] filter-name</b>                                                                                 |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress<br>config>service>template>epipe-sap-template>ingress |
| <b>Description</b> | This command enables the context to configure filter parameters.                                        |

---

## ip

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip</b> <i>name</i><br><b>no ip</b>                                                                                           |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter-name<br>config>service>template>epipe-sap-template>ingress>filter-name |
| <b>Description</b> | This command associates an existing IP filter policy with the template.                                                         |
| <b>Parameters</b>  | <i>name</i> — Specifies the IP filter policy name, up to 64 characters.                                                         |

## ipv6

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipv6</b> <i>name</i><br><b>no ipv6</b>                                                                                       |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter-name<br>config>service>template>epipe-sap-template>ingress>filter-name |
| <b>Description</b> | This command associates an existing IP filter policy with the template.                                                         |
| <b>Parameters</b>  | <i>name</i> — Specifies the IPv6 filter policy name, up to 64 characters.                                                       |

## mac

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mac</b> <i>name</i><br><b>no mac</b>                                                                                         |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress>filter-name<br>config>service>template>epipe-sap-template>ingress>filter-name |
| <b>Description</b> | This command associates an existing IP filter policy with the template.                                                         |
| <b>Parameters</b>  | <i>name</i> — Specifies the MAC filter policy name, up to 64 characters.                                                        |

## qos

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>qos</b> <i>policy-id</i><br><b>qos name</b> <i>sap-egress-policy-name</i><br><b>no qos</b> |
| <b>Context</b>     | config>service>template>epipe-sap-template>egress                                             |
| <b>Description</b> | This command associates an existing QoS policy with the template.                             |

---

**Parameters**     *policy-id* — The egress policy ID to associate with SAP or IP interface on egress. The policy ID must already exist.  
                          This variant of the command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **qos name sap-egress-policy-name** variant can be used in all configuration modes.

**Values**            1 to 65535

*sap-egress-policy-name* — The SAP egress QoS policy name to associate with the SAP on egress, up to 64 characters.

## qos

**Syntax**            **qos name sap-ingress-policy-name [shared-queuing]**  
                          **qos policy-id [shared-queuing]**  
                          **no qos**

**Context**           config>service>template>epipe-sap-template>ingress

**Description**      This command associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP) for the Epipe SAP template.

**Default**            none

**Parameters**       *sap-ingress-policy-name* — The SAP ingress QoS policy name to associate with the SAP on ingress.

*policy-id* — The ingress policy ID to associate with SAP or IP interface on ingress. The policy ID must already exist.  
                          This variant of the command is only supported in 'classic' configuration-mode (**configure system management-interface configuration-mode classic**). The **qos name sap-ingress-policy-name** variant can be used in all configuration modes.

**Values**            1 to 65535

**shared-queuing** — This keyword can only be specified on SAP ingress. Specify the ingress shared queue policy used by this SAP. When the value of this object is null, the SAP will use individual ingress QoS queues, instead of the shared ones.

## 2.17.2.9 Ipipe Global Commands

### ce-address-discovery

**Syntax**            **ce-address-discovery [keep]**  
                          **ce-address-discovery ipv6 [keep]**  
                          **no ce-address-discovery**

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>ipipe                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command specifies whether the service will automatically discover the CE IP addresses.</p> <p>When enabled, the addresses will be automatically discovered on SAPs that support address discovery, and on the spoke SDPs. When enabled, addresses configuration on the Ipipe SAP and spoke SDPs will not be allowed.</p> <p>If disabled, CE IP addresses must be manually configured for the SAPs to become operationally up.</p>                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>     | no ce-address-discovery                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>ipv6</b> — The <b>ipv6</b> keyword enables IPv6 CE address discovery support on the Ipipe so that both IPv4 and IPv6 address discovery are supported. If the <b>ipv6</b> keyword is not included, then only IPv4 address discovery is supported and IPv6 packets are dropped. For the 7450 ESS platforms, it requires mixed mode support.</p> <p><b>keep</b> — The <b>keep</b> keyword is only applicable to eth-legacy-fault-notification. This option maintains the CE address discovered even when the SAP on which the address was learned fails. The ARP entry will not be maintained if the SAP is administratively shutdown, the clear service id x {arp   neighbor} is used to remove the ARP entry or the node reboots.</p> |

## eth-legacy-fault-notification

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-legacy-fault-notification</b>                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>ipipe                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This is the top level of the hierarchy containing Ethernet to Legacy fault notification parameters. This context must activate using the no shutdown command before Ethernet to legacy fault notification can occur for iPipe services that make use of PPP, MLPPP or HDLC. This is only applicable to iPipe services with one legacy (PPP, MLPPP or HDLC) connection and an Ethernet SAP. No other services, not other combinations are supported.</p> |

## stack-capability-signaling

|                    |                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] stack-capability-signaling</b>                                                                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>ipipe                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command enables stack-capability signaling in the initial label mapping message of the Ipipe PW to indicate that IPv6 is supported.</p> <p>When enabled, the 7750 SR includes the stack-capability TLV with the IPv6 stack bit set according to the <b>ce-address-discovery ipv6</b> keyword, and also checks the value of the stack-capability TLV received from the far end.</p> |

This command must be blocked if no **ce-address-discovery** is specified, or the **ipv6** keyword is not included with the **ce-address-discovery** command.

This command is only applicable to the lpipe service and must be blocked for all other services.

This command has no effect if both SAPs on the lpipe service are local to the node.

For the 7450 ESS platforms, it requires mixed mode support.

**Default** no stack-capability-signaling

## 2.17.2.10 Circuit Emulation Commands

### cem

**Syntax** **cem**

**Context** config>service>cpipe>sap  
config>service>epipe>sap

**Description** This command enables the context to specify circuit emulation (CEM) properties.

### packet

**Syntax** **packet jitter-buffer** *milliseconds* [**payload-size** *bytes*]  
**packet payload-size** *bytes*  
**no packet**

**Context** config>service>cpipe>sap>cem  
config>service>epipe>sap>cem

**Description** This command specifies the jitter buffer size, in milliseconds, and payload size, in bytes.

**Default** The default value depends on the CEM SAP endpoint type, and if applicable, the number of timeslots as shown in [Table 14](#).

**Table 14** packet CEM SAP Endpoint Types

| Endpoint Type  | Timeslots | Default Jitter Buffer (in ms) |
|----------------|-----------|-------------------------------|
| unstructuredE1 | n/a       | 5                             |
| unstructuredT1 | n/a       | 5                             |

**Table 14** packet CEM SAP Endpoint Types (Continued)

| Endpoint Type     | Timeslots   | Default Jitter Buffer (in ms) |
|-------------------|-------------|-------------------------------|
| nxDS0 (E1/T1)     | —           | 32                            |
|                   | N = 1       | 16                            |
|                   | N = 2 to 4  | 8                             |
|                   | N = 5 to 15 | 5                             |
| nxDS0WithCas (E1) | N           | 8                             |
| nxDS0WithCas (T1) | N           | 12                            |

**Parameters** *milliseconds* — Specifies the jitter buffer size in milliseconds (ms).

Configuring the payload size and jitter buffer to values that result in less than 2 packet buffers or greater than 32 packet buffers is not allowed. Setting the jitter buffer value to 0 sets it back to the default value.

**Values** 1 to 250

**payload-size** *bytes* — Specifies the payload size (in bytes) of packets transmitted to the packet service network (PSN) by the CEM SAP. This determines the size of the data that will be transmitted over the service. If the size of the data received is not consistent with the payload size then the packet is considered malformed.

**Values** 0 | 16 to 2048

**Default** The default value depends on the CEM SAP endpoint type, and if applicable, the number of timeslots as shown in [Table 15](#).

**Table 15** CEM SAP Endpoint Types

| Endpoint Type     | Timeslots   | Default Payload Size (in bytes) |
|-------------------|-------------|---------------------------------|
| unstructuredE1    | n/a         | 256                             |
| unstructuredT1    | n/a         | 192                             |
| nxDS0 (E1/T1)     | N = 1       | 64                              |
|                   | N = 2 to 4  | N x 32                          |
|                   | N = 5 to 15 | N x 16                          |
|                   | N >= 16     | N x 8                           |
| nxDS0WithCas (E1) | N           | N x 16                          |
| nxDS0WithCas (T1) | N           | N x 24                          |

For all endpoint types except for nxDS0WithCas, the valid payload size range is from the default to 2048 bytes.

For nxDS0WithCas, the payload size divide by the number of timeslots must be an integer factor of the number of frames per trunk multi-frame (for example, 16 for E1 trunk and 24 for T1 trunk).

For 1xDS0, the payload size must be a multiple of 2.

For NxDS0, where  $N > 1$ , the payload size must be a multiple of the number of timeslots.

For unstructuredE1 and unstructuredT1, the payload size must be a multiple of 32 bytes.

Configuring the payload size and jitter buffer to values that result in less than 2 packet buffers or greater than 32 packet buffer is not allowed.

Setting the payload size to 0 sets it back to the default value.

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-mac</b> <i>ieee-address</i><br><b>no remote-mac</b>                                                                     |
| <b>Context</b>     | config>service>epipe>sap>cem                                                                                                      |
| <b>Description</b> | <p>This command defines the destination IEEE MAC address to be used to reach the remote end of the circuit emulation service.</p> |

---

|                   |                                                                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 00:00:00:00:00:00                                                                                                                                                                                                                                               |
| <b>Parameters</b> | <i>ieee-address</i> — Specifies the 48-bit MAC address in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## rtp-header

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] rtp-header                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>cpipe>sap>cem<br>config>service>epipe>sap>cem                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies whether an RTP header is used when packets are transmitted to the packet service network (PSN) by the CEM SAP. This mode must be enabled for differential-timed DS1/E1s. It can optionally be enabled for other DS1/E1s for interoperability purposes. |
| <b>Default</b>     | no rtp-header                                                                                                                                                                                                                                                                 |

## 2.17.2.11 ETH-CFM Service Commands

### eth-cfm

|                    |                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-cfm</b>                                                                                                 |
| <b>Context</b>     | config>service>epipe<br>config>service>epipe>sap<br>config>service>epipe>spoke-sdp<br>config>service>ipipe>sap |
| <b>Description</b> | This command enables the context to configure ETH-CFM parameters.                                              |

### tunnel-fault

|                |                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>tunnel-fault {accept   ignore}</b>                                                                                                |
| <b>Context</b> | config>service>epipe>eth-cfm<br>config>service>epipe>sap>eth-cfm<br>config>service>ipipe>eth-cfm<br>config>service>ipipe>sap>eth-cfm |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | Allows the individual service SAPs to react to changes in the tunnel MEP state. When tunnel-fault accept is configured at the service level, the SAP will react according to the service type, Epipe will set the operational flag and VPLS, IES and VPRN SAP operational state will become down on failure or up on clear. This command triggers the OAM mapping functions to mate SAPs and bindings in an Epipe service as well as setting the operational flag. If AIS generation is the requirement for the Epipe services this command is not required. See the <b>ais-enable</b> command under <b>config&gt;service&gt;epipe&gt;sap&gt;eth-cfm&gt;ais-enable</b> context for more details. This works in conjunction with the tunnel-fault accept on the individual SAPs. Both must be set to accept to react to the tunnel MEP state. By default the service level command is “ignore” and the sap level command is “accept”. This means simply changing the service level command to “accept” will enable the feature for all SAPs. This is not required for Epipe services that only wish to generate AIS on failure. |
| <b>Default</b>     | ignore (Service Level)<br><br>accept (SAP Level for Epipe and VPLS)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <b>accept</b> — Shares fate with the facility tunnel MEP.<br><b>ignore</b> — Does not share fate with the facility tunnel MEP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## ais-enable

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|

| <b>Context</b>     | config>service>epipe>sap>eth-cfm<br>config>service>epipe>sap>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the generation and the reception of AIS messages.                                                 |

## low-priority-defect

|                    |                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>low-priority-defect {allDef   macRemErrXcon}</b>                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>lag>eth-cfm>mep>ais<br>config>lag>eth-cfm>mep>ais<br>config>port>ethernet>eth-cfm>mep>ais<br>config>service>epipe>sap>eth-cfm>mep>ais<br>config>service>epipe>spoke-sdp>eth-cfm>mep>ais<br>config>service>vpls>mesh-sdp>eth-cfm>mep>ais                                                                                                           |
| <b>Description</b> | This command allows the operator to include all CCM Defect conditions or exclude the Remote Defect Indication CCM (DefRDICCM) as a trigger for generating AIS. AIS generation can only occur when the client-mep-level configuration option has been included. Changing this parameter will evaluate the MEP for AIS triggers based on the new criteria. |
| <b>Parameters</b>  | <b>allDef</b> — Keyword that includes any CCM defect condition to trigger AIS generation.                                                                                                                                                                                                                                                                |

**macRemErrXcon** — Keyword that excludes RDI CCM Defect condition to trigger AIS generation.

| <b>Description</b> | This command creates individual counters for the specified FCs without regard for profile. All countable packets that match a configured FC, regardless of profile, will be included in this counter.<br><br>A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.<br><br>Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-aware FC using the <b>fc-in-profile</b> command under the same context.<br><br>The <b>no</b> form of the command removes all previously defined FCs and stops counting for those FCs. |
| <b>Default</b>     | no fc                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Parameters** *fc-name* — Specifies the name of the FC for which to create an individual profile-unaware counter. In order for the counter to be used, the **config>oam-pm>session>ethernet>priority** command must be configured with a numerical value representing the FC name (7 = NC, 6 = H1, 5 = EF, 4 = H2, 3 = L1, 2 = AF, 1 = L2, 0 = BE), and the **config>oam-pm>session>ethernet>lmm>enable-fc-collection** command must be enabled.

**Values** nc, h1, ef, h2, l1, af, l2, be

## fc-in-profile

**Syntax** **fc-in-profile** *fc-name* [*fc-name* ]  
**no fc-in-profile**

**Context** config>service>epipe>sap>eth-cfm>collect-lmm-fc-stats  
config>service>epipe>spoke-sdp>eth-cfm>collect-lmm-fc-stats  
config>service>ipipe>sap>eth-cfm>collect-lmm-fc-stats

**Description** This command creates individual counters for the specified FCs with regard for profile. All countable packets that match a configured FC and are deemed to be in-profile will be included in this counter.

A differential is performed when this command is re-entered. Omitted FCs will stop counting, newly added FCs will start counting, and unchanged FCs will continue to count.

Up to eight FCs may be specified. An FC that is specified as part of this command for this specific context cannot be specified as a profile-unaware FC using the **fc** command under the same context.

The **no** form of the command removes all previously defined FCs and stops counting for those FCs.

**Default** no fc-in-profile

**Parameters** *fc-name* — Specifies the name of the FC for which to create an individual profile-aware counter. In order for the counter to be used, the **config>oam-pm>session>ethernet>priority** command must be configured with a numerical value representing the FC name (7 = NC, 6 = H1, 5 = EF, 4 = H2, 3 = L1, 2 = AF, 1 = L2, 0 = BE), and the **config>oam-pm>session>ethernet>lmm>enable-fc-collection** command must be enabled.

**Values** nc, h1, ef, h2, l1, af, l2, be

## collect-lmm-stats

**Syntax** [**no**] **collect-lmm-stats**

**Context** config>service>epipe>sap>eth-cfm  
config>service>epipe>spoke-sdp>eth-cfm

```
config>service>vpls>sap>eth-cfm
config>service>vpls>spoke-sdp>eth-cfm
config>service>vpls>mesh-sdp>eth-cfm
config>service>ipipe>sap>eth-cfm
```

**Description** This command enables the collection of statistics on the SAP or MPLS SDP binding on which the ETH- LMM test is configured. The collection of LMM statistics must be enabled if a MEP is launching or responding to ETH-LMM packets. If LMM statistics collection is not enabled, the counters in the LMM and LMR PDU do not represent accurate measurements and all measurements should be ignored. The **show sap-using eth-cfm collect-lmm-stats** command and the **show sdp-using eth-cfm collect-lmm-stats** command can be used to display which entities are collecting stats.

The **no** form of the command disables and deletes the counters for this SAP or MPLS SDP binding.

**Default** no collect-lmm-stats

## client-meg-level

**Syntax** **client-meg-level** *[[/level /level ...]]*  
**no client-meg-level**

**Context** config>service>epipe>sap>eth-cfm>mep  
config>service>epipe>spoke-sdp>eth-cfm>ais-enable

**Description** This command configures the client maintenance entity group (MEG) level or levels to use for AIS message generation. Up to 7 levels can be provisioned with the restriction that the client MEG level must be higher than the local MEG level.

**Parameters** *level* — Specifies the client MEG level.

**Values** 1 to 7

**Default** 1

## interface-support-enable

**Syntax** **[no] interface-support-enable**

**Context** config>service>epipe>sap>eth-cfm>mep>ais  
config>service>epipe>spoke-sdp>eth-cfm>mep>ais

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on operationally down MEPs will be triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled then transmission of the AIS PDU will be based on either the non-operational state of the entity or on any CCM defect condition. AIS generation will cease if BOTH operationally up state and CCM has no defect conditions. If the MEP is not CCM enabled then the operational state of the entity is the only consideration assuming this command is present for the MEP. |
| <b>Default</b>     | no interface-support-enabled (AIS will not be generated or stopped based on the state of the entity on) which the operationally down MEP is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## interval

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>interval</b> {1   60}<br><b>no interval</b>                                                       |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>ais-enable<br>config>service>epipe>spoke-sdp>eth-cfm>ais-enable |
| <b>Description</b> | This command specifies the transmission interval of AIS messages in seconds.                         |
| <b>Parameters</b>  | <b>1   60</b> — Specifies the transmission interval of AIS messages in seconds.<br><b>Default</b> 1  |

## priority

|                    |                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority</b> <i>priority-value</i><br><b>no priority</b>                                                                                  |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>aid-enable                                                    |
| <b>Description</b> | This command specifies the priority of AIS messages originated by the node.                                                                  |
| <b>Parameters</b>  | <i>priority-value</i> — Specifies the priority value of the AIS messages originated by the node.<br><b>Values</b> 0 to 7<br><b>Default</b> 1 |

## eth-tunnel

|                |                                                      |
|----------------|------------------------------------------------------|
| <b>Syntax</b>  | <b>eth-tunnel</b>                                    |
| <b>Context</b> | config>service>epipe>sap<br>config>service>ipipe>sap |

---

**Description** The command enables the context to configure Ethernet tunnel SAP parameters.

## path

**Syntax** **path** *path-index* **tag** *qtag* [*qtag*]  
**no path** *path-index*

**Context** config>service>epipe>sap>eth-tunnel  
config>service>ipipe>sap>eth-tunnel

**Description** This command configures Ethernet tunnel SAP path parameters.  
The **no** form of the command removes the values from the configuration.

**Default** none

**Parameters** *path-index* — Specifies the path index value.  
**Values** 1 to 16  
*qtag* [*qtag*] — Specifies the qtag value.  
**Values** 0 to 4094 | \*

## mep

**Syntax** **mep** *mep-id* **domain** *md-index* **association** *ma-index* [**direction** {**up** | **down**}] [**primary-vlan-enable**]  
**no mep** *mep-id* **domain** *md-index* **association** *ma-index*

**Context** config>service>epipe>sap>eth-cfm  
config>service>epipe>spoke-sdp>eth-cfm  
config>service>ipipe>sap>eth-cfm

**Description** This command provisions the maintenance endpoint (MEP).  
The **no** form of the command reverts to the default values.

**Parameters** *mep-id* — Specifies the maintenance endpoint identifier.  
**Values** 1 to 8191  
*md-index* — Specifies the maintenance domain (MD) index value.  
**Values** 1 to 4294967295  
*ma-index* — Specifies the maintenance association (MA) index value.  
**Values** 1 to 4294967295

**direction {up | down}** — Indicates the direction in which the MEP faces on the bridge port. The UP direction is not supported for all Fpipe services. For example, lpipe does not support the direction of UP for MEPs.

**up** — Sends ETH-CFM messages toward the MAC relay entity.

**down** — Sends ETH-CFM messages away from the MAC relay entity.

**primary-vlan-enable** — Provides a method for linking the MEP with the primary VLAN configured under the bridge-identifier for the MA. This must be configured as part of the creation step and can only be changed by deleting the MEP and re-creating it. Primary VLANs are only supported under Layer 2 Epipe and VPLS services.

## ccm-enable

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-enable</b>                                                                                                                 |
| <b>Context</b>     | config>service>epipe>spoke-sdp>eth-cfm>mep<br>config>service>epipe>sap>eth-cfm>mep                                                     |
| <b>Description</b> | This command enables the generation of CCM messages.<br><br>The <b>no</b> form of the command disables the generation of CCM messages. |

## ccm-ltm-priority

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-ltm-priority</b> <i>priority</i><br><b>no ccm-ltm-priority</b>                                                                                                           |
| <b>Context</b>     | config>service>epipe>spoke-sdp>eth-cfm>mep<br>config>service>epipe>sap>eth-cfm>mep<br>config>service>ipipe>sap>eth-cfm>mep                                                      |
| <b>Description</b> | This command specifies the priority value for CCMs and LTMs transmitted by the MEP.<br><br>The <b>no</b> form of the command removes the priority value from the configuration. |
| <b>Default</b>     | The highest priority on the bridge-port.                                                                                                                                        |
| <b>Parameters</b>  | <i>priority</i> — Specifies the priority of CCM and LTM messages.<br><br><b>Values</b> 0 to 7                                                                                   |

## ccm-padding-size

|               |                                                                                             |

|---------------|---------------------------------------------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep<br>config>service>ipipe>sap>eth-cfm>mep<br>config>service>epipe>sdp>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>mep<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep<br>config>service>vpls>mesh-sdp>eth-cfm>mep<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep<br>config>service>vpls>mesh-sdp>eth-cfm>mep<br>config>port>ethernet>eth-cfm>mep<br>config>lag>eth-cfm>eth-cfm>mep<br>config>router>if>eth-cfm>mep |
| <b>Description</b> | Set the byte size of the optional Data TLV to be included in the ETH-CC PDU. This will increase the size of the ETH-CC PDU by the configured value. The base size of the ETH-CC PDU, including the Interface Status TLV and Port Status TLV, is 83 bytes not including the Layer Two encapsulation. CCM padding is not supported when the CCM-Interval is less than one second.                                                                                                                                                          |
| <b>Default</b>     | [no] ccm-padding-size                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ccm-padding</i> — Specifies the byte size of the Optional Data TLV.<br><b>Values</b> 3 to 1500                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## csf-enable

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>csf-enable</b>                                                             |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command enables the reception and local processing of ETH-CSF frames.         |

## multiplier

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>multiplier</b> <i>multiplier-value</i><br><b>no multiplier</b>                                                               |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>csf-enable<br>config>service>epipe>spoke-sdp>eth-cfm>mep>csf-enable                        |
| <b>Description</b> | This command enables the multiplication factor applied to the receive time used to clear the CSF condition in increments of .5. |
| <b>Default</b>     | 3.5                                                                                                                             |

---

**Parameters**    *multiplier-value* — Specifies the multiplier used for timing out CSF.

**Values**        0.0 | 2.0 to 30.0

## ccm-tlv-ignore

**Syntax**        **ccm-tlv-ignore** [**interface-status**] [**port-status**]  
**no ccm-tlv-ignore**

**Context**        config>port>ethernet>eth-cfm>mep  
                   config>lag>eth-cfm>mep  
                   config>router>if>eth-cfm>mep

**Description**    This command allows the receiving MEP to ignore the specified TLVs in CCM PDU. Ignored TLVs will be reported as absent and will have no impact on the MEP state machine.

                  The **no** form of the command means the receiving MEP will process all recognized TLVs in the CCM PDU.

**Default**        no ccm-tlv-ignore

**Parameters**    **interface-status** — Ignores the interface status TLV on reception.  
                   **port-status** — Ignores the port status TLV on reception.

## eth-test-enable

**Syntax**        [**no**] **eth-test-enable**

**Context**        config>service>epipe>spoke-sdp>eth-cfm>mep  
                   config>service>epipe>sap>eth-cfm>mep  
                   config>service>ipipe>sap>eth-cfm>mep

**Description**    For this test to work, operators need to configure ETH-test parameters on both sender and receiver nodes. The ETH-test then can be done using the following OAM commands:

                  oam eth-cfm eth-test *mac-address* mep *mep-id* domain *md-index* association *ma-index*  
                   [priority *priority*] [data-length *data-length*]

                  A check is performed for both the provisioning and test to ensure the MEP is an Y.1731 MEP (MEP provisioned with domain format none, association format icc-based). If not, the operation fails. An error message in the CLI and SNMP indicates the problem.

## bit-error-threshold

**Syntax**        **bit-error-threshold** *errors*  
**no bit-error-threshold**

---

|                    |                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>eth-test-enable<br>config>service>epipe>spoke-sdp>eth-cfm>mep>eth-test-enable |
| <b>Description</b> | This command is used to specify the threshold value of bit errors.                                                 |
| <b>Parameters</b>  | <i>errors</i> — The threshold value of bit errors.                                                                 |
| <b>Values</b>      | 0 to 11840                                                                                                         |
| <b>Default</b>     | 1                                                                                                                  |

## test-pattern

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>test-pattern {all-zeros   all-ones} [crc-enable]</b><br><b>no test-pattern</b>                                                                                                       |
| <b>Context</b>     | config>service>epipe>spoke-sdp>eth-cfm>mep>eth-test-enable<br>config>service>epipe>sap>eth-cfm>mep>eth-test-enable<br>config>service>ipipe>sap>eth-cfm>mep>eth-test-enable              |
| <b>Description</b> | This command configures the test pattern for eth-test frames.<br><br>The <b>no</b> form of the command removes the values from the configuration.                                       |
| <b>Default</b>     | all-zeros                                                                                                                                                                               |
| <b>Parameters</b>  | <b>all-zeros</b> — Specifies to use all zeros in the test pattern.<br><b>all-ones</b> — Specifies to use all ones in the test pattern.<br><b>crc-enable</b> — Generates a CRC checksum. |

## fault-propagation-enable

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fault-propagation-enable {use-if-tlv   suspend-ccm}</b><br><b>no fault-propagation-enable</b>                                |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>mep<br>config>service>ipipe>sap>eth-cfm>mep      |
| <b>Description</b> | This command configures the fault propagation for the MEP.                                                                      |
| <b>Parameters</b>  | <b>use-if-tlv</b> — Specifies to use the interface TLV.<br><b>suspend-ccm</b> — Specifies to suspend continuity check messages. |

---

## grace

|                    |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>grace</b>                                                                                                                     |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep<br>config>service>epipe>spoke-sdp>eth-cfm>mep<br>config>service>ipipe>sap>eth-cfm>mep       |
| <b>Description</b> | This command enables the context to configure Nokia ETH-CFM Grace and ITU-T Y.1731 ETH-ED expected defect functional parameters. |

## eth-ed

|                    |                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>eth-ed</b>                                                                                                                                |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>grace<br>config>service>epipe>spoke-sdp>eth-cfm>mep>grace<br>config>service>ipipe>sap>eth-cfm>mep>grace |
| <b>Description</b> | This command enables the context to configure ITU-T Y.1731 ETH-ED expected defect functional parameters.                                     |

## max-rx-defect-window

|                    |                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-rx-defect-window</b> <i>seconds</i><br><b>no max-rx-defect-window</b>                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>grace>eth-ed<br>config>service>epipe>spoke-sdp>eth-cfm>mep>grace>eth-ed<br>config>service>ipipe>sap>eth-cfm>mep>grace>eth-ed                                                                                                                                                           |
| <b>Description</b> | This command limits the duration of the received ETH-ED expected defect window to the lower value of either the received value from the peer or this parameter.<br><br>The <b>no</b> form of the command removes the limitation, and any valid defect window value received from a peer MEP in the ETH-ED PDU will be used. |
| <b>Default</b>     | no max-rx-defect-window                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the duration, in seconds, of the maximum expected defect window.<br><br><b>Values</b> 1 to 86400                                                                                                                                                                                                 |

## priority

|               |                                                       |
|---------------|-------------------------------------------------------|
| <b>Syntax</b> | <b>priority</b> <i>priority</i><br><b>no priority</b> |
|---------------|-------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>grace>eth-ed<br>config>service>epipe>spoke-sdp>eth-cfm>mep>grace>eth-ed<br>config>service>ipipe>sap>eth-cfm>mep>grace>eth-ed                                                                                                                 |
| <b>Description</b> | This command sets the priority bits and determines the forwarding class based on the mapping of priority to FC.<br><br>The <b>no</b> form of the command disables the local priority configuration and sets the priority to the <b>ccm-ltm-priority</b> associated with this MEP. |
| <b>Default</b>     | no priority                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>priority</i> — Specifies the priority bit.<br><br><b>Values</b> 0 to 7                                                                                                                                                                                                         |

## rx-eth-ed

|                    |                                                                                                                                                                                                         |

| <b>Default</b>     | rx-eth-ed                                                                                                                                                                                               |

## tx-eth-ed

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] tx-eth-ed                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>epipe>sap>eth-cfm>mep>grace>eth-ed<br>config>service>epipe>spoke-sdp>eth-cfm>mep>grace>eth-ed<br>config>service>ipipe>sap>eth-cfm>mep>grace>eth-ed                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command enables the transmission of the ITU-T Y.1731 ETH-ED PDU from the MEP when a system soft reset notification is received for one or more cards.<br><br>The <b>config&gt;eth-cfm&gt;system&gt;grace-tx-enable</b> command must be configured to instruct the system that the node is capable of transmitting expected defect windows to the peers. Only one form of ETH-CFM grace (Nokia ETH-CFM Grace or ITU-T Y.1731 ETH-ED) may be transmitted. |

The **no** form of the command disables the transmission of the ITU-T Y.1731 ETH-ED PDU from the MEP.

**Default** no tx-eth-ed

## eth-vsm-grace

**Syntax** **eth-vsm-grace**

**Context** config>service>epipe>sap>eth-cfm>mep>grace  
config>service>epipe>spoke-sdp>eth-cfm>mep>grace  
config>service>ipipe>sap>eth-cfm>mep>grace

**Description** This command enables the context to configure Nokia ETH-CFM Grace functional parameters.

## rx-eth-vsm-grace

**Syntax** [**no**] **rx-eth-vsm-grace**

**Context** config>service>epipe>sap>eth-cfm>mep>grace>eth-vsm-grace  
config>service>epipe>spoke-sdp>eth-cfm>mep>grace>eth-vsm-grace  
config>service>ipipe>sap>eth-cfm>mep>grace>eth-vsm-grace

**Description** This command enables the reception and processing of the Nokia ETH-CFM Grace PDU on the MEP.

The Nokia Grace function is a vendor-specific PDU that informs MEP peers that the local node may be entering a period of expected defect.

The **no** form of the command disables the reception of the Nokia ETH-CFM Grace PDU on the MEP.

**Default** rx-eth-vsm-grace

## tx-eth-vsm-grace

**Syntax** [**no**] **tx-eth-vsm-grace**

**Context** config>service>epipe>sap>eth-cfm>mep>grace>eth-vsm-grace  
config>service>epipe>spoke-sdp>eth-cfm>mep>grace>eth-vsm-grace  
config>service>ipipe>sap>eth-cfm>mep>grace>eth-vsm-grace

**Description** This command enables the transmission of the Nokia ETH-CFM Grace PDU from the MEP when a system soft reset notification is received for one or more cards.

The Nokia Grace function is a vendor-specific PDU that informs MEP peers that the local node may be entering a period of expected defect.

The **config>eth-cfm>system>grace-tx-enable** command must be configured to instruct the system that the node is capable of transmitting expected defect windows to the peers. Only one form of ETH-CFM grace (Nokia ETH-CFM Grace or ITU-T Y.1731 ETH-ED) may be transmitted.

The **no** form of the command disables the transmission of the Nokia ETH-CFM Grace PDU from the MEP.

**Default** tx-eth-vsm-grace

## lbm-svc-act-responder

**Syntax** [no] lbm-svc-act-responder

**Context** config>service>epipe>sap>eth-cfm>mep  
config>service>epipe>spoke-sdp>eth-cfm>mep

**Description** This command enables the MEP to process service activation streams encapsulated in ETH-CFM LBM frames that are directed to the MEP. The MEP will be allocated additional resources to rapidly respond to a high-speed stream of LBM messages. A MEP created with this option will not validate any TLVs, will not validate the ETH-LBM MAC Address, and will not increment or compute any loopback statistics. Statistical computation and reporting is the responsibility of the test head-end. The ETH-CFM level of the high speed ETH-LBM stream must match the level of a MEP configured with this command. It must not target any lower ETH-CFM level the MEP will terminate. When the service activation test is complete, the MEP may be returned to standard processing by removing this command. If there is available bandwidth, the MEP will respond to other ETH-CFM PDUs, such as ETH-DMM marker packets, using standard processing.

The interaction between this command and the **tools perform service id service-id loopback eth** command must be carefully considered. It is recommended that either the **lbm-svc-act-responder** or the **tools perform service id service-id loopback eth** command be used at any given time within a service. If both commands must be configured, and the target reflection point is the MAC Swap Loopback function, the inbound stream of data must not include ETH-CFM traffic that is equal to or lower than the domain level of any configured MEP which would otherwise extract and process the ETH-CFM message. If the reflection target is a MEP configured with the **lbm-svc-act-responder** option, the mode (ingress or egress) of the SAP or SDP specified with this tools command and the MEP **direction** (up or down) must match when the functions are enabled on the same reflection point, and the domain level of the inbound ETH-LBM must be the same as that of the MEP configured with the **lbm-svc-act-responder** option. At no time should the two functions be conflicting with each other along the path of the stream. This conflict would lead to unpredictable and possibly destabilizing situations.

The **no** form of the command reverts to MEP LBM standard processing.

**Default** no lbm-svc-act-responder

## low-priority-defect

| <b>Syntax</b>      | <b>low-priority-defect</b> {allDef   macRemErrXcon   remErrXcon   errXcon   xcon   noXcon}                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |        |  |        |                                                                    |               |                                                              |            |                                                |         |                                 |      |                 |        |                                                |

| <b>Description</b> | This command allows Maintenance Intermediate Points (MIPs). The creation rules of the MIP are dependent on the mhf-creation configuration for the MA.<br><br>The <b>no</b> form of the command removes the MIP creation request.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | no mip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <b>mac</b> — Provides a method for manually configuring the MIP MAC address.<br><i>mac-address</i> — Specifies the MAC address of the MIP.<br><br><b>Values</b> 6-byte mac-address in the form of xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx of the MIP. The MAC address must be unicast. Using the all-zeros address is equivalent to the <b>no</b> form of this command.<br><br><b>default-mac</b> — Using the <b>no</b> command deletes the MIP. This parameter should be used if the operator wants to change the MAC address back to the default MAC without having to delete and reconfigure the MIP.<br><br><b>primary-vlan-enable</b> — Provides a method for linking the MIP with the primary VLAN configured under the bridge-identifier for the MA. This is only allowed if the mhf-creation method is static. MIPs cannot be changed from or to primary VLAN functions without first being deleted. This must be configured as part of the creation step and can only be changed by deleting the MIP and re-creating it. Primary VLANs are only supported under Layer 2 Epipe and VPLS services.<br><br><i>vlan-id</i> — Must match the VLAN id under the bridge-identifier for the MA that is appropriate for this service.<br><br><b>Values</b> 0 to 4094 |

| <b>Description</b> | <p>This command defines the levels of the ETH-CFM PDUs that will silently be discarded on ingress into the SAP or SDP binding from the wire. All ETH-CFM PDUs inbound to the SAP or SDP binding will be dropped that match the configured levels without regard for any other ETH-CFM criteria. No statistical information or drop count will be available for any ETH-PDU that is silently discarded by this option. The operator must configure a complete contiguous list of md-levels up to the highest level that will be dropped. The command must be retyped in complete form to modify a previous configuration, if the operator does not want to delete it first.</p> <p>The <b>no</b> form of the command removes the silent discarding of previously matching ETH-CFM PDUs.</p> |
| <b>Default</b>     | no squelch-ingress-levels                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>md-level</i> — Identifies the level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|                    | <b>Values</b> 0 to 7                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

### 2.17.2.12 Service Filter and QoS Policy Commands

## force-qinq-vc-forwarding

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command forces the data path to push two VLAN tags at network egress when sending traffic on SDP bindings or EVPN-MPLS destinations. The VLAN tag values are derived from the service-delimiting tags at the ingress, depending on the configured parameter. At network ingress this command, configured on EVPN-MPLS or the SDP-binding, pops two VLAN tags at most.</p> <p>The <b>no</b> version of this command does not make the data path to push any VLAN tags in SDP bindings or EVPN-MPLS, or pop two VLAN tags.</p>    |
| <b>Default</b>     | no force-qinq-vc-forwarding                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>c-tag-c-tag</i> — Pushes two tags with the same value derived from the inner service delimiting tag. At network ingress, two VLAN tags are extracted at most and the c-tag and s-tag p/de bits are propagated to the egress SAPs.</p> <p><i>s-tag-c-tag</i> — Pushes two tags that are copied from the QinQ service-delimiting VLAN values, and may be different. At network ingress, two VLAN tags are extracted at most and the p/de bits are propagated to the egress SAP service-delimiting s-tag and c-tag respectively.</p> |

## force-vlan-vc-forwarding

|                    |                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] force-vlan-vc-forwarding</b>                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>epipe>spoke-sdp<br>config>service>vpls>mesh-sdp<br>config>service>vpls>spoke-sdp                                                                                                                                              |
| <b>Description</b> | <p>This command forces vc-vlan-type forwarding in the data path for spoke and mesh SDPs which have either vc-type. This command is not allowed on vlan-vc-type SDPs.</p> <p>The <b>no</b> version of this command sets default behavior.</p> |
| <b>Default</b>     | By default this feature is disabled.                                                                                                                                                                                                         |

```

**Description** This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface.

Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.

The **filter** command is used to associate a filter policy with a specified *filter-id* with an ingress or egress SAP. The *filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

IPv6 filters are only supported by the 7450 ESS and 7750 SR but are not supported on a Layer 2 SAP that is configured with QoS MAC criteria. Also, MAC filters are not supported on a Layer 2 SAP that is configured with QoS IPv6 criteria.

**Special Cases** **Epipe** — Both MAC and IP filters are supported on an Epipe service SAP.

**Parameters** *ip-filter-id* — Specifies IP filter policy. The filter ID must already exist within the created IP filters.

**Values** 1 to 65535

*ipv6-filter-id* — Specifies the IPv6 filter policy for 7450 ESS or 7750 SR. The filter ID must already exist within the created IPv6 filters.

**Values** 1 to 65535

*mac-filter-id* — Specifies the MAC filter policy. The specified filter ID must already exist within the created MAC filters. The filter policy must already exist within the created MAC filters.

**Values** 1 to 65535

## I2tpv3

**Syntax** I2tpv3

| <b>Context</b>     | config>service>epipe>spoke-sdp>egress>l2tpv3<br>config>service>epipe>spoke-sdp>ingress>l2tpv3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command configures the RX/TX cookie for L2TPv3 spoke SDPs for Epipe services. The RX cookie must match the configured TX cookie on a far-end node, while the TX cookie must match the configured RX cookie on a far-end node. If a mismatch is detected between the configured (far-end binding cookie) to what is received by the local IP address of the SDP a flag is set and must be manually cleared by an operator.</p> <p>The purpose of the cookie is to provide validation against misconfiguration of service endpoints, and to ensure that the right service egress is being used.</p> <p>One egress cookie and up to two ingress cookies may be configured per spoke SDP binding. One or two cookies can be configured for matching ingress packets from the far-end node, in order to support cookie rollover without dropping packets. When a cookie is not configured, SR-OS assumes a value of 00:00:00:00:00:00:00:00.</p> <p>A cookie is not mandatory. An operator may delete an egress cookie or either or both ingress cookies.</p> |
| <b>Default</b>     | no cookie1 cookie2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>cookie1</i> — Specifies the first cookie, in the form of a 64-bit colon-separated hex value.</p> <p><i>cookie2</i> — Specifies the second cookie, in the form of a 64-bit colon-separated hex value.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>epipe>sap>egress>hsmda-queue-over<br>config>service>ipipe>sap>egress>hsmda-queue-over                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4-byte CRC (everything except the preamble and inter-frame gap). For example, this command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions. |

The accounting functions affected include:

- Offered High Priority / In-Profile Octet Counter
- Offered Low Priority / Out-of-Profile Octet Counter
- Discarded High Priority / In-Profile Octet Counter
- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 20 bytes may be added to the packet and up to 43 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As mentioned previously, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. When the queue group represents the last-mile bandwidth constraints for a subscriber, the offset allows the HSMDA queue group to provide an accurate accounting to prevent overrun and underrun conditions for the subscriber. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value can be overridden for the HSMDA queue at the SAP or subscriber profile level.

The **no** form of the command removes any accounting size changes to packets handled by the queue. The command does not affect overrides that may exist on SAPs or subscriber profiles associated with the queue.

**Parameters**     *add-bytes* — Specifies a byte value to add to packets for queue and queue group-level accounting functions. The corresponding byte value must be specified when executing the packet-byte-offset command.

**Values**            0 to 31

*sub-bytes* — Specifies a byte value to subtract from packets for queue and queue group-level accounting functions. The corresponding byte value must be specified when executing the packet-byte-offset command.

**Values**            1 to 64

## queue

**Syntax**            **queue** *queue-id* [**create**]  
**no queue** *queue-id*

**Context**            config>service>epipe>sap>egress>hsmda-queue-over  
config>service>ipipe>sap>egress>hsmda-queue-over

**Description**       This command, within the QoS policy hsmda-queue context, is a container for the configuration parameters controlling the behavior of an HSMDA queue. Unlike the standard QoS policy queue command, this command is not used to actually create or dynamically assign the queue to the object which the policy is applied. The queue identified by queue-id always exists on the SAP or subscriber context whether the command is executed or not. In the case of HSMDA SAPs and subscribers, all eight queues exist at the moment the system allocates an HSMDA queue group to the object (both ingress and egress).

### Best-Effort, Expedited and Auto-Expedite Queue Behavior Based on Queue-ID

With standard service queues, the scheduling behavior relative to other queues is based on two items, the queues Best-Effort or Expedited nature and the dynamic rate of the queue relative to the defined CIR. HSMDA queues are handled differently. The create time auto-expedite and explicit expedite and best-effort qualifiers have been eliminated and instead the scheduling behavior is based solely on the queues identifier. Queues with a queue-id equal to 1 are placed in scheduling class 1. Queues with queue-id 2 are placed in scheduling class 2. And so on up to scheduling class 8. Each scheduling class is either mapped directly to a strict scheduling priority level based on the class ID, or the class may be placed into a weighted scheduling class group providing byte fair weighted round robin scheduling

between the members of the group. Two weighted groups are supported and each may contain up to three consecutive scheduling classes. The weighted group assumes its highest member class inherent strict scheduling level for scheduling purposes. Strict priority level 8 has the highest priority while strict level 1 has the lowest. When grouping of scheduling classes is defined, some of the strict levels will not be in use.

### Single Type of HSM DA Queues

Another difference between HSM DA queues and standard service queues is the lack of Multipoint queues. At ingress, an HSM DA SAP or subscriber does not require Multipoint queues since all forwarding types (broadcast, multicast, unicast and unknown) forward to a single destination in the ingress forwarding plane on the IOM. Instead of a possible eight queues per forwarding type (for a total of up to 32) within the SAP ingress QoS policy, the hsm da-queues node supports a maximum of eight queues.

### Every HSM DA Queue Supports Profile Mode Implicitly

Unlike standard service queues, the HSM DA queues do not need to be placed into the special mode profile at create time in order to support ingress color aware policing. Each queue may handle in-profile, out-of-profile and profile undefined packets simultaneously. As with standard queues, the explicit profile of a packet is dependent on ingress sub-forwarding class to which the packet is mapped.

The **no** form of the command restores the defined queue-id to its default parameters. All HSM DA queues having the queue-id and associated with the QoS policy are re-initialized to default parameters.

**Parameters** *queue-id* — Specifies the HSM DA queue to use for packets in this forwarding class. This mapping is used when the SAP is on a HSM DA MDA.

**Values** 1 to 8

## rate

**Syntax** **rate** *pir-rate*  
**no rate**

**Context** config>service>epipe>sap>egress>hsm da-queue-over>queue  
config>service>ipipe>sap>egress>hsm da-queue-over>queue

**Description** This command specifies the administrative PIR by the user.

**Parameters** *pir-rate* — Configures the administrative PIR specified by the user.

**Values** 1 to 40000000, **max**

## wrr-weight

**Syntax** **wrr-weight** *value*

### no wrr-weight

| <b>Context</b>     | config>service>epipe>sap>egress>hsmda-queue-over<br>config>service>ipipe>sap>egress>hsmda-queue-over                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command assigns an HSMDA slope policy to the SAP. The policy may be assigned to an ingress or egress HSMDA queue. The policy contains the Maximum Buffer Size (MBS) that will be applied to the queue and the high and low priority RED slope definitions. The function of the MBS and RED slopes is to provide congestion control for an HSMDA queue. The MBS parameter defines the maximum depth a queue may reach when accepting packets. The low and high priority RED slopes provides for random early detection of congestion and slope based discards based on queue depth.</p> <p>An HSMDA slope policy can be applied to queues defined in the SAP ingress and SAP egress QoS policy HSMDA queues context. Once an HSMDA slope policy is applied to a SAP QoS policy queue, it cannot be deleted. Any edits to the policy are updated to all HSMDA queues indirectly associated with the policy.</p> |

**Default HSMDB Slope Policy**

An HSMDB slope policy named “default” always exists on the system and does not need to be created. The default policy is automatically applied to all HSMDB queues unless another HSMDB slope policy is specified for the queue. The default policy cannot be modified or deleted. Attempting to execute the **no hsmdb-slope-policy default** command results in an error.

The **no** form of the command removes the specified HSMDB slope policy from the configuration. If the HSMDB slope policy is currently associated with an HSMDB queue, the command will fail.

**Parameters** *hsmdb-slope-policy-name* — Specifies a HSMDB slope policy up to 32 characters in length. The HSMDB slope policy must exist prior to applying the policy name to an HSMDB queue.

**secondary-shaper**

**Syntax** **secondary-shaper** *secondary-shaper-name*  
**no secondary-shaper**

**Context** config>service>epipe>sap>egress>hsmdb-queue-over  
config>service>ipipe>sap>egress>hsmdb-queue-over

**Description** This command configures an HSMDB egress secondary shaper.

**Parameters** *secondary-shaper-name* — Specifies a secondary shaper name up to 32 characters in length.

**filter**

**Syntax** **filter** [ip *ip-filter-id*]  
**filter** [ipv6 *ipv6-filter-id*]  
**no filter** [ip *ip-filter-id*] [ipv6 *ipv6-filter-id*]  
**no filter** [ip *ip-filter-id*]

**Context** config>service>fpipes>sap>egress  
config>service>fpipes>sap>ingress  
config>service>cpipes>spoke-sdp>egress  
config>service>cpipes>spoke-sdp>ingress  
config>service>fpipes>spoke-sdp>egress  
config>service>fpipes>spoke-sdp>ingress  
config>service>ipipes>spoke-sdp>egress  
config>service>ipipes>sap>ingress  
config>service>ipipes>sap>egress  
config>service>ipipes>spoke-sdp>ingress

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command associates a filter policy with an ingress or egress Service Access Point (SAP) or IP interface.</p> <p>Filter policies control the forwarding and dropping of packets based on IP matching criteria. Only one filter can be applied to a SAP at a time.</p> <p>The <b>filter</b> command is used to associate a filter policy with a specified <i>ip-filter-id</i> with an ingress or egress SAP. The <i>ip-filter-id</i> must already be defined before the <b>filter</b> command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>IP filters apply only to RFC 2427-routed IP packets. Frames that do not contain IP packets will not be subject to the filter and will always be passed, even if the filter's default action is to drop.</p> <p>The <b>no</b> form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use <b>scope</b> command within the filter definition to change the scope to <b>local</b> or <b>global</b>. The default scope of a filter is <b>local</b>.</p> |
| <b>Parameters</b>  | <p><i>ip-filter-id</i> — Specifies IP filter policy. The filter ID must already exist within the created IP filters.</p> <p><b>Values</b> 1 to 65535</p> <p><i>ipv6-filter-id</i> — Specifies the IPv6 filter policy. The filter ID must already exist within the created IPv6 filters.</p> <p><b>Values</b> 1 to 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command provides ingress VLAN translation for two service-delimiting VLAN values, as opposed to the <b>vlan-translation</b> command that provides translation for only one service-delimiting VLAN value. This command is used with the <b>force-qinq-vc-forwarding</b> command so that the VLAN values that are pushed on SDP bindings or EVPN-MPLS can be normalized (translated). The command has no effect without the configuration of <b>force-qinq-vc-forwarding</b>, and can not be used in non-QinQ SAPs.</p> <p>The <b>no</b> version of the command disables QinQ VLAN translation.</p> |
| <b>Default</b>     | no qinq-vlan-translation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>s-tag.c-tag</i> — These are the VLAN tag values that are pushed on SDP bindings and EVPN-MPLS destinations when <b>force-qinq-vc-forwarding s-tag-c-tag</b> is configured. When <b>force-qinq-vc-forwarding c-tag-c-tag</b> is configured, only the c-tag value in qinq-vlan-translation s-tag.c-tag is pushed.</p> <p><b>Values</b>      <i>s-tag</i>: 0 to 4094<br/>                  <i>c-tag</i>: 0 to 4094</p>                                                                                                                                                                                  |

| <b>Description</b> | <p>This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.</p> <p>The <b>match-qinq-dot1p</b> command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The <b>top</b> and <b>bottom</b> keywords specify which position should be evaluated for QinQ encapsulated packets.</p> |

The setting also applies to classification based on the DE indicator bit.

The **no** form of this command reverts the dot1p and de bits matching to the default tag.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. [Table 16](#) defines the default behavior for Dot1P evaluation.

**Table 16 Default QinQ and TopQ SAP Dot1P Evaluation**

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |

| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Default** no match-qinq-dot1p (no filtering based on p-bits)

(top or bottom must be specified to override the default QinQ dot1p behavior)

**Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 17](#) defines the dot1p evaluation behavior when the top parameter is specified.

**Table 17 Top Position QinQ dpt1p Evaluation Behavior**

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| Null            | None                 | None                 |
| Null            | Dot1P (VLAN ID 0)    | Dot1P PBits          |
| Null            | Dot1Q                | Dot1Q PBits          |
| Null            | TopQ BottomQ         | TopQ PBits           |

**Table 17** Top Position QinQ dpt1p Evaluation Behavior (Continued)

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | TopQ PBits           |

**bottom** — The bottom parameter and the top parameter are mutually exclusive. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 18](#) defines the dot1p evaluation behavior when the bottom parameter is specified.

**Table 18** Bottom Position QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| Null            | None                          | None                 |
| Null            | Dot1P (VLAN ID 0)             | Dot1P PBits          |
| Null            | Dot1Q                         | Dot1Q PBits          |
| Null            | TopQ BottomQ                  | TopQ PBits           |
| Null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | None (Default SAP)            | None                 |
| Dot1Q           | Dot1P (Default SAP VLAN ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Table 19 Egress SAP Types**

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| Null            | No preserved Dot1P bits                               | None                                                         |
| Null            | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | No preserved Dot1P bits                               | New PBits marked using dot1p-value                           |
| Dot1Q           | Preserved Dot1P bits                                  | Preserved tag PBits remarked using dot1p-value               |
| TopQ            | No preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |
| QinQ            | No preserved Dot1P bits                               | TopQ PBits and BottomQ PBits marked using dot1p-value        |
| QinQ            | Preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits and BottomQ PBits marked using dot1p-value        |

The QinQ and TopQ SAP PBit/DEI bit marking follows the default behavior defined in the preceding table when **qinq-mark-top-only** is not specified.

The dot1p *dot1p-value* command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

A QinQ-encapsulated Ethernet port can have two different sap types:

For a TopQ SAP type, only the outer (top) tag is explicitly specified. For example, **sap 1/1/1:10.\***

For QinQ SAP type, both inner (bottom) and outer (top) tags are explicitly specified. For example, **sap 1/1/1:10.100**.

## 2.17.2.13 VLL Frame Relay Commands

### frame-relay

**Syntax** **frame-relay**

**Context** config>service>apipe>sap  
config>service>epipe>sap

```
config>service>fpipe>sap
config>service>ipipe>sap
```

**Description** This command enables the context to configure Frame Relay parameters.

## frf-12

**Syntax** [no] frf-12

**Context** config>service>epipe>sap>frame-relay  
config>service>ipipe>sap>frame-relay

**Description** This command enables the use of FRF12 headers.

The **no** form of the command disables the use of FRF12 headers.

## ete-fragment-threshold

**Syntax** **ete-fragment-threshold** *threshold*  
**no ete-fragment-threshold**

**Context** config>service>epipe>sap>frame-relay>frf-12  
config>service>ipipe>sap>frame-relay>frf-12

**Description** This command specifies the maximum length of a fragment to be transmitted.

The **no** form of the command reverts to the default.

**Parameters** *threshold* — The maximum length of a fragment to be transmitted.

**Values** 128 to 512

**Default** 0

## interleave

**Syntax** [no] interleave

**Context** config>service>epipe>sap>frame-relay>frf.12  
config>service>ipipe>sap>frame-relay>frf.12

**Description** This command enables interleaving of high priority frames and low priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation.

When this option is enabled, only frames of the FR SAP non-expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).

When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.

The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.

The **no** form of this command restores the default mode of operation.

**Default** no interleave

## scheduling-class

|                    |                                                                                                                                                                                    |               |        |                |   |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------|----------------|---|
| <b>Syntax</b>      | <b>scheduling-class</b> <i>class-id</i>                                                                                                                                            |               |        |                |   |
| <b>Context</b>     | config>service>apipe>sap>frame-relay<br>config>service>epipe>sap>frame-relay<br>config>service>fpipe>sap>frame-relay<br>config>service>ipipe>sap>frame-relay                       |               |        |                |   |
| <b>Description</b> | This command specifies the scheduling class to use for this SAP.                                                                                                                   |               |        |                |   |
| <b>Parameters</b>  | <i>class-id</i> — Specifies the scheduling class to use for this sap. <table> <tr> <td><b>Values</b></td><td>0 to 3</td></tr> <tr> <td><b>Default</b></td><td>0</td></tr> </table> | <b>Values</b> | 0 to 3 | <b>Default</b> | 0 |
| <b>Values</b>      | 0 to 3                                                                                                                                                                             |               |        |                |   |

### 2.17.2.14 ATM Commands

## encapsulation

|                    |                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>epipe>sap>atm                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the data encapsulation for an ATM PVCC delimited Epipe SAP. The definition references RFC 2684, <i>Multiprotocol Encapsulation over ATM AAL5</i> , and to the ATM Forum LAN Emulation specification. Ingress traffic that does not match the configured encapsulation will be dropped. |
| <b>Default</b>     | aal5snap-bridged                                                                                                                                                                                                                                                                                              |

---

|                   |                                                                                                                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>atm-encap-type</i> — Specifies the encapsulation type.                                                                                                                                                                                                    |
| <b>Values</b>     | <b>aal5snap-bridged</b> — Bridged encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.<br><b>aal5mux-bridged-eth-nofcs</b> — Bridged IP encapsulation for VC multiplexed circuit as defined in RFC 2684. |

## encapsulation

|                    |                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                               |

## 2.18.2 Command Descriptions

### 2.18.2.1 VLL Show Commands

The following command outputs are examples only; actual displays may differ depending on supported functionality and user configuration.

#### egress-label

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress-label</b> <i>start-label</i> [ <i>end-label</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | show>service                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command displays services using the range of egress labels. If only the mandatory <i>egress-label/1</i> parameter is specified, only services using the specified label are displayed.</p> <p>If both <i>egress-label/1</i> and <i>egress-label/2</i> parameters are specified, the services using the range of labels X where <i>egress-label/1</i> &lt;= X &lt;= <i>egress-label/2</i> are displayed.</p> <p>Use the <b>show router ldp bindings</b> command to display dynamic labels.</p> |
| <b>Parameters</b>  | <p><i>start-label</i> — The starting egress label value for which to display services using the label range. If only <i>start-label</i> is specified, services only using <i>start-label</i> are displayed.</p> <p><b>Values</b> 0, 18432 to 524287</p>                                                                                                                                                                                                                                               |

**end-label** — The ending egress label value for which to display services using the label range.

**Default** The *end-label* value.

**Values** 18432 to 524287

**Output** The following output is an example of egress label information, and [Table 20](#) describes the output fields.

### Sample Output

```
*A:ALA-12# show service egress-label 0 10000

**Table 20** Show Service Egress Label Output Fields

| Label  | Description                                                                                        |
|--------|----------------------------------------------------------------------------------------------------|
| Svc Id | The ID that identifies a service.                                                                  |
| Sdp Id | The ID that identifies an SDP.                                                                     |
| Type   | Indicates whether the SDP binding is spoke or mesh.                                                |
| I. Lbl | The VC label used by the far-end device to send packets to this device in this service by the SDP. |
| E. Lbl | The VC label used by this device to send packets to the far-end device in this service by the SDP. |

**Table 20 Show Service Egress Label Output Fields (Continued)**

| Label                    | Description                                                                          |
|--------------------------|--------------------------------------------------------------------------------------|
| Number of bindings found | The total number of SDP bindings that exist within the specified egress label range. |

all

- Syntax** all
- Context** show>service>id
- Description** This command displays detailed information for all aspects of the service.
- Output** The following output is an example of all service ID information, and [Table 21](#) describes the output fields.

### Sample Output

```
*A:PE# show service id 1 all

| Admin State                 | The administrative state of this SD for the 7450 ESS or 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Oper State                  | The operational state of this SDP for the 7450 ESS or 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Jitter Buffer (packets)     | Indicates the jitter buffer length in number of packet buffers for the 7450 ESS or 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Playout Threshold (packets) | Indicates the playout buffer packets threshold in number of packet buffers for the 7450 ESS or 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Playout Threshold (packets) | Indicates the current packet depth of the jitter buffer for the 7450 ESS or 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Peer Pw Bits                | <p>Indicates the bits set by the LDP peer when there is a fault on its side of the pseudowire for the 7450 ESS or 7750 SR. LAC failures occur on the SAP that has been configured on the pipe service, PSN bits are set by SDP-binding failures on the pipe service. The pwNotForwarding bit is set when none of the above failures apply, such as an MTU mismatch failure. This value is only applicable if the peer is using the pseudowire status signaling method to indicate faults.</p> <p>pwNotForwarding — Pseudowire not forwarding<br/> lacIngressFault Local — Attachment circuit RX fault<br/> lacEgressFault Local — Attachment circuit TX fault<br/> psnIngressFault Local — PSN-facing PW RX fault<br/> psnEgressFault Local — PSN-facing PW TX fault<br/> pwFwdingStandby — Pseudowire in standby mode</p> |
| Signaling Override          | Indicates the overriding signaled pseudowire type, as configured under the <b>signaled-vc-type-override</b> option for Apipes. This field is only displayed if <b>signaled-vc-type-override</b> is configured for the 7750 SR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## authentication

**Syntax** authentication

**Context** show>service>id

**Description** This command enables the context to display subscriber authentication information.

## statistics

|                    |                                                                                                                                                    |

**Table 22 Show Service-ID Base Output Fields**

| Label            | Description                                                                        |
|------------------|------------------------------------------------------------------------------------|
| Service Id       | The service identifier.                                                            |
| Vpn Id           | Specifies the VPN ID assigned to the service.                                      |
| Service Type     | The type of service: Epipe, Apipe, Fpipe, Ipipe, VPLS, IES, VPRN.                  |
| Description      | Generic information about the service.                                             |
| Customer Id      | The customer identifier.                                                           |
| Last Mgmt Change | The date and time of the most recent management-initiated change to this customer. |
| Adm              | The desired state of the service.                                                  |
| Oper             | The operating state of the service.                                                |
| Mtu              | The largest frame size (in octets) that the service can handle.                    |
| SAP Count        | The number of SAPs defined on the service.                                         |
| SDP Bind Count   | The number of SDPs bound to the service.                                           |
| Identifier       | Specifies the service access (SAP) and destination (SDP) points.                   |

**Table 22 Show Service-ID Base Output Fields (Continued)**

| Label             | Description (Continued)                                                                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type              | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP.                                                    |
| AdmMTU            | Specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end ESR, without requiring the packet to be fragmented.             |
| PBB Tunnel Point  | Specifies the endpoint in the B-VPLS environment where the Epipe terminates.                                                                                                         |
| Admin MTU         | Specifies the B-VPLS admin MTU.                                                                                                                                                      |
| Backbone-Flooding | Specifies whether or not the traffic is flooded in the B-VPLS for the destination instead of unicast. If the backbone destination MAC is in the B-VPLS FDB, then it will be unicast. |
| ISID              | The 24 bit field carrying the service instance identifier associated with the frame. It is used at the destination PE as a demultiplexor field.                                      |

## bgp-vpws

- Syntax** **bgp-vpws**
- Context** show>service>id
- Description** This command displays BGP VPWS related information for the service.
- Output** The following output is an example of BGP VPWS information.

### Sample Output

```

**Table 23** Show Service-ID Labels Output Fields

| Label  | Description                                                                                        |
|--------|----------------------------------------------------------------------------------------------------|
| Svc Id | The service identifier.                                                                            |
| Sdp Id | The SDP identifier.                                                                                |
| Type   | Indicates whether the SDP is a spoke or a mesh.                                                    |
| I. Lbl | The VC label used by the far-end device to send packets to this device in this service by the SDP. |
| E. Lbl | The VC label used by this device to send packets to the far-end device in this service by the SDP. |

## retailers

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retailers</b>                                                                                          |
| <b>Context</b>     | show>service>id                                                                                           |
| <b>Description</b> | This command displays the service ID of the retailer subscriber service to which this DHCP lease belongs. |

## sap

|                |                            |
|----------------|----------------------------|
| <b>Syntax</b>  | <b>sap sap-id [detail]</b> |
| <b>Context</b> | show>service>id            |

- Description** This command displays information for the SAPs associated with the service. If no optional parameters are specified, a summary of all associated SAPs is displayed.
- Parameters** *sap-id* — The ID that displays SAPs for the service in the form *slot/mdalport[.channel]*.  
**detail** — Displays detailed information for the SAP.
- Output** The following output is an example of SAP information, and [Table 24](#) describes the output fields.

**Sample Output**

```
*A:PE# show service id 1 sap 1/1/1 detail
```

```

| Ethertype          | Specifies an Ethernet type II Ethertype value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Admin State        | The administrative state of the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Oper State         | The operating state of the SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Flags              | Specifies the conditions that affect the operating status of this SAP.<br>Display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapIpipeCelpAddr, TodResourceUnavail, TodMssResourceUnavail, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode. |
| Last Status Change | The time of the most recent operating status change to this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 24 Show Service-ID SAP Output Fields (Continued)**

| Label              | Description (Continued)                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Last Mgmt Change   | The time of the most recent management-initiated change to this SAP.                                                                                             |
| Admin MTU          | The desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented. |
| Oper MTU           | The actual largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.  |
| Ingress qos-policy | The ingress QoS policy ID assigned to the SAP.                                                                                                                   |
| Egress qos-policy  | The egress QoS policy ID assigned to the SAP.                                                                                                                    |
| Ingress Filter-Id  | The ingress filter policy ID assigned to the SAP.                                                                                                                |
| Egress Filter-Id   | The egress filter policy ID assigned to the SAP.                                                                                                                 |
| Acct. Pol          | The accounting policy ID assigned to the SAP.                                                                                                                    |
| Collect Stats      | Specifies whether collect stats is enabled.                                                                                                                      |
| LLF Admin State    | Displays the Link Loss Forwarding administrative state.                                                                                                          |
| LLF Oper State     | Displays the Link Loss Forwarding operational state.                                                                                                             |
| pw-port            | <b>pw-id[:qtag1[.qtag2]] pw-id[:qtag1[.qtag2]] pw-2:1.1</b>                                                                                                      |

## sdp

**Syntax** **sdp** [[*sdp-id*[:*vc-id*]]] [**detail**]  
**sdp far-end** {*ip-address* | *ipv6-address*} [**detail**]  
**sdp** *sdp-id*[:*vc-id*] **mrp**

**Context** show>service>id

**Description** This command displays information for the SDPs associated with the service.  
If no optional parameters are specified, a summary of all associated SDPs is displayed.

**Parameters** *sdp-id* — Displays only information for the specified SDP ID.  
**Values** 1 to 17407  
*vc-id* — Displays only information for the specified virtual circuit ID.  
**Values** 1 to 4294967295  
*ip-address* — Displays only SDPs matching the specified far-end IPv4 address.

*ipv6-address* — Displays only SDPs matching the specified far-end IPv6 address.

**detail** — Displays detailed SDP information.

**mrp** — Displays detailed MRP information.

**Output** The following output is an example of SDP information, and [Table 25](#) describes the output fields.

### Sample Output

```
A:Dut-A# show service id 1 sdp detail

**Table 25 Show Service-ID SDP Output Fields**

| Label               | Description                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sdp Id              | The SDP identifier.                                                                                                                                                          |
| Type                | Indicates whether the SDP is a spoke or a mesh.                                                                                                                              |
| Split Horizon Group | Name of the split horizon group that the SDP belongs to.                                                                                                                     |
| VC Type             | The VC type, Ether, VLAN, or VPLS.                                                                                                                                           |
| VC Tag              | The explicit dot1q value used when encapsulating to the SDP far end.                                                                                                         |
| I. Lbl              | The VC label used by the far-end device to send packets to this device in this service by the SDP.                                                                           |
| Admin Path MTU      | The operating path MTU of the SDP is equal to the admin path MTU (when one is set) or the dynamically computed tunnel MTU, when no admin path MTU is set (the default case). |
| Oper Path MTU       | The actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented.             |
| Far End             | Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.                                                                                    |
| Delivery            | Specifies the type of delivery used by the SDP: GRE or MPLS.                                                                                                                 |

| Oper State                         | The current state of this SDP.                                                                                                                                                                                                                                                            |
| Ingress Label                      | The label used by the far-end device to send packets to this device in this service by this SDP.                                                                                                                                                                                          |
| Egress Label                       | The label used by this device to send packets to the far-end device in this service by the SDP.                                                                                                                                                                                           |
| Last Changed                       | The date and time of the most recent change to the SDP.                                                                                                                                                                                                                                   |
| Signaling                          | Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.                                                                                                                                                        |
| Admin State                        | The administrative state of the Keepalive process.                                                                                                                                                                                                                                        |
| Oper State                         | The operational state of the Keepalive process.                                                                                                                                                                                                                                           |
| Hello Time                         | Transmission frequency of the SDP echo request messages.                                                                                                                                                                                                                                  |
| Max Drop Count                     | Specifies the maximum number of consecutive SDP echo request messages that can be unacknowledged before the keepalive protocol reports a fault.                                                                                                                                           |
| Hello Msg Len                      | The length of the SDP echo request messages transmitted on this SDP.                                                                                                                                                                                                                      |
| Hold Down Time                     | Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.                                                                                                                                                                          |
| I. Fwd. Pkts.                      | Specifies the number of forwarded ingress packets.                                                                                                                                                                                                                                        |
| I. Dro. Pkts                       | Specifies the number of dropped ingress packets.                                                                                                                                                                                                                                          |
| E. Fwd. Pkts.                      | Specifies the number of forwarded egress packets.                                                                                                                                                                                                                                         |
| Associated LSP List                | When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the Far End field.<br><br>If the SDP type is GRE, then the following message displays:<br>SDP delivery mechanism is not MPLS. |
| Ingress Cookie1<br>Ingress Cookie2 | Specifies the ingress cookies configured for an L2TPv3 spoke-SDP binding for an Epipe service. One or two L2TPv3 ingress cookies may be configured.                                                                                                                                       |
| Egress Cookie                      | Specifies the egress cookies configured for an L2TPv3 spoke-SDPs for an Epipe service.                                                                                                                                                                                                    |

**Table 25 Show Service-ID SDP Output Fields (Continued)**

| Label            | Description (Continued)                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Session Mismatch | Specifies a mismatch detected between the configured (far-end binding) cookie to what is received by the local IP address of the L2TPv3 SDP. The flag is set when a mismatch is detected and must be manually cleared by an operator. |

The following examples show both sides (PE nodes) when control word is enabled:

## vccv-bfd

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vccv-bfd [session]</b>                                                                                                |
| <b>Context</b>     | show>service>id                                                                                                          |
| <b>Description</b> | This command shows whether VCCV BFD is configured for a particular service and information about the VCCV session state. |

The **show>service>id>vccv-bfd session** command gives a summary of all the VCCV sessions. Using both the sdp-id and the vc-id parameters gives VCCV BFD session information about a specific spoke-SDP.

For services where auto-discovery and signaling are used (for example, BGP VPWS, VPLS, and BGP-AD VPLS), use the **show>service>id>detail** command to determine the sdp-id and vc-id parameters allocated by the system.

**Parameters** **session** — Displays a summary of all VCCV sessions.

**Output** The following output is an example of VCCV BFD information.

### Sample Output

```
*A:Dut-C# show service id 1000 vccv-bfd session

## wholesalers

**Syntax** **wholesalers**

**Context** show>service>id

**Description** This command displays service wholesaler information.

## ingress-label

**Syntax** **ingress-label** *start-label* [*end-label*]

**Context** show>service

**Description** This command displays services using the range of ingress labels. If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using the range of labels X where *start-label* <= X <= *end-label* are displayed.

Use the **show router vprn-service-id ldp bindings** command to display dynamic labels.

**Parameters** *start-label* — The starting ingress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

**Values** 0, 18432 to 524287

*end-label* — The ending ingress label value for which to display services using the label range.

**Values** 18432 to 524287

**Default** The *start-label* value.

**Output** The following output is an example of ingress label information, and [Table 26](#) describes the output fields.

### Sample Output

```
*A:ALA-12# show service ingress-label 0

**Table 26** Show Service Ingress-Label Output Fields

| Label  | Description                                                                                             |
|--------|---------------------------------------------------------------------------------------------------------|
| Svc ID | The service identifier.                                                                                 |
| SDP Id | The SDP identifier.                                                                                     |
| Type   | Indicates whether the SDP is a spoke or a mesh.                                                         |
| I.Lbl  | The ingress label used by the far-end device to send packets to this device in this service by the SDP. |

**Table 26 Show Service Ingress-Label Output Fields (Continued)**

| Label                    | Description (Continued)                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------|
| E.Lbl                    | The egress label used by this device to send packets to the far-end device in this service by the SDP. |
| Number of Bindings Found | The number of SDP bindings within the label range specified.                                           |

## sap-using

**Syntax**     **sap-using** [**msap**] [**dyn-script**] [**description**]  
**sap-using** [**sap** *sap-id*] [**vlan-translation** | **anti-spoof**] [**description**]  
**sap-using** {**ingress** | **egress**} **atm-td-profile** *td-profile-id*  
**sap-using** {**ingress** | **egress**} **filter** *any-filter-id*  
**sap-using** {**ingress** | **egress**} **qos-policy** *qos-policy-id* [**msap**]  
**sap-using** **etree**

**Context**     show>service

**Description**     This command displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs.

The optional parameters restrict output to only SAPs matching the specified properties.

**Parameters**     **ingress** — Specifies matching an ingress policy.  
**egress** — Specifies matching an egress policy.  
*qos-policy-id* — The ingress or egress QoS Policy ID for which to display matching SAPs.  
**Values**     1 to 65535  
*td-profile-id* — Displays SAPs using this traffic description for the 7750 SR only.  
*filter-id* — The ingress or egress filter policy ID for which to display matching SAPs.  
**Values**     1 to 65535  
*sap-id* — Specifies the physical port identifier portion of the SAP definition.  
**dyn-script** — Displays dynamic service SAPs information.  
**msap** — Displays MSAPs.  
**vlan-translation** — Displays VLAN translation information.  
**anti-spoof** — Displays anti-spoof information.

**Output**     The following output is an example if SAP using information, and [Table 27](#) describes the output fields.

## Sample Output

```
*A:Dut-A# show service sap-using
```

```

**Table 27 Show Service SAP Output Fields**

| Label     | Description                                                                                     |
|-----------|-------------------------------------------------------------------------------------------------|
| Port ID   | The ID of the access port where the SAP is defined.                                             |
| Svc ID    | The service identifier.                                                                         |
| Sap MTU   | The SAP MTU value.                                                                              |
| Ing. QoS  | The SAP ingress QoS policy number specified on the ingress SAP.                                 |
| Ing Fltr  | The MAC or IP filter policy ID applied to the ingress SAP.                                      |
| Egr. QoS  | The SAP egress QoS policy number specified on the egress SAP for the 7450 ESS and 7750 SR only. |
| Egr. Fltr | The MAC or IP filter policy ID applied to the egress SAP.                                       |
| Adm       | The administrative state of the SAP.                                                            |
| Opr       | The operational state of the SAP.                                                               |

## sdp

**Syntax**

```

sdp sdp-id pw-port [pw-port-id]
sdp sdp-id pw-port
sdp sdp-id pw-port pw-port-id [statistics]
sdp [consistent | inconsistent | na] egressifs
sdp sdp-id keep-alive-history
sdp far-end {ip-address | ipv6-address} keep-alive-history
sdp [sdp-id] detail
sdp far-end {ip-address | ipv6-address} [detail]

```

**Context** show>service

**Description** This command displays information for the SDPs associated with the service.

If no optional parameters are specified, a summary of all associated SDPs is displayed.

- Parameters**
- sdp-id* — Specifies the SDP ID for which to display information.  
**Values** 1 to 17407
  - pw-port-id* — Specifies the pseudowire port identifier.  
**Values** 1 to 10239
  - ip-address* — Displays only SDPs with the specified far-end IPv4 address. 64 characters maximum.
  - ipv6-address* — Displays only SDPs with the specified far-end IPv6 address. 64 characters maximum.
  - detail** — Displays detailed SDP information.  
**Default** SDP summary output
  - keep-alive-history** — Displays the last fifty SDP keepalive events for the SDP.  
**Default** SDP summary output

**Output** The following outputs are examples of SDP information.

| <b>Description</b> | <p>This command displays the services matching certain usage properties. Not all syntax options are available for each router type.</p> <p>If no optional parameters are specified, all services defined on the system are displayed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><b>epipe</b> — Displays epipe services.</p> <p><b>ies</b> — Displays IES services.</p> <p><b>vpls</b> — Displays VPLS services.</p> <p><b>vprn</b> — Displays VPRN services.</p> <p><b>mirror</b> — Displays mirror services.</p> <p><b>apipe</b> — Displays Apipe services.</p> <p><b>fpipe</b> — Displays Fpipe services.</p> <p><b>ipipe</b> — Displays Ipipe services.</p> <p><b>cpipe</b> — Displays Cpipe services.</p> <p><b>etree</b> — Displays etree services.</p> <p><b>vsd</b> — Displays VSD services.</p> <p><b>b-vpls</b> — Specifies the B-component instance of the Provider Backbone Bridging (PBB/IEEE 802.1ah) feature. It represents the multi-point tunneling component that multiplexes multiple customer VPNs (ISIDs) together. It is similar to a regular VPLS instance that operates on the backbone MAC addresses.</p> <p><b>i-vpls</b> — Specifies the I-component instance of the Provider Backbone Bridging (PBB/IEEE 802.1ah) feature. It identifies the specific VPN entity associated to a customer multipoint (E-LAN) service. It is similar to a regular VPLS instance that operates on the customer MAC addresses.</p> <p><b>m-vpls</b> — Specifies the M-component (managed VPLS) instance of the Provider Backbone Bridging (PBB/IEEE 802.1ah) feature.</p> |

*sdp-id* — Displays only services bound to the specified SDP ID.

**Values** 1 to 17407

**Default** Services bound to any SDP ID.

*customer-id* — Displays services only associated with the specified customer ID.

**Values** 1 to 2147483647

**Default** Services associated with any customer.

*creation-origin* — Specifies the method by which the service was created.

**Values** manual, multi-segment-p-w, dyn-script, vsd

**Output** The following output is an example of service using information, and [Table 29](#) describes the output fields.

### Sample Output

```
*A:ALA-12# show service service-using customer 10

**Table 29** Show Service-Using Output Fields

| Label            | Description                                                                       |
|------------------|-----------------------------------------------------------------------------------|
| Service Id       | The service identifier.                                                           |
| Type             | Specifies the service type configured for the service ID.                         |
| Adm              | The desired state of the service.                                                 |
| Opr              | The operating state of the service.                                               |
| CustomerID       | The ID of the customer who owns this service.                                     |
| Last Mgmt Change | The date and time of the most recent management-initiated change to this service. |

## spoke-sdp-fec-using

- Syntax** `spoke-sdp-fec-using [spoke-sdp-fec-id spoke-sdp-fec-id] [saii-type2 global-id:prefix:ac-id] [taii-type2 global-id:prefix:ac-id] [path name] [expired]`
- Context** show>service
- Description** Displays the SDPs used by spoke-sdp-fecs at this node.
- Parameters** *spoke-sdp-fec-id* — Specifies the spoke-SDP FEC ID for which to show SDP information.  
**Values** 1 to 4294967295
- global-id* — Specifies the SAII or TAII global ID.  
**Values** 1 to 4294967295
- prefix* — Specifies the SAII or TAII prefix.  
**Values** a.b.c.d, 1 to 4294967295
- ac-id* — Specifies the SAII or TAII AC ID.  
**Values** 1 to 4294967295

**name** — Specifies the path name. 32 characters maximum.

**expired** — Displays information for expired SDPs.

**Output** The following output is an example of spoke-SDP information.

### Sample Output

```
*A:Dut-C# show service spoke-sdp-fec-using
=====
Service Spoke-SDP-Fec Information
=====
```

| SvcId | SpokeSdpFec | Oper-SdpBind     | SAII-Type2     |

## pw-port

**Syntax** **pw-port** [*pw-port-id*] [**detail**]  
**pw-port sdp** *sdp-id*  
**pw-port sdp none**  
**pw-port** *pw-port-id* **statistics**

**Context** show

**Description** Displays pseudowire port information.

If no optional parameters are specified, the command displays a summary of all defined PW ports. The optional parameters restrict output to only ports matching the specified properties.

**Parameters** *pw-port-id* — Specifies the pseudowire port identifier.

**Values** 1 to 10239

**detail** — Displays detailed port information that includes all the **pw-port** output fields.

*sdp-id* — The SDP ID for which to display matching PW port information.

**Values** 1 to 17407

**statistics** — Displays statistics information.

**Output** The following output is an example of PW port information, and [Table 30](#) described the output fields.

### Sample Output

```
*A:ALA-48>config>service# show pw-port
```

```
=====
PW Port Information
=====
PW Port   Encap      SDP      IfIndex      VC-Id
-----
1         dot1q      1        1526726657   1

**Table 30** Show PW-Port Output Fields

| Label       | Description                               |
|-------------|-------------------------------------------|
| PW Port     | The PW Port identifier.                   |
| Encap       | The encapsulation type of the PW Port.    |
| SDP         | The SDP identifier.                       |
| IfIndex     | The interface index used for the PW Port. |
| VC-Id       | The Virtual Circuit identifier.           |
| Description | The description string for the PW Port.   |

## connection-profile

- Syntax** `connection-profile [1 to 8000]`
- Context** `show`
- Description** This command displays connection profile information.
- Parameters** *conn-prof-id* — Specifies the connection profile ID.
- Values** 1 to 8000
- Output** The following output is an example of connection profile information.

### Sample Output

```
*A:Dut-A# show connection-profile

| <b>Description</b> | <p>This command clears commands for a specific service.</p> <p>For the 7450 ESS or 7750 SR, it clears the discovered IPv6 address of the neighboring CE associated with an iPipe SAP. When IPv6CP comes back up following the execution of this command on an IPv6CP SAP, the node will check to see if an IPv6 address has been learned for the remote CE attached to the lpipe service. If one has been learned, then this is used to bring up IPv6CP.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — The ID that uniquely identifies a service.</p> <p><b>Values</b>      <i>service-id</i>: 1 to 214748364<br/>                 <i>svc-name</i>: A string up to 64 characters long.</p> <p><i>service-name</i> — Neighboring IPv6 address, for the 7450 ESS or 7750 SR only.</p>                                                                                                                                                          |

### arp

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp</b>                                                                          |
| <b>Context</b>     | clear>service>id                                                                    |
| <b>Description</b> | This command clears all ARP entries. This command is only valid for lpipe services. |

### host-tracking

|                    |                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>host-tracking</b> [ <b>statistics</b> ]<br><b>host-tracking sap</b> <i>sap-id</i> [ <b>host</b> <i>ip-address</i> ] [ <b>statistics</b> ]                                                                                                                  |
| <b>Context</b>     | clear>service>id                                                                                                                                                                                                                                              |
| <b>Description</b> | This command clears host tracking data.                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>sap-id</i> — Specifies a SAP for which to clear host tracking data.</p> <p><i>ip-address</i> — Specifies the IP address of a host for which to clear tracking data.</p> <p><b>Values</b>      a.b.c.d</p> <p><b>statistics</b> — Clears statistics.</p> |

## mesh-sdp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | This command clears and resets the spoke-SDP bindings for the service.                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>sdp-id</i> — The spoke-SDP ID to be reset.</p> <p><b>Values</b> 1 to 17407</p> <p><i>vc-id</i> — The virtual circuit ID on the SDP ID to be reset.</p> <p><b>Values</b> 1 to 4294967295</p> <p><b>ingress-vc-label</b> — Specifies to clear the ingress VC label.</p> |

**l2tpv3** — Specifies to clear the session mismatch flag on the spoke-SDP binding after the flag was set to true by a detected mismatch between the configured parameters and the received parameters.

**vccv-bfd session** — Specifies to clear a VCCV BFD session for a specified spoke-SDP. Clearing the VCCV BFD session for a specified spoke-SDP will cause the session to go down and restart.

**vccv-bfd statistics** — Specifies to clear a VCCV BFD session statistics for a specified spoke-SDP.

| <b>Description</b> | This command clears SAP statistics for a SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition.<br><b>all</b> — Clears all SAP queue statistics and STP statistics.<br><b>counters</b> — Clears all queue statistics associated with the SAP.<br><b>stp</b> — Clears all STP statistics associated with the SAP.<br><b>l2pt</b> — Clears all L2PT statistics associated with the SAP.<br><b>mrp</b> — Clears all MRP statistics associated with the SAP.<br><i>group-name</i> — Specifies the group name, up to 32 characters.<br><i>encap-id</i> — Specifies the encapsulation ID.<br><b>Values</b> 0 to 16777215 |

## stp

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <b>Syntax</b>      | <b>stp</b>                                              |
| <b>Context</b>     | clear>service>statistics>id                             |
| <b>Description</b> | Clears all spanning tree statistics for the service ID. |

## sdp

|                    |                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sdp</b> <i>sdp-id</i> <b>keep-alive</b><br><b>sdp</b> <i>sdp-id</i> <b>pw-port</b> [1 to 10239]                                                                               |
| <b>Context</b>     | clear>service>statistics                                                                                                                                                         |
| <b>Description</b> | This command clears keepalive statistics associated with the SDP ID.                                                                                                             |
| <b>Parameters</b>  | <i>sdp-id</i> — The SDP ID for which to clear keepalive statistics.<br><b>Values</b> 1 to 17407<br><b>keep-alive</b> — Clears the keep-alive history associated with the SDP ID. |

---

### 2.18.2.3 VLL Debug Commands

#### id

|                    |                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>id</b> <i>service-id</i>                                                                                                                                    |
| <b>Context</b>     | debug>service                                                                                                                                                  |
| <b>Description</b> | This command debugs commands for a specific service.                                                                                                           |
| <b>Parameters</b>  | <i>service-id</i> — The ID that uniquely identifies a service.<br><b>Values</b> service-id: 1 to 214748364<br>svc-name: A string up to 64 characters in length |

#### sap

|                    |                                                      |
|--------------------|------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>sap</b> <i>sap-id</i>                        |
| <b>Context</b>     | debug>service>id                                     |
| <b>Description</b> | This command enables debugging for a particular SAP. |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the SAP ID.                |

#### event-type

|                    |                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>event-type</b> { <b>arp</b>   <b>config-change</b>   <b>oper-status-change</b>   <b>neighbor-discovery</b> }                                                                                                                                                                                                   |
| <b>Context</b>     | debug>service>id>sap                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | This command enables a particular debugging event type.<br><br>The <b>no</b> form of the command disables the event type debugging.                                                                                                                                                                                    |
| <b>Parameters</b>  | <b>arp</b> — Displays ARP events.<br><b>config-change</b> — Debugs configuration change events.<br><b>oper-status-change</b> — Debugs service operational status changes.<br><b>neighbor-discovery</b> — Displays the status of IPv6 neighbor discovery for the sap or the spoke-sdp for the 7450 ESS or 7750 SR only. |
| <b>Output</b>      | The following output is an example of event-type information.                                                                                                                                                                                                                                                          |

#### Sample Output

```
A:bksim180# debug service id 1000 sap 1/7/1 event-type arp
DEBUG OUTPUT show on CLI is as follows:

| <b>Context</b>     | debug>service>id>sdp                                                                                                                  |
| <b>Description</b> | This command enables a particular debugging event type.<br><br>The <b>no</b> form of the command disables the event type debugging.   |

---

**Parameters**

- config-change** — Debugs configuration change events.
- oper-status-change** — Debugs service operational status changes.
- neighbor-discovery** — Displays the status of IPv6 neighbor discovery for the sap or the spoke-sdp for the 7450 ESS or 7750 SR only.
- control-channel-status** —

## 2.18.2.4 VLL Tools Commands

### epipe-map-access-to-egress-port

**Syntax** **epipe-map-access-to-egress-port service** *service-id* [**end-service** *service-id*] | **lag** *lag-id* **summary**

**Context** tools>dump

**Description** This command will display the egress port that will be used to transmit traffic associated with the displayed Epipe service(s). The information displayed shows the egress port for traffic traveling from SAP to egress SDP or SAP.

This command will support Epipe services with the following combinations:

- SAP to SDP (with no endpoint configuration)
- SAP to SAP (with or without an ICB)
- SAP to SDP using endpoints with 1 or 2 SDPs

The command can be executed by specifying either a service ID, service-ID range or an ingress LAG ID.

This command will not display the egress port for traffic traveling from the SDP to egress SAP. This command also does not work with services that use policers or shared queues and also does not support PBB services.

This command replaces the command tools dump epipe-map-to-network, which has been deprecated.

**Parameters**

- service** *service-id* — Identifies the service ID for which the command will return the egress port. If used in conjunction with the end-service parameter, this value represent the beginning of the service ID range for which the command will be executed against.
- Values** 1 to 2148278316, *svc-name: 64 characters max*
- end-service** *service-id* — This parameter is used to identify the end of the service ID range for which the command will be executed against.
- Values** 1 to 2148278316, *svc-name: 64 characters max*

---

*lag-id* — This parameter caused the command to return the egress port for all service with SAPs associated with the specified LAG ID.

**Values**      1 to 800

---

## 3 Virtual Private LAN Service

### 3.1 VPLS Service Overview

VPLS as described in RFC 4905, *Encapsulation methods for transport of layer 2 frames over MPLS*, is a class of virtual private network service that allows the connection of multiple sites in a single bridged domain over a provider-managed IP/MPLS network. The customer sites in a VPLS instance appear to be on the same LAN, regardless of their location. VPLS uses an Ethernet interface on the customer-facing (access) side, which simplifies the LAN/WAN boundary and allows for rapid and flexible service provisioning.

VPLS offers a balance between point-to-point Frame Relay service and outsourced routed services (VPRN). VPLS enables each customer to maintain control of their own routing strategies. All customer routers in the VPLS service are part of the same subnet (LAN), which simplifies the IP addressing plan, especially when compared to a mesh constructed from many separate point-to-point connections. The VPLS service management is simplified since the service is not aware of nor participates in the IP addressing and routing.

A VPLS service provides connectivity between two or more SAPs on one (which is considered a local service) or more (which is considered a distributed service) service routers. The connection appears to be a bridged domain to the customer sites so protocols, including routing protocols, can traverse the VPLS service.

Other VPLS advantages include:

- VPLS is a transparent, protocol-independent service.
- There is no Layer 2 protocol conversion between LAN and WAN technologies.
- There is no need to design, manage, configure, and maintain separate WAN access equipment, which eliminates the need to train personnel on WAN technologies such as Frame Relay.

#### 3.1.1 VPLS Packet Walkthrough

This section provides an example of VPLS processing of a customer packet sent across the network from site A, which is connected to PE Router A, to site B, which is connected to PE Router C (see [Figure 56](#)).

**Figure 56 VPLS Service Architecture**

OSSG201

## 1. PE Router A (Figure 57)

- i. Service packets arriving at PE Router A are associated with a VPLS service instance based on the combination of the physical port and the IEEE 802.1Q tag (VLAN ID) in the packet.

**Figure 57 Access Port Ingress Packet Format and Lookup**

OSSG202

- ii. PE Router A learns the source MAC address in the packet and creates an entry in the FDB table that associates the MAC address with the service access point (SAP) on which it was received.

- iii. The destination MAC address in the packet is looked up in the FDB table for the VPLS instance. There are two possibilities: either the destination MAC address has already been learned (known MAC address) or the destination MAC address is not yet learned (unknown MAC address).

For a Known MAC Address (Figure 58)

- iv. If the destination MAC address has already been learned by PE Router A, an existing entry in the FDB table identifies the far-end PE router and the service VC-label (inner label) to be used before sending the packet to far-end PE Router C.
- v. PE Router A chooses a transport LSP to send the customer packets to PE Router C. The customer packet is sent on this LSP after the IEEE 802.1Q tag is stripped and the service VC-label (inner label) and the transport label (outer label) are added to the packet.

For an Unknown MAC Address (Figure 58)

If the destination MAC address has not been learned, PE Router A will flood the packet to both PE Router B and PE Router C that are participating in the service by using the VC-labels that each PE Router previously added for the VPLS instance. The packet is not sent to PE Router D because this VPLS service does not exist on that PE router.

**Figure 58 Network Port Egress Packet Format and Flooding**

OSSG203

## 2. Core Router Switching

All the core routers (“P” routers in IETF nomenclature) between PE Router A and PE Router B and PE Router C are Label Switch Routers (LSRs) that switch the packet based on the transport (outer) label of the packet until the packet arrives at the far-end PE Router. All core routers are unaware that this traffic is associated with a VPLS service.

### 3. PE Router C

- a. PE Router C strips the transport label of the received packet to reveal the inner VC-label. The VC-label identifies the VPLS service instance to which the packet belongs.
- b. PE Router C learns the source MAC address in the packet and creates an entry in the FDB table that associates the MAC address with PE Router A, and the VC-label that PE Router A added for the VPLS service on which the packet was received.
- c. The destination MAC address in the packet is looked up in the FDB table for the VPLS instance. Again, there are two possibilities: either the destination MAC address has already been learned (known MAC address) or the destination MAC address has not been learned on the access side of PE Router C (unknown MAC address).

For a Known MAC Address ([Figure 59](#))

If the destination MAC address has been learned by PE Router C, an existing entry in the FDB table identifies the local access port and the IEEE 802.1Q tag to be added before sending the packet to customer Location C. The egress Q tag may be different than the ingress Q tag.

## 3.2 VPLS Features

This section provides information about VPLS features.

### 3.2.1 VPLS Enhancements

Nokia's VPLS implementation includes several enhancements beyond basic VPN connectivity. The following VPLS features can be configured individually for each VPLS service instance:

- Extensive MAC and IP filter support (up to Layer 4). Filters can be applied on a per-SAP basis.
- Forwarding Database (FDB) management features on a per service-level basis including:
  - Configurable FDB size limit. On the 7450 ESS, it can be configured on a per-VPLS, per-SAP, and per spoke-SDP basis.
  - FDB size alarms. On the 7450 ESS, it can be configured on a per-VPLS basis.
  - MAC learning disable. On the 7450 ESS, it can be configured on a per-VPLS, per-SAP, and per spoke-SDP basis.
  - Discard unknown. On the 7450 ESS, it can be configured on a per-VPLS basis.
  - Separate aging timers for locally and remotely learned MAC addresses.
- Ingress rate limiting for broadcast, multicast, and unknown destination flooding on a per-SAP basis.
- Implementation of STP parameters on a per-VPLS, per-SAP, and per spoke-SDP basis.
- A split horizon group on a per-SAP and per spoke-SDP basis.
- DHCP snooping and anti-spoofing on a per-SAP and per-SDP basis for the 7450 ESS or 7750 SR.
- IGMP snooping on a per-SAP and per-SDP basis.
- Optional SAP and/or spoke-SDP redundancy to protect against node failure.

## 3.2.2 VPLS over MPLS

The VPLS architecture proposed in RFC 4762, *Virtual Private LAN Services Using LDP Signaling* specifies the use of provider equipment (PE) that is capable of learning, bridging, and replication on a per-VPLS basis. The PE routers that participate in the service are connected using MPLS Label Switched Path (LSP) tunnels in a full-mesh composed of mesh SDPs or based on an LSP hierarchy (Hierarchical VPLS (H-VPLS)) composed of mesh SDPs and spoke-SDPs.

Multiple VPLS services can be offered over the same set of LSP tunnels. Signaling specified in RFC 4905, *Encapsulation methods for transport of layer 2 frames over MPLS* is used to negotiate a set of ingress and egress VC labels on a per-service basis. The VC labels are used by the PE routers for demultiplexing traffic arriving from different VPLS services over the same set of LSP tunnels.

VPLS is provided over MPLS by:

- connecting bridging-capable provider edge routers with a full mesh of MPLS LSP tunnels
- negotiating per-service VC labels using *draft-Martini* encapsulation
- replicating unknown and broadcast traffic in a service domain
- enabling MAC learning over tunnel and access ports (see [VPLS MAC Learning and Packet Forwarding](#))
- using a separate FDB per VPLS service

## 3.2.3 VPLS Service Pseudowire VLAN Tag Processing

VPLS services can be connected using pseudowires that can be provisioned statically or dynamically and are represented in the system as either a mesh or a spoke-SDP. The mesh and spoke-SDP can be configured to process zero, one, or two VLAN tags as traffic is transmitted and received. In the transmit direction, VLAN tags are added to the frame being sent, and in the received direction, VLAN tags are removed from the frame being received. This is analogous to the SAP operations on a null, dot1q, and QinQ SAP.

The system expects a symmetrical configuration with its peer; specifically, it expects to remove the same number of VLAN tags from received traffic as it adds to transmitted traffic. When removing VLAN tags from a mesh or spoke-SDP, the system attempts to remove the configured number of VLAN tags (see the following configuration information); if fewer tags are found, the system removes the VLAN

tags found and forwards the resulting packet. As some of the related configuration parameters are local and not communicated in the signaling plane, an asymmetrical behavior cannot always be detected and so cannot be blocked. With an asymmetrical behavior, protocol extractions will not necessarily function as they would with a symmetrical configuration, resulting in an unexpected operation.

The VLAN tag processing is configured as follows on a mesh or spoke-SDP in a VPLS service:

- Zero VLAN tags processed — VPLS Service Pseudowire VLAN Tag Processing. This requires the configuration of **vc-type ether** under the mesh-SDP or spoke-SDP, or in the related PW template.
- One VLAN tag processed — This requires one of the following configurations:
  - **vc-type vlan** under the mesh-SDP or spoke-SDP, or in the related PW template
  - **vc-type ether** and **force-vlan-vc-forwarding** under the mesh-SDP or spoke-SDP, or in the related PW template
- Two VLAN tags processed—This requires the configuration of **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** under the mesh-SDP or spoke-SDP, or in the related PW template.

The PW template configuration provides support for BGP VPLS services and LDP VPLS services using BGP Auto-Discovery.

The following restrictions apply to VLAN tag processing:

- The configuration of **vc-type vlan** and **force-vlan-vc-forwarding** is mutually exclusive.
- BGP VPLS services operate in a mode equivalent to **vc-type ether**; consequently, the configuration of **vc-type vlan** in a PW template for a BGP VPLS service is ignored.
- **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** can be configured with the mesh-SDP or spoke-SDP signaled as either **vc-type ether** or **vc-type vlan**.
- The following are not supported with **force-qinq-vc-forwarding [c-tag-c-tag | s-tag-c-tag]** configured under the mesh-SDP or spoke-SDP, or in the related PW template:
  - Routed, E-Tree, or PBB VPLS services (including B-VPLS and I-VPLS)
  - L2PT termination on QinQ mesh-SDP or spoke-SDPs
  - IGMP/MLD/PIM snooping within the VPLS service
  - force-vlan-vc-forwarding under the same spoke-SDP or PW template
  - Eth-CFM LM tests

[Table 31](#) and [Table 32](#) describe the VLAN tag processing with respect to the zero, one, and two VLAN tag configuration described for the VLAN identifiers, Ethertype, ingress QoS classification (dot1p/DE), and QoS propagation to the egress (which can be used for egress classification and/or to set the QoS information in the innermost egress VLAN tag).

**Table 31 VPLS Mesh and Spoke-SDP VLAN Tag Processing: Ingress**

| Ingress (received on mesh or spoke-SDP)             | Zero VLAN tags | One VLAN tag                                              | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------|----------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN identifiers                                    | N/A            | Ignored                                                   | Both inner and outer ignored                                                                                                                                                                                                                                                                                                                            |
| Ethertype (to determine the presence of a VLAN tag) | N/A            | 0x8100 or value configured under <b>sdp vlan-vc-etype</b> | Both inner and outer VLAN tags: 0x8100, or outer VLAN tag value configured under <b>sdp vlan-vc-etype</b> (inner VLAN tag value must be 0x8100)                                                                                                                                                                                                         |
| Ingress QoS (dot1p/DE) classification               | N/A            | Ignored                                                   | Both inner and outer ignored                                                                                                                                                                                                                                                                                                                            |
| QoS (dot1p/DE) propagation to egress                | Dot1p/DE=0     | Dot1p/DE taken from received VLAN tag                     | Dot1p/DE taken as follows: <ul style="list-style-type: none"> <li>• If the egress encapsulation is a Dot1q SAP, Dot1p/DE bits are taken from the outer received VLAN tag.</li> <li>• If the egress encapsulation is QinQ SAP, the s-tag bits are taken from the outer received VLAN tag and the c-tag bits from the inner received VLAN tag.</li> </ul> |

**Table 32 VPLS Mesh and Spoke-SDP VLAN Tag Processing: Egress**

| Egress (sent on mesh or spoke-SDP)  | Zero VLAN tags | One VLAN tag                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VLAN identifiers (set in VLAN tags) | N/A            | <p>For one VLAN tag, one of the following applies:</p> <ul style="list-style-type: none"> <li>the <b>vlan-vc-tag</b> value configured in PW template or value under the mesh/spoke-SDP</li> <li>value from the inner tag received on a QinQ SAP or QinQ mesh/spoke-SDP</li> <li>value from the VLAN tag received on a dot1q SAP or mesh/spoke-SDP (with <b>vc-type vlan</b> or <b>force-vlan-vc-forwarding</b>)</li> <li>value from the outer tag received on a qtag.* SAP</li> <li>0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP</li> </ul> | <p>The inner and outer VLAN tags are derived from one of the following:</p> <ul style="list-style-type: none"> <li>vlan-vc-tag value configured in PW template or under the mesh/spoke-SDP: <ul style="list-style-type: none"> <li>If c-tag-c-tag is configured, both inner and outer tags are taken from the vlan-vc-tag value.</li> <li>If s-tag-c-tag is configured, only the s-tag value is taken from vlan-vc-tag.</li> </ul> </li> <li>value from the inner tag received on a QinQ SAP or QinQ mesh/spoke-SDP for the c-tag-c-tag option and value from outer/inner tag received on a QinQ SAP or QinQ mesh/spoke-SDP for the s-tag-c-tag configuration option</li> <li>value from the VLAN tag received on a dot1q SAP or mesh/spoke-SDP (with vc-type vlan or force-vlan-vc-forwarding) for the c-tag-c-tag option and value from the VLAN tag for the outer tag and zero for the inner tag</li> </ul> |

**Table 32 VPLS Mesh and Spoke-SDP VLAN Tag Processing: Egress (Continued)**

| Egress (sent on mesh or spoke-SDP)       | Zero VLAN tags | One VLAN tag                                                                                                                                                                                                                                                                                                                                                                                                    | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          |                |                                                                                                                                                                                                                                                                                                                                                                                                                 | <ul style="list-style-type: none"> <li>value from the outer tag received on a qtag.* SAP for the c-tag-c-tag option and value from the VLAN tag for the outer tag and zero for the inner tag</li> <li>value 0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP Ethertype (set in VLAN tags)</li> </ul>                                                                                                                                                              |
| Ethertype (set in VLAN tags)             | N/A            | 0x8100 or value configured under <b>sdp vlan-vc-etype</b>                                                                                                                                                                                                                                                                                                                                                       | Both inner and outer VLAN tags: 0x8100, or outer VLAN tag value configured under <b>sdp vlan-vc-etype</b> (inner VLAN tag value will be 0x8100)                                                                                                                                                                                                                                                                                                                                                    |
| Egress QoS (dot1p/DE) (set in VLAN tags) | N/A            | <p>Taken from the innermost ingress service delimiting tag, one of the following applies:</p> <ul style="list-style-type: none"> <li>the inner tag received on a QinQ SAP or QinQ mesh/spoke-SDP</li> <li>value from the VLAN tag received on a dot1q SAP or mesh/spoke-SDP (with <b>vc-type vlan</b> or <b>force-vlan-vc-forwarding</b>)</li> <li>value from the outer tag received on a qtag.* SAP</li> </ul> | <p>Inner and outer dot1p/DE:</p> <p>If <b>c-tag-c-tag</b> is configured, the inner and outer dot1p/DE bits are both taken from the innermost ingress service delimiting tag. It can be one of the following:</p> <ul style="list-style-type: none"> <li>inner tag received on a QinQ SAP</li> <li>value from the VLAN tag received on a dot1q SAP or spoke-SDP (with <b>vc-type vlan</b> or <b>force-vlan-vc-forwarding</b>)</li> <li>value from the outer tag received on a qtag.* SAP</li> </ul> |

**Table 32 VPLS Mesh and Spoke-SDP VLAN Tag Processing: Egress (Continued)**

| Egress (sent on mesh or spoke-SDP)       | Zero VLAN tags | One VLAN tag                                                                                                                                                                                                               | Two VLAN Tags (enabled by force-qinq-vc-forwarding [c-tag-c-tag   s-tag-c-tag])                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------------------------------------|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Egress QoS (dot1p/DE) (set in VLAN tags) | N/A            | <ul style="list-style-type: none"> <li>0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP</li> </ul> <p><b>Note:</b> Neither the inner nor outer dot1p/DE values can be explicitly set.</p> | <ul style="list-style-type: none"> <li>0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP</li> </ul> <p>If <b>s-tag-c-tag</b> is configured, the inner and outer dot1p/DE bits are taken from the inner and outer ingress service delimiting tag (respectively). They can be:</p> <ul style="list-style-type: none"> <li>inner and outer tags received on a QinQ SAP or QinQ mesh/spoke-SDP</li> <li>value from the VLAN tag received on a dot1q SAP or mesh/spoke-SDP (with <b>vc-type vlan</b> or force-vlan-vc-forwarding) for the outer tag and zero for the inner tag</li> <li>value from the outer tag received on a qtag.* SAP for the outer tag and zero for the inner tag</li> <li>value 0 if there is no service delimiting VLAN tag at the ingress SAP or mesh/spoke-SDP</li> </ul> |

Any non-service delimiting VLAN tags are forwarded transparently through the VPLS service. SAP egress classification is possible on the outermost customer VLAN tag received on a mesh or spoke-SDP using the **ethernet-ctag** parameter in the associated SAP egress QoS policy.

---

## 3.2.4 VPLS MAC Learning and Packet Forwarding

The 7950 XRS, 7750 SR, and 7450 ESS perform the packet replication required for broadcast and multicast traffic across the bridged domain. MAC address learning is performed by the router to reduce the amount of unknown destination MAC address flooding.

The 7450 ESS, 7750 SR, and 7950 XRS routers learn the source MAC addresses of the traffic arriving on their access and network ports.

Each router maintains an FDB for each VPLS service instance and learned MAC addresses are populated in the FDB table of the service. All traffic is switched based on MAC addresses and forwarded between all objects in the VPLS service. Unknown destination packets (for example, the destination MAC address has not been learned) are forwarded on all objects to all participating nodes for that service until the target station responds and the MAC address is learned by the routers associated with that service.

### 3.2.4.1 MAC Learning Protection

In a Layer 2 environment, subscribers or customers connected to SAPs A or B can create a denial of service attack by sending packets sourcing the gateway MAC address. This will move the learned gateway MAC from the uplink SDP/SAP to the subscriber's or customer's SAP causing all communication to the gateway to be disrupted. If local content is attached to the same VPLS (D), a similar attack can be launched against it. Communication between subscribers or customers is also disallowed but split horizon will not be sufficient in the topology shown in [Figure 60](#).

**Figure 60 MAC Learning Protection**

OSSG189

The 7450 ESS, 7750 SR, and 7950 XRS routers enable MAC learning protection capability for SAPs and SDPs. With this mechanism, forwarding and learning rules apply to the non-protected SAPs. Assume hosts H1, H2, and H3 (Figure 60) are non-protected while IES interfaces G and H are protected. When a frame arrives at a protected SAP/SDP, the MAC is learned as usual. When a frame arrives from a non-protected SAP or SDP, the frame must be dropped if the source MAC address is protected and the MAC address is not relearned. The system allows only packets with a protected MAC destination address.

The system can be configured statically. The addresses of all protected MACs are configured. Only the IP address can be included and use a dynamic mechanism to resolve the MAC address (**cpe-ping**). All protected MACs in all VPLS instances in the network must be configured.

To eliminate the ability of a subscriber or customer to cause a DoS attack, the node restricts the learning of protected MAC addresses based on a statically defined list. Also, the destination MAC address is checked against the protected MAC list to verify that a packet entering a restricted SAP has a protected MAC as a destination.

### 3.2.4.2 DEI in IEEE 802.1ad

The IEEE 802.1ad-2005 standard allows drop eligibility to be conveyed separately from priority in Service VLAN TAGs (S-TAGs) so that all of the previously introduced traffic types can be marked as drop eligible. The S-TAG has a new format where the priority and discard eligibility parameters are conveyed in the 3-bit Priority Code Point (PCP) field and, respectively, in the DE bit (Figure 61).

**Figure 61** DE Bit in the 802.1ad S-TAG

The DE bit allows the S-TAG to convey eight forwarding classes/distinct emission priorities, each with a drop eligible indication.

When the DE bit is set to 0 (DE=FALSE), the related packet is not discard eligible. This is the case for the packets that are within the CIR limits and must be given priority in case of congestion. If the DEI is not used or backwards compliance is required, the DE bit should be set to zero on transmission and ignored on reception.

When the DE bit is set to 1 (DE=TRUE), the related packet is discard eligible. This is the case for the packets that are sent above the CIR limit (but below the PIR). In case of congestion, these packets will be the first ones to be dropped.

### 3.2.5 VPLS Using G.8031 Protected Ethernet Tunnels

The use of MPLS tunnels provides a way to scale the core while offering fast failover times using MPLS FRR. In environments where Ethernet services are deployed using native Ethernet backbones, Ethernet tunnels are provided to achieve the same fast failover times as in the MPLS FRR case. There are still service provider environments where Ethernet services are deployed using native Ethernet backbones.

The Nokia VPLS implementation offers the capability to use core Ethernet tunnels compliant with ITU-T G.8031 specification to achieve 50 ms resiliency for backbone failures. This is required to comply with the stringent SLAs provided by service providers in the current competitive environment. The implementation also allows a LAG-emulating Ethernet tunnel providing a complimentary native Ethernet E-LAN capability. The LAG-emulating Ethernet tunnels and G.8031 protected Ethernet tunnels operate independently (refer to “*LAG emulation using Ethernet Tunnels*” in the *Services Overview Guide*).

When using Ethernet tunnels, the Ethernet tunnel logical interface is created first. The Ethernet tunnel has member ports that are the physical ports supporting the links. The Ethernet tunnel controls SAPs that carry G.8031 and 802.1ag control traffic and user data traffic. Ethernet Service SAPs are configured on the Ethernet tunnel. Optionally, when tunnels follow the same paths, end-to-end services are configured with same-fate Ethernet tunnel SAPs, which carry only user data traffic, and share the fate of the Ethernet tunnel port (if properly configured).

When configuring VPLS and B-VPLS using Ethernet tunnels, the services are very similar.

Refer to the *IEEE 802.1ah PBB Guide* for examples.

### 3.2.6 Pseudowire Control Word

The **control-word** command enables the use of the control word individually on each mesh SDP or spoke-SDP. By default, the control word is disabled. When the control word is enabled, all VPLS packets, including the BPDU frames, are encapsulated with the control word. The Targeted LDP (T-LDP) control plane behavior will be the same as the control word for VLL services. The configuration for the two directions of the Ethernet pseudowire should match.

### 3.2.7 Table Management

The following sections describe VPLS features related to management of the FDB.

### 3.2.7.1 Selective MAC Address Learning

Source MAC addresses are learned in a VPLS service by default with an entry allocated in the FDB for each address on all line cards. Therefore, all MAC addresses are considered to be global. This operation can be modified so that the line card allocation of some MAC addresses is selective, based on where the service has a configured object.

An example of the advantage of selective MAC address learning is for services to benefit from the higher MAC address scale of some line cards (particularly for network interfaces used by mesh or spoke-SDPs, EVPN-VXLAN tunnels, and EVPN-MPLS destinations) while using lower MAC address scale cards for the SAPs.

Selective MAC addresses are those learned locally and dynamically in the data path (displayed in the **show** output with type “L”) or by EVPN (displayed in the **show** output with type “Evpn”, excluding those with the sticky bit set, which are displayed with type “EvpnS”). An exception is when a MAC address configured as a conditional static MAC address is learned dynamically on an object other than its monitored object; this can be displayed with type “L” or “Evpn” but is learned as global because of the conditional static MAC configuration.

Selective MAC addresses have FDB entries allocated on line cards where the service has a configured object. When a MAC address is learned, it is allocated an FDB entry on all line cards on which the service has a SAP configured (for LAG or Ethernet tunnel SAPs, the MAC address is allocated an FDB entry on all line cards on which that LAG or Ethernet tunnel has configured ports) and on all line cards that have a network interface port if the service is configured with VXLAN, EVPN-MPLS, or a mesh or spoke-SDP.

When using selective learning in an I-VPLS service, the learned CMACs are allocated FDB entries on all the line cards where the I-VPLS service has a configured object and on the line cards on which the associated B-VPLS has a configured object. When using selective learning in a VPLS service with **allow-ip-intf-bind** configured (for it to become an R-VPLS), FDB entries are allocated on all line cards on which there is an IES or VPRN interface.

If a new configured object is added to a service and there are sufficient MAC FDB resources available on the new line cards, the selective MAC addresses present in the service are allocated on the new line cards. Otherwise, if any of the selective MAC addresses currently learned in the service cannot be allocated an FDB entry on the new line cards, those MAC addresses will be deleted from all line cards. Such a deletion increments the FailedMacCmplxMapUpdts statistic displayed in the **tools dump service vpls-fdb-stats** output.

When the set of configured objects changes for a service using selective learning, the system must reallocate its FDB entries accordingly, which can cause FDB entry "allocate" or "free" operations to become pending temporarily. The pending operations can be displayed using the **tools dump service id fdb** command.

When a global MAC address is to be learned, there must be a free FDB entry in the service and system FDBs and on all line cards in the system for it to be accepted. When a selective MAC address is to be learned, there must be a free FDB entry in the service and system FDBs and on all line cards where the service has a configured object for it to be accepted.

To demonstrate the selective MAC address learning logic, consider the following:

- a system has three line cards: 1, 2, and 3
- two VPLS services are configured on the system:
  - VPLS 1 having learned MAC addresses M1, M2, and M3 and has configured SAPs 1/1/1 and 2/1/1
  - VPLS 2 having learned MAC addresses M4, M5, and M6 and has configured SAPs 2/1/2 and 3/1/1

This is shown in [Table 33](#).

**Table 33      MAC Address Learning Logic Example**

|       | Learned MAC addresses | Configured SAPs        |
|-------|-----------------------|------------------------|
| VPLS1 | M1, M2, M3            | SAP 1/1/1<br>SAP 2/1/1 |
| VPLS2 | M4, M5, M6            | SAP 2/1/2<br>SAP 3/1/1 |

[Figure 62](#) shows the FDB entry allocation when the MAC addresses are global and when they are selective. Notice that in the selective case, all MAC addresses are allocated FDB entries on line card 2, but line card 1 and 3 only have FDB entries allocated for services VPLS 1 and VPLS 2, respectively.

**Figure 62 MAC FDB Entry Allocation: Global versus Selective**

| MAC FDB Entry Allocation: Global (Default) |        |             |        |             |        |
|--------------------------------------------|--------|-------------|--------|-------------|--------|
| Line Card 1                                |        | Line Card 2 |        | Line Card 3 |        |
| VPLS 1                                     | VPLS 2 | VPLS 1      | VPLS 2 | VPLS 1      | VPLS 2 |
| M1                                         | M4     | M1          | M4     | M1          | M4     |
| M2                                         | M5     | M2          | M5     | M2          | M5     |
| M3                                         | M6     | M3          | M6     | M3          | M6     |

| MAC FDB Entry Allocation: Selective |        |             |        |             |        |
|-------------------------------------|--------|-------------|--------|-------------|--------|
| Line Card 1                         |        | Line Card 2 |        | Line Card 3 |        |
| VPLS 1                              | VPLS 2 | VPLS 1      | VPLS 2 | VPLS 1      | VPLS 2 |
| M1                                  |        | M1          | M4     |             | M4     |
| M2                                  |        | M2          | M5     |             | M5     |
| M3                                  |        | M3          | M6     |             | M6     |

sw0069

Selective MAC address learning can be enabled as follows within any VPLS service, except for B-VPLS and R-VPLS services:

```
configure
  service
    vpls <service-id> create
    [no] selective-learned-fdb
```

Enabling selective MAC address learning has no effect on single line card systems.

When selective learning is enabled or disabled in a VPLS service, the system may need to reallocate FDB entries; this can cause temporary pending FDB entry allocate or free operations. The pending operations can be displayed using the **tools dump service id fdb** command.

### 3.2.7.1.1 Example Operational Information

The **show** and **tools dump** command output can display the global and selective MAC addresses along with the MAC address limits and the number of allocated and free MAC-address FDB entries. The **show** output displays the system and card FDB usage, while the **tools** output displays the FDB per service with respect to MAC addresses and cards.

The configuration for the following output is similar to the simple example above:

- the system has three line cards: 1, 2, and 5
- the system has two VPLS services:
  - VPLS 1 is an EVPN-MPLS service with a SAP on 5/1/1:1 and uses a network interface on 5/1/5.
  - VPLS 2 has two SAPs on 2/1/1:2 and 2/1/2:2.

The first output shows the default where all MAC addresses are global. The second enables selective learning in the two VPLS services.

### Global MAC address learning only (default)

By default, VPLS 1 and 2 are not configured for selective learning, so all MAC addresses are global:

```
*A:PE1# show service id [1,2] fdb | match expression ", Service|Sel Learned FDB"
Forwarding Database, Service 1
Sel Learned FDB    : Disabled
Forwarding Database, Service 2
Sel Learned FDB    : Disabled
*A:PE1#
```

Traffic is sent into the services, resulting in the following MAC addresses being learned:

```
*A:PE1# show service fdb-mac
=====
Service Forwarding Database

No. of Entries: 8
-----
Legend:  L=Learned O=Oam P=Protected-MAC C=Conditional S=Static Lf=Leaf
=====
*A:PE1#
```

A total of eight MAC addresses are learned. There are two MAC addresses learned locally on SAP 5/1/1:1 in service VPLS 1 (type “L”), and another two MAC addresses learned using EVPN with the sticky bit set, also in service VPLS 1 (type “EvpnS”). A further two sets of two MAC addresses are learned on SAP 2/1/1:2 and 2/1/2:2 in service VPLS 2 (type “L”).

The system and line card FDB usage is shown as follows:

```
*A:PE1# show service system fdb-usage
=====
FDB Usage

Card        Selective    Allocated    Limit        Free
-----
1           0              8            511999       511991
2           0              8            511999       511991
5           0              8            511999       511991
-----
=====
*A:PE1#
```

The system MAC address limit is 511999, of which eight are allocated, and the rest are free. All eight MAC addresses are global and are allocated on cards 1, 2, and 5. There are no selective MAC addresses. This output can be reduced to specific line cards by specifying the card’s slot ID as a parameter to the command.

To see the MAC address information per service, **tools dump** commands can be used, as follows for VPLS 1. The following output displays the card status:

```
*A:PE1# tools dump service id 1 fdb card-status
=====
VPLS FDB Card Status at 01/31/2017 08:44:38
=====
Card        Allocated    PendAlloc    PendFree
-----
1           4            0            0
2           4            0            0
5           4            0            0
=====
*A:PE1#
```

All of the line cards have four FDB entries allocated in VPLS 1. The “PendAlloc” and “PendFree” columns show the number of pending MAC address allocate and free operations, which are all zero.

The following output displays the MAC address status for VPLS 1:

```
*A:PE1# tools dump service id 1 fdb mac-status
=====
VPLS FDB MAC status at 01/31/2017 08:44:38
=====
MAC Address          Type          Status : Card list
-----
00:00:00:00:01:01    Global        Allocated : All
00:00:00:00:01:02    Global        Allocated : All
00:00:00:00:01:03    Global        Allocated : All
00:00:00:00:01:04    Global        Allocated : All
=====
*A:PE1#
```

The type and card list for each MAC address in VPLS 1 is displayed. VPLS 1 has learned four MAC addresses: the two local MAC addresses on SAP 5/1/1:1 and the two EvpnS MAC addresses. Each MAC address has an FDB entry allocated on all line cards. This output can be further reduced by optionally including a specified MAC address, a specific card, and the operational pending state.

### Selective and global MAC address learning

Selective MAC address learning is now enabled in VPLS 1 and VPLS 2, as follows:

```
*A:PE1# show service id [1,2] fdb | match expression ", Service|Sel Learned FDB"
Forwarding Database, Service 1
Sel Learned FDB    : Enabled
Forwarding Database, Service 2
Sel Learned FDB    : Enabled
*A:PE1#
```

The MAC addresses learned are the same, with the same traffic being sent; however, there are now selective MAC addresses that are allocated FDB entries on different line cards.

The system and line card FDB usage is as follows:

```
*A:PE1# show service system fdb-usage
=====
FDB Usage
=====
System
-----
Limit:      511999
Allocated:  8
Free:       511991
Global:     2
-----
Line Cards
-----
Card          Selective      Allocated      Limit          Free
```

```

-----
1          0          2          511999          511997
2          4          6          511999          511993
5          2          4          511999          511995
-----
=====
*A:PE1#

```

The system MAC address limit and allocated numbers have not changed but now there are only two global MAC addresses; these are the two EvpnS MAC addresses.

There are two FDB entries allocated on card 1, which are the global MAC addresses; there are no services or network interfaces configured on card 1, so the FDB entries allocated are for the global MAC addresses.

Card 2 has six FDB entries allocated in total: two for the global MAC addresses plus four for the selective MAC addresses in VPLS 2 (these are the two sets of two local MAC addresses in VPLS 2 on SAP 2/1/1:2 and 2/1/2:2).

Card 5 has four FDB entries allocated in total: two for the global MAC addresses plus two for the selective MAC addresses in VPLS 1 (these are the two local MAC addresses in VPLS 1 on SAP 5/1/1:1).

This output can be reduced to specific line cards by specifying the card's slot ID as a parameter to the command.

To see the MAC address information per service, **tools dump** commands can be used for VPLS 1.

The following output displays the card status:

```

*A:PE1# tools dump service id 1 fdb card-status
=====
VPLS FDB Card Status at 01/31/2017 08:44:39
=====
Card          Allocated          PendAlloc          PendFree
-----
1              2              0              0
2              2              0              0
5              4              0              0
=====
*A:PE1#

```

There are two FDB entries allocated on line card 1, two on line card 2, and four on line card 5. The "PendAlloc" and "PendFree" columns are all zeros.

The following output displays the MAC address status for VPLS 1:

```

*A:PE1# tools dump service id 1 fdb mac-status
=====
VPLS FDB MAC status at 01/31/2017 08:44:39
=====

```

```

MAC Address      Type      Status : Card list
-----
00:00:00:00:01:01  Select    Allocated : 5
00:00:00:00:01:02  Select    Allocated : 5
00:00:00:00:01:03  Global    Allocated : All
00:00:00:00:01:04  Global    Allocated : All
=====
*A:PE1#

```

The type and card list for each MAC address in VPLS 1 is displayed. VPLS 1 has learned four MAC addresses: the two local MAC addresses on SAP 5/1/1:1 and the two EvpnS MAC addresses. The local MAC addresses are selective and have FDB entries allocated only on card 5. The global MAC addresses are allocated on all line cards. This output can be further reduced by optionally including a specified MAC address, a specific card, and the operational pending state.

### 3.2.7.2 System FDB Size

The system FDB table size is configurable as follows:

```

configure
  service
    system
      fdb-table-size table-size

```

where table-size can have values in the range from 255999 to 2047999 (2000k).

The default, minimum, and maximum values for the table size are dependent on the chassis type. To support more than 500k MAC addresses, the CPMs provisioned in the system must have at least 16 GB memory. The maximum system FDB table size also limits the maximum FDB table size of any card within the system.

The actual achievable maximum number of MAC addresses depends on the MAC address scale supported by the active cards and whether selective learning is enabled.

If an attempt is made to configure the system FDB table size such that:

- the new size is greater than or equal to the current number of allocated FDB entries, the command succeeds and the new system FDB table size is used
- the new size is less than the number of allocated FDB entries, the command fails with an error message. In this case, the user is expected to reduce the current FDB usage (for example, by deleting statically configured MAC addresses, shutting down EVPN, clearing learned MACs, and so on) to lower the number of allocated MAC addresses in the FDB so that it does not exceed the system FDB table size being configured.

The logic when attempting a rollback is similar; however, when rolling back to a configuration where the system FDB table size is smaller than the current system FDB table size, the system will flush all learned MAC addresses (by performing a **shutdown** then **no shutdown** in all VPLS services) to allow the rollback to continue.

The system FDB table size can be larger than some of the line card FDB sizes, resulting in the possibility that the current number of allocated global MAC addresses is larger than the maximum FDB size supported on some line cards. When a new line card is provisioned, the system checks whether the line card's FDB can accommodate all of the currently allocated global MAC addresses. If it can, then the provisioning succeeds; if it cannot, then the provisioning fails and an error is reported. If the provisioning fails, the number of global MACs allocated must be reduced in the system to a number that the new line card can accommodate, then the **card-type** must be reprovisioned.

### 3.2.7.3 Per-VPLS Service FDB Size

The following MAC table management features are available for each instance of a SAP or spoke-SDP within a particular VPLS service instance:

- MAC FDB size limits — Allows users to specify the maximum number of MAC FDB entries that are learned locally for a SAP or remotely for a spoke-SDP. If the configured limit is reached, no new addresses will be learned from the SAP or spoke-SDP until at least one FDB entry is aged out or cleared.
  - When the limit is reached on a SAP or spoke-SDP, packets with unknown source MAC addresses are still forwarded (this default behavior can be changed by configuration). By default, if the destination MAC address is known, it is forwarded based on the FDB, and if the destination MAC address is unknown, it will be flooded. Alternatively, if discard unknown is enabled at the VPLS service level, any packets from unknown source MAC addresses are discarded at the SAP.
  - The log event SAP MAC Limit Reached is generated when the limit is reached. When the condition is cleared, the log event SAP MAC Limit Reached Condition Cleared is generated.
  - Disable learning allows users to disable the dynamic learning function on a SAP or a spoke-SDP of a VPLS service instance.
  - Disable aging allows users to turn off aging for learned MAC addresses on a SAP or a spoke-SDP of a VPLS service instance.

### **3.2.7.4 System FDB Size Alarms**

High and low watermark alarms give warning when the system MAC FDB usage is high. An alarm is generated when the number of FDB entries allocated in the system FDB reaches 95% of the total system FDB table size and is cleared when it reduces to 90% of the system FDB table size. These percentages are not configurable.

### **3.2.7.5 Line Card FDB Size Alarms**

High and low watermark alarms give warning when a line card's MAC FDB usage is high. An alarm is generated when the number of FDB entries allocated in a line card FDB reaches 95% of its maximum FDB table size and is cleared when it reduces to 90% of its maximum FDB table size. These percentages are not configurable.

### **3.2.7.6 Per VPLS FDB Size Alarms**

The size of the VPLS FDB can be configured with a low watermark and a high watermark, expressed as a percentage of the total FDB size limit. If the actual FDB size grows above the configured high watermark percentage, an alarm is generated. If the FDB size falls below the configured low watermark percentage, the alarm is cleared by the system.

### **3.2.7.7 Local and Remote Aging Timers**

Like a Layer 2 switch, learned MACs within a VPLS instance can be aged out if no packets are sourced from the MAC address for a specified period of time (the aging time). In each VPLS service instance, there are independent aging timers for locally learned MAC and remotely learned MAC entries in the FDB. A local MAC address is a MAC address associated with a SAP because it ingresses on a SAP. A remote MAC address is a MAC address received by an SDP from another router for the VPLS instance. The local-age timer for the VPLS instance specifies the aging time for locally learned MAC addresses, and the remote-age timer specifies the aging time for remotely learned MAC addresses.

In general, the remote-age timer is set to a longer period than the local-age timer to reduce the amount of flooding required for unknown destination MAC addresses. The aging mechanism is considered a low priority process. In most situations, the aging out of MAC addresses happens within tens of seconds beyond the age time. However, it, can take up to two times their respective age timer to be aged out.

---

### **3.2.7.8 Disable MAC Aging**

The MAC aging timers can be disabled, which will prevent any learned MAC entries from being aged out of the FDB. When aging is disabled, it is still possible to manually delete or flush learned MAC entries. Aging can be disabled for learned MAC addresses on a SAP or a spoke-SDP of a VPLS service instance.

### **3.2.7.9 Disable MAC Learning**

When MAC learning is disabled for a service, new source MAC addresses are not entered in the VPLS FDB, whether the MAC address is local or remote. MAC learning can be disabled for individual SAPs or spoke-SDPs.

### **3.2.7.10 Unknown MAC Discard**

Unknown MAC discard is a feature that discards all packets ingressing the service where the destination MAC address is not in the FDB. The normal behavior is to flood these packets to all endpoints in the service.

Unknown MAC discard can be used with the disable MAC learning and disable MAC aging options to create a fixed set of MAC addresses allowed to ingress and traverse the service.

### **3.2.7.11 VPLS and Rate Limiting**

Traffic that is normally flooded throughout the VPLS can be rate limited on SAP ingress through the use of service ingress QoS policies. In a service ingress QoS policy, individual queues can be defined per forwarding class to provide shaping of broadcast traffic, MAC multicast traffic, and unknown destination MAC traffic.

### **3.2.7.12 MAC Move**

The MAC move feature is useful to protect against undetected loops in a VPLS topology as well as the presence of duplicate MACs in a VPLS service.

If two clients in the VPLS have the same MAC address, the VPLS will experience a high relearn rate for the MAC. When MAC move is enabled, the 7450 ESS, 7750 SR, or 7950 XRS will shut down the SAP or spoke-SDP and create an alarm event when the threshold is exceeded.

MAC move allows sequential order port blocking. By configuration, some VPLS ports can be configured as “non-blockable”, which allows a simple level of control of which ports are being blocked during loop occurrence. There are two sophisticated control mechanisms that allow blocking of ports in a sequential order:

1. Configuration capabilities to group VPLS ports and to define the order in which they should be blocked
2. Criteria defining when individual groups should be blocked

For the first control mechanism, configuration CLI is extended by definition of “primary” and “secondary” ports. Per default, all VPLS ports are considered “tertiary” ports unless they are explicitly declared primary or secondary. The order of blocking will always follow a strict order starting from tertiary to secondary, and then primary.

The definition of criteria for the second control mechanism is the number of periods during which the specified relearn rate has been exceeded. The mechanism is based on the cumulative factor for every group of ports. Tertiary VPLS ports are blocked if the relearn rate exceeds the configured threshold during one period, while secondary ports are blocked only when relearn rates are exceeded during two consecutive periods, and primary ports when exceeded during three consecutive periods. The retry timeout period must be larger than the period before blocking the highest priority port so that the retry timeout sufficiently spans across the period required to block all ports in sequence. The period before blocking the highest priority port is the cumulative factor of the highest configured port multiplied by 5 seconds (the retry timeout can be configured through the CLI).

### **3.2.7.13 Auto-Learn MAC Protect**

This section provides information about auto-learn-mac-protect and restrict-protected-src discard-frame features.

VPLS solutions usually involve learning MAC addresses in order for traffic to be forwarded to the correct SAP/SDP. If a MAC address is learned on the wrong SAP/SDP, traffic would be redirected away from its intended destination. This could occur through a misconfiguration, a problem in the network, or by a malicious source creating a DoS attack, and is applicable to any type of VPLS network; for example, mobile backhaul or residential service delivery networks. The auto-learn-mac-protect feature can be used to safeguard against the possibility of MAC addresses being learned on the wrong SAP/SDP.

This feature provides the ability to automatically protect source MAC addresses that have been learned on a SAP or a spoke/mesh SDP and prevent frames with the same protected source MAC address from entering into a different SAP/spoke or mesh SDP.

This is a complementary solution to features such as mac-move and mac-pinning, but has the advantage that MAC moves are not seen and it has a low operational complexity. If a MAC is initially learned on the wrong SAP/SDP, the operator can clear the MAC from the MAC FDB in order for it to be relearned on the correct SAP/SDP.

Two separate commands are used, which provide the configuration flexibility of separating the identification (learning) function from the application of the restriction (discard).

The **auto-learn-mac-protect** and **restrict-protected-src** commands allow the following functions:

- the ability to enable the automatic protection of a learned MAC using the **auto-learn-mac-protect** command under a SAP/spoke or mesh SDP/SHG context
- the ability to discard frames associated with automatically protected MACs instead of shutting down the entire SAP/SDP as with the restrict-protected-src feature. This is enabled using a **restrict-protected-src discard-frame** command in the SAP/spoke or mesh SDP/SHG context. An optimized alarm mechanism is used to generate alarms related to these discards. The frequency of alarm generation is fixed to be, at most, one alarm per MAC address per forwarding complex per 10 minutes in a VPLS service.

If the auto-learn-mac-protect or restrict-protected-src discard-frame feature is configured under an SHG, the operation applies only to SAPs in the SHG, not to spoke-SDPs in the SHG. If required, these parameters can also be enabled explicitly under specific SAPs/spoke-SDPs within the SHG.

Applying or removing auto-learn-mac-protect or restrict-protected-src discard-frame to/from a SAP, spoke or mesh SDP, or SHG, will clear the MACs on the related objects (for the SHG, this results in clearing the MACs only on the SAPs within the SHG).

The use of restrict-protected-src discard-frame is mutually exclusive with both the **restrict-protected-src [alarm-only]** command and with the configuration of manually protected MAC addresses, using the **mac-protect** command, within a specified VPLS.

The following rules govern the changes to the state of protected MACs:

- Automatically learned protected MACs are subject to normal removal, aging (unless disabled), and flushing, at which time the associated entries are removed from the FDB.
- Automatically learned protected MACs can only move from their learned SAP/spoke or mesh SDP if they enter a SAP/spoke or mesh SDP without restrict-protected-src enabled.

If a MAC address does legitimately move between SAPs/spoke or mesh SDPs after it has been automatically protected on a specified SAP/spoke or mesh SDP (thereby causing discards when received on the new SAP/spoke or mesh SDP), the operator must manually clear the MAC from the FDB for it to be learned in the new/correct location.

MAC addresses that are manually created (using static-mac, static-host with a MAC address specified, or oam mac-populate) will not be protected even if they are configured on a SAP/spoke or mesh SDP that has auto-learn-mac-protect enabled on it. Also, the MAC address associated with an R-VPLS IP interface is protected within its VPLS service such that frames received with this MAC address as the source address are discarded (this is not based on the auto-learn MAC protect function). However, VRRP MAC addresses associated with an R-VPLS IP interface are not protected either in this way or using the auto-learn MAC protect function.

MAC addresses that are dynamically created (learned, using static-host with no MAC address specified, or lease-populate) will be protected when the MAC address is learned on a SAP/spoke or mesh SDP that has auto-learn-mac-protect enabled on it.

The actions of the following features are performed in the order listed.

1. Restrict-protected-src
2. MAC-pinning
3. MAC-move

### 3.2.7.13.1 Operation

[Figure 63](#) shows a specific configuration using auto-learn-mac-protect and restrict-protected-src discard-frame in order to describe their operation for the 7750 SR, 7450 ESS, or 7950 XRS.

**Figure 63 Auto-Learn-Mac-Protect Operation**

A VPLS service is configured with SAP1 and SDP1 connecting to access devices and SAP2, SAP3, and SDP2 connecting to the core of the network. The auto-learn-mac-protect feature is enabled on SAP1, SAP3, and SDP1, and restrict-protected-src discard-frame is enabled on SAP1, SDP1, and SDP2. The following series of events describes the details of the functionality:

Assume that the FDB is empty at the start of each sequence.

Sequence 1:

1. A frame with source MAC A enters SAP1, MAC A is learned on SAP1, and MAC-A/SAP1 is protected because of the presence of the auto-learn-mac-protect on SAP1.
2. All subsequent frames with source MAC A entering SAP1 are forwarded into the VPLS.
3. Frames with source MAC A enter either SDP1 or SDP2, these frames are discarded, and an alarm indicating MAC A and SDP1/SDP2 is initiated because of the presence of the restrict-protected-src discard-frame on SDP1/SDP2.
4. The above continues, with MAC-A/SAP1 protected in the FDB until MAC A on SAP1 is removed from the FDB.

Sequence 2:

1. A frame with source MAC A enters SAP1, MAC A is learned on SAP1, and MAC-A/SAP1 is protected because of the presence of the auto-learn-mac-protect on SAP1.
2. A frame with source MAC A enters SAP2. As restrict-protected-src is not enabled on SAP2, MAC A is relearned on SAP2 (but not protected), replacing the MAC-A/SAP1 entry in the FDB.

3. All subsequent frames with source MAC A entering SAP2 are forwarded into the VPLS. This is because restrict-protected-src is not enabled on SAP2 and auto-learn-mac-protect is not enabled on SAP2, so the FDB is not changed.
4. A frame with source MAC A enters SAP1, MAC A is relearned on SAP1, and MAC-A/SAP1 is protected because of the presence of the auto-learn-mac-protect on SAP1.

Sequence 3:

1. A frame with source MAC A enters SDP2, MAC A is learned on SDP2, but is not protected as auto-learn-mac-protect is not enabled on SDP2.
2. A frame with source MAC A enters SDP1, and MAC A is relearned on SDP1 because previously it was not protected. Consequently, MAC-A/SDP1 is protected because of the presence of the auto-learn-mac-protect on SDP1.

Sequence 4:

1. A frame with source MAC A enters SAP1, MAC A is learned on SAP1, and MAC-A/SAP1 is protected because of the presence of the auto-learn-mac-protect on SAP1.
2. A frame with source MAC A enters SAP3. As restrict-protected-src is not enabled on SAP3, MAC A is relearned on SAP3 and the MAC-A/SAP1 entry is removed from the FDB with MAC-A/SAP3 being added as protected to the FDB (because auto-learn-mac-protect is enabled on SAP3).
3. All subsequent frames with source MAC A entering SAP3 are forwarded into the VPLS.
4. A frame with source MAC A enters SAP1, these frames are discarded, and an alarm indicating MAC A and SAP1 is initiated because of the presence of the restrict-protected-src discard-frame on SAP1.

Example Use

[Figure 64](#) shows a possible configuration using auto-learn-mac-protect and restrict-protected-src discard-frame in a mobile backhaul network, with the focus on PE1 for the 7750 SR or 7950 XRS.

**Figure 64 Auto-Learn-Mac-Protect Example**

To protect the MAC addresses of the BNG/RNCs on PE1, the **auto-learn-mac-protect** command is enabled on the pseudowires connecting PE1 to PE2 and PE3. Enabling the **restrict-protected-src discard-frame** command on the SAPs toward the eNodeBs will prevent frames with the source MAC addresses of the BNG/RNCs from entering PE1 from the eNodeBs.

The MAC addresses of the eNodeBs are protected in two ways. In addition to the above commands, enabling the **auto-learn-mac-protect** command on the SAPs toward the eNodeBs will prevent the MAC addresses of the eNodeBs being learned on the wrong eNodeB SAP. Enabling the **restrict-protected-src discard-frame** command on the pseudowires connecting PE1 to PE2 and PE3 will protect the eNodeB MAC addresses from being learned on the pseudowires. This may happen if their MAC addresses are incorrectly injected into VPLS 40 on PE2/PE3 from another eNodeB aggregation PE.

The above configuration is equally applicable to other Layer 2 VPLS-based aggregation networks; for example, to business or residential service networks.

---

### 3.2.8 Split Horizon SAP Groups and Split Horizon Spoke SDP Groups

Within the context of VPLS services, a loop-free topology within a fully meshed VPLS core is achieved by applying a split horizon forwarding concept that packets received from a mesh SDP are never forwarded to other mesh SDPs within the same service. The advantage of this approach is that no protocol is required to detect loops within the VPLS core network.

In applications such as DSL aggregation, it is useful to extend this split horizon concept also to groups of SAPs and/or spoke-SDPs. This extension is referred to as a split horizon SAP group or residential bridging.

Traffic arriving on a SAP or a spoke-SDP within a split horizon group will not be copied to other SAPs and spoke-SDPs in the same split horizon group (but will be copied to SAPs/spoke-SDPs in other split horizon groups if these exist within the same VPLS).

### 3.2.9 VPLS and Spanning Tree Protocol

Nokia's VPLS service provides a bridged or switched Ethernet Layer 2 network. Equipment connected to SAPs forward Ethernet packets into the VPLS service. The 7450 ESS, 7750 SR, or 7950 XRS participating in the service learns where the customer MAC addresses reside, on ingress SAPs or ingress SDPs.

Unknown destinations, broadcasts, and multicasts are flooded to all other SAPs in the service. If SAPs are connected together, either through misconfiguration or for redundancy purposes, loops can form and flooded packets can keep flowing through the network. The Nokia implementation of the STP is designed to remove these loops from the VPLS topology. This is done by putting one or several SAPs and/or spoke-SDPs in the discarding state.

Nokia's implementation of STP incorporates some modifications to make the operational characteristics of VPLS more effective.

The STP instance parameters allow the balancing between resiliency and speed of convergence extremes. Modifying particular parameters can affect the behavior. For information on command usage, descriptions, and CLI syntax, see [Configuring a VPLS Service with CLI](#).

### 3.2.9.1 Spanning Tree Operating Modes

Per VPLS instance, a preferred STP variant can be configured. The STP variants supported are:

- `rstp` — Rapid Spanning Tree Protocol (RSTP) compliant with IEEE 802.1D-2004 - default mode
- `dot1w` — Compliant with IEEE 802.1w
- `comp-dot1w` — Operation as in RSTP but backwards compatible with IEEE 802.1w (this mode allows interoperability with some MTU types)
- `mstp` — Compliant with the Multiple Spanning Tree Protocol specified in IEEE 802.1Q-REV/D5.0-09/2005. This mode of operation is only supported in a Management VPLS (M-VPLS).

While the 7450 ESS, 7750 SR, or 7950 XRS initially use the mode configured for the VPLS, it will dynamically fall back (on a per-SAP basis) to STP (IEEE 802.1D-1998) based on the detection of a BPDU of a different format. A trap or log entry is generated for every change in spanning tree variant.

Some older 802.1w compliant RSTP implementations may have problems with some of the features added in the 802.1D-2004 standard. Interworking with these older systems is improved with the `comp-dot1w` mode. The differences between the RSTP mode and the `comp-dot1w` mode are:

- The RSTP mode implements the improved convergence over shared media feature; for example, RSTP will transition from discarding to forwarding in 4 seconds when operating over shared media. The `comp-dot1w` mode does not implement this 802.1D-2004 improvement and transitions conform to 802.1w in 30 seconds (both modes implement fast convergence over point-to-point links).
- In the RSTP mode, the transmitted BPDUs contain the port's designated priority vector (DPV) (conforms to 802.1D-2004). Older implementations may be confused by the DPV in a BPDU and may fail to recognize an agreement BPDU correctly. This would result in a slow transition to a forwarding state (30 seconds). For this reason, in the `comp-dot1w` mode, these BPDUs contain the port's port priority vector (conforms to 802.1w).

The 7450 ESS, 7750 SR, and 7950 XRS support two BPDU encapsulation formats, and can dynamically switch between the following supported formats (on a per-SAP basis):

- IEEE 802.1D STP
- Cisco PVST

---

### 3.2.9.2 Multiple Spanning Tree

The Multiple Spanning Tree Protocol (MSTP) extends the concept of IEEE 802.1w RSTP by allowing grouping and associating VLANs to Multiple Spanning Tree Instances (MSTI). Each MSTI can have its own topology, which provides architecture enabling load balancing by providing multiple forwarding paths. At the same time, the number of STP instances running in the network is significantly reduced as compared to Per VLAN STP (PVST) mode of operation. Network fault tolerance is also improved because a failure in one instance (forwarding path) does not affect other instances.

The Nokia implementation of M-VPLS is used to group different VPLS instances under a single RSTP instance. Introducing MSTP into the M-VPLS allows interoperating with traditional Layer 2 switches in an access network and provides an effective solution for dual homing of many business Layer 2 VPNs into a provider network.

#### 3.2.9.2.1 Redundancy Access to VPLS

The GigE MAN portion of the network is implemented with traditional switches. Using MSTP running on individual switches facilitates redundancy in this part of the network. To provide dual homing of all VPLS services accessing from this part of the network, the VPLS PEs must participate in MSTP.

This can be achieved by configuring M-VPLS on VPLS-PEs (only PEs directly connected to the GigE MAN network), then assigning different managed-VLAN ranges to different MSTP instances. Typically, the M-VPLS would have SAPs with null encapsulations (to receive, send, and transmit MSTP BPDUs) and a mesh SDP to interconnect a pair of VPLS PEs.

Different access scenarios are displayed in [Figure 65](#) as an example of network diagrams dually connected to the PBB PEs:

- Access Type A — Source devices connected by null or dot1q SAPs
- Access Type B — One QinQ switch connected by QinQ/801ad SAPs
- Access Type C — Two or more ES devices connected by QinQ/802.1ad SAPs

**Figure 65 Access Resiliency**

The following mechanisms are supported for the I-VPLS:

- STP/RSTP can be used for all access types.
- M-VPLS with MSTP can be used as is just for access type A. MSTP is required for access type B and C.
- LAG and MC-LAG can be used for access type A and B.
- Split-horizon-group does not require residential.

PBB I-VPLS inherits current STP configurations from the regular VPLS and M-VPLS.

### 3.2.9.3 MSTP for QinQ SAPs

MSTP runs in a M-VPLS context and can control SAPs from source VPLS instances. QinQ SAPs are supported. The outer tag is considered by MSTP as part of VLAN range control.

---

### 3.2.9.4 Provider MSTP

Provider MSTP is specified in IEEE-802.1ad-2005. It uses a provider bridge group address instead of a regular bridge group address used by STP, RSTP, and MSTP BPDUs. This allows for implicit separation of source and provider control planes.

The 802.1ad access network sends PBB PE P-MSTP BPDUs using the specified MAC address and also works over QinQ interfaces. P-MSTP mode is used in PBBN for core resiliency and loop avoidance.

Similar to regular MSTP, the STP mode (for example, PMSTP) is only supported in VPLS services where the m-VPLS flag is configured.

#### 3.2.9.4.1 MSTP General Principles

MSTP represents a modification of RSTP that allows the grouping of different VLANs into multiple MSTIs. To enable different devices to participate in MSTIs, they must be consistently configured. A collection of interconnected devices that have the same MST configuration (region-name, revision, and VLAN-to-instance assignment) comprises an MST region.

There is no limit to the number of regions in the network, but every region can support a maximum of 16 MSTIs. Instance 0 is a special instance for a region, known as the Internal Spanning Tree (IST) instance. All other instances are numbered from 1 to 4094. IST is the only spanning-tree instance that sends and receives BPDUs (typically, BPDUs are untagged). All other spanning-tree instance information is included in MSTP records (M-records), which are encapsulated within MSTP BPDUs. This means that a single BPDU carries information for multiple MSTIs, which reduces overhead of the protocol.

Any MSTI is local to an MSTP region and completely independent from an MSTI in other MST regions. Two redundantly connected MST regions will use only a single path for all traffic flows (no load balancing between MST regions or between MST and SST region).

Traditional Layer 2 switches running MSTP protocol assign all VLANs to the IST instance per default. The operator may then “re-assign” individual VLANs to a specified MSTI by configuring per VLAN assignment. This means that an SR-series PE can be considered as a part of the same MST region only if the VLAN assignment to IST and MSTIs is identical to the one of Layer 2 switches in the access network.

### 3.2.9.4.2 MSTP in the SR-series Platform

The SR-series platform uses a concept of M-VPLS to group different SAPs under a single STP instance. The VLAN range covering SAPs to be managed by a specified M-VPLS is declared under a specific M-VPLS SAP definition. MSTP mode-of-operation is only supported in an M-VPLS.

When running MSTP, by default, all VLANs are mapped to the CIST. At the VPLS level, VLANs can be assigned to specific MSTIs. When running RSTP, the operator must explicitly indicate, per SAP, which VLANs are managed by that SAP.

### 3.2.9.5 Enhancements to the Spanning Tree Protocol

To interconnect PE devices across the backbone, service tunnels (SDPs) are used. These service tunnels are shared among multiple VPLS instances. The Nokia implementation of the STP incorporates some enhancements to make the operational characteristics of VPLS more effective. The implementation of STP on the router is modified in order to guarantee that service tunnels will not be blocked in any circumstance without imposing artificial restrictions on the placement of the root bridge within the network. The modifications introduced are fully compliant with the 802.1D-2004 STP specification.

When running MSTP, spoke-SDPs cannot be configured. Also, ensure that all bridges connected by mesh SDPs are in the same region. If not, the mesh will be prevented from becoming active (trap is generated).

To achieve this, all mesh SDPs are dynamically configured as either root ports or designated ports. The PE devices participating in each VPLS mesh determine (using the root path cost learned as part of the normal protocol exchange) which of the 7450 ESS, 7750 SR, or 7950 XRS devices is closest to the root of the network. This PE device is internally designated as the primary bridge for the VPLS mesh. As a result of this, all network ports on the primary bridges are assigned the designated port role and therefore remain in the forwarding state.

The second part of the solution ensures that the remaining PE devices participating in the STP instance see the SDP ports as a lower-cost path to the root rather than a path that is external to the mesh. Internal to the PE nodes participating in the mesh, the SDPs are treated as zero-cost paths toward the primary bridge. As a consequence, the path through the mesh is seen as lower cost than any alternative and the PE node will designate the network port as the root port. This approach ensures that network ports always remain in forwarding state.

In combination, these two features ensure that network ports will never be blocked and will maintain interoperability with bridges external to the mesh that are running STP instances.

### 3.2.9.5.1 L2PT Termination

L2PT is used to transparently transport protocol data units (PDUs) of Layer 2 protocols such as STP, CDP, VTP, PAGP, and UDLD. This allows running these protocols between customer CPEs without involving backbone infrastructure.

The 7450 ESS, 7750 SR, and 7950 XRS routers allow transparent tunneling of PDUs across the VPLS core. However, in some network designs, the VPLS PE is connected to CPEs through a legacy Layer 2 network, rather than having direct connections. In such environments, termination of tunnels through such infrastructure is required.

L2PT tunnels PDUs by overwriting MAC destination addresses at the ingress of the tunnel to a proprietary MAC address such as 01-00-0c-cd-cd-d0. At the egress of the tunnel, this MAC address is then overwritten back to the MAC address of the respective Layer 2 protocol.

The 7450 ESS, 7750 SR, and 7950 XRS routers support L2PT termination for STP BPDUs. More specifically:

- At ingress of every SAP/spoke-SDP that is configured as L2PT termination, all PDUs with a MAC destination address of 01-00-0c-cd-cd-d0 will be intercepted and their MAC destination address will be overwritten to the MAC destination address used for the corresponding protocol (PVST, STP, RSTP). The type of the STP protocol can be derived from LLC and SNAP encapsulation.
- In the egress direction, all STP PDUs received on all VPLS ports will be intercepted and L2PT encapsulation will be performed for SAP/spoke-SDPs configured as L2PT termination points. Because of implementation reasons, PDU interception and redirection to CPM can be performed only at ingress. Therefore, to comply with the above requirement, as soon as at least one port of a specified VPLS service is configured as L2PT termination port, redirection of PDUs to CPM will be set on all other ports (SAPs, spoke-SDPs, and mesh SDPs) of the VPLS service.

L2PT termination can be enabled only if STP is disabled in a context of the specified VPLS service.

---

### 3.2.9.5.2 BPDU Translation

VPLS networks are typically used to interconnect different customer sites using different access technologies such as Ethernet and bridged-encapsulated ATM PVCs. Typically, different Layer 2 devices can support different types of STP, even if they are from the same vendor. In some cases, it is necessary to provide BPDU translation in order to provide an interoperable e2e solution.

To address these network designs, BPDU format translation is supported on 7450 ESS, 7750 SR, and 7950 XRS devices. If enabled on a specified SAP or spoke-SDP, the system will intercept all BPDUs destined for that interface and perform required format translation such as STP-to-PVST or vice versa.

Similarly, BPDU interception and redirection to the CPM is performed only at ingress, meaning that as soon as at least one port within a specified VPLS service has BPDU translation enabled, all BPDUs received on any of the VPLS ports will be redirected to the CPM.

BPDU translation requires all encapsulation actions that the data path would perform for a specified outgoing port (such as adding VLAN tags depending on the outer SAP and the SDP encapsulation type) and adding or removing all the required VLAN information in a BPDU payload.

This feature can be enabled on a SAP only if STP is disabled in the context of the specified VPLS service.

### 3.2.9.5.3 L2PT and BPDU Translation

Cisco Discovery Protocol (CDP), Digital Trunking Protocol (DTP), Port Aggregation Protocol (PAGP), Uni-directional Link Detection (UDLD), and Virtual Trunk Protocol (VTP) are supported. These protocols automatically pass the other protocols tunneled by L2PT toward the CPM and all carry the same specific Cisco MAC.

The existing L2PT limitations apply.

- The protocols apply only to VPLS.
- The protocols are mutually exclusive with running STP on the same VPLS as soon as one SAP has L2PT enabled.
- Forwarding occurs on the CPM.

## 3.2.10 VPLS Redundancy

The VPLS standard (RFC 4762, *Virtual Private LAN Services Using LDP Signaling*) includes provisions for hierarchical VPLS, using point-to-point spoke-SDPs. Two applications have been identified for spoke-SDPs:

- to connect Multi-Tenant Units (MTUs) to PEs in a metro area network
- to interconnect the VPLS nodes of two metro networks

In both applications, the spoke-SDPs serve to improve the scalability of VPLS. While node redundancy is implicit in non-hierarchical VPLS services (using a full mesh of SDPs between PEs), node redundancy for spoke-SDPs needs to be provided separately.

Nokia routers have implemented special features for improving the resilience of hierarchical VPLS instances, in both MTU and inter-metro applications.

### 3.2.10.1 Spoke SDP Redundancy for Metro Interconnection

When two or more meshed VPLS instances are interconnected by redundant spoke-SDPs (as shown in [Figure 66](#)), a loop in the topology results. To remove such a loop from the topology, STP can be run over the SDPs (links) that form the loop, such that one of the SDPs is blocked. As running STP in each and every VPLS in this topology is not efficient, the node includes functionality that can associate a number of VPLSs to a single STP instance running over the redundant SDPs. Therefore, node redundancy is achieved by running STP in one VPLS, and applying the conclusions of this STP to the other VPLS services. The VPLS instance running STP is referred to as the “management VPLS” or M-VPLS.

If the active node fails, STP on the management VPLS in the standby node will change the link states from disabled to active. The standby node will then broadcast a MAC flush LDP control message in each of the protected VPLS instances, so that the address of the newly active node can be relearned by all PEs in the VPLS.

It is possible to configure two management VPLS services, where both VPLS services have different active spokes (this is achieved by changing the path cost in STP). By associating different user VPLSs with the two management VPLS services, load balancing across the spokes can be achieved.

**Figure 66** HVPLS with Spoke Redundancy

### 3.2.10.2 Spoke SDP Based Redundant Access

This feature provides the ability to have a node deployed as MTUs (Multi-Tenant Units) to be multi-homed for VPLS to multiple routers deployed as PEs without requiring the use of M-VPLS.

In the configuration example shown in [Figure 66](#), the MTUs have spoke-SDPs to two PE devices. One is designated as the primary and one as the secondary spoke-SDP. This is based on a precedence value associated with each spoke.

The secondary spoke is in a blocking state (both on receive and transmit) as long as the primary spoke is available. When the primary spoke becomes unavailable (due to link failure, PEs failure, and so on), the MTUs immediately switch traffic to the backup spoke and start receiving traffic from the standby spoke. Optional revertive operation (with configurable switch-back delay) is supported. Forced manual switchover is also supported.

To speed up the convergence time during a switchover, MAC flush is configured. The MTUs generate a MAC flush message over the newly unblocked spoke when a spoke change occurs. As a result, the PEs receiving the MAC flush will flush all MACs associated with the impacted VPLS service instance and forward the MAC flush to the other PEs in the VPLS network if “propagate-mac-flush” is enabled.

### 3.2.10.3 Inter-Domain VPLS Resiliency Using Multi-Chassis Endpoints

Inter-domain VPLS refers to a VPLS deployment where sites may be located in different domains. An example of inter-domain deployment can be where different metro domains are interconnected over a Wide Area Network (Metro1-WAN-Metro2) or where sites are located in different autonomous systems (AS1-ASBRs-AS2).

Multi-chassis endpoint (MC-EP) provides an alternate solution that does not require RSTP at the gateway VPLS PEs while still using pseudowires to interconnect the VPLS instances located in the two domains. It is supported in both VPLS and PBB-VPLS on the B-VPLS side.

MC-EP expands the single chassis endpoint based on active-standby pseudowires for VPLS, shown in [Figure 67](#).

**Figure 67 HVPLS Resiliency Based on AS Pseudowires**

The active-standby pseudowire solution is appropriate for the scenario when only one VPLS PE (MTUs) needs to be dual-homed to two core PEs (PE1 and PE2). When multiple VPLS domains need to be interconnected, the above solution provides a single point of failure at the MTU-s. The example shown in [Figure 68](#) can be used.

**Figure 68 Multi-Chassis Pseudowire Endpoint for VPLS**

The two gateway pairs, PE3-PE3' and PE1-PE2, are interconnected using a full mesh of four pseudowires out of which only one pseudowire is active at any time.

The concept of pseudowire endpoint for VPLS provides multi-chassis resiliency controlled by the MC-EP pair, PE3-PE3' in this example. This scenario, referred to as multi-chassis pseudowire endpoint for VPLS, provides a way to group pseudowires distributed between PE3 and PE3' chassis in a virtual endpoint that can be mapped to a VPLS instance.

The MC-EP inter-chassis protocol is used to ensure configuration and status synchronization of the pseudowires that belong to the same MC-EP group on PE3 and PE3'. Based on the information received from the peer shelf and the local configuration, the master shelf will make a decision on which pseudowire will become active.

The MC-EP solution is built around the following components:

- Multi-chassis protocol used to perform the following functions:
  - Selection of master chassis.
  - Synchronization of the pseudowire configuration and status.
  - Fast detection of peer failure or communication loss between MC-EP peers using either centralized BFD, if configured, or its own keep-alive mechanism.
- T-LDP signaling of pseudowire status:
  - Informs the remote PEs about the choices made by the MC-EP pair.

- Pseudowire data plane — Represented by the four pseudowires inter-connecting the gateway PEs.
  - Only one of the pseudowires is activated based on the primary/secondary, preference configuration, and pseudowire status. In case of a tie, the pseudowire located on the master chassis will be chosen.
  - The rest of the pseudowires are blocked locally on the MC-EP pair and on the remote PEs as long as they implement the pseudowire active/standby status.

### 3.2.10.3.1 Fast Detection of Peer Failure using BFD

Although the MC-EP protocol has its own keep-alive mechanisms, sharing a common mechanism for failure detection with other protocols (for example, BGP, RSVP-TE) scales better. MC-EP can be configured to use the centralized BFD mechanism.

Similar to other protocols, MC-EP will register with BFD if the **bfd-enable** command is active under the **config>redundancy>multi-chassis>peer>mc-ep** context. As soon as the MC-EP application is activated using no shutdown, it tries to open a new BFD session or register automatically with an existing one. The source-ip configuration under redundancy multi-chassis peer-ip is used to determine the local interface while the peer-ip is used as the destination IP for the BFD session. After MC-EP registers with an active BFD session, it will use it for fast detection of MC-EP peer failure. If BFD registration or BFD initialization fails, the MC-EP will keep using its own keep-alive mechanism and it will send a trap to the NMS signaling the failure to register with/open a BFD session.

To minimize operational mistakes and wrong peer interpretation for the loss of BFD session, the following additional rules are enforced when the MC-EP is registering with a BFD session:

- Only the centralized BFD sessions using system or loopback IP interfaces (source-ip parameter) are accepted in order for MC-EP to minimize the false indication of peer loss.
- If the BFD session associated with MC-EP protocol is using a system/loopback interface, the following actions are not allowed under the interface: IP address change, “shutdown”, “no bfd” commands. If one of these actions is required under the interface, the operator needs to disable BFD using the following procedures:
  - The **no bfd-enable** command in the **config>redundancy>multi-chassis>peer>mc-ep** context — this is the recommended procedure.

- The **shutdown** command in the **config>redundancy>multi-chassis>peer>mc-ep** or from under **config>redundancy>multi-chassis>peer** contexts.

MC-EP keep-alives are still exchanged for the following reasons:

- As a backup; if the BFD session does not come up or is disabled, the MC-EP protocol will use its own keep-alives for failure detection.
- To ensure the database is cleared if the remote MC-EP peer is shut down or misconfigured (each x seconds; one second suggested as default).

If MC-EP deregisters with BFD using the **no bfd-enable** command, the following processing steps occur:

- The local peer indicates to the MC-EP peer that the local BFD is being disabled using the MC-EP peer-config-TLV fields ([BFD local: BFD remote]). This is done to avoid the wrong interpretation of the BFD session loss.
- The remote peer acknowledges reception indicating through the same peer-config-TLV fields that it is deregistering with the BFD session.
- Both MC-EP peers deregister and use only keep-alives for failure detection.
- There should be no pseudowire status change during this process.

Traps are sent when the status of the monitoring of the MC-EP session through BFD changes in the following instances:

- When red/mc/peer is no shutdown and BFD is not enabled, a notification is sent indicating BFD is not monitoring the MC-EP peering session.
- When BFD changes to open, a notification is sent indicating BFD is monitoring the MC-EP peering session.
- When BFD changes to down/close, a notification is sent indicating BFD is not monitoring the MC-EP peering session.

### 3.2.10.3.2 MC-EP Passive Mode

The MC-EP mechanisms are built to minimize the possibility of loops. It is possible that human error could create loops through the VPLS service. One way to prevent loops is to enable the MAC move feature in the gateway PEs (PE3, PE3', PE1, and PE2).

An MC-EP passive mode can also be used on the second PE pair, PE1 and PE2, as a second layer of protection to prevent any loops from occurring if the operator introduces operational errors on the MC-EP PE3, PE3' pair. An example is shown in [Figure 69](#).

**Figure 69 MC-EP in Passive Mode**

OSSG251

When in passive mode, the MC-EP peers stay dormant as long as one active pseudowire is signaled from the remote end. If more than one pseudowire belonging to the passive MC-EP becomes active, the PE1 and PE2 pair applies the MC-EP selection algorithm to select the best choice and blocks all others. No signaling is sent to the remote pair to avoid flip-flop behavior. A trap is generated each time MC-EP in passive mode activates. Every occurrence of this kind of trap should be analyzed by the operator as it is an indication of possible misconfiguration on the remote (active) MC-EP peering.

For the MC-EP passive mode to work, the pseudowire status signaling for active/standby pseudowires should be enabled. This requires the following CLI configurations:

For the remote MC-EP PE3, PE3' pair:

```
config>service>vpls>endpoint# no suppress-standby-signaling
```

When MC-EP passive mode is enabled on the PE1 and PE2 pair, the following command is always enabled internally, regardless of the actual configuration:

```
config>service>vpls>endpoint no ignore-standby-signaling
```

### 3.2.10.4 Support for Single Chassis Endpoint Mechanisms

In cases of SC-EP, there is a consistency check to ensure that the configuration of the member pseudowires is the same. For example, mac-pining, mac-limit, and ignore standby signaling must be the same. In the MC-EP case, there is no consistency check between the member endpoints located on different chassis. The operator must carefully verify the configuration of the two endpoints to ensure consistency.

The following rules apply for suppress-standby-signaling and ignore-standby parameters:

- Regular MC-EP mode (non-passive) will follow the suppress-standby-signaling and ignore-standby settings from the related endpoint configuration.
- For MC-EP configured in passive mode, the following settings will be used, regardless of previous configuration: **suppress-standby-sig** and **no ignore-standby-sig**. It is expected that when passive mode is used at one side, the regular MC-EP side will activate signaling with **no suppress-stdby-sig**.
- When passive mode is configured in just one of the nodes in the MC-EP peering, the other node will be forced to change to passive mode. A trap is sent to the operator to signal the wrong configuration.

This section also describes how the main mechanisms used for single chassis endpoint are adapted for the MC-EP solution.

#### 3.2.10.4.1 MAC Flush Support in MC-EP

In an MC-EP scenario, failure of a pseudowire or gateway PE will determine activation of one of the next best pseudowires in the MC-EP group. This section describes the MAC flush procedures that can be applied to ensure blackhole avoidance.

[Figure 70](#) shows a pair of PE gateways (PE3 and PE3) running MC-EP toward PE1 and PE2 where F1 and F2 are used to indicate the possible direction of the MAC flush, signaled using T-LDP MAC withdraw message. PE1 and PE2 can only use regular VPLS pseudowires and do not have to use an MC-EP or a regular pseudowire endpoint.

**Figure 70 MAC Flush in the MC-EP Solution**

OSSG252

Regular MAC flush behavior will apply for the LDP MAC withdraw sent over the T-LDP sessions associated with the active pseudowire in the MC-EP; for example, PE3 to PE1. That includes any Topology Change Notification (TCN) events or failures associated with SAPs or pseudowires not associated with the MC-EP.

The following MAC flush behaviors apply to changes in the MC-EP pseudowire selection:

- If the local PW2 becomes active on PE3:
  - On PE3, the MACs mapped to PW1 are moved to PW2.
  - A T-LDP flush-all-but-mine message is sent toward PE2 in the F2 direction and is propagated by PE2 in the local VPLS mesh.
  - No MAC flush is sent in the F1 direction from PE3.
- If one of the pseudowires on the pair PE3 becomes active; for example, PW4:
  - On PE3, the MACs mapped to PW1 are flushed, the same as for a regular endpoint.
  - PE3 must be configured with **send-flush-on-failure** to send a T-LDP flush-all-from-me message toward VPLS mesh in the F1 direction.
  - PE3 sends a T-LDP flush-all-but-mine message toward PE2 in the F2 direction, which is propagated by PE2 in the local VPLS mesh. When MC-EP is in passive mode and the first spoke becomes active, a no mac flush-all-but-mine message will be generated.

### 3.2.10.4.2 Block-on-Mesh-Failure Support in MC-EP Scenario

The following rules describe how the block-on-mesh-failure operates with the MC-EP solution (see [Figure 70](#)):

- If PE3 does not have any forwarding path toward Domain1 mesh, it should block both PW1 and PW2 and inform PE3 so one of its pseudowires can be activated.
- To allow the use of block-on-mesh-failure for MC-EP, a block-on-mesh-failure parameter can be specified in the **config>service>vpls>endpoint** context with the following rules:
  - The default is **no block-on-mesh-failure** to allow for easy migration.
  - For a spoke-SDP to be added under an endpoint, the setting for its **block-on-mesh-failure** parameter must be in synchronization with the endpoint parameter.
  - After the spoke-SDP is added to an endpoint, the configuration of its **block-on-mesh-failure** parameter is disabled. A change in endpoint configuration for the **block-on-mesh-failure** parameter is propagated to the individual spoke-SDP configuration.
  - When a spoke-SDP is removed from the endpoint group, it will inherit the last configuration from the endpoint parameter.
  - Adding an MC-EP under the related endpoint configuration does not affect the above behavior.

Before Release 7.0, the **block-on-mesh-failure** command could not be enabled under **config>service>vpls>endpoint** context. For a spoke-SDP to be added to an (single-chassis) endpoint, its **block-on-mesh-failure** had to be disabled (**config>service>vpls>spoke-sdp>no block-on-mesh-failure**). Then, the configuration of **block-on-mesh-failure** under a spoke-SDP is blocked.

- If **block-on-mesh-failure** is enabled on PE1 and PE2, these PEs will signal pseudowire standby status toward the MC-EP PE pair. PE3 and PE3 should consider the pseudowire status signaling from remote PE1 and PE2 when making the selection of the active pseudowire.

### 3.2.10.4.3 Support for Force Spoke SDP in MC-EP

In a regular (single chassis) endpoint scenario, the following command can be used to force a specific SDP binding (pseudowire) to become active:

```
tools perform service id service-id endpoint endpoint-name
force
```

In the MC-EP case, this command has a similar effect when there is a single forced SDP binding in an MC-EP. The forced SDP binding (pseudowire) will be elected as active.

However, when the command is run at the same time as both MC-EP PEs, when the endpoints belong to the same MC-EP, the regular MC-EP selection algorithm (for example, the operational status  $\Rightarrow$  precedence value) will be applied to determine the winner.

#### 3.2.10.4.4 Revertive Behavior for Primary Pseudowires in an MC-EP

For a single-chassis endpoint, a revert-time command is provided under the VPLS endpoint. Refer to the [VPLS Service Configuration Command Reference](#) for syntax and command usage information.

In a regular endpoint, the revert-time setting affects just the pseudowire defined as primary (precedence 0). For a failure of the primary pseudowire followed by restoration, the revert-timer is started. After it expires, the primary pseudowire takes the active role in the endpoint. This behavior does not apply for the case when both pseudowires are defined as secondary; that is, if the active secondary pseudowire fails and is restored, it will stay in standby until a configuration change or a force command occurs.

In the MC-EP case, the revertive behavior is supported for pseudowire defined as primary (precedence 0). The following rules apply:

- The revert-time setting under each individual endpoint control the behavior of the local primary pseudowire if one is configured under the local endpoint.
- The secondary pseudowires behave as in the regular endpoint case.

#### 3.2.10.5 Using B-VPLS for Increased Scalability and Reduced Convergence Times

The PBB-VPLS solution can be used to improve scalability of the solution and to reduce convergence time. If PBB-VPLS is deployed starting at the edge PEs, the gateway PEs will contain only B-VPLS instances. The MC-EP procedures described for regular VPLS apply.

PBB-VPLS can also be enabled just on the gateway MC-EP PEs, as shown in [Figure 71](#).

**Figure 71 MC-EP with B-VPLS**

OSSG487

Multiple I-VPLS instances may be used to represent in the gateway PEs the customer VPLS instances using the PBB-VPLS M:1 model described in the PBB section. A backbone VPLS (B-VPLS) is used in this example to administer the resiliency for all customer VPLS instances at the domain borders. Just one MC-EP is required to be configured in the B-VPLS to address hundreds or even thousands of customer VPLS instances. If load balancing is required, multiple B-VPLS instances may be used to ensure even distribution of the customers across all the pseudowires interconnecting the two domains. In this example, four B-VPLSs will be able to load share the customers across all four possible pseudowire paths.

The use of MC-EP with B-VPLS is strictly limited to cases where VPLS mesh exists on both sides of a B-VPLS. For example, active/standby pseudowires resiliency in the I-VPLS context where PE3 and PE3' are PE-rs cannot be used because there is no way to synchronize the active/standby selection between the two domains.

For a similar reason, MC-LAG resiliency in the I-VPLS context on the gateway PEs participating in the MC-EP (PE3 and PE3') should not be used.

For the PBB topology in [Figure 71](#), block-on-mesh-failure in the I-VPLS domain will not have any effect on the B-VPLS MC-EP side. That is because mesh failure in one I-VPLS should not affect other I-VPLSs sharing the same B-VPLS.

### 3.2.10.6 MAC Flush Additions for PBB VPLS

The scenario shown in [Figure 72](#) is used to define the blackholing problem in PBB-VPLS using MC-EP.

**Figure 72 MC-EP with B-VPLS Failure Scenario**

OSSG319

In the topology shown in [Figure 72](#), PEA and PEB are regular VPLS PEs participating in the VPLS mesh deployed in the metro and WAN region, respectively. As the traffic flows between CEs with CMAC X and CMAC Y, the FDB entries in PEA, PE3, PE1 and PEB are installed. An LDP flush-all-but-mine message will be sent from PE3 to PE2 to clear the B-VPLS FDBs. The traffic between CMAC X and CMAC Y will be blackholed as long as the entries from the VPLS and I-VPLS FDBs along the path are not removed. This may take as long as 300 seconds, the usual aging timer used for MAC entries in a VPLS FDB.

A MAC flush is required in the I-VPLS space from PBB PEs to PEA and PEB to avoid blackholing in the regular VPLS space.

In the case of a regular VPLS, the following procedure is used:

- PE3 sends a flush-all-from-me message toward its local blue I-VPLS mesh to PE3 and PEA when its MC-EP becomes disabled.
- PE3 sends a flush-all-but-mine message on the active PW4 to PE2, which is then propagated by PE2 (propagate-mac-flush must be on) to PEB in the WAN I-VPLS mesh.

For consistency, a similar procedure is used for the B-VPLS case as shown in [Figure 73](#).

**Figure 73 MC-EP with B-VPLS MAC Flush Solution**

OSSG320

In this example, the MC-EP activates B-VPLS PW4 because of either a link/node failure or because of an MC-EP selection re-run that affected the previously active PW1. As a result, the endpoint on PE3 containing PW1 goes down.

The following steps apply:

- PE3 sends, in the local I-VPLS context, an LDP flush-all-from-me message (marked with F1) to PEA and to the other regular VPLS PEs, including PE3. The following command enables this behavior on a per I-VPLS basis:  
**config>service>vpls ivpls>send-flush-on-bvpls-failure.**
  - Result: PEA, PE3, and the other local VPLS PEs in the metro clear the VPLS FDB entries associated with PW to PE3.
- PE3 clears the entries associated with PW1 and sends, in the B-VPLS context, an LDP flush-all-but-mine message (marked with F2) toward PE2 on the active PW4.
  - Result: PE2 clears the B-VPLS FDB entries not associated with PW4.
- PE2 propagates the MAC flush-all-but-mine (marked with F3) from B-VPLS in the related I-VPLS contexts toward all participating VPLS PEs; for example, in the blue I-VPLS to PEB, PE1. It also clears all the CMAC entries associated with I-VPLS pseudowires.

The following command enables this behavior on a per I-VPLS basis:

**config>service>vpls ivpls>propagate-mac-flush-from-bvpls**

- Result: PEB, PE1, and the other local VPLS PEs in the WAN clear the VPLS FDB entries associated with PW to PE2.

- This command does not control the propagation in the related I-VPLS of the B-VPLS LDP MAC flush containing a PBB TLV (BMAC and ISID list).
- Similar to regular VPLS, LDP signaling of the MAC flush will follow the active topology; for example, no MAC flush will be generated on standby pseudowires.

Other failure scenarios are addressed using the same or a subset of the above steps:

- If the pseudowire (PW2) in the same endpoint with PW1 becomes active instead of PW4, there will be no MAC flush of F1 type.
- If the pseudowire (PW3) in the same endpoint becomes active instead of PW4, the same procedure applies.

For an SC/MC endpoint configured in a B-VPLS, failure/deactivation of the active pseudowire member always generates a local MAC flush of all the BMAC associated with the pseudowire. It never generates a MAC move to the newly active pseudowire even if the endpoint stays up. That is because in SC-EP/MC-EP topology, the remote PE might be the terminating PBB PE and may not be able to reach the BMAC of the other remote PE. Therefore, connectivity between them exists only over the regular VPLS mesh.

For the same reasons, Nokia recommends that static BMAC not be used on SC/MC endpoints.

### 3.2.11 VPLS Access Redundancy

A second application of hierarchical VPLS is using MTUs that are not MPLS-enabled that must have Ethernet links to the closest PE node. To protect against failure of the PE node, an MTU can be dual-homed and have two SAPs on two PE nodes.

There are several mechanisms that can be used to resolve a loop in an access circuit; however, from an operations perspective, they can be subdivided into two groups:

- STP-based access, with or without M-VPLS.
- Non-STP based access using mechanisms such as MC-LAG, MC-APS, MC-Ring.

### 3.2.11.1 STP-based Redundant Access to VPLS

**Figure 74 Dual-homed MTUs in Two-Tier Hierarchy H-VPLS**

In the configuration shown in [Figure 74](#), STP is activated on the MTU and two PEs in order to resolve a potential loop. STP only needs to run in a single VPLS instance, and the results of the STP calculations are applied to all VPLSs on the link.

In this configuration, the scope of the STP domain is limited to MTU and PEs, while any topology change needs to be propagated in the whole VPLS domain including mesh SDPs. This is done by using so-called MAC-flush messages defined by RFC 4762. In the case of STP as an loop resolution mechanism, every TCN received in the context of an STP instance is translated into an LDP-MAC address withdrawal message (also referred to as a MAC-flush message) requesting to clear all FDB entries except the ones learned from the originating PE. Such messages are sent to all PE peers connected through SDPs (mesh and spoke) in the context of VPLS services, which are managed by the specified STP instance.

### 3.2.11.2 Redundant Access to VPLS Without STP

The Nokia implementation also includes alternative methods for providing a redundant access to Layer 2 services, such as MC-LAG, MC-APS, or MC-Ring. Also in this case, the topology change event needs to be propagated into the VPLS topology in order to provide fast convergence. The topology change propagation and its corresponding MAC flush processing in a VPLS service without STP is described in [Dual Homing to a VPLS Service](#).

## 3.2.12 Object Grouping and State Monitoring

This feature introduces a generic operational group object that associates different service endpoints (pseudowires, SAPs, IP interfaces) located in the same or in different service instances.

The operational group status is derived from the status of the individual components using certain rules specific to the application using the feature. A number of other service entities, the monitoring objects, can be configured to monitor the operational group status and to perform certain actions as a result of status transitions. For example, if the operational group goes down, the monitoring objects will be brought down.

### 3.2.12.1 VPLS Applicability — Block on VPLS a Failure

This feature is used in VPLS to enhance the existing BGP MH solution by providing a block-on-group failure function similar to the block-on-mesh failure feature implemented for LDP VPLS. On the PE selected as the Designated Forwarder (DF), if the rest of the VPLS endpoints fail (pseudowire spokes/pseudowire mesh and/or SAPs), there is no path forward for the frames sent to the MH site selected as DF. The status of the VPLS endpoints, other than the MH site, is reflected by bringing down/up the objects associated with the MH site.

Support for the feature is provided initially in VPLS and B-VPLS instance types for LDP VPLS, with or without BGP-AD and for BGP VPLS. The following objects may be placed as components of an operational group: BGP VPLS pseudowires, SAPs, spoke-pseudowire, BGP-AD pseudowires. The following objects are supported as monitoring objects: BGP MH site, individual SAP, spoke-pseudowire.

The following rules apply:

- An object can only belong to one group at a time.
- An object that is part of a group cannot monitor the status of any group.
- An object that monitors the status of a group cannot be part of any group.
- An operational group may contain any combination of member types: SAP, spoke-pseudowire, BGP-AD or BGP VPLS pseudowires.
- An operational group may contain members from different VPLS service instances.
- Objects from different services may monitor the operational group.
- The operational group feature may co-exist in parallel with the block-on-mesh failure feature as long as they are running in different VPLS instances.

There are two steps involved in enabling the block-on-mesh failure feature in a VPLS scenario:

1. Identify a set of objects whose forwarding state should be considered as a whole group, then group them under an operational group using the **oper-group** CLI command.
2. Associate other existing objects (clients) with the **oper-group** command using the **monitor-group** CLI command; its forwarding state will be derived from the related operational group state.

The status of the operational group (oper-group) is dictated by the status of one or more members according to the following rule:

- The oper-group goes down if all the objects in the oper-group go down; the oper-group comes up if at least one of the components is up.
- An object in the oper-group is considered down if it is not forwarding traffic in at least one direction. That could be because the operational state is down or the direction is blocked through some resiliency mechanisms.
- If an oper-group is configured but no members are specified yet, its status is considered up. As soon as the first object is configured, the status of the oper-group is dictated by the status of the provisioned members.
- For BGP-AD or BGP VPLS pseudowires associated with the oper-group (under the **config>service-vpls>bgp>pw-template-binding** context), the status of the oper-group is down as long as the pseudowire members are not instantiated (auto-discovered and signaled).

A simple configuration example is described for the case of a BGP VPLS mesh used to interconnect different customer locations. If we assume a customer edge (CE) device is dual-homed to two PEs using BGP MH, the following configuration steps apply:

- The oper-group bgp-vpls-mesh is created.
- The BGP VPLS mesh is added to the bgp-vpls-mesh group through the pseudowire template used to create the BGP VPLS mesh.
- The BGP MH site defined for the access endpoint is associated with the bgp-vpls-mesh group; its status from now on will be influenced by the status of the BGP VPLS mesh.

A simple configuration example follows:

```
service>oper-group bgp-vpls-mesh-1 create
service>vpls>bgp>pw-template-binding> oper-group bgp-vpls-mesh-1
service>vpls>site> monitor-group bgp-vpls-mesh-1
```

---

### 3.2.13 MAC Flush Message Processing

The previous sections described operating principles of several redundancy mechanisms available in the context of VPLS service. All of them rely on MAC flush messages as a tool to propagate topology change in a context of the specified VPLS. This section summarizes basic rules for generation and processing of these messages.

As described in respective sections, the 7450 ESS, 7750 SR, and 7950 XRS support two types of MAC flush message: flush-all-but-mine and flush-mine. The main difference between these messages is the type of action they signal. Flush-all-but-mine messages request clearing of all FDB entries that were learned from all other LDP peers except the originating PE. This type is also defined by RFC 4762 as an LDP MAC address withdrawal with an empty MAC address list.

Flush-all-mine messages request clearing all FDB entries learned from the originating PE. This means that this message has the opposite effect of the flush-all-but-mine message. This type is not included in the RFC 4762 definition and it is implemented using vendor-specific TLV.

The advantages and disadvantages of the individual types should be apparent from examples in the previous section. The description here summarizes actions taken on reception and the conditions under which individual messages are generated.

Upon reception of MAC flush messages (regardless of the type), an SR-series PE will take the following actions:

- Clears FDB entries of all indicated VPLS services conforming to the definition.
- Propagates the message (preserving the type) to all LDP peers, if the propagate-mac-flush flag is enabled at the corresponding VPLS level.

The flush-all-but-mine message is generated under the following conditions:

- The flush-all-but-mine message is received from the LDP peer and the propagate-mac-flush flag is enabled. The message is sent to all LDP peers in the context of the VPLS service it was received.
- The TCN message in a context of STP instance is received. The flush-all-but-mine message is sent to all LDP peers connected with spoke and mesh SDPs in a context of VPLS service controlled by the specified STP instance (based on M-VPLS definition). If all LDP peers are in the STP domain, that is, the M-VPLS and the uVPLS (user VPLS) both have the same topology, the router will not send any flush-all-but-mine message. If the router has uVPLS LDP peers outside the STP domain, the router will send flush-all-but-mine messages to all its uVPLS peers.

**Note:** The 7750 SR will not send a withdrawal if the M-VPLS does not contain a mesh SDP. A mesh SDP must be configured in the M-VPLS to send withdrawals.

- The flush-all-but-mine message is generated when switchover between spoke-SDPs of the same endpoint occurs. The message is sent to the LDP peer connected through the newly active spoke-SDP.

The flush-mine message is generated under the following conditions:

- The flush-mine message is received from the LDP peer and the propagate-mac-flush flag is enabled. The message is sent to all LDP peers in the context of the VPLS service it was received.
- The flush-mine message is generated when a SAP or SDP transitions from operationally up to an operationally down state and the send-flush-on-failure flag is enabled in the context of the specified VPLS service. The message is sent to all LDP peers connected in the context of the specified VPLS service. The send-flush-on-failure flag is blocked in M-VPLS and is only allowed to be configured in a VPLS service managed by M-VPLS. This is to prevent both messages being sent at the same time.
- The flush-mine message is generated when an MC-LAG SAP or MC-APS SAP transitions from an operationally up state to an operationally down state. The message is sent to all LDP peers connected in the context of the specified VPLS service.
- The flush-mine message is generated when an MC-Ring SAP transitions from operationally up to an operationally down state or when MC-Ring SAP transitions to slave state. The message is sent to all LDP peers connected in the context of the specified VPLS service.

### 3.2.13.1 Dual Homing to a VPLS Service

**Figure 75** Dual-homed CE Connection to VPLS

OSSG117

Figure 75 shows a dual-homed connection to VPLS service (PE-A, PE-B, PE-C, PE-D) and operation in case of link failure (between PE-C and L2-B). Upon detection of a link failure, PE-C will send MAC-address-withdraw messages, which will indicate to all LDP peers that they should flush all MAC addresses learned from PE-C. This will lead to a broadcasting of packets addressing affected hosts and relearning in case an alternative route exists.

The message described here is different than the message described in RFC 4762, *Virtual Private LAN Services Using LDP Signaling*. The difference is in the interpretation and action performed in the receiving PE. According to the standard definition, upon receipt of a MAC withdraw message, all MAC addresses, except the ones learned from the source PE, are flushed. This section specifies that all MAC addresses learned from the source are flushed. This message has been implemented as an LDP address withdraw message with vendor-specific type, length, and value (TLV), and is called the flush-all-from-me message.

The RFC 4762 compliant message is used in VPLS services for recovering from failures in STP (Spanning Tree Protocol) topologies. The mechanism described in this section represents an alternative solution.

The advantage of this approach (as compared to STP-based methods) is that only the affected MAC addresses are flushed and not the full forwarding database. While this method does not provide a mechanism to secure alternative loop-free topology, the convergence time is dependent on the speed that the specified CE device will open an alternative link (L2-B switch in [Figure 75](#)) as well as on the speed that PE routers will flush their FDB.

In addition, this mechanism is effective only if PE and CE are directly connected (no hub or bridge) as the mechanism reacts to the physical failure of the link.

### 3.2.13.2 MC-Ring and VPLS

The use of multi-chassis ring control in a combination with the plain VPLS SAP is supported by the FDB in individual ring nodes, in case the link (or ring node) failure cannot be cleared on the 7750 SR or 7950 XRS.

This combination is not easily blocked in the CLI. If configured, the combination may be functional but the switchover times will be proportional to MAC aging in individual ring nodes and/or to the relearning rate due to downstream traffic.

Redundant plain VPLS access in ring configurations, therefore, exclude corresponding SAPs from the multi-chassis ring operation. Configurations such as M-VPLS can be applied.

### 3.2.14 ACL Next-Hop for VPLS

The ACL next-hop for VPLS feature enables an ACL that has a forward to a SAP or SDP action specified to be used in a VPLS service to direct traffic with specific match criteria to a SAP or SDP. This allows traffic destined for the same gateway to be split and forwarded differently based on the ACL.

**Figure 76 Application 1 Diagram**

Policy routing is a popular tool used to direct traffic in Layer 3 networks. As Layer 2 VPNs become more popular, especially in network aggregation, policy forwarding is required. Many providers are using methods such as DPI servers, transparent firewalls, or Intrusion Detection/Prevention Systems (IDS/IPS). Since these devices are bandwidth limited, providers want to limit traffic forwarded through them. In the setup shown in [Figure 76](#), a mechanism is required to direct some traffic coming from a SAP to the DPI without learning, and other traffic coming from the same SAP directly to the gateway uplink-based learning.

This feature will allow the provider to create a filter that will forward packets to a specific SAP or SDP. The packets are then forwarded to the destination SAP regardless of learned destination. The SAP can either terminate a Layer 2 firewall, perform deep packet inspection (DPI) directly, or may be configured to be part of a cross-connect bridge into another service. This will be useful when running the DPI remotely using VLLs. If an SDP is used, the provider can terminate it in a remote VPLS or VLL service where the firewall is connected. The filter can be configured under a SAP or SDP in a VPLS service. All packets (unicast, multicast, broadcast, and unknown) can be delivered to the destination SAP/SDP.

The filter may be associated with SAPs/SDPs belonging to a VPLS service only if all actions in the ACL forward to SAPs/SDPs that are within the context of that VPLS. Other services do not support this feature. An ACL that contains this feature is allowed, but the system will drop any packet that matches an entry with this action.

### 3.2.15 SDP Statistics for VPLS and VLL Services

The simple three-node network in [Figure 77](#) shows two MPLS SDPs and one GRE SDP defined between the nodes. These SDPs connect VPLS1 and VPLS2 instances that are defined in the three nodes. With this feature, the operator will have local CLI-based as well as SNMP-based statistics collection for each VC used in the SDPs. This will allow for traffic management of tunnel usage by the different services and with aggregation of the total tunnel usage.

**Figure 77 SDP Statistics for VPLS and VLL Services**

OSSG208

SDP statistics allow providers to bill customers on a per-SDP per-byte basis. This destination-based billing model can be used by providers with a variety of circuit types and have different costs associated with the circuits. An accounting file allows the collection of statistics in bulk.

### 3.2.16 BGP Auto-Discovery for LDP VPLS

BGP Auto-Discovery (BGP AD) for LDP VPLS is a framework for automatically discovering the endpoints of a Layer 2 VPN, offering an operational model similar to that of an IP VPN. This allows carriers to leverage existing network elements and functions, including but not limited to, route reflectors and BGP policies to control the VPLS topology.

BGP AD complements an already established and well-deployed Layer 2 VPN signaling mechanism target LDP, providing one-touch provisioning for LDP VPLS, where all the related PEs are discovered automatically. The service provider may make use of existing BGP policies to regulate the exchanges between PEs in the same, or in different, autonomous system (AS) domains. The addition of BGP AD procedures does not require carriers to uproot their existing VPLS deployments nor to change the signaling protocol.

### 3.2.16.1 BGP AD Overview

The BGP protocol establishes neighbor relationships between configured peers. An open message is sent after the completion of the three-way TCP handshake. This open message contains information about the BGP peer sending the message. This message contains Autonomous System Number (ASN), BGP version, timer information, and operational parameters, including capabilities. The capabilities of a peer are exchanged using two numerical values: the Address Family Identifier (AFI) and Subsequent Address Family Identifier (SAFI). These numbers are allocated by the Internet Assigned Numbers Authority (IANA). BGP AD uses AFI 65 (L2VPN) and SAFI 25 (BGP VPLS). The complete list of allocations are at: <http://www.iana.org/assignments/address-family-numbers> and SAFI <http://www.iana.org/assignments/safi-namespace>.

### 3.2.16.2 Information Model

Following the establishment of the peer relationship, the discovery process begins as soon as a new VPLS service instance is provisioned on the PE.

Two VPLS identifiers are used to indicate the VPLS membership and the individual VPLS instance:

- VPLS-ID — Membership information, and unique network-wide identifier; the same value is assigned for all VPLS switch instances (VSIs) belonging to the same VPLS. VPLS-ID is encodable and carried as a BGP extended community in one of the following formats:
  - A two-octet AS-specific extended community
  - An IPv4 address-specific extended community
- VSI-ID — The unique identifier for each individual VSI, built by concatenating a route distinguisher (RD) with a 4-byte identifier (usually the system IP of the VPLS PE), encoded and carried in the corresponding BGP NLRI.

To advertise this information, BGP AD employs a simplified version of the BGP VPLS NLRI where just the RD and the next 4 bytes are used to identify the VPLS instance. There is no need for Label Block and Label Size fields as T-LDP will signal the service labels later on.

The format of the BGP AD NLRI is very similar to the one used for IP VPN, as shown in [Figure 78](#). The system IP may be used for the last 4 bytes of the VSI ID, further simplifying the addressing and the provisioning process.

**Figure 78      BGP AD NLRI versus IP VPN NLRI**

Network Layer Reachability Information (NLRI) is exchanged between BGP peers indicating how to reach prefixes. The NLRI is used in the Layer 2 VPN case to tell PE peers how to reach the VSI, rather than specific prefixes. The advertisement includes the BGP next hop and a route target (RT). The BGP next hop indicates the VSI location and is used in the next step to determine which signaling session is used for pseudowire signaling. The RT, also coded as an extended community, can be used to build a VPLS full mesh or an HVPLS hierarchy through the use of BGP import/export policies.

BGP is only used to discover VPN endpoints and the corresponding far-end PEs. It is not used to signal the pseudowire labels. This task remains the responsibility of targeted-LDP (T-LDP).

**3.2.16.3      FEC Element for T-LDP Signaling**

Two LDP FEC elements are defined in RFC 4447, *PW Setup & Maintenance Using LDP*. The original pseudowire-ID FEC element 128 (0x80) employs a 32-bit field to identify the virtual circuit ID and was used extensively in the initial VPWS and VPLS deployments. The simple format is easy to understand, but does not provide the required information model for BGP auto-discovery function. To support BGP AD and other new applications, a new Layer 2 FEC element, the generalized FEC (0x81), is required.

The generalized pseudowire-ID FEC element has been designed for auto-discovery applications. It provides a field, the address group identifier (AGI), that is used to signal the membership information from the VPLS-ID. Separate address fields are provided for the source and target address associated with the VPLS endpoints, called the Source Attachment Individual Identifier (SAII) and Target Attachment Individual Identifier (TAII), respectively. These fields carry the VSI ID values for the two instances that are to be connected through the signaled pseudowire.

The detailed format for FEC 129 is shown in [Figure 79](#).

**Figure 79      Generalized Pseudowire-ID FEC Element**

0987

Each of the FEC fields are designed as a sub-TLV equipped with its own type and length, providing support for new applications. To accommodate the BGP AD information model, the following FEC formats are used:

- AGI (type 1) is identical in format and content to the BGP extended community attribute used to carry the VPLS-ID value.
- Source AII (type 1) is a 4-byte value to carry the local VSI-ID (outgoing NLRI minus the RD).
- Target AII (type 1) is a 4-byte value to carry the remote VSI-ID (incoming NLRI minus the RD).

### 3.2.16.4 BGP-AD and Target LDP (T-LDP) Interaction

BGP is responsible for discovering the location of VSIs that share the same VPLS membership. LDP protocol is responsible for setting up the pseudowire infrastructure between the related VSIs by exchanging service-specific labels between them.

Once the local VPLS information is provisioned in the local PE, the related PEs participating in the same VPLS are identified through BGP AD exchanges. A list of far-end PEs is generated and will trigger the creation, if required, of the necessary T-LDP sessions to these PEs and the exchange of the service-specific VPN labels. The steps for the BGP AD discovery process and LDP session establishment and label exchange are shown in [Figure 80](#).

**Figure 80 BGP-AD and T-LDP Interaction**

OSSG210

Key:

1. Establish I-BGP connectivity RR.
2. Configure VPN (10) on edge node (PE3).
3. Announce VPN to RR using BGP-AD.

4. Send membership update to each client of the cluster.
5. LDP exchange or inbound FEC filtering (IFF) of non-match or VPLS down.
6. Configure VPN (10) on edge node (PE2).
7. Announce VPN to RR using BGP-AD.
8. Send membership update to each client of the cluster.
9. LDP exchange or inbound FEC filtering (IFF) of non-match or VPLS down.
10. Complete LDP bidirectional pseudowire establishment FEC 129.

### 3.2.16.5 SDP Usage

Service Access Points (SAPs) are linked to transport tunnels using Service Distribution Points (SDPs). The service architecture allows services to be abstracted from the transport network.

MPLS transport tunnels are signaled using the Resource Reservation Protocol (RSVP-TE) or by the Label Distribution Protocol (LDP). The capability to automatically create an SDP only exists for LDP-based transport tunnels. Using a manually provisioned SDP is available for both RSVP-TE and LDP transport tunnels. Refer to the appropriate *7450 ESS*, *7750 SR*, *7950 XRS*, and *VSR MPLS Guide* for more information about MPLS, LDP, and RSVP.

GRE transport tunnels use GRE encapsulation and can be used with manually provisioned or auto created SDPs.

### 3.2.16.6 Automatic Creation of SDPs

When BGP AD is used for LDP VPLS, with an LDP or GRE transport tunnel, there is no requirement to manually create an SDP. The LDP or GRE SDP can be automatically instantiated using the information advertised by BGP AD. This simplifies the configuration on the service node.

The use of an automatically created GRE tunnel is enabled by creating the PW template used within the service with the parameter **auto-gre-sdp**. The GRE SDP and SDP binding is created after a matching BGP route has been received.

Enabling LDP on the IP interfaces connecting all nodes between the ingress and the egress builds transport tunnels based on the best IGP path. LDP bindings are automatically built and stored in the hardware. These entries contain an MPLS label pointing to the best next hop along the best path toward the destination.

When two endpoints need to connect and no SDP exists, a new SDP will automatically be constructed. New services added between two endpoints that already have an automatically created SDP will be immediately used; no new SDP will be constructed. The far-end information is learned from the BGP next hop information in the NLRI. When services are withdrawn with a BGP\_Unreach-NLRI, the automatically established SDP will remain up while at least one service is connected between those endpoints. An automatically created SDP will be removed and the resources released when the only or last service is removed.

The service provider has the option of associating the auto-discovered SDP with a split horizon group using the pw-template-binding option, to control the forwarding between pseudowires and to prevent Layer 2 service loops.

An auto-discovered SDP using a pw-template-binding without a split horizon group configured will have similar traffic flooding behavior as a spoke-SDP.

### 3.2.16.7 Manually Provisioned SDP

The carrier is required to manually provision the SDP if they create transport tunnels using RSVP-TE. Operators have the option to choose a manually configured SDP if they use LDP as the tunnel signaling protocol. The functionality is the same regardless of the signaling protocol.

Creating a BGP AD-enabled VPLS service on an ingress node with the manually provisioned SDP option causes the tunnel manager to search for an existing SDP that connects to the far-end PE. The far-end IP information is learned from the BGP next hop information in the NLRI. If a single SDP exists to that PE, it is used. If no SDP is established between the two endpoints, the service will remain down until a manually configured SDP becomes active.

When multiple SDPs exist between two endpoints, the tunnel manager will select the appropriate SDP. The algorithm will prefer SDPs with the best (lower) metric. If there are multiple SDPs with equal metrics, the operational state of the SDPs with the best metric will be considered. If the operational state is the same, the SDP with the higher SDP-ID will be used. If an SDP with a preferred metric is found with an operational state that is not active, the tunnel manager will flag it as ineligible and restart the algorithm.

### 3.2.16.8 Automatic Instantiation of Pseudowires (SDP Bindings)

The choice of manual or auto-provisioned SDPs has limited impact on the amount of required provisioning. Most of the savings are achieved through the automatic instantiation of the pseudowire infrastructure (SDP bindings). This is achieved for every auto-discovered VSI through the use of the pseudowire template concept. Each VPLS service that uses BGP AD contains the pw-template-binding option defining specific Layer 2 VPN parameters. This command references a PW template, which defines the pseudowire parameters. The same PW template may be referenced by multiple VPLS services. As a result, changes to these pseudowire templates have to be treated with caution as they may impact many customers simultaneously.

The Nokia implementation provides for safe handling of pseudowire templates. Changes to the pseudowire templates are not automatically propagated. Tools are provided to evaluate and distribute the changes. The following command is used to distribute changes to a PW template at the service level to one or all services that use that template:

**PERs-4# tools perform service id 300 eval-pw-template 1 allow-service-impact**

If the service ID is omitted, all services will be updated. The type of change made to the PW template will influence how the service is impacted:

- Adding or removing a split-horizon-group will cause the router to destroy the original object and re-create it using the new value.
- Changing parameters in the **vc-type {ether | vlan}** command requires LDP to re-signal the labels.

Both of these changes are service affecting. Other changes will not be service affecting.

### 3.2.16.9 Mixing Statically Configured and Auto-Discovered Pseudowires in a VPLS

The services implementation allows for manually provisioned and auto-discovered pseudowire (SDP bindings) to coexist in the same VPLS instance (for example, both FEC128 and FEC 129 are supported). This allows for gradual introduction of auto-discovery into an existing VPLS deployment.

As FEC 128 and 129 represent different addressing schemes, it is important to ensure that only one is used at any time between the same two VPLS instances. Otherwise, both pseudowires may become active causing a loop that might adversely impact the correct functioning of the service. It is recommended that FEC128 pseudowire be disabled as soon as the FEC129 addressing scheme is introduced in a portion of the network. Alternatively, RSTP may be used during the migration as a safety mechanism to provide additional protection against operational errors.

### 3.2.16.10 Resiliency Schemes

The use of BGP AD on the network side, or in the backbone, does not affect the different resiliency schemes Nokia has developed in the access network. This means that both Multi-Chassis Link Aggregation (MC-LAG) and Management-VPLS (M-VPLS) can still be used.

BGP AD may coexist with Hierarchical-VPLS (H-VPLS) resiliency schemes (for example, dual-homed MTUs devices to different PE-rs nodes) using existing methods (M-VPLS and statically configured active/standby pseudowire endpoint).

If provisioned SDPs are used by BGP AD, M-VPLS may be employed to provide loop avoidance. However, it is currently not possible to auto-discover active/standby pseudowires and to instantiate the related endpoint.

### 3.2.17 BGP VPLS

The Nokia BGP VPLS solution, compliant with RFC 4761, *Virtual Private LAN Service (VPLS) Using BGP for Auto-Discovery and Signaling*, is described in this section.

**Figure 81 BGP VPLS Solution**

OSSG488

Figure 81 shows the service representation for BGP VPLS mesh. The major BGP VPLS components and the deltas from LDP VPLS with BGP AD are as follows:

- Data plane is identical with the LDP VPLS solution; for example, VPLS instances interconnected by pseudowire mesh. Split horizon groups may be used for loop avoidance between pseudowires.
- Addressing is based on a 2-byte VE-ID assigned to the VPLS instance.
  - BGP-AD for LDP VPLS: 4-byte VSI-ID (system IP) identifies the VPLS instance.
- The target VPLS instance is identified by the Route Target (RT) contained in the MP-BGP advertisement (extended community attribute).
  - BGP-AD: a new MP-BGP extended community is used to identify the VPLS. RT is used for topology control.
- Auto-discovery is MP-BGP based; the same AFI, SAFI is used as for LDP VPLS BGP-AD.
  - The BGP VPLS updates are distinguished from the BGP-AD updates based on the value of the NLRI prefix length: 17 bytes for BGP VPLS, 12 bytes for BGP-AD.
  - BGP-AD NLRI is shorter since there is no need to carry pseudowire label information as T-LDP does the pseudowire signaling for LDP VPLS.
- Pseudowire label signaling is MP-BGP based. Therefore, the BGP NLRI content also includes label-related information; for example, block offset, block size, and label base.
  - LDP VPLS: target LDP (T-LDP) is used for signaling the pseudowire service label.
  - The Layer 2 extended community proposed in RFC 4761 is used to signal pseudowire characteristics; for example, VPLS status, control word, and sequencing.

### 3.2.17.1 Pseudowire Signaling Details

The pseudowire is set up using the following NLRI fields:

- VE Block offset (VBO): used to define each VE-ID set for which the NLRI is targeted:
  - $VBO = n * VBS + 1$ ; for  $VBS = 8$ , this results in 1, 9, 17, 25, ...
  - Targeted Remote VE-IDs are from VBO to  $(VBO + VBS - 1)$
- VE Block size (VBS): defines how many contiguous pseudowire labels are reserved, starting with the Label Base:
  - Nokia implementation always uses a value of eight (8).
- Label Base (LB): local allocated label base:
  - The next eight consecutive labels available are allocated for remote PEs.

This BGP update is telling the other PEs that accept the RT: reach me (VE-ID = x), use a pseudowire label of  $LB + VE-ID - VBO$  using the BGP NLRI for which  $VBO \leq \text{local VE-ID} < VBO + VBS$ .

Following is an example of how this algorithm works, assuming PE1 has VE-ID 7 configured:

- PE1 allocates a label block of eight consecutive labels available, starting with LB = 1000.
- PE1 starts sending a BGP update with pseudowire information of VBO = 1, VBS = 8, LB = 1000 in the NLRI.
- This pseudowire information will be accepted by all participating PEs with VE-IDs from 1 to 8.
- Each of the receiving PEs will use the pseudowire label =  $LB + VE-ID - VBO$  to send traffic back to the originator PE. For example, VE-ID 2 will use pseudowire label 1001.

Assuming that VE-ID = 10 is configured in another PE4, the following procedure applies:

- PE4 sends a BGP update with the new VE-ID in the network that will be received by all the other participating PEs, including PE1.
- Upon reception, PE1 will generate another label block of 8 labels for the VBO = 9. For example, the initial PE will create new pseudowire signaling information of VBO = 9, VBS = 8, LB = 3000, and insert it in a new NLRI and BGP update that is sent in the network.
- This new NLRI will be used by the VE-IDs from 9 to 16 to establish pseudowires back to the originator PE1. For example, PE4 with VE-ID 10 will use pseudowire label 3001 to send VPLS traffic back to PE1.

- The PEs owning the set of VE-IDs from 1 to 8 will ignore this NLRI.

In addition to the pseudowire label information, the **Layer2 Info Extended Community** attribute must be included in the BGP update for BGP VPLS to signal the attributes of all the pseudowires that converge toward the originator VPLS PE.

The format is as follows:

|                                    |
|------------------------------------|
| Extended community type (2 octets) |
| Encaps Type (1 octet)              |
| Control Flags (1 octet)            |
| Layer-2 MTU (2 octet)              |
| Reserved (2 octets)                |

The meaning of the fields are as follows:

- Extended community type – the value allocated by IANA for this attribute is 0x800A
- Encaps Type – Encapsulation type; identifies the type of pseudowire encapsulation. The only value used by BGP VPLS is 19 (13 in HEX). This value identifies the encapsulation to be used for pseudowire instantiated through BGP signaling, which is the same as the one used for Ethernet pseudowire type in regular VPLS. There is no support for an equivalent Ethernet VLAN pseudowire in BGP VPLS in BGP signaling.
- Control Flags – control information regarding the pseudowires (see [Figure 81](#))
- Layer 2 MTU – the Maximum Transmission Unit to be used on the pseudowires
- Reserved – this field is reserved and must be set to zero and ignored on reception except where it is used for VPLS preference.

For inter-AS, the preference information must be propagated between autonomous systems. Consequently, as the VPLS preference in a BGP-VPLS or BGP multi-homing update extended community is zero, the local preference is copied by the egress ASBR into the VPLS preference field before sending the update to the eBGP peer. The adjacent ingress ASBR then copies the received VPLS preference into the local preference to prevent the update being considered malformed.

[Figure 82](#) shows the detailed format for the control flags bit vector.

**Figure 82 Control Flag Bit Vector Format**

The following bits in the control flags are defined as follows:

- S – sequenced delivery of frames that must or must not be used when sending VPLS packets to this PE, depending on whether S is 1 or 0, respectively
- C – a Control word that must or must not be present when sending VPLS packets to this PE, depending on whether C is 1 or 0, respectively. By default, Nokia implementation uses value 0.
- MBZ – Must Be Zero bits, set to zero when sending and ignored when receiving
- D – indicates the status of the whole VPLS instance (VSI); D = 0 if Admin and Operational status are up, D = 1 otherwise

Following are the events that set the D-bit to 1 to indicate VSI down status in the BGP update message sent out from a PE:

- Local VSI is shut down administratively using **config service vpls shutdown** command.
- All the related endpoints (SAPs or LDP pseudowires) are down.
- There are no related endpoints (SAPs or LDP pseudowires) configured yet in the VSI.
  - The intent is to save the core bandwidth by not establishing the BGP pseudowires to an empty VSI.
- Upon reception of a BGP update message with D-bit set to 1, all the receiving VPLS PEs must mark related pseudowires as down.

The following events do not set the D-bit to 1:

- The local VSI is deleted; a BGP update with UNREACH-NLRI is sent out. Upon reception, all remote VPLS PEs must remove the related pseudowires and BGP routes.
- If the local SDP goes down, only the BGP pseudowires mapped to that SDP go down. There is no BGP update sent.

### 3.2.17.2 Supported VPLS Features

BGP VPLS includes support for a new type of pseudowire signaling based on MP-BGP, based on the existing VPLS instance; therefore, it inherits all the existing Ethernet switching functions.

The use of an automatically created GRE tunnel is enabled by creating the PW template used within the service with the parameter **auto-gre-sdp**. The GRE SDP and SDP binding is created after a matching BGP route has been received.

Following are some of the most important VPLS features ported to BGP VPLS:

- VPLS data plane features: for example, FDB management, SAPs, LAG access, and BUM rate limiting
- MPLS tunneling: LDP, LDP over RSVP-TE, RSVP-TE, GRE, and MP-BGP based on RFC 3107 (Inter-AS option C solution)

**Note:** Pre-provisioned SDPs must be configured when RSVP-signaled transport tunnels are used.

- HVPLS topologies, hub and spoke traffic distribution
- Coexists with LDP VPLS (with or without BGP-AD) in the same VPLS instance:
  - LDP and BGP-signaling should operate in disjoint domains to simplify loop avoidance.
- Coexists with BGP-based multi-homing
- BGP VPLS is supported as the control plane for B-VPLS
- Supports IGMP/PIM snooping for IPv4
- Support for High Availability is provided
- Ethernet Service OAM toolset is supported: IEEE 802.1ag, Y.1731.
  - Not supported OAM features: CPE Ping, MAC trace/ping/populate/purge
- Support for RSVP and LSP P2MP LSP for VPLS/B-VPLS BUM

### 3.2.18 VCCV BFD Support for VPLS Services

The SR OS supports RFC 5885, which specifies a method for carrying BFD in a pseudowire associated channel. For general information about VCCV BFD, limitations, and configuring, see the VLL Services chapter.

VCCV BFD is supported on the following VPLS services:

- T-LDP spoke-SDP termination on VPLS (including I-VPLS, B-VPLS, and R-VPLS)
- H-VPLS spoke-SDP
- BGP VPLS
- VPLS with BGP auto-discovery

To configure VCCV BFD for H-VPLS (where the pseudowire template does not apply), configure the BFD template using the **config>service>vpls>spoke-sdp>bfd-template** *name* command, then enable it using the **config>service>vpls>spoke-sdp>bfd-enable** command.

For BGP VPLS, a BFD template is referenced from the pseudowire template binding context. To configure VCCV BFD for BGP VPLS, use the **config>service>vpls>bgp>pw-template-binding>bfd-template** *name* command and enable it using the **config>service>vpls>bgp>pw-template-binding>bfd-enable** command.

For BGP-AD VPLS, a BFD template is referenced from the pseudowire template context. To configure VCCV BFD for BGP-AD, use the **config>service>vpls>bgp-ad>pw-template-binding>bfd-template** *name* command, and enable it using the **config>service>vpls>bgp-ad>pw-template-binding>bfd-enable** command.

### 3.2.19 BGP Multi-Homing for VPLS

This section describes BGP-based procedures for electing a designated forwarder among the set of PEs that are multi-homed to a customer site. Only the local PEs are actively participating in the selection algorithm. The PEs remote from the dual-homed CE are not required to participate in the designated forwarding election for a remote dual-homed CE.

The main components of the BGP-based multi-homing solution for VPLS are:

- Provisioning model
- MP-BGP procedures
- Designated Forwarder Election
- Blackhole avoidance – indicating the designated forwarder change toward the core PEs and access PEs or CEs
- The interaction with pseudowire signaling (BGP/LDP)

**Figure 83 BGP Multi-Homing for VPLS**

OSSG489

Figure 83 shows the VPLS using BGP multi-homing for the case of multi-homed CEs. Although the figure shows the case of a pseudowire infrastructure signaled with LDP for an LDP VPLS using BGP-AD for discovery, the procedures are identical for BGP VPLS or for a mix of BGP- and LDP-signaled pseudowires.

### 3.2.19.1 Information Model and Required Extensions to L2VPN NLRI

VPLS Multi-homing using BGP-MP expands on the BGP AD and BGP VPLS provisioning model. The addressing for the multi-homed site is still independent from the addressing for the base VSI (VSI-ID or, respectively, VE-ID). Every multi-homed CE is represented in the VPLS context through a site-ID, which is the same on the local PEs. The site-ID is unique within the scope of a VPLS. It serves to differentiate between the multi-homed CEs connected to the same VPLS Instance (VSI). For example, in Figure 84, CE5 will be assigned the same site-ID on both PE1 and PE4. For the same VPLS instance, different site-IDs are assigned for multi-homed CE5 and CE6; for example, site-ID 5 is assigned for CE5 and site-ID 6 is assigned for CE6. The single-homed CEs (CE1, 2, 3, and 4) do not require allocation of a multi-homed site-ID. They are associated with the addressing for the base VSI, either VSI-ID or VE-ID.

The new information model required changes to the BGP usage of the NLRI for VPLS. The extended MH NLRI for Multi-Homed VPLS is compared with the BGP AD and BGP VPLS NRIs in Figure 84.

**Figure 84 BGP MH-NLRI for VPLS Multi-Homing**

| BGP VPLS (RFC 4761)            | LDP VPLS (RFC 4762)            | BGP and/or LDP VPLS            |
|--------------------------------|--------------------------------|--------------------------------|
| <b>BGP BPLS NLRI</b>           | <b>BGP AD NLRI</b>             | <b>BGP MH NLRI</b>             |
| (2) Length=17                  | (2) Length=12                  | (2) Length=17                  |
| Route Distinguisher (8 Octets) | Route Distinguisher (8 Octets) | Route Distinguisher (8 Octets) |
| VE ID (2)                      | VSI-ID (System IP) (4)         | Site-ID (2)                    |
| VE BI Off (2)                  | VBS Not Used (2)               | ZEROs (2)                      |
| VE BI Size (2)                 | LB Not Used (3)                | ZEROs (3)                      |
| Label Base (3)                 |                                |                                |

OSSG490

The BGP VPLS NLRI described in RFC 4761 is used to carry a 2-byte site-ID that identifies the MH site. The last seven bytes of the BGP VPLS NLRI used to instantiate the pseudowire are not used for BGP-MH and are zeroed out. This NLRI format translates into the following processing path in the receiving VPLS PE:

- BGP VPLS PE: no label information means there is no need to set up a BGP pseudowire.
- BGP AD for LDP VPLS: length =17 indicates a BGP VPLS NLRI that does not require any pseudowire LDP signaling.

The processing procedures described in this section start from the above identification of the BGP update as not destined for pseudowire signaling.

The RD ensures that the NLRIs associated with a certain site-ID on different PEs are seen as different by any of the intermediate BGP nodes (RRs) on the path between the multi-homed PEs. That is, different RDs must be used on the MH PEs every time an RR or an ASBR is involved to guarantee the MH NLRIs reach the PEs involved in VPLS MH.

The L2-Info extended community from RFC 4761 is used in the BGP update for MH NLRI to initiate a MAC flush for blackhole avoidance, to indicate the operational and admin status for the MH site or the DF election status.

After the pseudowire infrastructure between VSIs is built using either RFC 4762, *Virtual Private LAN Service (VPLS) Using Label Distribution Protocol (LDP) Signaling*, or RFC 4761 procedures, or a mix of pseudowire signaling procedures, on activation of a multi-homed site, an election algorithm must be run on the local and remote PEs to determine which site will be the designated forwarder (DF). The end result is that all the related MH sites in a VPLS will be placed in standby except for the site selected as DF. Nokia BGP-based multi-homing solution uses the DF election procedure described in the IETF working group document *draft-ietf-bess-vpls-multihoming-01*. The implementation allows the use of BGP local preference and the received VPLS preference, but does not support setting the VPLS preference to a non-zero value.

---

### 3.2.19.2 Supported Services and Multi-Homing Objects

This feature is supported for the following services:

- LDP VPLS with or without BGP-AD
- BGP VPLS (BGP multi-homing for inter-AS BGP-VPLS services is not supported)
- mix of the above
- PBB B-VPLS on BCB
- PBB I-VPLS (see [IEEE 802.1ah Provider Backbone Bridging](#) for more information)

The following access objects can be associated with MH Site:

- SAPs
- SDP bindings (pseudowire object), both mesh-SDP and spoke-SDP
- Split Horizon Group
  - Under the SHG we can associate either one or multiple of the following objects: SAPs, pseudowires (BGP VPLS, BGP-AD, provisioned and LDP-signaled spoke-SDP and mesh-SDP)

### 3.2.19.3 Blackhole Avoidance

Blackholing refers to the forwarding of frames to a PE that is no longer carrying the designated forwarder. This could happen for traffic from:

- Core PE participating in the main VPLS
- Customer Edge devices (CEs)
- Access PEs – pseudowires between them and the MH PEs are associated with MH sites

Changes in DF election results or MH site status must be detected by all of the above network elements to provide for Blackhole Avoidance.

### 3.2.19.3.1 MAC Flush to the Core PEs

Assuming that there is a transition of the existing DF to non-DF status, the PE that owns the MH site experiencing this transition will generate a MAC flush-all-from-me (negative MAC flush) toward the related core PEs. Upon reception, the remote PEs will flush all the MACs learned from the MH PE.

MAC flush-all-from-me indication message is sent using the following core mechanisms:

- For LDP VPLS running between core PEs, existing LDP MAC flush will be used.
- For pseudowire signaled with BGP VPLS, MAC flush will be provided implicitly using the L2-Info Extended community to indicate a transition of the active MH site; for example, the attached objects going down or more generically, the entire site going from Designated Forwarder (DF) to non-DF.
- Double flushing will not happen as it is expected that between any pair of PEs there will exist only one type of pseudowires – either BGP or LDP pseudowire, but not both.

### 3.2.19.3.2 Indicating non-DF status toward the access PE or CE

For the CEs or access PEs, support is provided for indicating the blocking of the MH site using the following procedures:

- For MH Access PE running LDP pseudowires, the LDP standby-status is sent to all LDP pseudowires.
- For MH CEs, site deactivation is linked to a CCM failure on a SAP that has a down MEP configured.

### 3.2.19.4 BGP Multi-Homing for VPLS Inter-Domain Resiliency

BGP MH for VPLS can be used to provide resiliency between different VPLS domains. An example of a multi-homing topology is shown in [Figure 85](#).

**Figure 85 BGP MH Used in an HVPLS Topology**

LDP VPLS domains are interconnected using a core VPLS domain, either BGP VPLS or LDP VPLS. The gateway PEs, for example PE2 and PE3, are running BGP multi-homing where one MH site is assigned to each of the pseudowires connecting the access PE, PE7, and PE8 in this example.

Alternatively, the MH site can be associated with multiple access pseudowires using an access SHG. The **config>service>vpls>site>failed-threshold** command can be used to indicate the number of pseudowire failures that are required for the MH site to be declared down.

### 3.2.20 Multicast-Aware VPLS

VPLS is a Layer 2 service; therefore, multicast and broadcast frames are normally flooded in a VPLS. Broadcast frames are targeted to all receivers. However, for IP multicast, normally for a multicast group, only some receivers in the VPLS are interested. Flooding to all sites can cause wasted network bandwidth and unnecessary replication on the ingress PE router.

To avoid this condition, VPLS is IP multicast-aware; therefore, it forwards IP multicast traffic based on multicast states to the object on which the IP multicast traffic is requested. This is achieved by enabling the following related IP multicast protocol snooping:

- IGMP snooping
- MLD snooping
- PIM snooping

### 3.2.20.1 IGMP Snooping for VPLS

When IGMP snooping is enabled in a VPLS service, IGMP messages received on SAPs and SDPs are snooped in order to determine the scope of the flooding for a specified stream or (S,G). IGMP snooping operates in a proxy mode, where the system summarizes upstream IGMP reports and responds to downstream queries. See “IGMP Snooping” in the *7450 ESS, 7750 SR, and VSR Triple Play Service Delivery Architecture Guide* for a description of IGMP snooping.

Streams are sent to all SAPs/SDPs on which there is a multicast router (either discovered dynamically from received query messages or configured statically using the **mrouter-port** command) and on which an active join for that stream has been received. The mrouter port configuration adds a (\*,\*) entry into the MFIB, which causes all groups (and IGMP messages) to be sent out of the respective object and causes IGMP messages received on that object to be discarded.

Directly connected multicast sources are supported when IGMP snooping is enabled.

IGMP snooping is enabled at the service level and is not supported in the following services:

- B-VPLS
- Routed I-VPLS
- PBB B-VPLS services

IGMP snooping is not supported on a router configured with **enable-inter-as-vpn** or **enable-rr-vpn-forwarding**.

IGMP snooping is not supported under the following forms of default SAP:

- \*
- \*.null
- \*.\*.

IGMP snooping is not supported in a VPLS service configured with a connection profile VLAN SAP.

---

### 3.2.20.2 MLD Snooping for VPLS

MLD snooping is an IPv6 version of IGMP snooping. The guidelines and procedures are similar to IGMP snooping as previously described. However, MLD snooping uses MAC-based forwarding. See [MAC-Based IPv6 Multicast Forwarding](#) for more information. Directly connected multicast sources are supported when MLD snooping is enabled.

MLD snooping is enabled at the service level and is not supported in the following services:

- B-VPLS
- Routed I-VPLS
- EVPN-MPLS services
- PBB-EVPN services

MLD snooping is not supported under the following forms of default SAP:

- \*
- \*.null
- \*. \*

MLD snooping is not supported in a VPLS service configured with a connection profile VLAN SAP.

### 3.2.20.3 PIM Snooping for VPLS

PIM snooping for VPLS allows a VPLS PE router to build multicast states by snooping PIM protocol packets that are sent over the VPLS. The VPLS PE then forwards multicast traffic based on the multicast states. When all receivers in a VPLS are IP multicast routers running PIM, multicast forwarding in the VPLS is efficient when PIM snooping for VPLS is enabled.

Because of PIM join/prune suppression, in order to make PIM snooping operate over VPLS pseudowires, two options are available: plain PIM snooping and PIM proxy. PIM proxy is the default behavior when PIM snooping is enabled for a VPLS.

PIM snooping is supported for both IPv4 and IPv6 multicast by default and can be configured to use SG-based forwarding (see [IPv6 Multicast Forwarding](#) for more information).

Directly connected multicast sources are supported when PIM snooping is enabled.

---

The following restrictions apply to PIM snooping:

- PIM snooping for IPv4 and IPv6 is not supported:
  - in the following services:
    - PBB B-VPLS
    - R-VPLS (including I-VPLS and BGP EVPN)
    - PBB-EVPN B-VPLS
    - EVPN-VXLAN R-VPLS
  - on a router configured with **enable-inter-as-vpn** or **enable-rr-vpn-forwarding**
  - under the following forms of default SAP:
    - \*
    - \*.null
    - \*.\*
  - in a VPLS service configured with a connection profile VLAN SAP
  - with connected SR OSs configured with **improved-assert**
  - with subscriber management in the VPLS service
  - as a mechanism to drive MCAC
- PIM snooping for IPv6 is not supported:
  - in the following services:
    - PBB I-VPLS
    - BGP-VPLS
    - BGP EVPN (including PBB-EVPN)
    - VPLS E-Tree
    - Management VPLS
  - with the configuration of MLD snooping

### 3.2.20.3.1 Plain PIM Snooping

In a plain PIM snooping configuration, VPLS PE routers only snoop; PIM messages are generated on their own. Join/prune suppression must be disabled on CE routers.

When plain PIM snooping is configured, if a VPLS PE router detects a condition where join/prune suppression is not disabled on one or more CE routers, the PE router will put PIM snooping into the PIM proxy state. A trap is generated that reports the condition to the operator and is logged to the syslog. If the condition changes, for example, join/prune suppression is disabled on CE routers, the PE reverts to the plain PIM snooping state. A trap is generated and is logged to the syslog.

### 3.2.20.3.2 PIM Proxy

For PIM proxy configurations, VPLS PE routers perform the following:

- snoop hellos and flood hellos in the fast data path
- consume join/prune messages from CE routers
- generate join/prune messages upstream using the IP address of one of the downstream CE routers
- run an upstream PIM state machine to determine whether a join/prune message should be sent upstream

Join/prune suppression is not required to be disabled on CE routers, but it requires all PEs in the VPLS to have PIM proxy enabled. Otherwise, CEs behind the PEs that do not have PIM proxy enabled may not be able to get multicast traffic that they are interested in if they have join/prune suppression enabled.

When PIM proxy is enabled, if a VPLS PE router detects a condition where join/prune suppression is disabled on all CE routers, the PE router puts PIM proxy into a plain PIM snooping state to improve efficiency. A trap is generated to report the scenario to the operator and is logged to the syslog. If the condition changes, for example, join/prune suppression is enabled on a CE router, PIM proxy is placed back into the operational state. Again, a trap is generated to report the condition to the operator and is logged to the syslog.

### 3.2.20.4 IPv6 Multicast Forwarding

When MLD snooping or PIM snooping for IPv6 is enabled, the forwarding of IPv6 multicast traffic is MAC-based; see [MAC-Based IPv6 Multicast Forwarding](#) for more information.

The operation with PIM snooping for IPv6 can be changed to SG-based forwarding; see [SG-Based IPv6 Multicast Forwarding](#) for more information.

The following command configures the IPv6 multicast forwarding mode with the default being **mac-based**:

```
configure service vpls mcast-ipv6-snooping-scope {sg-
  based | mac-based}
```

The forwarding mode can only be changed when PIM snooping for IPv6 is disabled.

### 3.2.20.4.1 MAC-Based IPv6 Multicast Forwarding

This section describes IPv6 multicast address to MAC address mapping and IPv6 multicast forwarding entries.

For IPv6 multicast address to MAC address mapping, Ethernet MAC addresses in the range of 33-33-00-00-00-00 to 33-33-FF-FF-FF-FF are reserved for IPv6 multicast. To map an IPv6 multicast address to a MAC-layer multicast address, the low-order 32 bits of the IPv6 multicast address are mapped directly to the low-order 32 bits in the MAC-layer multicast address.

For IPv6 multicast forwarding entries, IPv6 multicast snooping forwarding entries are based on MAC addresses, while native IPv6 multicast forwarding entries are based on IPv6 addresses. When both MLD snooping or PIM snooping for IPv6 and native IPv6 multicast are enabled on the same device, both types of forwarding entries are supported on the same forward plane, although they are used for different services.

The following output shows a service with PIM snooping for IPv6 that has received joins for two multicast groups from different sources. As the forwarding mode is MAC-based, there is a single MFIB entry created to forward these two groups.

```

### 3.2.20.4.2 SG-Based IPv6 Multicast Forwarding

When PIM snooping for IPv6 is configured, SG-based forwarding can be enabled, which causes the IPv6 multicast forwarding to be based on both the source (if specified) and destination IPv6 address in the received join.

Enabling SG-based forwarding increases the MFIB usage if the source IPv6 address or higher 96 bits of the destination IPv6 address varies in the received joins compared to using MAC-based forwarding.

The following output shows a service with PIM snooping for IPv6 that has received joins for two multicast groups from different sources. As the forwarding mode is SG-based, there are two MFIB entries, one for each of the two groups.

```

=====

\*A: PE#

SG-based IPv6 multicast forwarding is supported when both plain PIM snooping and PIM proxy are supported.

SG-based forwarding is only supported on FP3- or higher-based line cards. It is supported in all services in which PIM snooping for IPv6 is supported, with the same restrictions.

It is not supported in the following services:

- PBB B-VPLS
- PBB I-VPLS
- Routed-VPLS (including with I-VPLS and BGP-EVPN)
- BGP-EVPN-MPLS (including PBB-EVPN)
- VPLS E-Tree
- Management VPLS

In any specific service, SG-based forwarding and MLD snooping are mutually exclusive. Consequently, MLD snooping uses MAC-based forwarding.

It is not supported in services with:

- subscriber management
- multicast VLAN Registration
- video interface

It is not supported on connected SR OS routers configured with **improved-assert**.

It is not supported with the following forms of default SAP:

- \*
- \*.null
- \*. \*

### 3.2.20.5 PIM and IGMP/MLD Snooping Interaction

When both PIM snooping for IPv4 and IGMP snooping are enabled in the same VPLS service, multicast traffic is forwarded based on the combined multicast forwarding table. When PIM snooping is enabled, IGMP queries are forwarded but not snooped, consequently the IGMP querier needs to be seen either as a PIM neighbor in the VPLS service or the SAP towards it configured as an IGMP mrouter port.

There is no interaction between PIM snooping for IPv6 and PIM snooping for IPv4/IGMP snooping when all are enabled within the same VPLS service. The configurations of PIM snooping for IPv6 and MLD snooping are mutually exclusive.

When PIM snooping is enabled within a VPLS service, all IP multicast traffic and flooded PIM messages (these include all PIM snooped messages when not in PIM proxy mode and PIM hellos when in PIM proxy mode) will be sent to any SAP or SDP binding configured with an IGMP-snooping mrouter port. This will occur even without IGMP-snooping enabled, but is not supported in a BGP-VPLS or M-VPLS service.

### 3.2.20.6 Multi-Chassis Synchronization for Layer 2 Snooping States

To achieve a faster failover in scenarios with redundant active/standby routers performing Layer 2 multicast snooping, it is possible to synchronize the snooping state from the active router to the standby router, so that if a failure occurs the standby router has the Layer 2 multicast snooped states and is able to forward the multicast traffic immediately. Without this capability, there would be a longer delay in re-establishing the multicast traffic path due to having to wait for the Layer 2 states to be snooped.

Multi-chassis synchronization (MCS) is enabled per peer router and uses a **sync-tag**, which is configured on the objects requiring synchronization on both of the routers. This allows MCS to map the state of a set of objects on one router to a set of objects on the other router. Specifically, objects relating to a **sync-tag** on one router are backed up by, or are backing up, the objects using the same **sync-tag** on the other router (the state is synchronized from the active object on one router to its backup objects on the standby router).

The object type must be the same on both routers; otherwise, a mismatch error is reported. The same **sync-tag** value can be reused for multiple peer/object combinations, where each combination represents a different set of synchronized objects; however, a **sync-tag** cannot be configured on the same object to more than one peer.

The **sync-tag** is configured per port and can relate to a specific set of dot1q or QinQ VLANs on that port, as follows.

**CLI Syntax:**

```
configure
  redundancy
    multi-chassis
      peer ip-address [create]
      sync
        port port-id [sync-tag sync-tag]
        [create]
        range encap-range sync-tag
        sync-tag
```

For IGMP snooping and PIM snooping for IPv4 to work correctly with MCS on QinQ ports using x.\* SAPs, one of the following must be true:

- MCS is configured with a **sync-tag** for the entire port.
- The IGMP snooping SAP and the MCS **sync-tag** must be provisioned with the same Q-tag values when using the range parameter.

### 3.2.20.6.1 IGMP Snooping Synchronization

MCS for IGMP snooping synchronizes the join/prune state information from IGMP messages received on the related port/VLANs corresponding to their associated **sync-tag**. It is enabled as follows.

**CLI Syntax:**

```
configure
  redundancy
    multi-chassis
      peer ip-address [create]
      sync
        igmp-snooping
```

IGMP snooping synchronization is supported wherever IGMP snooping is supported (except in EVPN for VXLAN). See [IGMP Snooping for VPLS](#) for more information. IGMP snooping synchronization is also only supported for the following active/standby redundancy mechanisms:

- MC-LAG
- MC-Ring
- Single-Active Multihoming (EVPN-MPLS and PBB-EVPN I-VPLS)
- Single-Active Multihoming (EVPN-MPLS VPRN and IES routed VPLS)

Configuring an mrouter port under an object that has the synchronization of IGMP snooping states enabled is not recommended. The mrouter port configuration adds a (\*,\*) entry into the MFIB, which causes all groups (and IGMP messages) to be sent out of the respective object. In addition, the **mrouter port** command causes all IGMP messages on that object to be discarded. However, the (\*,\*) entry is not synchronized by MCS. Consequently, the mrouter port could cause the two MCS peers to be forwarding different sets of multicast streams out of the related object when each is active.

### 3.2.20.6.2 MLD Snooping Synchronization

MCS for MLD snooping is not supported. The command is not blocked for backward-compatibility reasons, but has no effect on the system if configured.

### 3.2.20.6.3 PIM Snooping for IPv4 Synchronization

MCS for PIM snooping for IPv4 synchronizes the neighbor information from PIM hellos and join/prune state information from PIM for IPv4 messages received on the related SAPs and spoke-SDPs corresponding to the **sync-tag** associated with the related ports and SDPs, respectively. Use the following CLI syntax to enable MCS for PIM snooping for IPv4 synchronization.

**CLI Syntax:**

```

configure
  redundancy
    multi-chassis
      peer ip-address [create]
      sync
      pim-snooping [saps] [spoke-sdps]
  
```

Any PIM hello state information received over the MCS connection from the peer router takes precedence over locally snooped hello information. This ensures that any PIM hello messages received on the active router that are then flooded, for example through the network backbone, and received over a local SAP or SDP on the standby router are not inadvertently used in the standby router's VPLS service.

The synchronization of PIM snooping state is only supported for manually configured spoke-SDPs. It is not supported for spoke-SDPs configured within an endpoint.

When synchronizing the PIM state between two spoke-SDPs, if both spoke-SDPs go down, the PIM state is maintained on both until one becomes active, in order to ensure that the PIM state is preserved when a spoke-SDP recovers.

Appropriate actions based on the expiration of PIM-related timers on the standby router are only taken after it has become the active peer for the related object (after a failover).

PIM snooping for IPv4 synchronization is supported wherever PIM snooping for IPv4 is supported, excluding the following services:

- BGP-VPLS
- VPLS E-Tree
- management VPLS

See [PIM Snooping for VPLS](#) for more details.

PIM snooping for IPv4 synchronization is also only supported for the following active/standby redundancy mechanisms on dual-homed systems:

- MC-LAG
- BGP Multi-homing
- active/standby pseudowires
- Single-Active Multi-homing (EVPN-MPLS and PBB-EVPN I-VPLS)

Configuring an mrouter port under an object that has the synchronization of PIM snooping for IPv4 states enabled is not recommended. The mrouter port configuration adds a (\*,\*) entry into the MFIB, which causes all groups (and PIM messages) to be sent out of the respective object. In addition, the **mrouter port** command causes all PIM messages on that object to be discarded. However, the (\*,\*) entry is not synchronized by MCS. Consequently, the mrouter port could cause the two MCS peers to be forwarding different sets of multicast streams out of the related object when each is active.

### 3.2.20.7 VPLS Multicast-Aware High Availability Features

The following features are High Availability capable:

- Configuration redundancy — All the VPLS multicast-aware configurations can be synchronized to the standby CPM.
- Local snooping states as well as states distributed by LDP can be synchronized to the standby CPM.
- Operational states can also be synchronized; for example, the operational state of PIM proxy.

### 3.2.21 RSVP and LDP P2MP LSP for Forwarding VPLS/B-VPLS BUM and IP Multicast Packets

This feature enables the use of a P2MP LSP as the default tree for forwarding Broadcast, Unicast unknown, and Multicast (BUM) packets of a VPLS or B-VPLS instance. The P2MP LSP is referred to in this case as the Inclusive Provider Multicast Service Interface (I-PMSI).

When enabled, this feature relies on BGP Auto-Discovery (BGP-AD) or BGP-VPLS to discover the PE nodes participating in a specified VPLS/B-VPLS instance. The BGP route contains the information required to signal both the point-to-point (P2P) PWs used for forwarding unicast known Ethernet frames and the RSVP P2MP LSP used to forward the BUM frames. The root node signals the P2MP LSP based on an LSP template associated with the I-PMSI at configuration time. The leaf node will automatically join the P2MP LSP that matches the I-PMSI tunnel information discovered via BGP.

If IGMP or PIM snooping are configured on the VPLS instance, multicast packets matching an L2 multicast Forwarding Information Base (FIB) record will also be forwarded over the P2MP LSP.

The user enables the use of an RSVP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS/B-VPLS instance using the following commands:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>rsvp>lsp-template  
p2mp-lsp-template-name
```

The user enables the use of an LDP P2MP LSP as the I-PMSI for forwarding Ethernet BUM and IP multicast packets in a VPLS instance using the following command:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>mldp
```

After the user performs a **no shutdown** under the context of the inclusive node and the expiration of a delay timer, BUM packets will be forwarded over an automatically signaled mLDP P2MP LSP or over an automatically signaled instance of the RSVP P2MP LSP specified in the LSP template.

The user can specify that the node is both root and leaf in the VPLS instance:

```
config>service>vpls [b-vpls]>provider-tunnel>inclusive>root-and-leaf
```

The **root-and-leaf** command is required; otherwise, this node will behave as a leaf-only node by default. When the node is leaf only for the I-PMSI of type P2MP RSVP LSP, no PMSI Tunnel Attribute is included in BGP-AD route update messages and, therefore, no RSVP P2MP LSP is signaled, but the node can join an RSVP P2MP LSP rooted at other PE nodes participating in this VPLS/B-VPLS service. The user must still configure a LSP template even if the node is a leaf only. For the I-PMSI of type mLDP, the leaf-only node will join I-PMSI rooted at other nodes it discovered, but will not include a PMSI Tunnel Attribute in BGP route update messages. This way, a leaf-only node will forward packets to other nodes in the VPLS/B-VPLS using the point-to-point spoke-SDPs.

BGP-AD (or BGP-VPLS) must have been enabled in this VPLS/B-VPLS instance or the execution of the **no shutdown** command under the context of the inclusive node is failed and the I-PMSI will not come up.

Any change to the parameters of the I-PMSI, such as disabling the P2MP LSP type or changing the LSP template, requires that the inclusive node be first shut down. The LSP template is configured in MPLS.

If the P2MP LSP instance goes down, VPLS/B-VPLS immediately reverts the forwarding of BUM packets to the P2P PWs. However, the user can restore at any time the forwarding of BUM packets over the P2P PWs by performing a **shutdown** under the context of the inclusive node.

This feature is supported with VPLS, H-VPLS, B-VPLS, and BGP-VPLS. It is not supported with I-VPLS and R-VPLS.

### 3.2.22 MPLS Entropy Label and Hash Label

The router supports the MPLS entropy label (RFC 6790) and the Flow Aware Transport label (known as the hash label) (RFC 6391). These labels allow LSR nodes in a network to load-balance labeled packets in a much more granular fashion than allowed by simply hashing on the standard label stack. See the *7450 ESS*, *7750 SR*, *7950 XRS*, and *VSR MPLS Guide* for further information.

---

## 3.3 Routed VPLS and I-VPLS

This section provides information about Routed VPLS (R-VPLS) and I-VPLS. R-VPLS and I-VPLS apply to the 7450 ESS and 7750 SR.

### 3.3.1 IES or VPRN IP Interface Binding

For the remainder of this section R-VPLS and Routed I-VPLS will both be described as a VPLS service and differences will be pointed out where applicable.

A standard IP interface within an existing IES or VPRN service context may be bound to a service name. Subscriber and group IP interfaces are not allowed to bind to a VPLS or I-VPLS service context or I-VPLS. A VPLS service only supports binding for a single IP interface.

While an IP interface may only be bound to a single VPLS service, the routing context containing the IP interface (IES or VPRN) may have other IP interfaces bound to other VPLS service contexts of the same type (all VPLS or all I-VPLS). That is, R-VPLS allows the binding of IP interfaces in IES or VPRN services to be bound to VPLS services and Routed I-VPLS allows of IP interfaces in IES or VPRN services to be bound to I-VPLS services.

#### 3.3.1.1 Assigning a Service Name to a VPLS Service

When a service name is applied to any service context, the name and service ID association is registered with the system. A service name cannot be assigned to more than one service ID.

Special consideration is given to a service name that is assigned to a VPLS service that has the **config>service>vpls>allow-ip-int-bind** command enabled. If a name is applied to the VPLS service while the flag is set, the system will scan the existing IES and VPRN services for an IP interface that is bound to the specified service name. If an IP interface is found, the IP interface will be attached to the VPLS service associated with the name. Only one interface can be bound to the specified name.

If the **allow-ip-int-bind** command is not enabled on the VPLS service, the system will not attempt to resolve the VPLS service name to an IP interface. As soon as the **allow-ip-int-bind** flag is configured on the VPLS, the corresponding IP interface will be bound and become operational up. There is no need to toggle the **shutdown/no shutdown** command.

---

If an IP interface is not currently bound to the service name used by the VPLS service, no action is taken at the time of the service name assignment.

### **3.3.1.2 Service Binding Requirements**

If the defined service ID is created on the system, the system will check to ensure that the service type is VPLS. If the service type is not VPLS or I-VPLS, service creation will not be allowed and the service ID will remain undefined within the system.

If the created service type is VPLS, the IP interface will be eligible to enter the operationally up state.

### **3.3.1.3 Bound Service Name Assignment**

If a bound service name is assigned to a service within the system, the system will first check to ensure the service type is VPLS or I-VPLS. Secondly, the system will ensure that the service is not already bound to another IP interface via the service ID. If the service type is not VPLS or I-VPLS or the service is already bound to another IP interface via the service ID, the service name assignment will fail.

If a single VPLS service ID and service name is assigned to two separate IP interfaces, the VPLS service will not be allowed to enter the operationally up state.

### **3.3.1.4 Binding a Service Name to an IP Interface**

An IP interface within an IES or VPRN service context may be bound to a service name at any time. Only one interface can be bound to a service.

When an IP interface is bound to a service name and the IP interface is administratively up, the system will scan for a VPLS service context using the name and take the following actions:

- If the name is not currently in use by a service, the IP interface will be placed in an operationally down: Non-existent service name or inappropriate service type state.
- If the name is currently in use by a non-VPLS service or the wrong type of VPLS service, the IP interface will be placed in the operationally down: Non-existent service name or inappropriate service type state.

- If the name is currently in use by a VPLS service without the **allow-ip-int-bind** flag set, the IP interface will be placed in the operationally down: VPLS service **allow-ip-int-bind** flag not set state. There is no need to toggle the **shutdown/no shutdown** command.
- If the name is currently in use by a valid VPLS service and the **allow-ip-int-bind** flag is set, the IP interface will be eligible to be placed in the operationally up state depending on other operational criteria being met.

### 3.3.1.5 Bound Service Deletion or Service Name Removal

If a VPLS service is deleted while bound to an IP interface, the IP interface will enter the Down: Non-existent svc-ID operational state. If the IP interface was bound to the VPLS service name, the IP interface will enter the Down: Non-existent svc-name operational state. No console warning is generated.

If the created service type is VPLS, the IP interface will be eligible to enter the operationally up state.

### 3.3.1.6 IP Interface Attached VPLS Service Constraints

Once a VPLS service has been bound to an IP interface through its service name, the service name assigned to the service cannot be removed or changed unless the IP interface is first unbound from the VPLS service name.

A VPLS service that is currently attached to an IP interface cannot be deleted from the system unless the IP interface is unbound from the VPLS service name.

The **allow-ip-int-bind** flag within an IP interface attached VPLS service cannot be reset. The IP interface must first be unbound from the VPLS service name to reset the flag.

### 3.3.1.7 IP Interface and VPLS Operational State Coordination

When the IP interface is successfully attached to a VPLS service, the operational state of the IP interface will be dependent upon the operational state of the VPLS service.

The VPLS service remains down until at least one virtual port (SAP, spoke-SDP, or mesh SDP) is operational.

---

### 3.3.2 IP Interface MTU and Fragmentation

The VPLS service is affected by two MTU values: port MTUs and the VPLS service MTU. The MTU on each physical port defines the largest Layer 2 packet (including all DLC headers) that may be transmitted out a port. The VPLS has a service level MTU that defines the largest packet supported by the service. This MTU does not include the local encapsulation overhead for each port (QinQ, Dot1Q, TopQ, or SDP service delineation fields and headers) but does include the remainder of the packet.

As virtual ports are created in the system, the virtual port cannot become operational unless the configured port MTU minus the virtual port service delineation overhead is greater than or equal to the configured VPLS service MTU. Therefore, an operational virtual port is ensured to support the largest packet traversing the VPLS service. The service delineation overhead on each Layer 2 packet is removed before forwarding into a VPLS service. VPLS services do not support fragmentation and must discard any Layer 2 packet larger than the service MTU after the service delineation overhead is removed.

When an IP interface is associated with a VPLS service, the IP-MTU is based on either the administrative value configured for the IP interface or an operational value derived from VPLS service MTU. The operational IP-MTU cannot be greater than the VPLS service MTU minus 14 bytes.

- If the configured (administrative) IP-MTU is configured for a value greater than the normalized IP-MTU, based on the VPLS service-MTU, then the operational IP-MTU is reset to equal the normalized IP-MTU value (VPLS service MTU – 14 bytes).
- If the configured (administrative) IP-MTU is configured for a value less than or equal to the normalized IP-MTU, based on the VPLS service-MTU, then the operational IP-MTU is set to equal the configured (administrative) IP-MTU value.

#### 3.3.2.1 Unicast IP Routing into a VPLS Service

The VPLS service MTU and the IP interface MTU parameters may be changed at any time.

---

### 3.3.3 ARP and VPLS FDB Interactions

Two address-oriented table entries are used when routing into a VPLS service. On the routing side, an ARP entry is used to determine the destination MAC address used by an IP next-hop. In the case where the destination IP address in the routed packet is a host on the local subnet represented by the VPLS instance, the destination IP address is used as the next-hop IP address in the ARP cache lookup. If the destination IP address is in a remote subnet that is reached by another router attached to the VPLS service, the routing lookup will return the local IP address on the VPLS service of the remote router. If the next-hop is not currently in the ARP cache, the system will generate an ARP request to determine the destination MAC address associated with the next-hop IP address.

IP routing to all destination hosts associated with the next-hop IP address stops until the ARP cache is populated with an entry for the next-hop. The ARP cache may be populated with a static ARP entry for the next-hop IP address. While dynamically populated ARP entries will age out according to the ARP aging timer, static ARP entries never age out.

The second address table entry that affects VPLS routed packets is the MAC destination lookup in the VPLS service context. The MAC associated with the ARP table entry for the IP next-hop may or may not currently be populated in the VPLS Layer 2 FDB table. While the destination MAC is unknown (not populated in the VPLS FDB), the system will flood all packets destined for that MAC (routed or bridged) to all virtual ports within the VPLS service context. Once the MAC is known (populated in the VPLS FDB), all packets destined for the MAC (routed or bridged) will be targeted to the specific virtual port where the MAC has been learned.

As with ARP entries, static MAC entries may be created in the VPLS FDB. Dynamically learned MAC addresses are allowed to age out or be flushed from the VPLS FDB while static MAC entries always remain associated with a specific virtual port. Dynamic MACs may also be relearned on another VPLS virtual port than the current virtual port in the FDB. In this case, the system will automatically move the MAC FDB entry to the new VPLS virtual port.

The MAC address associated with the R-VPLS IP interface is protected within its VPLS service such that frames received with this MAC address as the source address are discarded. VRRP MAC addresses are not protected in this way.

### 3.3.3.1 R-VPLS Specific ARP Cache Behavior

In typical routing behavior, the system uses the IP route table to select the egress interface, and then at the egress forwarding engine, an ARP entry is used to forward the packet to the appropriate Ethernet MAC. With R-VPLS, the egress IP interface may be represented by a multiple egress forwarding engine (wherever the VPLS service virtual ports exist).

To optimize routing performance, the ingress forwarding engine processing has been augmented to perform an ingress ARP lookup in order to resolve which VPLS MAC address the IP frame must be routed toward. This MAC address may be currently known or unknown within the VPLS FDB. If the MAC is unknown, the packet is flooded by the ingress forwarding engine to all egress forwarding engines where the VPLS service exists. When the MAC is known on a virtual port, the ingress forwarding engine forwards the packet to the correct egress forwarding engine. [Table 34](#) describes how the ARP cache and MAC FDB entry states interact at ingress and [Table 35](#) describes the corresponding egress behavior.

**Table 34 Ingress Routed to VPLS Next-Hop Behavior**

| Next-Hop ARP Cache Entry  | Next-Hop MAC FDB Entry | Ingress Behavior                                                                                                    |
|---------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------|
| ARP Cache Miss (No Entry) | Known or Unknown       | Flood to all egress forwarding engines associated with the VPLS or I-VPLS context.                                  |
|                           | Unknown                | Flood to all egress forwarding engines associated with the VPLS or I-VPLS context.                                  |
|                           | Unknown                | Flood to all egress forwarding engines associated with the VPLS for forwarding to all VPLS or I-VPLS virtual ports. |

**Table 35 Egress R-VPLS Next-Hop Behavior**

| Next-Hop ARP Cache Entry  | Next-Hop MAC FDB Entry | Egress Behavior                                                                                                                                                                                                                   |
|---------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ARP Cache Miss (No Entry) | Known                  | No ARP entry. The MAC address is unknown and the ARP request is flooded out of all virtual ports of the VPLS or I-VPLS instance.                                                                                                  |
|                           | Unknown                | Request control engine processing the ARP request to transmit out of all virtual ports associated with the VPLS or I-VPLS service. Only the first egress forwarding engine ARP processing request triggers an egress ARP request. |

**Table 35 Egress R-VPLS Next-Hop Behavior (Continued)**

| Next-Hop ARP Cache Entry | Next-Hop MAC FDB Entry | Egress Behavior                                                                         |
|--------------------------|------------------------|-----------------------------------------------------------------------------------------|
| ARP Cache Hit            | Known                  | Forward out of specific egress VPLS or I-VPLS virtual ports where MAC has been learned. |
|                          | Unknown                | Flood to all egress VPLS or I-VPLS virtual ports on forwarding engine.                  |

### 3.3.4 The allow-ip-int-bind VPLS Flag

The **allow-ip-int-bind** flag on a VPLS service context is used to inform the system that the VPLS service is enabled for routing support. The system uses the setting of the flag as a key to determine the types of ports and forwarding planes the VPLS service may span.

The system also uses the flag state to define which VPLS features are configurable on the VPLS service to prevent enabling a feature that is not supported when routing support is enabled.

#### 3.3.4.1 R-VPLS SAPs Only Supported on Standard Ethernet Ports

The **allow-ip-int-bind** flag is set (routing support enabled) on a VPLS/I-VPLS service. SAPs within the service can be created on standard Ethernet, HSMDA, and CCAG ports. ATM and POS are not supported.

#### 3.3.4.2 LAG Port Membership Constraints

If a LAG has a non-supported port type as a member, a SAP for the routing-enabled VPLS service cannot be created on the LAG. Once one or more routing enabled VPLS SAPs are associated with a LAG, a non-supported Ethernet port type cannot be added to the LAG membership.

---

### 3.3.4.3 R-VPLS Feature Restrictions

When the **allow-ip-int-bind** flag is set on a VPLS service, the following restrictions apply. The flag also cannot be enabled while any of these features are applied to the VPLS service:

- SAP ingress QoS policies applied to the VPLS SAPs cannot have MAC match criteria defined.
- SDPs used in spoke or mesh SDP bindings cannot be configured as GRE.
- The VPLS service type cannot be B-VPLS or M-VPLS.
- MVR from R-VPLS and to another SAP is not supported.
- Enhanced and Basic Subscriber Management (BSM) features cannot be enabled.
- Network domain on SDP bindings cannot be enabled.
- Per-service hashing is not supported.
- BGP-VPLS is not supported.
- Ingress queuing for split horizon groups is not supported.
- Multiple virtual routers are not supported.

### 3.3.4.4 Routed I-VPLS Feature Restrictions

The following restrictions apply to routed I-VPLS:

- Multicast is not supported.
- VC-VLANs are not supported on SDPs.
- **force-qtag-forwarding** is not supported.
- Control words are not supported on B-VPLS SDPs.
- Hash label is not supported on B-VPLS SDPs.

### 3.3.5 IPv4 and IPv6 Multicast Routing Support

IPv4 and IPv6 multicast routing is supported in a R-VPLS service through its IP interface when the source of the multicast stream is on one side of its IP interface and the receivers are on either side of the IP interface. For example, the source for multicast stream G1 could be on the IP side sending to receivers on both other regular IP interfaces and the VPLS of the R-VPLS service, while the source for group G2 could be on the VPLS side sending to receivers on both the VPLS and IP side of the R-VPLS service.

IPv4 and IPv6 multicast routing is not supported with Multicast VLAN Registration functions or the configuration of a video interface within the associated VPLS service. It is also not supported in a routed I-VPLS service, or for IPv6 multicast in BGP EVPN-MPLS routed VPLS services. Forwarding IPv4 or IPv6 multicast traffic from the R-VPLS IP interface into its VPLS service on a P2MP LSP is not supported.

The IP interface of a R-VPLS supports the configuration of both PIM and IGMP for IPv4 multicast and for both PIM and MLD for IPv6 multicast.

To forward IPv4/IPv6 multicast traffic from the VPLS side of the R-VPLS service to the IP side, the **forward-ipv4-multicast-to-ip-int** and/or **forward-ipv6-multicast-to-ip-int** parameters must be configured as follows:

```
configure
  service
    vpls <service-id>
      allow-ip-int-bind
        forward-ipv4-multicast-to-ip-int
        forward-ipv6-multicast-to-ip-int
      exit
    exit
  exit
exit
```

Enabling IGMP snooping or MLD snooping in the VPLS service is optional, where supported. If IGMP/MLD snooping is enabled, IGMP/MLD must be enabled on the R-VPLS IP interface in order for multicast traffic to be sent into, or received from, the VPLS service. IPv6 multicast uses MAC-based forwarding; see [MAC-Based IPv6 Multicast Forwarding](#) for more information.

If both IGMP/MLD and PIM for IPv4/IPv6 are configured on the R-VPLS IP interface in a redundant PE topology, the associated IP interface on one of the PEs must be configured as both the PIM designated router and the IGMP/MLD querier. This ensures that the multicast traffic is sent into the VPLS service, as IGMP/MLD joins are only propagated to the IP interface if it is the IGMP/MLD querier. An alternative to this is to configure the R-VPLS IP interface in the VPLS service as an mrouter port, as follows:

```
configure
service
  vpls <service-id>
    allow-ip-int-bind
    igmp-snooping
    mrouter-port
    mld-snooping
    mrouter-port
  exit
exit
exit
exit
```

This configuration achieves a faster failover in scenarios with redundant routers where multicast traffic is sent to systems on the VPLS side of their R-VPLS services and IGMP/MLD snooping is enabled in the VPLS service. If the active router fails, the remaining router does not have to wait until it sends an IGMP/MLD query into the VPLS service before it starts receiving IGMP/MLD joins, and starts sending the multicast traffic into the VPLS service. When the mrouter port is configured as above, all IGMP/MLD joins (and multicast traffic) are sent to the VPLS service IP interface.

IGMP/MLD snooping should only be enabled when systems, as opposed to PIM routers, are connected to the VPLS service. If IGMP/MLD snooping is enabled when the VPLS service is used for transit traffic for connected PIM routers, the IGMP/MLD snooping would prevent multicast traffic being forwarded between the PIM routers (as PIM snooping is not supported). A workaround would be to configure the VPLS SAPs and spoke-SDPs (and the R-VPLS IP interface) to which the PIM routers are connected as mrouter ports.

If IMPM is enabled on an FP on which there is a R-VPLS service with **forward-ipv4-multicast-to-ip-int** or **forward-ipv6-multicast-to-ip-int** configured, the IPv4/IPv6 multicast traffic received in the VPLS service that is forwarded through the IP interface will be IMPM-managed even without IGMP/MLD snooping being enabled. This does not apply to traffic that is only flooded within the VPLS service.

When IPv4/IPv6 multicast traffic is forwarded from a VPLS SAP through the R-VPLS IP interface, the packet count is doubled in the following statistics to represent both the VPLS and IP replication (this reflects the capacity used for this traffic on the ingress queues, which is subject to any configured rates and IMPM capacity management):

- Offered queue statistics
- IMPM managed statistics
- IMPM unmanaged statistics for policed traffic

IPv4 or IPv6 multicast traffic entering the IP side of the R-VPLS service and exiting over a multi-port LAG on the VPLS side of the service is sent on a single link of that egress LAG, specifically the link used for all broadcast, unknown, and multicast traffic.

An example of IPv4/IPv6 multicast in a R-VPLS service is shown in [Figure 86](#). There are two R-VPLS IP interfaces connected to an IES service with the upper interface connected to a VPLS service in which there is a PIM router and the lower interface connected to a VPLS service in which there is a system using IGMP/MLD.

**Figure 86 IPv4/IPv6 Multicast with a Router VPLS Service**

0775

The IPv4/IPv6 multicast traffic entering the IES/VRN service through the regular IP interface is replicated to both the other regular IP interface and the two R-VPLS interfaces if PIM/IGMP/MLD joins have been received on the respective IP interfaces. This traffic will be flooded into both VPLS services unless IGMP/MLD snooping is enabled in the lower VPLS service, in which case it is only sent to the system originating the IGMP/MLD join.

The IPv4/IPv6 multicast traffic entering the upper VPLS service from the connected PIM router will be flooded in that VPLS service and, if related joins have been received, forwarded to the regular IP interfaces in the IES/VRN. It will also be forwarded to the lower VPLS service if an IGMP/MLD join is received on its IP interface, and will be flooded in that VPLS service unless IGMP/MLD snooping is enabled.

The IPv4/IPv6 multicast traffic entering the lower VPLS service from the connected system will be flooded in that VPLS service, unless IGMP/MLD snooping is enabled, in which case it will only be forwarded to SAPs, spoke-SDPs, or the R-VPLS IP interface if joins have been received on them. It will be forwarded to the regular IP interfaces in the IES/VP RN service if related joins have been received on those interfaces, and it will also be forwarded to the upper VPLS service if a PIM IPv4/IPv6 join is received on its IP interface, this being flooded in that VPLS service.

### **3.3.6 BGP Auto-Discovery (BGP-AD) for R-VPLS Support**

BGP Auto-Discovery (BGP-AD) for R-VPLS is supported. BGP-AD for LDP VPLS is an already supported framework for automatically discovering the endpoints of a Layer 2 VPN offering an operational model similar to that of an IP VPN.

### **3.3.7 R-VPLS Caveats**

#### **3.3.7.1 VPLS SAP Ingress IP Filter Override**

When an IP Interface is attached to a VPLS or an I-VPLS service context, the VPLS SAP provisioned IP filter for ingress routed packets may be optionally overridden in order to provide special ingress filtering for routed packets. This allows different filtering for routed packets and non-routed packets. The filter override is defined on the IP interface bound to the VPLS service name. A separate override filter may be specified for IPv4 and IPv6 packet types.

If a filter for a specified packet type (IPv4 or IPv6) is not overridden, the SAP specified filter is applied to the packet (if defined).

### **3.3.7.2 IP Interface Defined Egress QoS Reclassification**

The SAP egress QoS policy defined forwarding class and profile reclassification rules are not applied to egress routed packets. To allow for egress reclassification, a SAP egress QoS policy ID may be optionally defined on the IP interface that will be applied to routed packets that egress the SAPs on the VPLS or I-VPLS service associated with the IP interface. Both unicast directed and MAC unknown flooded traffic apply to this rule. Only the reclassification portion of the QoS policy is applied, which includes IP precedence or DSCP classification rules and any defined IP match criteria and their associated actions.

The policers and queues defined within the QoS policy applied to the IP interface are not created on the egress SAPs of the VPLS service. Instead, the QoS policy applied to the egress SAPs defines the egress policers and queues that will be used by both routed and non-routed egress packets. The forwarding class mappings defined in the egress SAP's QoS policy will also define which policer or queue will handle each forwarding class for both routed and non-routed packets.

### **3.3.7.3 Remarking for VPLS and Routed Packets**

The remarking of packets to and from an IP interface in an R-VPLS service corresponds to that supported on IP interface, even though the packets ingress or egress a SAP in the VPLS service bound to the IP service. Specifically, this results in the ability to remark the DSCP/prec for these packets.

Packets ingressing and egressing SAPs in the VPLS service (not routed through the IP interface) support the regular VPLS QoS and, therefore, the DSCP/prec cannot be remarked.

### **3.3.7.4 7450 Mixed Mode Chassis**

The mixed mode on the 7450 ESS that allows 7750 SR-based IOMs to be populated and operational in a 7450 ESS chassis supports R-VPLS as long as all the forwarding plane and port type restrictions are observed.

### **3.3.7.5 IPv4 Multicast Routing**

When using IPv4 Multicast routing, the following are not supported:

- multicast VLAN registration functions within the associated VPLS service
- configuration of a video ISA within the associated VPLS service
- configuration of MFIB-allowed MDA destinations under spoke/mesh SDPs within the associated VPLS service
- IPv4 multicast routing is not supported in Routed I-VPLS.
- RFC 6037 multicast tunnel termination (including when the system is a bud node) is not supported on the R-VPLS IP interface for multicast traffic received in the VPLS service.
- Forwarding of multicast traffic from the VPLS side of the service to the IP interface side of the service is not supported for R-VPLS services in which VXLAN is enabled.

### **3.3.7.6 R-VPLS Supported Routing-related Protocols**

The following protocols are supported on IP interfaces bound to a VPLS service:

- BGP
- OSPF
- ISIS
- PIM
- IGMP
- BFD
- VRRP
- ARP
- DHCP Relay

### **3.3.7.7 Spanning Tree and Split Horizon**

A R-VPLS context supports all spanning tree and split horizon capabilities that a non-R-VPLS service supports.

---

## 3.4 VPLS Service Considerations

This section describes the 7450 ESS, 7750 SR, and 7950 XRS service features and any special capabilities or considerations as they relate to VPLS services.

### 3.4.1 SAP Encapsulations

VPLS services are designed to carry Ethernet frame payloads, so the services can provide connectivity between any SAPs and SDPs that pass Ethernet frames. The following SAP encapsulations are supported on the 7450 ESS, 7750 SR, and 7950 XRS VPLS services:

- Ethernet null
- Ethernet dot1q
- Ethernet QinQ
- SONET/SDH BCP-null
- SONET/SDH BCP-dot1q
- ATM VC with RFC 2684 Ethernet bridged encapsulation (See [ATM/Frame Relay PVC Access and Termination on a VPLS Service.](#))
- FR VC with RFC 2427 Ethernet bridged encapsulation (See [ATM/Frame Relay PVC Access and Termination on a VPLS Service.](#))

### 3.4.2 VLAN Processing

The SAP encapsulation definition on Ethernet ingress ports defines which VLAN tags are used to determine the service to which the packet belongs:

1. Null encapsulation defined on ingress — Any VLAN tags are ignored and the packet goes to a default service for the SAP.
2. Dot1q encapsulation defined on ingress — Only first label is considered.
3. QinQ encapsulation defined on ingress— Both labels are considered.  
The SAP can be defined with a wildcard for the inner label (for example, "100:100.\*"). In this situation, all packets with an outer label of 100 will be treated as belonging to the SAP. If, on the same physical link, there is also a SAP defined with a QinQ encapsulation of 100:100.1, then traffic with 100:1 will go to that SAP and all other traffic with 100 as the first label will go to the SAP with the 100:100.\* definition.

In situations 2 and 3 above, traffic encapsulated with tags for which there is no definition are discarded.

### 3.4.3 Ingress VLAN Swapping

This feature is supported on VPLS and VLL service where the end-to-end solution is built using two node solutions (requiring SDP connections between the nodes).

In VLAN swapping, only the VLAN ID value will be copied to the inner VLAN position. Ethertype of the inner tag will be preserved and all consecutive nodes will work with that value. Similarly, the dot1p bits value of outer tag will not be preserved.

**Figure 87 Ingress VLAN Swapping**

Fig\_36

Figure 87 describes the network where, at user access side (DSLAM facing SAPs), every subscriber is represented by several QinQ SAPs with inner-tag encoding service and outer-tag encoding subscriber (DSL line). The aggregation side (BRAS or PE-facing SAPs) is represented by a DSL line number (inner VLAN tag) and DSLAM (outer VLAN tag). The effective operation on the VLAN tag is to drop the inner tag at the access side and push another tag at the aggregation side.

### 3.4.4 Service Auto-Discovery using Multiple VLAN Registration Protocol (MVRP)

IEEE 802.1ak Multiple VLAN Registration Protocol (MVRP) is used to advertise throughout a native Ethernet switching domain one or multiple VLAN IDs to automatically build native Ethernet connectivity for multiple services. These VLAN IDs can be either Customer VLAN IDs (CVID) in an enterprise switching environment, Stacked VLAN IDs (SVID) in a Provider Bridging, QinQ Domain (refer to IEEE 802.1ad), or Backbone VLAN IDs (BVID) in a Provider Backbone Bridging (PBB) domain (refer to IEEE 802.1ah).

The initial focus of Nokia MVRP implementation is a Service Provider QinQ domain with or without a PBB core. The QinQ access into a PBB core example is used throughout this section to describe the MVRP implementation. With the exception of end-station components, a similar solution can be used to address a QinQ only or enterprise environments.

The components involved in the MVRP control plane are shown in [Figure 88](#).

**Figure 88 Infrastructure for MVRP Exchanges**

OSSG492

All the devices involved are QinQ switches with the exception of the PBB BEB which delimits the QinQ domain and ensures the transition to the PBB core. The circles represent Management VPLS instances interconnected by SAPs to build a native Ethernet switching domain used for MVRP control plane exchanges.

The following high-level steps are involved in auto-discovery of VLAN connectivity in a native Ethernet domain using MVRP:

- Configure the MVRP infrastructure
  - This requires the configuration of a Management VPLS (M-VPLS) context.
  - MSTP may be used in M-VPLS to provide the loop-free topology over which the MVRP exchanges take place.
- Instantiate related VLAN FDB, trunks in the MVRP, M-VPLS scope
  - The VLAN FDBs (VPLS instances) and associated trunks (SAPs) are instantiated in the same Ethernet switches and on the same “trunk ports” as the M-VPLS.
  - There is no need to instantiate data VPLS instances in the BEB. I-VPLS instances and related downward-facing SAPs will be provisioned manually because the ISID-to-VLAN association must be configured.
- MVRP activation of service connectivity
  - When the first two customer UNI and/or PBB end-station SAPs are configured on different Ethernet switches in a certain service context, the MVRP exchanges will activate service connectivity.

#### **3.4.4.1 Configure the MVRP Infrastructure using an M-VPLS Context**

The following provisioning steps apply:

- Configure M-VPLS instances in the switches that will participate in MVRP control plane
- Configure under the M-VPLS the untagged SAPs to be used for MVRP exchanges; only dot1q or qinq ports are accepted for MVRP enabled M-VPLS
- Configure MVRP parameters at M-VPLS instance or SAP level

#### **3.4.4.2 Instantiate Related VLAN FDBs and Trunks in MVRP Scope**

This requires the configuration in the M-VPLS, under vpls-group, of the following attributes: VLAN ranges, vpls-template and vpls-sap-template bindings. As soon as the VPLS group is enabled, the configured attributes are used to auto-instantiate, on a per-VLAN basis, a VPLS FDB and related SAPs in the switches and on the “trunk ports” specified in the M-VPLS context. The trunk ports are ports associated with an M-VPLS SAP not configured as an end-station.

The following procedure is used:

- The vpls-template binding is used to instantiate the VPLS instance where the service ID is derived from the VLAN value as per service-range configuration.
- The vpls-sap-template binding is used to create dot1q SAPs by deriving from the VLAN value the service delimiter as per service-range configuration.

The above procedure may be used outside of the MVRP context to pre-provision a large number of VPLS contexts that share the same infrastructure and attributes.

The MVRP control of the auto-instantiated services can be enabled using the **mvrp-control** command under vpls-group:

- If mvrp-control is disabled, the auto-created VPLS instances and related SAPs are ready to forward.
- If mvrp-control is enabled, the auto-created VPLS instances will be instantiated initially with an empty flooding domain. The MVRP exchanges will gradually enable service connectivity according to the operator configuration – between configured SAPs in the data VPLS context.
  - This also provides protection against operational mistakes that may generate flooding throughout the auto-instantiated VLAN FDBs.

From an MVRP perspective, these SAPs can be either “full MVRP” or “end-station” interfaces.

A full MVRP interface is a full participant in the local M-VPLS scope:

- VLAN attributes received in an MVRP registration on this MVRP interface are declared on all the other full MVRP SAPs in the control VPLS.
- VLAN attributes received in an MVRP registration on other full MVRP interfaces in the local M-VPLS context are declared on this MVRP interface.

In an MVRP end-station interface, the attributes registered on that interface have local significance:

- VLAN attributes received in an MVRP registration on this interface are not declared on any other MVRP SAPs in the control VPLS. The attributes are registered only on the local port.
- Only locally active VLAN attributes are declared on the end-station interface; VLAN attributes registered on any other MVRP interfaces are not declared on end-station interfaces.
- Also defining an M-VPLS SAP as an end-station does not instantiate any objects on the local switch; the command is used just to define which SAP needs to be monitored by MVRP to declare the related VLAN value.

The following example describes the M-VPLS configuration required to auto-instantiate the VLAN FDBs and related trunks in non-PBB switches:

**Example:**

```
mrp
  no shutdown
  mvrp
    shutdown
  mvrp
    no shutdown
sap 1/1/1:0
  mrp mvrp
    no shutdown
sap 2/1/2:0
  mrp mvrp
    no shutdown
sap 3/1/10:0
  mrp mvrp
    no shutdown
vpls-group 1
  service-range 100-2000
  vpls-template-binding Autovpls1
  sap-template-binding Autosap1
  mvrp-control
  no shutdown
```

A similar M-VPLS configuration may be used to auto-instantiate the VLAN FDBs and related trunks in PBB switches. The vpls-group command is replaced by the endstation command under the downward-facing SAPs as in the following example:

**Example:**

```
config>service>vpls control-mvrp m-vpls create customer
1
[.]
sap 1/1/1:0
  mvrp mvrp
    endstation-vid-group 1 vlan-id 100-2000
  no shutdown
```

### 3.4.4.3 MVRP Activation of Service Connectivity

As new Ethernet services are activated, UNI SAPs need to be configured and associated with the VLAN IDs (VPLS instances) auto-created using the procedures described in the previous sections. These UNI SAPs may be located in the same VLAN domain or over a PBB backbone. When UNI SAPs are located in different VLAN domains, an intermediate service translation point must be used at the PBB BEB, which maps the local VLAN ID through an I-VPLS SAP to a PBB ISID. This BEB SAP will be playing the role of an end-station from an MVRP perspective for the local VLAN domain.

This section will discuss how MVRP is used to activate service connectivity between a BEB SAP and a UNI SAP located on one of the switches in the local domain. A similar procedure is used in the case of UNI SAPs configured on two switches located in the same access domain. No end-station configuration is required on the PBB BEB if all the UNI SAPs in a service are located in the same VLAN domain.

The service connectivity instantiation through MVRP is shown in [Figure 89](#).

**Figure 89 Service Instantiation with MVRP - QinQ to PBB Example**

In this example, the UNI and service translation SAPs are configured in the data VPLS represented by the gray circles. This instance and associated trunk SAPs were instantiated using the procedures described in the previous sections. The following configuration steps are involved:

- on the BEB, an I-VPLS SAP must be configured toward the local switching domain – see yellow triangle facing downward
- on the UNI facing the customer, a “customer” SAP is configured on the bottom left switch – see yellow triangle facing upward

As soon as the first UNI SAP becomes active in the data VPLS on the ES, the associated VLAN value is advertised by MVRP throughout the related M-VPLS context. As soon as the second UNI SAP becomes available on a different switch, or in our example on the PBB BEB, the MVRP proceeds to advertise the associated VLAN value throughout the same M-VPLS. The trunks that experience MVRP declaration and registration in both directions will become active, instantiating service connectivity as represented by the big and small yellow circles shown in the figure.

A hold-time parameter (**config>service>vpls>mrp>mvrp>hold-time**) is provided in the M-VPLS configuration to control when the end-station or last UNI SAP is considered active from an MVRP perspective. The hold-time controls the amount of MVRP advertisements generated on fast transitions of the end-station or UNI SAPs.

If the **no hold-time** setting is used:

- MVRP will stop declaring the VLAN only when the last provisioned UNI SAP associated locally with the service is deleted.
- MVRP will start declaring the VLAN as soon as the first provisioned SAP is created in the associated VPLS instance, regardless of the operational state of the SAP.

If a non-zero “hold-time” setting is used:

- When a SAP in down state is added, MVRP does not declare the associated VLAN attribute. The attribute is declared immediately when the SAP comes up.
- When the SAP goes down, MVRP will wait until “hold-time” expiry before withdrawing the declaration.

For QinQ end-station SAPs, only **no hold-time** setting is allowed.

Only the following PBB Epipe and I-VPLS SAP types are eligible to activate MVRP declarations:

- dot1q: for example, 1/1/2:100
- qinq or qinq default: for example, 1/1/1:100.1 and respectively 1/1/1:100.\*, respectively; the outer VLAN 100 will be used as MVRP attribute as long as it belongs to the MVRP range configured for the port
- null port and dot1q default cannot be used

Examples of steps required to activate service connectivity for VLAN 100 using MVRP follows.

In the data VPLS instance (VLAN 100) controlled by MVRP, on the QinQ switch:

**Example:**

```
config>service>vpls 100
  sap 9/1/1:10 //UNI sap using CVID 10 as service
  delimiter
  no shutdown
```

In I-VPLS on PBB BEB:

**Example:**

```
config>service>vpls 1000 i-vpls
  sap 8/1/2:100 //sap (using MVRP VLAN 100 on
  endstation port in M-VPLS
```

no shutdown

### 3.4.4.4 MVRP Control Plane

MVRP is based on the IEEE 802.1ak MRP specification where STP is the supported method to be used for loop avoidance in a native Ethernet environment. M-VPLS and the associated MSTP (or P-MSTP) control plane provides the loop avoidance component in the Nokia implementation. Nokia MVRP may also be used in a non-MSTP, loop free topology.

### 3.4.4.5 STP-MVRP Interaction

[Table 36](#) shows the expected interaction between STP (MSTP or P-MSTP) and MVRP.

**Table 36** MSTP and MVRP Interaction Table

| Item | M-VPLS Service xSTP | M-VPLS SAP STP      | Register/Declare Data VPLS VLAN on M-VPLS SAP | DSFS (Data SAP Forwarding State) controlled by | Data Path Forwarding with MVRP enabled controlled by |
|------|---------------------|---------------------|-----------------------------------------------|------------------------------------------------|------------------------------------------------------|
| 1    | (p)MSTP             | Enabled             | Based on M-VPLS SAP's MSTP forwarding state   | MSTP only                                      | DSFS and MVRP                                        |
| 2    | (p)MSTP             | Disabled            | Based on M-VPLS SAP's operating state         | None                                           | MVRP                                                 |
| 3    | Disabled            | Enabled or Disabled | Based on M-VPLS SAP's operating state         | None                                           | MVRP                                                 |

Notes:

- Running STP in data VPLS instances controlled by MVRP is not allowed.
- Running STP on MVRP-controlled end-station SAPs is not allowed.

### 3.4.4.5.1 Interaction Between MVRP and Instantiated SAP Status

This section describes how MVRP reacts to changes in the instantiated SAP status.

There are a number of mechanisms that may generate operational or admin down status for the SAPs and VPLS instances controlled by MVRP:

1. Port down
2. MAC move
3. Port MTU too small
4. Service MTU too small

The shutdown of the whole instantiated VPLS or instantiated SAPs is disabled in both VPLS and VPLS SAP templates. The **no shutdown** option is automatically configured.

In the **port down** case, MVRP will also be operationally down on the port so no VLAN declaration will take place.

When MAC move is enabled in a data VPLS controlled by MVRP, in case a MAC move happens, one of the instantiated SAPs controlled by MVRP may be blocked. The SAP blocking by MAC move is not reported though to the MVRP control plane. As a result, MVRP keeps declaring and registering the related VLAN value on the control SAPs, including the one that shares the same port with the instantiate SAP blocked by MAC move, as long as MVRP conditions are met. For MVRP, an active control SAP is one that has MVRP enabled and MSTP is not blocking it for the VLAN value on the port. Also in the related data VPLS, one of the two conditions must be met for the declaration of the VLAN value: there must be either a local user SAP or at least one MVRP registration received on one of the control SAPs for that VLAN.

In the last two cases, VLAN attributes get declared or registered even when the instantiated SAP is operationally down, also with the MAC move case.

### 3.4.4.5.2 Using Temporary Flooding to Optimize Failover Times

MVRP advertisements use the active topology, which may be controlled through loop avoidance mechanisms like MSTP. When the active topology changes as a result of network failures, the time it takes for MVRP to bring up the optimal service connectivity may be added on top of the regular MSTP convergence time. Full connectivity also depends on the time it takes for the system to complete flushing of bad MAC entries.

To minimize the effects of MAC flushing and MVRP convergence, a temporary flooding behavior is implemented. When enabled, the temporary flooding eliminates the time it takes to flush the MAC tables. In the initial implementation, the temporary flooding is initiated only on reception of an STP TCN.

While temporary flooding is active, all the frames received in the extended data VPLS context are flooded while the MAC flush and MVRP convergence takes place. The extended data VPLS context comprises all instantiated trunk SAPs regardless of MVRP activation status. A timer option is also available to configure a fixed period of time, in seconds, during which all traffic is flooded (BUM or known unicast). Once the flood-time expires, traffic will be delivered according to the regular FDB content. The timer value should be configured to allow auxiliary processes like MAC flush and MVRP to converge. The temporary flooding behavior applies to all VPLS types. MAC learning continues during temporary flooding. Temporary flooding behavior is enabled using the **temp-flooding** command under **config> service>vpls** or **config> service>template>vpls-template** contexts and is supported in VPLS regardless of whether MVRP is enabled.

The following rules apply for temporary flooding in VPLS:

- If discard-unknown is enabled, there is no temporary flooding.
- Temporary flooding while active applies also to static MAC entries; after the MAC FDB is flushed it reverts back to the static MAC entries.
- If MAC learning is disabled, fast or temporary flooding is still enabled.
- Temporary flooding is not supported in B-VPLS context when MMRP is enabled. The use of a flood-time procedure provides a better procedure for this kind of environment.

## 3.4.5 VPLS E-Tree Services

This section describes VPLS E-Tree services.

### 3.4.5.1 VPLS E-Tree Services Overview

The VPLS E-Tree service offers a VPLS service with Root and Leaf designated access SAPs and SDP bindings, which prevent any traffic flow from leaf to leaf directly. With a VPLS E-Tree, the split horizon group capability is inherent for leaf SAPs (or SDP bindings) and extends to all the remote PEs that are part of the same VPLS E-Tree service. This feature is based on IETF Draft *draft-ietf-l2vpn-vpls-pe-etree*.

A VPLS E-Tree service may support an arbitrary number of leaf access (leaf-ac) interfaces, root access (root-ac) interfaces, and root-leaf tagged (root-leaf-tag) interfaces. Leaf-ac interfaces are supported on SAPs and SDP binds and can only communicate with root-ac interfaces (also supported on SAPs and SDP binds). Leaf-ac to leaf-ac communication is not allowed. Root-leaf-tag interfaces (supported on SAPs and SDP bindings) are tagged with root and leaf VIDs to allow remote VPLS instances to enforce the E-Tree forwarding.

Figure 90 shows a network with two root-ac interfaces and several leaf-ac SAPs (also could be SDPs). The figure indicates two VIDs in use to each service within the service with no restrictions on the AC interfaces. The service guarantees no leaf-ac to leaf-ac traffic.

Figure 90 E-Tree Service

al\_0459

3.4.5.2 Leaf-ac and Root-ac SAPs

Figure 91 shows the terminology used for E-Tree in IETF Draft *draft-ietf-l2vpn-vpls-pe-etree* and a mapping to SR OS terms.

An Ethernet service access SAP is characterized as either a leaf-ac or a root-ac for a VPLS E-Tree service. As far as SR OS is concerned, these are normal SAPs with either no tag (Null), priority tag, or dot1q or QinQ encapsulation on the frame. Functionally, a root-ac is a normal SAP and does not need to be differentiated from the regular SAPs except that it will be associated with a root behavior in a VPLS E-Tree.

Leaf-ac SAPs have restrictions; for example, a SAP configured for a leaf-ac can never send frames to another leaf-ac directly (local) or through a remote node. Leaf-ac SAPs on the same VPLS instance behave as if they are part of a split horizon group (SHG) locally. Leaf-ac SAPs that are on other nodes need to have the traffic marked as originating “from a Leaf” in the context of the VPLS service when carried on PWs and SAPs with tags (VLANs).

Root-ac SAPs on the same VPLS can talk to any root-ac or leaf-ac.

**Figure 91 Mapping PE Model to VPLS Service**

### 3.4.5.3 Leaf-ac and Root-ac SDP Binds

Untagged SDP binds for access can also be designated as root-ac or leaf-ac. This type of E-Tree interface is required for devices that do not support E-Tree, such as the 7210 SAS, to enable them to be connected with pseudowires. Such devices are root or leaf only and do not require having a tagged frame with a root or leaf indication.

### 3.4.5.4 Root-leaf-tag SAPs

Support on root-leaf-tag SAPs requires that the outer VID is overloaded to indicate root and leaf. To support the SR service model for a SAP, the ability to send and receive two different tags on a single SAP has been added. Figure 92 shows the behavior when a root-ac and leaf-ac exchange traffic over a root-leaf-tag SAP. Although the figure shows two SAPs connecting VPLS instances 1 and 2, the CLI will show a single SAP with the format:

```
sap 2/1/1:25 root-leaf-tag leaf-tag 26 create
```

**Figure 92** Leaf and Root Tagging dot1q

The root-leaf-tag SAP performs all of the operations for egress and ingress traffic for both tags (root and leaf):

- When receiving a frame, the outer tag VID will be compared against the configured root or leaf VIDs and the frame forwarded accordingly.
- When transmitting, the system will add a root VLAN (in the outer tag) on frames with an internal indication of Root, and a leaf VLAN on frames with an internal indication of Leaf.

### 3.4.5.5 Root-leaf-tag SDP Binds

Typically, in a VPLS environment over MPLS, mesh and spoke-SDP binds interconnect the local VPLS instances to remote PEs. To support VPLS E-Tree, the root and leaf traffic is sent over the SDP bind using a fixed VLAN tag value. The SR OS implementation uses a fixed VLAN ID 1 for root and fixed VLAN ID 2 for leaf. The root and leaf tags are considered a global value and signaling is not supported. The vc-type on root-leaf-tag SDP binds must be VLAN. The vlan-vc-tag command will be blocked in root-leaf-tag SDP-binds.

Figure 93 shows the behavior when leaf-ac or root-ac interfaces exchange traffic over a root-leaf-tag SDP-binding.

**Figure 93 Leaf and Root Tagging PW**

al\_0462

### 3.4.5.6 Interaction between VPLS E-Tree Services and Other Features

As a general rule, any CPM-generated traffic is always root traffic (STP, OAM, and so on) and any received control plane frame is marked with a root/leaf indication based on which E-Tree interface it arrived at. Some other particular feature interactions are as follows:

- **ETH-CFM and E-Tree** — ETH-CFM allows the operator to verify connectivity between the various endpoints of the service as well as execute troubleshooting and performance gathering functions. Continuity Checking, ETH-CC, is a method by which endpoints are configured and messages are passed between them at regular configured intervals. When CCM-enabled MEPs are configured, all MEPs in the same maintenance association, the grouping typically along the service lines, must know about every other endpoint in the service. This is the main principle behind continuity verification (all endpoints in communication).

Although the maintenance points configured within the E-Tree service adhere to the forwarding rules of the Leaf and the Root, local population of the MEP database used by the ETH-CFM function may make it appear that the forwarding plane is broken when it is not. All MEPs that are locally configured within a service will automatically be added to the local MEP database.

However, because of the Leaf and Root forwarding rules, not all of these MEPs can receive the required peer CCM-message to avoid CCM Defect conditions. It is suggested, when deploying CCM enabled MEPs in an E-Tree configuration, these CCM-enabled MEPs are configured on Root entities. If Leaf access requires CCM verification, then down MEPs in separate maintenance associations should be configured. This consideration is only for operators who need to deploy CCM in E-Tree environments. No other ETH-CFM tools query or use this database.

- **Legacy OAM commands** (cpe-ping, mac-ping, mac-trace, mac-populate, and mac-purge) are not supported in E-Tree service contexts. Although some configuration may result in normal behavior for some commands, not all commands or configurations will yield the expected results. Standards-based ETH-CFM tools should be used in place of the proprietary legacy OAM command set:
- **IGMP and PIM snooping for IPv4** work on VPLS E-Tree services. Routers should use root-ac interfaces so that the multicast traffic can be delivered properly.
- **xSTP** is supported in VPLS E-Tree services; however, when configuring STP in VPLS E-Tree services, the following considerations apply:
  - STP must be carefully used so that STP does not block undesired objects.
  - xSTP is not aware of the leaf-to-leaf topology; for example, for leaf-to-leaf traffic, even if there is no loop in the forwarding plane, xSTP may block leaf-ac SAPs or SDP binds.
  - Since xSTP is not aware of the root-leaf topology either, root ports might end up blocked before leaf interfaces.
  - When xSTP is used as a access redundancy mechanism, Nokia recommends that the dual-homed device is connected to the same type of E-Tree AC, to avoid unexpected forwarding behaviors when xSTP converges.

- Redundancy mechanisms such as MC-LAG, SDP bind end-points, or BGP-MH are fully supported on VPLS E-Tree services. However, eth-tunnel SAPs or eth-ring control SAPs are not supported on VPLS E-Tree services.

## 3.5 Configuring a VPLS Service with CLI

This section provides information to configure a VPLS service using the command line interface.

### 3.5.1 Basic Configuration

The following fields require specific input (there are no defaults) to configure a basic VPLS service:

- Customer ID (refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide* for more information)
- For a local service, configure two SAPs, specifying local access ports and encapsulation values.
- For a distributed service, configure a SAP and an SDP for each far-end node.

The following example shows a sample configuration of a local VPLS service on ALA-1.

```
*A:ALA-1>config>service>vpls# info
-----
...
    vpls 9001 customer 6 create
        description "Local VPLS"
        stp
            shutdown
        exit
    sap 1/2/2:0 create
        description "SAP for local service"
    exit
    sap 1/1/5:0 create
        description "SAP for local service"
    exit
    no shutdown
-----
*A:ALA-1>config>service>vpls#
```

The following example shows a sample configuration of a distributed VPLS service between ALA-1, ALA-2, and ALA-3.

```
*A:ALA-1>config>service# info
-----
...
    vpls 9000 customer 6 create
        shutdown
        description "This is a distributed VPLS."
    exit
...

```

```
-----
*A:ALA-1>config>service#

*A:ALA-2>config>service# info
-----
...
    vpls 9000 customer 6 create
        description "This is a distributed VPLS."
        stp
            shutdown
        exit
        sap 1/1/5:16 create
            description "VPLS SAP"
        exit
        spoke-sdp 2:22 create
        exit
        mesh-sdp 8:750 create
        exit
        no shutdown
    exit
...
-----
*A:ALA-2>config>service#

*A:ALA-3>config>service# info
-----
...
    vpls 9000 customer 6 create
        description "This is a distributed VPLS."
        stp
            shutdown
        exit
        sap 1/1/3:33 create
            description "VPLS SAP"
        exit
        spoke-sdp 2:22 create
        exit
        mesh-sdp 8:750 create
        exit
        no shutdown
    exit
...
-----
*A:ALA-3>config>service#
```

## 3.5.2 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure both local and distributed VPLS services and provides the CLI commands.

For VPLS services:

**Step 1.** Associate VPLS service with a customer ID

**Step 2.** Define SAPs:

- Select node(s) and port(s)
- Optional — Select QoS policies other than the default (configured in config>qos context)
- Optional — Select filter policies (configured in config>filter context)
- Optional — Select accounting policy (configured in config>log context)

**Step 3.** Associate SDPs for (distributed services)

**Step 4.** Modify STP default parameters (optional) (see [VPLS and Spanning Tree Protocol](#))

**Step 5.** Enable service

### 3.5.3 Configuring VPLS Components

Use the CLI syntax displayed in the following sections to configure VPLS components.

#### 3.5.3.1 Creating a VPLS Service

Use the following CLI syntax to create a VPLS service.

**CLI Syntax:**

```
config>service# vpls service-id [customer customer-id]
                        [vpn vpn-id] [m-vpls] [b-vpls | i-vpls] [create]
                        description description-string
                        no shutdown
```

The following example shows a VPLS configuration:

```
*A:ALA-1>config>service>vpls# info
-----
...
    vpls 9000 customer 6 create
        description "This is a distributed VPLS."
        stp
            shutdown
        exit
    exit
...
-----
*A:ALA-1>config>service>vpls#
```

### 3.5.3.2 Enabling Multiple MAC Registration Protocol (MMRP)

Once MMRP is enabled in the B-VPLS, it advertises the presence of the I-VPLS instances associated with this B-VPLS.

The following example shows a configuration with MMRP enabled.

```
*A:PE-B>config>service# info
-----
      vpls 11 customer 1 vpn 11 i-vpls create
        backbone-vpls 100:11
        exit
        stp
          shutdown
        exit
        sap 1/5/1:11 create
        exit
        sap 1/5/1:12 create
        exit
        no shutdown
      exit
      vpls 100 customer 1 vpn 100 b-vpls create
        service-mtu 2000
        stp
          shutdown
        exit
        mrp
          flood-time 10
          no shutdown
        exit
        sap 1/5/1:100 create
        exit
        spoke-sdp 3101:100 create
        exit
        spoke-sdp 3201:100 create
        exit
        no shutdown
      exit
-----
*A:PE-B>config>service#
```

Since I-VPLS 11 is associated with B-VPLS 100, MMRP advertises the group B-MAC 01:1e:83:00:00:0b) associated with I-VPLS 11 through a declaration on all the B-SAPs and B-SDPs. If the remote node also declares an I-VPLS 11 associated with its B-VPLS 10, then this results in a registration for the group B-MAC. This also creates the MMRP multicast tree (MFIB entries). In this case, sdp 3201:100 is connected to a remote node that declares the group B-MAC.

The following show commands display the current MMRP information for this scenario:

```
*A:PE-C# show service id 100 mrp
-----
MRP Information
```

```
-----

### 3.5.3.2.1 Enabling MAC Move

The **mac-move** feature is useful to protect against undetected loops in your VPLS topology as well as the presence of duplicate MACs in a VPLS service. For example, if two clients in the VPLS have the same MAC address, the VPLS will experience a high re-learn rate for the MAC and will shut down the SAP or spoke-SDP when the threshold is exceeded.

Use the following CLI syntax to configure **mac-move** parameters.

**CLI Syntax:**

```
config>service# vpls service-id [customer customer-id]
[vpn vpn-id] [m-vpls]
mac-move
    primary-ports
        spoke-sdp
        cumulative-factor
    exit
    secondary-ports
        spoke-sdp
        sap
    exit
    move-frequency frequency
    retry-timeout timeout
    no shutdown
```

The following example shows a **mac-move** configuration:

```
*A:ALA-2009>config>service>vpls>mac-move# show service id 500 mac-move
=====
Service Mac Move Information
=====
Service Id      : 500                Mac Move      : Enabled

### 3.5.3.2.2 Configuring STP Bridge Parameters in a VPLS

Modifying some of the Spanning Tree Protocol parameters allows the operator to balance STP between resiliency and speed of convergence extremes. Modifying particular parameters, as follows, must be done in the constraints of the following two formulas:

$$2 \times (\text{Bridge\_Forward\_Delay} - 1.0 \text{ seconds}) \geq \text{Bridge\_Max\_Age}$$

$$\text{Bridge\_Max\_Age} \geq 2 \times (\text{Bridge\_Hello0\_Time} + 1.0 \text{ seconds})$$

The following STP parameters can be modified at VPLS level:

- [Bridge STP Admin State](#)
- [Mode](#)
- [Bridge Priority](#)
- [Max Age](#)
- [Forward Delay](#)
- [Hello Time](#)
- [MST Instances](#)
- [MST Max Hops](#)
- [MST Name](#)
- [MST Revision](#)

STP always uses the locally configured values for the first three parameters (Admin State, Mode, and Priority).

For the parameters Max Age, Forward Delay, Hello Time, and Hold Count, the locally configured values are only used when this bridge has been elected root bridge in the STP domain; otherwise, the values received from the root bridge are used. The exception to this rule is: when STP is running in RSTP mode, the Hello Time is always taken from the locally configured parameter. The other parameters are only used when running mode MSTP.

## Bridge STP Admin State

The administrative state of STP at the VPLS level is controlled by the **shutdown** command.

When STP on the VPLS is administratively disabled, any BPDUs are forwarded transparently through the 7450 ESS, 7750 SR, or 7950 XRS. When STP on the VPLS is administratively enabled, but the administrative state of a SAP or spoke-SDP is down, BPDUs received on such a SAP or spoke-SDP are discarded.

**CLI Syntax:**     `config>service>vpls service-id# stp  
no shutdown`

## Mode

To be compatible with the different iterations of the IEEE 802.1D standard, the 7450 ESS, 7750 SR, and 7950 XRS support several variants of the Spanning Tree protocol:

- **rstp** — Rapid Spanning Tree Protocol (RSTP) compliant with IEEE 802.1D-2004 - default mode.
- **dot1w** — Compliant with IEEE 802.1w.
- **comp-dot1w** — Operation as in RSTP but backwards compatible with IEEE 802.1w (this mode was introduced for interoperability with some MTU types).
- **mstp** — Compliant with the Multiple Spanning Tree Protocol specified in IEEE 802.1Q REV/D5.0-09/2005. This mode of operation is only supported in an M-VPLS.
- **pmstp** — Compliant with the Multiple Spanning Tree Protocol specified in IEEE 802.1Q REV/D3.0-04/2005 but with some changes to make it backwards compatible to 802.1Q 2003 edition and IEEE 802.1w.

See section [Spanning Tree Operating Modes](#) for more information about these modes.

**CLI Syntax:**     `config>service>vpls service-id# stp  
mode {rstp | comp-dot1w | dot1w | mstp}`

**Default:** rstp

### Bridge Priority

The **bridge-priority** command is used to populate the priority portion of the bridge ID field within outbound BPDUs (the most significant 4 bits of the bridge ID). It is also used as part of the decision process when determining the best BPDU between messages received and sent. When running MSTP, this is the bridge priority used for the CIST.

All values will be truncated to multiples of 4096, conforming with IEEE 802.1t and 802.1D-2004.

**CLI Syntax:**    `config>service>vpls service-id# stp  
                  priority bridge-priority`

**Range:** 1 to 65535

**Default:** 32768

**Restore Default:** no priority

### Max Age

The **max-age** command indicates how many hops a BPDU can traverse the network starting from the root bridge. The message age field in a BPDU transmitted by the root bridge is initialized to 0. Each other bridge will take the message\_age value from BPDUs received on their root port and increment this value by 1. Therefore, the message\_age reflects the distance from the root bridge. BPDUs with a message age exceeding max-age are ignored.

STP uses the max-age value configured in the root bridge. This value is propagated to the other bridges by the BPDUs.

The default value of **max-age** is 20. This parameter can be modified within a range of 6 to 40, limited by the standard STP parameter interaction formulas.

**CLI Syntax:**    `config>service>vpls service-id# stp  
                  max-age max-info-age`

**Range:** 6 to 40 seconds

**Default:** 20 seconds

**Restore Default:** no max-age

### Forward Delay

RSTP, as defined in the IEEE 802.1D-2004 standards, will normally transition to the forwarding state by a handshaking mechanism (rapid transition), without any waiting times. If handshaking fails (for example, on shared links, as follows), the system falls back to the timer-based mechanism defined in the original STP (802.1D-1998) standard.

A shared link is a link with more than two Ethernet bridges (for example, a shared 10/100BaseT segment). The `port-type` command is used to configure a link as point-to-point or shared (see section [SAP Link Type](#)).

For timer-based transitions, the 802.1D-2004 standard defines an internal variable `forward-delay`, which is used in calculating the default number of seconds that a SAP or spoke-SDP spends in the discarding and learning states when transitioning to the forwarding state. The value of the `forward-delay` variable depends on the STP operating mode of the VPLS instance:

- In RSTP mode, but only when the SAP or spoke-SDP has not fallen back to legacy STP operation, the value configured by the **hello-time** command is used.
- In all other situations, the value configured by the **forward-delay** command is used.

**CLI Syntax:**     `config>service>vpls service-id# stp  
                  forward-delay seconds`

**Range:** 4 to 30 seconds

**Default:** 15 seconds

**Restore Default:** no forward-delay

### Hello Time

The **hello-time** command configures the Spanning Tree Protocol (STP) hello time for the Virtual Private LAN Service (VPLS) STP instance.

The *seconds* parameter defines the default timer value that controls the sending interval between BPDU configuration messages by this bridge, on ports where this bridge assumes the designated role.

The active hello time for the spanning tree is determined by the root bridge (except when the STP is running in RSTP mode, then the hello time is always taken from the locally configured parameter).

The configured hello-time value can also be used to calculate the bridge forward delay; see [Forward Delay](#).

**CLI Syntax:**     `config>service>vpls service-id# stp  
hello-time hello-time`

**Range:** 1 to 10 seconds

**Default:** 2 seconds

**Restore Default:** no hello-time

### Hold Count

The **hold-count** command configures the peak number of BPDUs that can be transmitted in a period of one second.

**CLI Syntax:**     `config>service>vpls service-id# stp  
hold-count count-value`

**Range:** 1 to 10

**Default:** 6

**Restore Default:** no hold-count

### MST Instances

You can create up to 15 mst-instances. They can range from 1 to 4094. By changing path-cost and priorities, you can ensure that each instance will form it's own tree within the region, therefore ensure that different VLANs follow different paths.

You can assign non-overlapping VLAN ranges to each instance. VLANs that are not assigned to an instance are implicitly assumed to be in instance 0, which is also called the CIST. This CIST cannot be deleted or created.

The parameters that can be defined per instance are mst-priority and vlan-range.

- **mst-priority** — The bridge-priority for this specific mst-instance. It follows the same rules as bridge-priority. For the CIST, the bridge-priority is used.
- **vlan-range** — The VLANs are mapped to this specific mst-instance. If no VLAN-ranges are defined in any mst-instances, then all VLANs are mapped to the CIST.

### MST Max Hops

The mst-max-hops command defines the maximum number of hops the BPDU can traverse inside the region. Outside the region, max-age is used.

### MST Name

The MST name defines the name that the operator gives to a region. Together with MST revision and the VLAN to mst-instance mapping, it forms the MST configuration identifier. Two bridges that have the same MST configuration identifier form a region if they exchange BPDUs.

### MST Revision

The MST revision together with MST-name and VLAN to MST-instance mapping define the MST configuration identifier. Two bridges that have the same MST configuration identifier form a region if they exchange BPDUs.

## 3.5.3.3 Configuring GSMP Parameters

The following parameters must be configured in order for GSMP to function:

- One or more GSMP sessions
- One or more ANCP policies
- For basic subscriber management only, ANCP static maps
- For enhanced subscriber management only, associate subscriber profiles with ANCP policies

Use the following CLI syntax to configure GSMP parameters.

**CLI Syntax:**

```
config>service>vpls# gsmp
group name [create]
    ancp
        dynamic-topology-discover
        oam
        description description-string
        hold-multiplier multiplier
        keepalive seconds
        neighbor ip-address [create]
            description v
            local-address ip-address
```

```

        priority-marking dscp dscp-name
        priority-marking prec ip-prec-value
        [no] shutdown
    [no] shutdown
[no] shutdown

```

This example shows a GSMP group configuration.

```

A:ALA-48>config>service>vpls>gsmp# info
-----
        group "group1" create
            description "test group config"
            neighbor 10.10.10.104 create
                description "neighbor1 config"
                local-address 10.10.10.103
                no shutdown
            exit
            no shutdown
        exit
        no shutdown
-----
A:ALA-48>config>service>vpls>gsmp#

```

### 3.5.3.4 Configuring a VPLS SAP

A default QoS policy is applied to each ingress and egress SAP. Additional QoS policies can be configured in the **config>qos** context. There are no default filter policies. Filter policies are configured in the **config>filter** context and must be explicitly applied to a SAP.

Use the following CLI syntax to create:

- [Local VPLS SAPs](#)
- [Distributed VPLS SAPs](#)

#### 3.5.3.4.1 Local VPLS SAPs

To configure a local VPLS service, enter the **sap sap-id** command twice with different port IDs in the same service configuration.

The following example shows a local VPLS configuration:

```

*A:ALA-1>config>service# info
-----
...
        vpls 90001 customer 6 create
            description "Local VPLS"
            stp

```

```

        shutdown
    exit
    sap 1/2/2:0 create
        description "SAP for local service"
    exit
    sap 1/1/5:0 create
        description "SAP for local service"
    exit
    no shutdown
exit
-----
*A:ALA-1>config>service#
*A:ALA-1>config>service# info
-----
    vpls 1150 customer 1 create
        fdb-table-size 1000
        fdb-table-low-wmark 5
        fdb-table-high-wmark 80
        local-age 60
        stp
            shutdown
    exit
    sap 1/1/1:1155 create
    exit
    sap 1/1/2:1150 create
    exit
    no shutdown
exit
-----
*A:ALA-1>config>service#

```

### 3.5.3.4.2 Distributed VPLS SAPs

To configure a distributed VPLS service, you must configure service entities on originating and far-end nodes. You must use the same service ID on all ends (for example, create a VPLS service ID 9000 on ALA-1, ALA-2, and ALA-3). A distributed VPLS consists of a SAP on each participating node and an SDP bound to each participating node.

For SDP configuration information, refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide*. For SDP binding information, see [Configuring SDP Bindings](#).

The following example shows a configuration of VPLS SAPs configured for ALA-1, ALA-2, and ALA-3.

```

*A:ALA-1>config>service# info
-----
...
    vpls 9000 customer 6 vpn 750 create
        description "Distributed VPLS services."
        stp
            shutdown

```

```

        exit
        sap 1/2/5:0 create
        description "VPLS SAP"
        multi-service-site "West"
        exit
    exit
...
-----
*A:ALA-1>config>service#

*A:ALA-2>config>service# info
-----
...
    vpls 9000 customer 6 vpn 750 create
    description "Distributed VPLS services."
    stp
    shutdown
    exit
    sap 1/1/2:22 create
    description "VPLS SAP"
    multi-service-site "West"
    exit
    exit
...
-----
*A:ALA-2>config>service#

*A:ALA-3>config>service# info
-----
...
    vpls 9000 customer 6 vpn 750 create
    description "Distributed VPLS services."
    stp
    shutdown
    exit
    sap 1/1/3:33 create
    description "VPLS SAP"
    multi-service-site "West"
    exit
    exit
...
-----
*A:ALA-3>config>service#

```

### 3.5.3.4.3 Configuring SAP-Specific STP Parameters

When a VPLS has STP enabled, each SAP within the VPLS has STP enabled by default. The operation of STP on each SAP is governed by:

- [SAP STP Administrative State](#)
- [SAP Virtual Port Number](#)
- [SAP Priority](#)

- [SAP Path Cost](#)
- [SAP Edge Port](#)
- [SAP Auto Edge](#)
- [SAP Link Type](#)

### SAP STP Administrative State

The administrative state of STP within a SAP controls how BPDUs are transmitted and handled when received. The allowable states are:

- SAP Admin Up

The default administrative state is up for STP on a SAP. BPDUs are handled in the normal STP manner on a SAP that is administratively up.

- SAP Admin Down

An administratively down state allows a service provider to prevent a SAP from becoming operationally blocked. BPDUs will not originate out the SAP toward the customer.

If STP is enabled on VPLS level, but disabled on the SAP, received BPDUs are discarded. Discarding the incoming BPDUs allows STP to continue to operate normally within the VPLS service while ignoring the down SAP. The specified SAP will always be in an operationally forwarding state.

**Note:** The administratively down state allows a loop to form within the VPLS.

**CLI Syntax:**    `config>service>vpls>sap>stp#`  
                  `[no] shutdown`

**Range:** shutdown or no shutdown

**Default:** no shutdown (SAP admin up)

### SAP Virtual Port Number

The virtual port number uniquely identifies a SAP within configuration BPDUs. The internal representation of a SAP is unique to a system and has a reference space much bigger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a SAP and identifies it with its own virtual port number that is unique to every other SAP defined on the VPLS. The virtual port number is assigned at the time that the SAP is added to the VPLS.

Since the order in which SAPs are added to the VPLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance. To achieve consistency after a reboot, the virtual port number can be specified explicitly.

**CLI Syntax:**     `config>service>vpls>sap# stp`  
                  `port-num number`

**Range:** 1 to 2047

**Default:** (automatically generated)

**Restore Default:** no port-num

### SAP Priority

SAP priority allows a configurable tiebreaking parameter to be associated with a SAP. When configuration BPDUs are being received, the configured SAP priority will be used in some circumstances to determine whether a SAP will be designated or blocked. These are the values used for CIST when running MSTP for the 7450 ESS or 7750 SR.

In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (0 to 255 also) to create a 16-bit value. In the latest STP standard (802.1D-2004), only the upper 4 bits of the port priority field are used to encode the SAP priority. The remaining 4 bits are used to extend the port ID field into a 12-bit virtual port number field. The virtual port number uniquely references a SAP within the STP instance. See [SAP Virtual Port Number](#) for more information about the virtual port number.

STP computes the actual SAP priority by taking the configured priority value and masking out the lower four bits. The result is the value that is stored in the SAP priority parameter. For example, if a value of 0 was entered, masking out the lower 4 bits would result in a parameter value of 0. If a value of 255 was entered, the result would be 240.

The default value for SAP priority is 128. This parameter can be modified within a range of 0 to 255; 0 being the highest priority. Masking causes the values actually stored and displayed to be 0 to 240, in increments of 16.

**CLI Syntax:**    `config>service>vpls>sap>stp#  
                  priority stp-priority`

**Range:** 0 to 255 (240 largest value, in increments of 16)

**Default:** 128

**Restore Default:** no priority

### SAP Path Cost

The SAP path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that SAP. When BPDUs are sent out of other egress SAPs, the newly calculated root path cost is used. These are the values used for CIST when running MSTP.

STP suggests that the path cost is defined as a function of the link bandwidth. Since SAPs are controlled by complex queuing dynamics, in the 7450 ESS, 7750 SR, and 7950 XRS the STP path cost is a purely static configuration.

The default value for SAP path cost is 10. This parameter can be modified within a range of 1 to 65535; 1 being the lowest cost.

**CLI Syntax:**    `config>service>vpls>sap>stp#  
                  path-cost sap-path-cost`

**Range:** 1 to 200000000

**Default:** 10

**Restore Default:** no path-cost

### SAP Edge Port

The SAP edge-port command is used to reduce the time it takes a SAP to reach the forwarding state when the SAP is on the edge of the network, and therefore has no further STP bridge to handshake with.

The edge-port command is used to initialize the internal OPER\_EDGE variable. At any time, when OPER\_EDGE is false on a SAP, the normal mechanisms are used to transition to the forwarding state (see [Forward Delay](#)). When OPER\_EDGE is true, STP assumes that the remote end agrees to transition to the forwarding state without actually receiving a BPDU with an agreement flag set.

The OPER\_EDGE variable will dynamically be set to false if the SAP receives BPDUs (the configured edge-port value does not change). The OPER\_EDGE variable will dynamically be set to true if auto-edge is enabled and STP concludes there is no bridge behind the SAP.

When STP on the SAP is administratively disabled, and re-enabled, the OPER\_EDGE is re-initialized to the value configured for edge-port.

Valid values for SAP edge-port are enabled and disabled, with disabled being the default.

**CLI Syntax:**     config>service>vpls>sap>stp#  
                  [no] edge-port

**Default:** no edge-port

### SAP Auto Edge

The SAP **edge-port** command is used to instruct STP to dynamically decide whether the SAP is connected to another bridge.

If auto-edge is enabled, and STP concludes there is no bridge behind the SAP, the OPER\_EDGE variable will dynamically be set to true. If auto-edge is enabled, and a BPDU is received, the OPER\_EDGE variable will dynamically be set to true (see [SAP Edge Port](#)).

Valid values for SAP auto-edge are enabled and disabled with enabled being the default.

**CLI Syntax:**     config>service>vpls>sap>stp#  
                  [no] auto-edge

**Default:** auto-edge

### SAP Link Type

The SAP **link-type** parameter instructs STP on the maximum number of bridges behind this SAP. If there is only a single bridge, transitioning to forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected by a shared media, their SAPs should all be configured as shared, and timer-based transitions are used.

Valid values for SAP link-type are shared and pt-pt with pt-pt, being the default.

**CLI Syntax:**    `config>service>vpls>sap>stp#`  
                  `link-type {pt-pt | shared}`

**Default:** link-type pt-pt

**Restore Default:** no link-type

#### 3.5.3.4.4 STP SAP Operational States

The operational state of STP within a SAP controls how BPDUs are transmitted and handled when received. Defined states are:

- [Operationally Disabled](#)
- [Operationally Discarding](#)
- [Operationally Learning](#)
- [Operationally Forwarding](#)

#### Operationally Disabled

Operationally disabled is the normal operational state for STP on a SAP in a VPLS that has any of the following conditions:

- VPLS state administratively down
- SAP state administratively down
- SAP state operationally down

If the SAP enters the operationally up state with the STP administratively up and the SAP STP state is up, the SAP will transition to the STP SAP discarding state.

When, during normal operation, the router detects a downstream loop behind a SAP or spoke-SDP, BPDUs can be received at a very high rate. To recover from this situation, STP will transition the SAP to disabled state for the configured forward-delay duration.

### Operationally Discarding

A SAP in the discarding state only receives and sends BPDUs, building the local correct STP state for each SAP while not forwarding actual user traffic. The duration of the discarding state is explained in section [Forward Delay](#).

**Note:** In previous versions of the STP standard, the discarding state was called a blocked state.

### Operationally Learning

The learning state allows population of the MAC forwarding table before entering the forwarding state. In this state, no user traffic is forwarded.

### Operationally Forwarding

Configuration BPDUs are sent out of a SAP in the forwarding state. Layer 2 frames received on the SAP are source learned and destination forwarded according to the FDB. Layer 2 frames received on other forwarding interfaces and destined for the SAP are also forwarded.

### SAP BPDU Encapsulation State

IEEE 802.1d (referred as Dot1d) and Cisco's per VLAN Spanning Tree (PVST) BPDU encapsulations are supported on a per-SAP basis for the 7450 ESS and 7750 SR. STP is associated with a VPLS service like PVST is associated per VLAN. The main difference resides in the Ethernet and LLC framing and a type-length-value (TLV) field trailing the BPDU.

[Table 37](#) shows differences between Dot1d and PVST Ethernet BPDU encapsulations based on the interface encap-type field.

Each SAP has a Read-Only operational state that shows which BPDU encapsulation is currently active on the SAP. The states are:

- **Dot1d** — This state specifies that the switch is currently sending IEEE 802.1d standard BPDUs. The BPDUs are tagged or non-tagged based on the encapsulation type of the egress interface and the encapsulation value defined in the SAP. A SAP defined on an interface with encapsulation type dot1q continues in the dot1d BPDU encapsulation state until a PVST encapsulated BPDU is received, in which case, the SAP will convert to the PVST encapsulation state. Each received BPDU must be properly IEEE 802.1q tagged if the interface encapsulation type is defined as dot1q. PVST BPDUs will be silently discarded if received when the SAP is on an interface defined with a null encapsulation type.
- **PVST** — This state specifies that the switch is currently sending proprietary encapsulated BPDUs. PVST BPDUs are only supported on Ethernet interfaces with the encapsulation type set to dot1q. The SAP continues in the PVST BPDU encapsulation state until a dot1d encapsulated BPDU is received, in which case, the SAP reverts to the dot1d encapsulation state. Each received BPDU must be properly IEEE 802.1q tagged with the encapsulation value defined for the SAP. PVST BPDUs are silently discarded if received when the SAP is on an interface defined with a null encapsulation type.

Dot1d is the initial and only SAP BPDU encapsulation state for SAPs defined on Ethernet interface with encapsulation type set to null.

Each transition between encapsulation types optionally generates an alarm that can be logged and optionally transmitted as an SNMP trap on the 7450 ESS or 7750 SR.

### 3.5.3.4.5 Configuring VPLS SAPs with Split Horizon

To configure a VPLS service with a split horizon group, add the **split-horizon-group** parameter when creating the SAP. Traffic arriving on a SAP within a split horizon group will not be copied to other SAPs in the same split horizon group.

The following example shows a VPLS configuration with split horizon enabled:

```
*A:ALA-1>config>service# info
-----
...
vpls 800 customer 6001 vpn 700 create
  description "VPLS with split horizon for DSL"
  stp
    shutdown
  exit
  sap 1/1/3:100 split-horizon-group DSL-group1 create
    description "SAP for residential bridging"
  exit
  sap 1/1/3:200 split-horizon-group DSL-group1 create
    description "SAP for residential bridging"
  exit
  split-horizon-group DSL-group1
```

```

        description "Split horizon group for DSL"
        exit
        no shutdown
    exit
...
-----
*A:ALA-1>config>service#

```

### 3.5.3.4.6 Configuring MAC Learning Protection

To configure MAC learning protection, configure split horizon, MAC protection, and SAP parameters on the 7450 ESS or 7750 SR.

The following example shows a VPLS configuration with split horizon enabled:

```

A:ALA-48>config>service>vpls# info
-----
        description "IMA VPLS"
        split-horizon-group "DSL-group1" create
            restrict-protected-src
            restrict-unprotected-dst
        exit
        mac-protect
            mac ff:ff:ff:ff:ff:ff
        exit
        sap 1/1/9:0 create
            ingress
                scheduler-policy "SLA1"
                qos 100 shared-queuing
            exit
            egress
                scheduler-policy "SLA1"
                filter ip 10
            exit
            restrict-protected-src
            arp-reply-agent
            host-connectivity-verify source-ip 10.144.145.1
        exit
...
-----
A:ALA-48>config>service>vpls#

```

### 3.5.3.5 Configuring SAP Subscriber Management Parameters

Use the following CLI syntax to configure subscriber management parameters on a VPLS service SAP on the 7450 ESS and 7750 SR. The policies and profiles that are referenced in the **def-sla-profile**, **def-sub-profile**, **non-sub-traffic**, and **sub-ident-policy** commands must already be configured in the **config>subscr-mgmt** context.

**CLI Syntax:**

```

config>service>vpls service-id
  sap sap-id [split-horizon-group group-name]
    sub-sla-mgmt
      def-sla-profile default-sla-profile-name
      def-sub-profile default-subscriber-profile-name
      mac-da-hashing
      multi-sub-sap [number-of-sub]
      no shutdown
      single-sub-parameters
        non-sub-traffic sub-profile sub-profile-name sla-profile sla-profile-name
        [subscriber sub-ident-string]
        profiled-traffic-only
        sub-ident-policy sub-ident-policy-name

```

The following example shows a subscriber management configuration:

```

A:ALA-48>config>service>vpls#
-----
      description "Local VPLS"
      stp
        shutdown
      exit
      sap 1/2/2:0 create
        description "SAP for local service"
        sub-sla-mgmt
          def-sla-profile "sla-profile1"
          sub-ident-policy "SubIdent1"
        exit
      exit
      sap 1/1/5:0 create
        description "SAP for local service"
      exit
      no shutdown
-----
A:ALA-48>config>service>vpls#

```

### 3.5.3.6 MSTP Control over Ethernet Tunnels

When MSTP is used to control VLANs, a range of VLAN IDs is normally used to specify the VLANs to be controlled on the 7450 ESS and 7750 SR.

If an Ethernet tunnel SAP is to be controlled by MSTP, the Ethernet tunnel SAP ID needs to be within the VLAN range specified under the mst-instance.

```

vpls 400 customer 1 m-vpls create
  stp
    mode mstp
    mst-instance 111 create

```

```

        vlan-range 1-100
    exit
    mst-name "abc"
    mst-revision 1
    no shutdown
exit
sap 1/1/1:0 create // untagged
exit
sap eth-tunnel-1 create
exit
no shutdown
exit
vpls 401 customer 1 create
    stp
        shutdown
    exit
    sap 1/1/1:12 create
    exit
    sap eth-tunnel-1:12 create
        // Ethernet tunnel SAP ID 12 falls within the VLAN
        // range for mst-instance 111
        eth-tunnel
            path 1 tag 1000
            path 8 tag 2000
        exit
    exit
    no shutdown
exit

```

### 3.5.3.7 Configuring SDP Bindings

VPLS provides scaling and operational advantages. A hierarchical configuration eliminates the need for a full mesh of VCs between participating devices. Hierarchy is achieved by enhancing the base VPLS core mesh of VCs with access VCs (spoke) to form two tiers. Spoke-SDPs are generally created between Layer 2 switches and placed at the Multi-Tenant Unit (MTU). The PE routers are placed at the service provider's Point of Presence (POP). Signaling and replication overhead on all devices is considerably reduced.

A spoke-SDP is treated like the equivalent of a traditional bridge port where flooded traffic received on the spoke-SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received (unless a split horizon group was defined on the spoke-SDP; see section [Configuring VPLS Spoke-SDPs with Split Horizon](#)).

A spoke-SDP connects a VPLS service between two sites and, in its simplest form, could be a single tunnel LSP. A set of ingress and egress VC labels are exchanged for each VPLS service instance to be transported over this LSP. The PE routers at each end treat this as a virtual spoke connection for the VPLS service in the same way as the PE-MTU connections. This architecture minimizes the signaling overhead and avoids a full mesh of VCs and LSPs between the two metro networks.

A mesh SDP bound to a service is logically treated like a single bridge “port” for flooded traffic where flooded traffic received on any mesh SDP on the service is replicated to other “ports” (spoke-SDPs and SAPs) and not transmitted on any mesh SDPs.

A VC-ID can be specified with the SDP-ID. The VC-ID is used instead of a label to identify a virtual circuit. The VC-ID is significant between peer SRs on the same hierarchical level. The value of a VC-ID is conceptually independent from the value of the label or any other datalink specific information of the VC.

[Figure 94](#) shows an example of a distributed VPLS service configuration of spoke and mesh SDPs (unidirectional tunnels) between routers and MTUs.

### 3.5.3.8 Configuring Overrides on Service SAPs

The following output shows a service SAP queue override configuration example:

```
*A:ALA-48>config>service>vpls>sap# info
-----
...
exit
ingress
    scheduler-policy "SLA1"
    scheduler-override
        scheduler "sched1" create
        parent weight 3 cir-weight 3
        exit
    exit
    policer-control-policy "SLA1-p"
    policer-control-override create
        max-rate 50000
    exit
    qos 100 multipoint-shared
    queue-override
        queue 1 create
        rate 1500000 cir 2000
        exit
    exit
    policer-override
        policer 1 create
        rate 10000
        exit
    exit
```

```

exit
egress
  scheduler-policy "SLA1"
  policer-control-policy "SLA1-p"
  policer-control-override create
    max-rate 60000
  exit
  qos 100
  queue-override
    queue 1 create
      adaptation-rule pir max cir max
    exit
  exit
  policer-override
    policer 1 create
      mbs 2000 kilobytes
    exit
  exit
  filter ip 10
exit
-----
*A:ALA-48>config>service>vpls>sap#

```

**Figure 94 SDPs — Unidirectional Tunnels**

OSSG032

Use the following CLI syntax to create mesh or spoke-SDP bindings with a distributed VPLS service. SDPs must be configured prior to binding. Refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Services Overview Guide* for information about creating SDPs.

Use the following CLI syntax to configure mesh SDP bindings.

**CLI Syntax:**

```
config>service# vpls service-id
mesh-sdp sdp-id[:vc-id] [vc-type {ether | vlan}]
    egress
        filter {ip ip-filter-id|mac mac-filter-id}
        mfib-allowed-mda-destinations
            mda mda-id
        vc-label egress-vc-label
    ingress
        filter {ip ip-filter-id|mac mac-filter-id}
        vc-label ingress-vc-label
    no shutdown
    static-mac ieee-address
    vlan-vc-tag 0..4094
```

Use the following CLI syntax to configure spoke-SDP bindings.

**CLI Syntax:**

```
config>service# vpls service-id
spoke-sdp sdp-id[:vc-id] [vc-type {ether | vlan}] [split-
horizon-group group-name]
    egress
        filter {ip ip-filter-id|mac mac-filter-id}
        vc-label egress-vc-label
    ingress
        filter {ip ip-filter-id|mac mac-filter-id}
        vc-label ingress-vc-label
    limit-mac-move [non-blockable]
    vlan-vc-tag 0..4094
    no shutdown
    static-mac ieee-address
    stp
        path-cost stp-path-cost
        priority stp-priority
        no shutdown
    vlan-vc-tag [0..4094]
```

The following examples show SDP binding configurations for ALA-1, ALA-2, and ALA-3 for VPLS service ID 9000 for customer 6:

```
*A:ALA-1>config>service# info
-----
...
vpls 9000 customer 6 create
```

```

        description "This is a distributed VPLS."
        stp
            shutdown
        exit
        sap 1/2/5:0 create
        exit
        spoke-sdp 2:22 create
        exit
        mesh-sdp 5:750 create
        exit
        mesh-sdp 7:750 create
        exit
        no shutdown
    exit
-----
*A:ALA-1>config>service#

*A:ALA-2>config>service# info
-----
...
    vpls 9000 customer 6 create
        description "This is a distributed VPLS."
        stp
            shutdown
        exit
        sap 1/1/2:22 create
        exit
        spoke-sdp 2:22 create
        exit
        mesh-sdp 5:750 create
        exit
        mesh-sdp 7:750 create
        exit
        no shutdown
    exit
-----

*A:ALA-3>config>service# info
-----
...
    vpls 9000 customer 6 create
        description "This is a distributed VPLS."
        stp
            shutdown
        exit
        sap 1/1/3:33 create
        exit
        spoke-sdp 2:22 create
        exit
        mesh-sdp 5:750 create
        exit
        mesh-sdp 7:750 create
        exit
        no shutdown
    exit
-----
*A:ALA-3>config>service#

```

### 3.5.3.8.1 Configuring Spoke-SDP Specific STP Parameters

When a VPLS has STP enabled, each spoke-SDP within the VPLS has STP enabled by default. The operation of STP on each spoke-SDP is governed by:

- [Spoke-SDP STP Administrative State](#)
- [Spoke-SDP Virtual Port Number](#)
- [Spoke-SDP Priority](#)
- [Spoke-SDP Path Cost](#)
- [Spoke-SDP Edge Port](#)
- [Spoke-SDP Auto Edge](#)
- [Spoke-SDP Link Type](#)

#### Spoke-SDP STP Administrative State

The administrative state of STP within a spoke-SDP controls how BPDUs are transmitted and handled when received. The allowable states are:

- Spoke-SDP Admin Up

The default administrative state is up for STP on a spoke-SDP. BPDUs are handled in the normal STP manner on a spoke-SDP that is administratively up.

- Spoke-SDP Admin Down

An administratively down state allows a service provider to prevent a spoke-SDP from becoming operationally blocked. BPDUs will not originate out the spoke-SDP toward the customer.

If STP is enabled on VPLS level, but disabled on the spoke-SDP, received BPDUs are discarded. Discarding the incoming BPDUs allows STP to continue to operate normally within the VPLS service while ignoring the down spoke-SDP. The specified spoke-SDP will always be in an operationally forwarding state.

**Note:** The administratively down state allows a loop to form within the VPLS.

**CLI Syntax:** `config>service>vpls>spoke-sdp>stp#  
[no] shutdown`

**Range:** shutdown or no shutdown

**Default:** no shutdown (spoke-SDP admin up)

### Spoke-SDP Virtual Port Number

The virtual port number uniquely identifies a spoke-SDP within configuration BPDUs. The internal representation of a spoke-SDP is unique to a system and has a reference space much bigger than the 12 bits definable in a configuration BPDU. STP takes the internal representation value of a spoke-SDP and identifies it with its own virtual port number that is unique to every other spoke-SDP defined on the VPLS. The virtual port number is assigned at the time that the spoke-SDP is added to the VPLS.

Since the order in which spoke-SDPs are added to the VPLS is not preserved between reboots of the system, the virtual port number may change between restarts of the STP instance. To achieve consistency after a reboot, the virtual port number can be specified explicitly.

**CLI Syntax:**     `config>service>vpls>spoke-sdp# stp  
                  port-num number`

**Range:** 1 to 2047

**Default:** automatically generated

**Restore Default:** no port-num

### Spoke-SDP Priority

Spoke-SDP priority allows a configurable tiebreaking parameter to be associated with a spoke-SDP. When configuration BPDUs are being received, the configured spoke-SDP priority will be used in some circumstances to determine whether a spoke-SDP will be designated or blocked.

In traditional STP implementations (802.1D-1998), this field is called the port priority and has a value of 0 to 255. This field is coupled with the port number (0 to 255 also) to create a 16-bit value. In the latest STP standard (802.1D-2004), only the upper 4 bits of the port priority field are used to encode the spoke-SDP priority. The remaining 4 bits are used to extend the port ID field into a 12-bit virtual port number field. The virtual port number uniquely references a spoke-SDP within the STP instance. See [Spoke-SDP Virtual Port Number](#) for more information about the virtual port number.

STP computes the actual spoke-SDP priority by taking the configured priority value and masking out the lower four bits. The result is the value that is stored in the spoke-SDP priority parameter. For instance, if a value of 0 was entered, masking out the lower 4 bits would result in a parameter value of 0. If a value of 255 was entered, the result would be 240.

The default value for spoke-SDP priority is 128. This parameter can be modified within a range of 0 to 255; 0 being the highest priority. Masking causes the values actually stored and displayed to be 0 to 240, in increments of 16.

**CLI Syntax:**     `config>service>vpls>spoke-sdp>stp#  
                  priority stp-priority`

**Range:** 0 to 255 (240 largest value, in increments of 16)

**Default:** 128

**Restore Default:** no priority

### Spoke-SDP Path Cost

The spoke-SDP path cost is used by STP to calculate the path cost to the root bridge. The path cost in BPDUs received on the root port is incremented with the configured path cost for that spoke-SDP. When BPDUs are sent out of other egress spoke-SDPs, the newly calculated root path cost is used.

STP suggests that the path cost is defined as a function of the link bandwidth. Since spoke-SDPs are controlled by complex queuing dynamics, the STP path cost is a purely static configuration.

The default value for spoke-SDP path cost is 10. This parameter can be modified within a range of 1 to 200000000 (1 is the lowest cost).

**CLI Syntax:**     `config>service>vpls>spoke-sdp>stp#  
                  path-cost stp-path-cost`

**Range:** 1 to 200000000

**Default:** 10

**Restore Default:** no path-cost

### Spoke-SDP Edge Port

The spoke-SDP edge-port command is used to reduce the time it takes a spoke-SDP to reach the forwarding state when the spoke-SDP is on the edge of the network, and therefore has no further STP bridge to handshake with.

The edge-port command is used to initialize the internal OPER\_EDGE variable. At any time, when OPER\_EDGE is false on a spoke-SDP, the normal mechanisms are used to transition to the forwarding state (see [Forward Delay](#)). When OPER\_EDGE is true, STP assumes that the remote end agrees to transition to the forwarding state without actually receiving a BPDU with an agreement flag set.

The OPER\_EDGE variable will dynamically be set to false if the spoke-SDP receives BPDUs (the configured edge-port value does not change). The OPER\_EDGE variable will dynamically be set to true if auto-edge is enabled and STP concludes there is no bridge behind the spoke-SDP.

When STP on the spoke-SDP is administratively disabled and re-enabled, the OPER\_EDGE is re-initialized to the spoke-SDP configured for edge-port.

Valid values for spoke-SDP edge-port are enabled and disabled, with disabled being the default.

**CLI Syntax:**     config>service>vpls>spoke-sdp>stp#  
                  [no] edge-port

**Default:** no edge-port

### Spoke-SDP Auto Edge

The spoke-SDP edge-port command is used to instruct STP to dynamically decide whether the spoke-SDP is connected to another bridge.

If auto-edge is enabled, and STP concludes there is no bridge behind the spoke-SDP, the OPER\_EDGE variable will dynamically be set to true. If auto-edge is enabled, and a BPDU is received, the OPER\_EDGE variable will dynamically be set to true (see [Spoke-SDP Edge Port](#)).

Valid values for spoke-SDP auto-edge are enabled and disabled, with enabled being the default.

**CLI Syntax:**     config>service>vpls>spoke-sdp>stp#  
                  [no] auto-edge

**Default:** auto-edge

### Spoke-SDP Link Type

The spoke-SDP link-type command instructs STP on the maximum number of bridges behind this spoke-SDP. If there is only a single bridge, transitioning to forwarding state will be based on handshaking (fast transitions). If more than two bridges are connected by a shared media, their spoke-SDPs should all be configured as shared, and timer-based transitions are used.

Valid values for spoke-SDP link-type are shared and pt-pt, with pt-pt being the default.

**CLI Syntax:** `config>service>vpls>spoke-sdp>stp#  
link-type {pt-pt|shared}`

**Default:** link-type pt-pt

**Restore Default:** no link-type

#### 3.5.3.8.2 Spoke-SDP STP Operational States

The operational state of STP within a spoke-SDP controls how BPDUs are transmitted and handled when received. Defined states are:

- [Operationally Disabled](#)
- [Operationally Discarding](#)
- [Operationally Learning](#)
- [Operationally Forwarding](#)

#### Operationally Disabled

Operationally disabled is the normal operational state for STP on a spoke-SDP in a VPLS that has any of the following conditions:

- VPLS state administratively down
- Spoke-SDP state administratively down
- Spoke-SDP state operationally down

If the spoke-SDP enters the operationally up state with the STP administratively up and the spoke-SDP STP state is up, the spoke-SDP will transition to the STP spoke-SDP discarding state.

When, during normal operation, the router detects a downstream loop behind a spoke-SDP, BPDUs can be received at a very high rate. To recover from this situation, STP will transition the spoke-SDP to a disabled state for the configured forward-delay duration.

### Operationally Discarding

A spoke-SDP in the discarding state only receives and sends BPDUs, building the local correct STP state for each spoke-SDP while not forwarding actual user traffic. The duration of the discarding state is explained in section [Forward Delay](#).

**Note:** In previous versions of the STP standard, the discarding state was called a blocked state.

### Operationally Learning

The learning state allows population of the MAC forwarding table before entering the forwarding state. In this state, no user traffic is forwarded.

### Operationally Forwarding

Configuration BPDUs are sent out of a spoke-SDP in the forwarding state. Layer 2 frames received on the spoke-SDP are source learned and destination forwarded according to the FDB. Layer 2 frames received on other forwarding interfaces and destined for the spoke-SDP are also forwarded.

### Spoke-SDP BPDUs Encapsulation States

IEEE 802.1D (referred as dot1d) and Cisco's per VLAN Spanning Tree (PVST) BPDUs encapsulations are supported on a per spoke-SDP basis. STP is associated with a VPLS service like PVST is per VLAN. The main difference resides in the Ethernet and LLC framing and a type-length-value (TLV) field trailing the BPDUs.

[Table 37](#) shows differences between dot1D and PVST Ethernet BPDUs encapsulations based on the interface encap-type field.

**Table 37 Spoke-SDP BPDU Encapsulation States**

| Field              | dot1d<br>encap-type null | dot1d<br>encap-type dot1q | PVST<br>encap-type<br>null | PVST<br>encap-type dot1q   |
|--------------------|--------------------------|---------------------------|----------------------------|----------------------------|
| Destination MAC    | 01:80:c2:00:00:00        | 01:80:c2:00:00:00         | N/A                        | 01:00:0c:cc:cc:cd          |
| Source MAC         | Sending Port MAC         | Sending Port MAC          | N/A                        | Sending Port MAC           |
| EtherType          | N/A                      | 0x81 00                   | N/A                        | 0x81 00                    |
| Dot1p and CFI      | N/A                      | 0xe                       | N/A                        | 0xe                        |
| Dot1q              | N/A                      | VPLS spoke-SDP ID         | N/A                        | VPLS spoke-SDP encap value |
| Length             | LLC Length               | LLC Length                | N/A                        | LLC Length                 |
| LLC DSAP SSAP      | 0x4242                   | 0x4242                    | N/A                        | 0xaaaa (SNAP)              |
| LLC CNTL           | 0x03                     | 0x03                      | N/A                        | 0x03                       |
| SNAP OUI           | N/A                      | N/A                       | N/A                        | 00 00 0c (Cisco OUI)       |
| SNAP PID           | N/A                      | N/A                       | N/A                        | 01 0b                      |
| CONFIG or TCN BPDU | Standard 802.1d          | Standard 802.1d           | N/A                        | Standard 802.1d            |
| TLV: Type and Len  | N/A                      | N/A                       | N/A                        | 58 00 00 00 02             |
| TLV: VLAN          | N/A                      | N/A                       | N/A                        | VPLS spoke-SDP encap value |
| Padding            | As Required              | As Required               | N/A                        | As Required                |

Each spoke-SDP has a Read Only operational state that shows which BPDU encapsulation is currently active on the spoke-SDP. The following states apply:

- **Dot1d** specifies that the switch is currently sending IEEE 802.1D standard BPDUs. The BPDUs will be tagged or non-tagged based on the encapsulation type of the egress interface and the encapsulation value defined in the spoke-SDP. A spoke-SDP defined on an interface with encapsulation type dot1q will continue in the dot1d BPDU encapsulation state until a PVST encapsulated BPDU is received, after which the spoke-SDP will convert to the PVST encapsulation state. Each received BPDU must be properly IEEE 802.1q tagged if the interface encapsulation type is defined as dot1q.

- **PVST** specifies that the switch is currently sending proprietary encapsulated BPDUs. PVST BPDUs are only supported on Ethernet interfaces with the encapsulation type set to dot1q. The spoke-SDP continues in the PVST BPDU encapsulation state until a dot1d encapsulated BPDU is received, in which case the spoke-SDP reverts to the dot1d encapsulation state. Each received BPDU must be properly IEEE 802.1q tagged with the encapsulation value defined for the spoke-SDP.

Dot1d is the initial and only spoke-SDP BPDU encapsulation state for spoke-SDPs defined on an Ethernet interface with encapsulation type set to null.

Each transition between encapsulation types optionally generates an alarm that can be logged and optionally transmitted as an SNMP trap.

### 3.5.3.8.3 Configuring VPLS Spoke-SDPs with Split Horizon

To configure spoke-SDPs with a split horizon group, add the split-horizon-group parameter when creating the spoke-SDP. Traffic arriving on a SAP or spoke-SDP within a split horizon group will not be copied to other SAPs or spoke-SDPs in the same split horizon group.

The following example shows a VPLS configuration with split horizon enabled:

```

-----
*A:ALA-1>config>service# *A:ALA-1>config>service# info
-----
...
vpls 800 customer 6001 vpn 700 create
  description "VPLS with split horizon for DSL"
  stp
    shutdown
  exit
  spoke-sdp 51:15 split-horizon-group DSL-group1 create
  exit
  split-horizon-group DSL-group1
    description "Split horizon group for DSL"
  exit
  no shutdown
exit
...
-----
*A:ALA-1>config>service#

```

## 3.5.4 Configuring VPLS Redundancy

This section discusses VPLS redundancy service management tasks.

### 3.5.4.1 Creating a Management VPLS for SAP Protection

This section provides a brief overview of the tasks that must be performed to configure a management VPLS for SAP protection and provides the CLI commands; see [Figure 95](#). The following tasks should be performed on both nodes providing the protected VPLS service.

Before configuring a management VPLS, see [VPLS Redundancy](#) for an introduction to the concept of management VPLS and SAP redundancy.

1. Create an SDP to the peer node.
2. Create a management VPLS.
3. Define a SAP in the M-VPLS on the port toward the MTU. The port must be dot1q or qinq tagged. The SAP corresponds to the (stacked) VLAN on the MTU in which STP is active.
4. Optionally, modify STP parameters for load balancing.
5. Create a mesh SDP in the M-VPLS using the SDP defined in Step 1. Ensure that this mesh SDP runs over a protected LSP (see the following note).
6. Enable the management VPLS service and verify that it is operationally up.
7. Create a list of VLANs on the port that are to be managed by this management VPLS.
8. Create one or more user VPLS services with SAPs on VLANs in the range defined by Step 6.

**Note:** The mesh SDP should be protected by a backup LSP or Fast Reroute. If the mesh SDP went down, STP on both nodes would go to forwarding state and a loop would occur.

**Figure 95 Example Configuration for Protected VPLS SAP**

OSSG047

Use the following CLI syntax to create a management VPLS on the 7450 ESS or 7750 SR.

**CLI Syntax:**

```
config>service# sdp sdp-id mpls create
far-end ip-address
lsp lsp-name
no shutdown
```

**CLI Syntax:**

```
vpls service-id customer customer-id [m-vpls] create
description description-string
sap sap-id create
managed-vlan-list
range vlan-range
mesh-sdp sdp-id:vc-id create
stp
no shutdown
```

The following example shows a VPLS configuration:

```
*A:ALA-1>config>service# info
-----
...
sdp 300 mpls create
far-end 10.0.0.20
lsp "toALA-A2"
```

```

        no shutdown
    exit
    vpls 1 customer 1 m-vpls create
        sap 1/1/1:1 create
            managed-vlan-list
                range 100-1000
            exit
        exit
    mesh-sdp 300:1 create
    exit
    stp
    exit
    no shutdown
    exit
...
-----
*A:ALA-1>config>service#

```

### 3.5.4.2 Creating a Management VPLS for Spoke-SDP Protection

This section provides a brief overview of the tasks that must be performed to configure a management VPLS for spoke-SDP protection and provides the CLI commands; see [Figure 96](#). The following tasks should be performed on all four nodes providing the protected VPLS service. Before configuring a management VPLS, see [Configuring a VPLS SAP](#) for an introduction to the concept of management VPLS and spoke-SDP redundancy.

1. Create an SDP to the local peer node (node ALA-A2 in the following example).
2. Create an SDP to the remote peer node (node ALA-B1 in the following example).
3. Create a management VPLS.
4. Create a spoke-SDP in the M-VPLS using the SDP defined in Step 1. Ensure that this mesh SDP runs over a protected LSP (see note below).
5. Enable the management VPLS service and verify that it is operationally up.
6. Create a spoke-SDP in the M-VPLS using the SDP defined in Step 2. Optionally, modify STP parameters for load balancing (see [Configuring Load Balancing with Management VPLS](#)).
7. Create one or more user VPLS services with spoke-SDPs on the tunnel SDP defined by Step 2.

As long as the user spoke-SDPs created in step 7 are in this same tunnel SDP with the management spoke-SDP created in step 6, the management VPLS will protect them.

**Note:** The SDP should be protected by, for example, a backup LSP or Fast Reroute. If the SDP went down, STP on both nodes would go to forwarding state and a loop would occur.

**Figure 96** Example Configuration for Protected VPLS Spoke-SDP

Use the following CLI syntax to create a management VPLS for spoke-SDP protection.

**CLI Syntax:**

```
config>service# sdp sdp-id mpls create
far-end ip-address
lsp lsp-name
no shutdown
```

**CLI Syntax:**

```
vpls service-id customer customer-id [m-vpls] create
description description-string
mesh-sdp sdp-id:vc-id create
spoke-sdp sdp-id:vc-id create
stp
no shutdown
```

The following example shows a VPLS configuration:

```
*A:ALA-A1>config>service# info
-----
...
    sdp 100 mpls create
        far-end 10.0.0.30
        lsp "toALA-B1"
        no shutdown
    exit
    sdp 300 mpls create
        far-end 10.0.0.20
        lsp "toALA-A2"
        no shutdown
    exit
    vpls 101 customer 1 m-vpls create
        spoke-sdp 100:1 create
        exit
        meshspoke-sdp 300:1 create
        exit
        stp
        exit
        no shutdown
    exit
...
-----
*A:ALA-A1>config>service#
```

### 3.5.4.3 Configuring Load Balancing with Management VPLS

With the concept of management VPLS, it is possible to load balance the user VPLS services across the two protecting nodes. This is done by creating two management VPLS instances, where both instances have different active QinQ spokes (by changing the STP path-cost). When user VPLS services are associated with either of the two management VPLS services, the traffic will be split across the two QinQ spokes. Load balancing can be achieved in both the SAP protection and spoke-SDP protection scenarios.

[Figure 97](#) shows an example configuration for load balancing across two protected VPLS spoke-SDPs.

**Figure 97** Example Configuration for Load Balancing Across Two Protected VPLS Spoke-SDPs

Use the following CLI syntax to create load balancing across two management VPLS instances.

**CLI Syntax:**

```
config>service# sdp sdp-id mpls create
far-end ip-address
lsp lsp-name
no shutdown
```

**CLI Syntax:**

```
vpls service-id customer customer-id [m-vpls] create
description description-string
mesh-sdp sdp-id:vc-id create
spoke-sdp sdp-id:vc-id create
stp
path-cost
stp
no shutdown
```

**Note:** The STP path costs in each peer node should be reversed.

The following example shows the VPLS configuration on ALA-A1 (top left, IP address 10.0.0.10):

```

*A:ALA-A1>config>service# info
-----
...
    sdp 101 mpls create
        far-end 10.0.0.30
        lsp "1toALA-B1"
        no shutdown
    exit
    sdp 102 mpls create
        far-end 10.0.0.30
        lsp "2toALA-B1"
        no shutdown
    exit
...
    vpls 101 customer 1 m-vpls create
        spoke-sdp 101:1 create
            stp
            path-cost 1
        exit
        exit
        mesh-sdp 300:1 create
        exit
        stp
        exit
        no shutdown
    exit
    vpls 102 customer 1 m-vpls create
        spoke-sdp 102:2 create
            stp
            path-cost 1000
        exit
        exit
        mesh-sdp 300:2 create
        exit
        stp
        exit
        no shutdown
    exit
...
-----
*A:ALA-A1>config>service#

```

The following example shows the VPLS configuration on ALA-A2 (bottom left, IP address 10.0.0.20):

```

*A:ALA-A2>config>service# info
-----
...
    sdp 101 mpls create
        far-end 10.0.0.40
        lsp "1toALA-B2"
        no shutdown
    exit
    sdp 102 mpls create
        far-end 10.0.0.40
        lsp "2toALA-B2"
        no shutdown
    exit

```

```

...
vpls 101 customer 1 m-vpls create
    spoke-sdp 101:1 create
        stp
        path-cost 1000
    exit
    exit
    mesh-sdp 300:1 create
    exit
    stp
    exit
    no shutdown
exit
vpls 102 customer 1 m-vpls create
    spoke-sdp 102:2 create
        stp
        path-cost 1
    exit

```

### 3.5.4.4 Configuring Selective MAC Flush

Use the following CLI syntax to enable selective MAC flush in a VPLS.

**CLI Syntax:**     `config>service# vpls service-id  
                          send-flush-on-failure`

Use the following CLI syntax to disable selective MAC flush in a VPLS.

**CLI Syntax:**     `config>service# vpls service-id  
                          no send-flush-on-failure`

### 3.5.4.5 Configuring Multi-Chassis Endpoints

The following output shows configuration examples of multi-chassis redundancy and the VPLS configuration. The configurations in the graphics depicted in [Inter-Domain VPLS Resiliency Using Multi-Chassis Endpoints](#) are represented in this output.

Node mapping to the following examples in this section:

- PE3 = Dut-B
- PE3' = Dut-C
- PE1 = Dut-D
- PE2 = Dut-E

PE3 Dut-B

### 3.5.5 ATM/Frame Relay PVC Access and Termination on a VPLS Service

The application as shown in [Figure 98](#) provides access to a VPLS service to Frame Relay and ATM users connected either directly or through an ATM access network to a 7750 SR PE node. The 7750 SR supports a Frame Relay or an ATM VC-delimited Service Access Point (SAP) terminating on a VPLS service.

**Figure 98 ATM/Frame Relay PVC Access and Termination on a VPLS Example**

RFC 2427-encapsulated or RFC 2684-encapsulated untagged Ethernet/802.3 frames (with or without Frame Check Sequence (FCS)) or BPDUs from a customer's bridge device are received on a specified SAP over an ATM or Frame Relay interface on the 7750 SR. The Frame Relay or ATM-related encapsulation is stripped and the frames (without FCS) are forwarded toward destination SAPs either locally, or using SDPs associated with the VPLS service (as required by destination MAC address VPLS processing). In the egress direction, the received untagged frames are encapsulated into RFC 2427 or RFC 2684 (no Q-tags are added, no FCS in the forwarded frame) and sent over ATM or a FR VC toward the customer CPE.

When AAL5 RFC 2427/2684-encapsulated tagged frames are received from the customer's bridge on an FR/ATM SAP, the tags are transparent and the frames are processed as described above with the exception that the frames forwarded toward the destination(s) will have the received tags preserved. Similarly in the egress direction, the received tagged Ethernet frames are encapsulated as is (that is, Q-tags are again transparent and preserved) into RFC 2427/2684 and sent over the FR/ATM PVC toward the customer CPE. Since the tagging is transparent, the 7750 SR performs unqualified MAC learning (for example, MAC addresses are learned without reference to VLANs they are associated with). Because of that, MAC addresses used must be unique across all the VLANs used by the customer for a specified VPLS service instance. If a customer wants a per-VLAN separation, the VLAN traffic that needs to be separated must come on different VCs (different SAPs) associated with different VPLS service instances.

All VPLS functionality available on the 7750 SR is applicable to FR and ATM-delimited VPLS SAPs. For example, bridged PDUs received over ATM SAP can be tunneled through or dropped, all FIB functionality applies, packet level QoS and MAC filtering applies, and so on. Also, split horizon groups are applicable to ATM SAPs terminating on VPLS. That is, frame forwarding between ATM SAPs, also referred to as VCI-to-VCI forwarding, within the same group is disabled.

The Ethernet pseudowire is established using Targeted LDP (TLDP) signaling and uses the ether, vlan, or vpls VC type on the SDP. The SDP can be an MPLS or a GRE type.

### 3.5.6 Configuring BGP Auto-Discovery

This section provides important information to explain the different configuration options used to populate the required BGP AD and generate the LDP generalized pseudowire-ID FEC fields. There are a large number of configuration options that are available with this feature. Not all these configuration options are required to start using BGP AD. At the end of this section, it will be apparent that a simple configuration will automatically generate the required values used by BGP and LDP. In most cases, deployments will provide full mesh connectivity between all nodes across a VPLS instance. However, capabilities are available to influence the topology and build hierarchies or hub and spoke models.

#### 3.5.6.1 Configuration Steps

Using [Figure 99](#), assume PE6 was previously configured with VPLS 100 as indicated by the configurations code in the upper right. The BGP AD process will commence after PE134 is configured with the VPLS 100 instance, as shown in the upper left. This shows a basic BGP AD configuration. The minimum requirement for enabling BGP AD on a VPLS instance is configuring the VPLS-ID and pointing to a pseudowire template.

**Figure 99 BGP AD Configuration Example**

OSSG244

In many cases, VPLS connectivity is based on a pseudowire mesh. To reduce the configuration requirement, the BGP values can be automatically generated using the VPLS-ID and the MPLS router-ID. By default, the lower six bytes of the VPLS-ID are used to generate the RD and the RT values. The VSI-ID value is generated from the MPLS router-ID. All of these parameters are configurable and can be coded to suit requirements and build different topologies.

```

PE134>config>service>vpls>bgp-ad#
[no] shutdown - Administratively enable/disable BGP auto-discovery
vpls-id - Configure VPLS-ID
vsi-id + Configure VSI-id
  
```

The **show service** command shows the service information, the BGP parameters, and the SDP bindings in use. When the discovery process is completed successfully, each endpoint will have an entry for the service.

```

PE134># show service l2-route-table
=====

```

When only one of the endpoints has an entry for the service in the I2-routing-table, it is most likely a problem with the RT values used for import and export. This would most likely happen when different import and export RT values are configured using a router policy or the route-target command.

Service-specific commands continue to be available to show service-specific information, including status:

```

* indicates that the corresponding row element may have been truncated.

```

BGP AD will advertise the VPLS-ID in the extended community attribute, VSI-ID in the NLRI, and the local PE ID in the BGP next hop. At the receiving PE, the VPLS-ID is compared against locally provisioned information to determine whether the two PEs share a common VPLS. If they do, the BGP information is used in the signaling phase (see [Configuring BGP VPLS](#)).

### 3.5.6.2 LDP Signaling

T-LDP is triggered when the VPN endpoints have been discovered using BGP. The T-LDP session between the PEs is established when a session does not exist. The far-end IP address required for the T-LDP identification is learned from the BGP AD next hop information. The pw-template and pw-template-binding configuration statements are used to establish the automatic SDP or to map to the appropriate SDP. The FEC129 content is built using the following values:

- AGI from the locally configured VPLS-ID

- SAIL from the locally configured VSI-ID
- TAIL from the VSI-ID contained in the last 4 bytes of the received BGP NLRI

Figure 100 shows the different detailed phases of the LDP signaling path, post BGP AD completion. It also indicates how some fields can be auto-generated when they are not specified in the configuration.

**Figure 100 BGP AD Triggering LDP Functions**

OSSG247

The following command shows the LDP peering relationships that have been established (see Figure 101). The type of adjacency is displayed in the “Adj Type” column. In this case, the type is “Both” meaning link and targeted sessions have been successfully established.

**Figure 101 Show Router LDP Session Output**

```
PERs6# show router ldp session
```

LDP Sessions

| Peer LDP Id        | Adj Type | State       | Msg Sent | Msg Recv | Up Time     |
|--------------------|----------|-------------|----------|----------|-------------|
| 1.1.1.134:0        | Both     | Established | 21482    | 21482    | 0d 15:38:44 |
| No. of Sessions: 1 |          |             |          |          |             |

0988

The following command shows the specific LDP service label information broken up per FEC element type: 128 or 129, basis (see Figure 102). The information for FEC element 129 includes the AGI, SAIL, and the TAIL.

**Figure 102 Show Router LDP Bindings FEC-Type Services**

```

### 3.5.6.3 Pseudowire Template

The pseudowire template is defined under the top-level service command (**config>service> pw-template**) and specifies whether to use an automatically generated SDP or manually configured SDP. It also provides the set of parameters required for establishing the pseudowire (SDP binding) as follows:

```
PERs6>config>service# pw-template 1 create
-[no] pw-template <policy-id> [use-provisioned-sdp | prefer-provisioned-sdp]
<policy-id> : [1..2147483647]
<use-provisioned-s*> : keyword
<prefer-provisioned*> : keyword
```

|                      |                                                                       |
|----------------------|-----------------------------------------------------------------------|
| [no] accounting-pol* | - Configure accounting-policy to be used                              |
| [no] auto-learn-mac* | - Enable/Disable automatic update of MAC protect list                 |
| [no] block-on-peer*  | - Enable/Disable block traffic on peer fault                          |
| [no] collect-stats   | - Enable/disable statistics collection                                |
| [no] control word    | - Enable/Disable the use of Control Word                              |
| [no] disable-aging   | - Enable/disable aging of MAC addresses                               |
| [no] disable-learn*  | - Enable/disable learning of new MAC addresses                        |
| [no] discard-unknow* | - Enable/disable discarding of frames with unknown source MAC address |
| egress               | + Spoke SDP binding egress configuration                              |
| [no] force-qinq-vc*  | - Forces qinq-vc-type forwarding in the data-path                     |
| [no] force-vlan-vc*  | - Forces vlan-vc-type forwarding in the data-path                     |
| [no] hash-label      | - Enable/disable use of hash-label                                    |
| igmp-snooping        | + Configure IGMP snooping parameters                                  |
| in gress             | + Spoke SDP binding ingress configuration                             |
| [no] l2pt-terminati* | - Configure L2PT termination on this spoke SDP                        |

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| [no] limit-mac-move    | - Configure mac move                                                   |
| [no] mac-pinning       | - Enable/disable MAC address pinning on this spoke SDP                 |
| [no] max-nbr-mac-ad*   | - Configure the maximum number of MAC entries in the FDB from this SDP |
| [no] restrict-protect* | - Enable/disable protected src MAC restriction                         |
| [no] sdp-exclude       | - Configure excluded SDP group                                         |
| [no] sdp-include       | - Configure included SDP group                                         |
| [no] split-horizon-*   | + Configure a split horizon group                                      |
| stp                    | + Configure STP parameters                                             |
| vc-type                | - Configure VC type                                                    |
| [no] vlan-vc-tag       | - Configure VLAN VC tag                                                |

A **pw-template-binding** command configured within the VPLS service under the **bgp-ad** sub-command is a pointer to the pw-template that should be used. If a VPLS service does not specify an import-rt list, then that binding applies to all route targets accepted by that VPLS. The **pw-template-bind** command can select a different template on a per import-rt basis. It is also possible to specify specific pw-templates for some route targets with a VPLS service and use the single **pw-template-binding** command to address all unspecified but accepted imported targets.

**Figure 103 PW-Template-Binding CLI Syntax**

```
PERs6>config>service>vpls>bgp-ad# pw-template-binding
- pw-template-binding <policy-id> [split-horizon-group <group-name>] [import-
rt
  {ext-community, ... (upto 5 max)}]
- no pw-template-binding <policy-id>

<policy-id>          : [1..2147483647]
<group-name>         : [32 chars max]
<ext-community>      : target:{<ip-addr:comm-val>|<as-number:ext-comm-val>}
                        ip-addr      - a.b.c.d
                        comm-val     - [0..65535]
                        as-number    - [1..65535]
                        ext-comm-val - [0..4294967295]
```

0990

It is important to understand the significance of the split horizon group used by the pw-template. Traditionally, when a VPLS instance was manually created using mesh-SDP bindings, these were automatically placed in a common split horizon group to prevent forwarding between the pseudowire in the VPLS instances. This prevents loops that would have otherwise occurred in the Layer 2 service. When automatically discovering VPLS service using BGP AD, the service provider has the option of associating the auto-discovered pseudowire with a split horizon group to control the forwarding between pseudowires.

## 3.5.7 Configuring BGP VPLS

This section provides a configuration example required to bring up BGP VPLS in the VPLS PEs depicted in [Figure 104](#).

**Figure 104 BGP VPLS Example**

The red BGP VPLS is configured in the PE24, PE25, and PE26 using the commands shown in the following CLI examples:

```
*A:PE24>config>service>vpls# info
-----
      bgp
        route-distinguisher 65024:600
        route-target export target:65019:600 import target:65019:600
        pw-template-binding 1
      exit
    bgp-vpls
      max-ve-id 100
      ve-name 24
      ve-id 24
    exit
    no shutdown
  exit
  sap 1/1/20:600.* create
  exit
  no shutdown
-----

*A:PE24>config>service>vpls#

*A:PE25>config>service>vpls# info
-----
      bgp
        route-distinguisher 65025:600
        route-target export target:65019:600 import target:65019:600
        pw-template-binding 1
```

```

        exit
        bgp-vpls
            max-ve-id 100
            ve-name 25
            ve-id 25
        exit
        no shutdown
    exit
    sap 1/1/19:600.* create
    exit
    no shutdown
-----
*A:PE25>config>service>vpls#

*A:PE26>config>service>vpls# info
-----
    bgp
        route-distinguisher 65026:600
        route-target export target:65019:600 import target:65019:600
        pw-template-binding 1
    exit
    bgp-vpls
        max-ve-id 100
        ve-name 26
        ve-id 26
    exit
    no shutdown
    exit
    sap 5/2/20:600.* create
    exit
    no shutdown
-----
*A:PE26>config>service>vpls#

```

### 3.5.7.1 Configuring a VPLS Management Interface

Use the following CLI syntax to create a VPLS management interface:

**CLI Syntax:**

```

config>service>vpls# interface ip-int-name
address ip-address[/mask] [netmask]
arp-timeout seconds
description description-string
mac ieee-address
no shutdown
static-arp ip-address ieee-address

```

The following example shows the configuration.

```

A:ALA-49>config>service>vpls>interface# info detail
-----
    no description
    mac 14:31:ff:00:00:00

```

```
address 10.231.10.10/24
no arp-timeout
no shutdown
-----
A:ALA-49>config>service>vpls>interface#
```

### 3.5.8 Configuring Policy-Based Forwarding for Deep Packet Inspection (DPI) in VPLS

The purpose of policy-based forwarding is to capture traffic from a customer and perform a deep packet inspection (DPI) and forward traffic, if allowed, by the DPI on the 7450 ESS or 7750 SR.

In the following example, the split horizon groups are used to prevent flooding of traffic. Traffic from customers enter at SAP 1/1/5:5. Due to the mac-filter 100 that is applied on ingress, all traffic with dot1p 07 marking will be forwarded to SAP 1/1/22:1, which is the DPI.

DPI performs packet inspection/modification and either drops the traffic or forwards the traffic back into the box through SAP 1/1/21:1. Traffic will then be sent to spoke-SDP 3:5.

SAP 1/1/23:5 is configured to determine whether the VPLS service is flooding all the traffic. If flooding is performed by the router, traffic would also be sent to SAP 1/1/23:5 (which it should not).

[Figure 105](#) shows an example to configure policy-based forwarding for deep packet inspection on a VPLS service. For information about configuring filter policies, refer to the *7450 ESS, 7750 SR, 7950 XRS, and VSR Router Configuration Guide*.

**Figure 105 Policy-Based Forwarding For Deep Packet Inspection**

The following example shows the service configuration:

```
*A:ALA-48>config>service# info
-----
...
vpls 10 customer 1 create
  service-mtu 1400
  split-horizon-group "dpi" residential-group create
  exit
  split-horizon-group "split" create
  exit
  stp
    shutdown
  exit
  igmp-host-tracking
    expiry-time 65535
    no shutdown
  exit
  sap 1/1/21:1 split-horizon-group "split" create
    disable-learning
    static-mac 00:00:00:31:11:01 create
  exit
  sap 1/1/22:1 split-horizon-group "dpi" create
    disable-learning
    static-mac 00:00:00:31:12:01 create
  exit
  sap 1/1/23:5 create
    static-mac 00:00:00:31:13:05 create
  exit
```

```

        no shutdown
    exit
...
-----
*A:ALA-48>config>service#

```

The following example shows the MAC filter configuration:

```

*A:ALA-48>config>filter# info
-----
...
    mac-filter 100 create
        default-action forward
        entry 10 create
            match
                dot1p 7 7
            exit
            log 101
            action forward sap 1/1/22:1
        exit
    exit
...
-----
*A:ALA-48>config>filter#

```

The following example shows the service configuration with a MAC filter:

```

*A:ALA-48>config>service# info
-----
...
    vpls 10 customer 1 create
        service-mtu 1400
        split-horizon-group "dpi" residential-group create
        exit
        split-horizon-group "split" create
        exit
        stp
            shutdown
        exit
        igmp-host-tracking
            expiry-time 65535
            no shutdown
        exit
        sap 1/1/5:5 split-horizon-group "split" create
            ingress
                filter mac 100
            exit
            static-mac 00:00:00:31:15:05 create
        exit
        sap 1/1/21:1 split-horizon-group "split" create
            disable-learning
            static-mac 00:00:00:31:11:01 create
        exit
        sap 1/1/22:1 split-horizon-group "dpi" create
            disable-learning
            static-mac 00:00:00:31:12:01 create
        exit

```

```

        sap 1/1/23:5 create
            static-mac 00:00:00:31:13:05 create
        exit
        spoke-sdp 3:5 create
        exit
        no shutdown
    exit
....
-----
*A:ALA-48>config>service#

```

### 3.5.9 Configuring VPLS E-Tree Services

When configuring a VPLS E-Tree service, the **etree** keyword must be specified when the VPLS service is created. This is the first operation required before any SAPs or SDPs are added to the service, since the E-Tree service type affects the operations of the SAPs and SDP bindings.

When configuring AC SAPs, the configuration model is very similar to normal SAPs. Since the VPLS service must be designated as an E-Tree, the default AC SAP is a root-ac SAP. An E-Tree service with all root-ac behaves just as a regular VPLS service. A leaf-ac SAP must be configured for leaf behavior.

For root-leaf-tag SAPs, the SAP is created with both root and leaf VIDs. The 1/1/1:x.\* or 1/1/1:x would be the typical format, where x designates the root tag. A leaf-tag is configured at SAP creation and replaces the x with a leaf-tag VID. Combined statistics for root and leaf SAPs are reported under the SAP. There are no individual statistics shown for root and leaf.

The following example illustrates the configuration of a VPLS E-Tree service with root-ac (default configuration for SAPs and SDP binds) and leaf-ac interfaces, as well as a root leaf tag SAP and SDP bind.

In the example, the SAP 1/1/7:2006.200 is configured using the root-leaf-tag parameter, where the outer VID 2006 is used for root traffic and the outer VID 2007 is used for leaf traffic.

```

*A:ALA-48>config>service# info
-----
...
    service vpls 2005 etree customer 1 create
        sap 1/1/1:2005 leaf-ac create
        exit
        sap 1/1/7:2006.200 root-leaf-tag leaf-tag 2007 create
        exit
        sap 1/1/7:0.* create
        exit
        spoke-sdp 12:2005 vc-type vlan root-leaf-tag create
            no shutdown

```

```
        exit
    spoke-sdp 12:2006 leaf-ac create
        no shutdown
    exit
    no shutdown
exit
....
*A:ALA-48>config>service# info
-----
```

## 3.6 Service Management Tasks

This section describes VPLS service management tasks.

### 3.6.1 Modifying VPLS Service Parameters

You can change existing service parameters. The changes are applied immediately. To display a list of services, use the **show service service-using vpls** command. Enter the parameter such as description, SAP, SDP, and/or service-MTU command syntax, then enter the new information.

The following shows a modified VPLS configuration:

```
*A:ALA-1>config>service>vpls# info
-----
description "This is a different description."
disable-learning
disable-aging
discard-unknown
local-age 500
remote-age 1000
stp
    shutdown
exit
sap 1/1/5:22 create
    description "VPLS SAP"
exit
spoke-sdp 2:22 create
exit
no shutdown
-----
*A:ALA-1>config>service>vpls#
```

### 3.6.2 Modifying Management VPLS Parameters

To modify the range of VLANs on an access port that are to be managed by an existing management VPLS, the new range should be defined, then the old range removed. If the old range is removed before a new range is defined, all customer VPLS services in the old range will become unprotected and may be disabled.

**CLI Syntax:**    config>service# vpls *service-id*  
                  sap *sap-id*  
                      managed-vlan-list  
                      [no] range *vlan-range*

### 3.6.3 Deleting a Management VPLS

As with normal VPLS service, a management VPLS cannot be deleted until SAPs and SDPs are unbound (deleted), interfaces are shut down, and the service is shut down on the service level.

Use the following CLI syntax to delete a management VPLS service.

**CLI Syntax:**

```
config>service
[no] vpls service-id
shutdown
[no] spoke-sdp sdp-id
[no] mesh-sdp sdp-id
shutdown
[no] sap sap-id
shutdown
```

### 3.6.4 Disabling a Management VPLS

You can shut down a management VPLS without deleting the service parameters.

When a management VPLS is disabled, all associated user VPLS services are also disabled (to prevent loops). If this is not needed, un-manage the user's VPLS service by removing them from the managed-vlan-list or moving the spoke-SDPs to another tunnel SDP.

**CLI Syntax:**

```
config>service
vpls service-id
shutdown
```

**Example:**

```
config>service# vpls 1
config>service>vpls# shutdown
config>service>vpls# exit
```

### 3.6.5 Deleting a VPLS Service

A VPLS service cannot be deleted until SAPs and SDPs are unbound (deleted), interfaces are shut down, and the service is shut down on the service level.

Use the following CLI syntax to delete a VPLS service.

**CLI Syntax:**

```
config>service
```

```
[no] vpls service-id
      shutdown
      [no] mesh-sdp sdp-id
            shutdown
      sap sap-id [split-horizon-group group-name]
      no sap sap-id
            shutdown
```

### 3.6.6 Disabling a VPLS Service

You can shut down a VPLS service without deleting the service parameters.

**CLI Syntax:**    config>service> vpls *service-id*  
                 [no] shutdown

**Example:**       config>service# vpls 1  
                 config>service>vpls# shutdown  
                 config>service>vpls# exit

### 3.6.7 Re-enabling a VPLS Service

Use the following CLI syntax to re-enable a VPLS service that was shut down.

**CLI Syntax:**    config>service> vpls *service-id*  
                 [no] shutdown

**Example:**       config>service# vpls 1  
                 config>service>vpls# no shutdown  
                 config>service>vpls# exit

## 3.7 VPLS Service Configuration Command Reference

This section describes the VPLS service configuration command reference.

### 3.7.1 Command Hierarchies

#### 3.7.1.1 Global Commands

```

config
  — service
    — system
      — fdb-table-size table-size
      — no fdb-table-size
    — vpls service-id [customer customer-id] [vpn vpn-id] [m-vpls] [b-vpls | i-vpls] [etree]
      [name name] [create]

**Description** This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.

The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described below in Special Cases.

The **no** form of this command places the entity into an administratively enabled state.

**Special Cases** **Service Admin State** — Bindings to an SDP within the service will be put into the out-of-service state when the service is shut down. While the service is shut down, all customer packets are dropped and counted as discards for billing and debugging purposes.

**Service Operational State** — A service is regarded as operational providing that two SAPs or one SDP is operational.

**SDP (global)** — When an SDP is shut down at the global service level, all bindings to that SDP are put into the out-of-service state and the SDP itself is put into the administratively and operationally down states. Packets that would normally be transmitted using this SDP binding will be discarded and counted as dropped packets.

**SDP (service level)** — Shutting down an SDP within a service only affects traffic on that service from entering or being received from the SDP. The SDP itself may still be operationally up for other services.

**SDP Keepalives** — Enables SDP connectivity monitoring keepalive messages for the SDP ID. Default state is disabled (shutdown), in which case the operational state of the SDP ID is not affected by the keepalive message state.

**VPLS SAPs and SDPs** — SAPs are created in a VPLS and SDPs are bound to a VPLS in the administratively up default state. The created SAP will attempt to enter the operationally up state. An SDP will attempt to go into the in-service state when bound to the VPLS.

**Routed VPLS with forward-ipv4-multicast-to-ip-int and IGMP Snooping** — To enable IGMP snooping (configured using **igmp-snooping no shutdown**) in a routed VPLS supporting the forwarding of multicast traffic from the VPLS to the IP interface (configured using **forward-ipv4-multicast-to-ip-int**), it is necessary to enable IGMP on the routed VPLS IP interface.

**Routed VPLS with forward-ipv6-multicast-to-ip-int and MLD Snooping** — To enable MLD snooping (configured using **mld-snooping no shutdown**) in a routed VPLS supporting the forwarding of multicast traffic from the VPLS to the IP interface (configured using **forward-ipv6-multicast-to-ip-int**) it is necessary to enable MLD on the routed VPLS IP interface.

| <b>Context</b>     | config>service>system                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command configures the maximum system FDB table size, which is dependent on the chassis type. CPMs with at least 16 GB of memory are required when exceeding 500k MAC addresses in a system. The table size cannot be reduced below its default value, which is also chassis-dependent.</p> <p>The maximum system FDB table size also limits the maximum FDB table size of any card within the system.</p> <p>The <b>no</b> version of this command sets the table size to its default.</p> <p>The command default depends on the chassis type and available memory.</p> |
| <b>Parameters</b>  | <p><i>table-size</i> — Specifies the maximum system FDB table size.</p> <p><b>Values</b> 255999 to 2047999</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command creates or edits a Virtual Private LAN Services (VPLS) instance. The <b>vpls</b> command is used to create or maintain a VPLS service. If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>A VPLS service connects multiple customer sites together acting like a zero-hop, Layer 2 switched domain. A VPLS is always a logical full mesh.</p> <p>When creating a service, you must enter the <b>customer</b> keyword and specify a <i>customer-id</i> to associate the service with a customer. The <i>customer-id</i> must already exist, having been created using the <b>customer</b> command in the <b>service</b> context. The <i>customer-id</i> must already exist having been created using the <b>customer</b> command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>To create a management VPLS on the 7450 ESS, the m-vpls keyword must be specified. See section <b>Hierarchical VPLS Redundancy</b> for an introduction to the concept of management VPLS.</p> <p>Once a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>More than one VPLS service may be created for a single customer ID.</p> <p>By default, no VPLS instances exist until they are explicitly created.</p> <p>The <b>no</b> form of this command deletes the VPLS service instance with the specified <i>service-id</i>. The service cannot be deleted until all SAPs and SDPs defined within the service ID have been shutdown and deleted, and the service has been shutdown.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — Specifies unique service identification number identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every router on which this service is defined.</p> <p><b>Values</b>      <i>service-id</i>: 1 to 2147483647<br/>                   <i>svc-name</i>: 64 characters maximum</p> <p><b>customer</b> <i>customer-id</i> — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.</p> <p><b>Values</b>      1 to 2147483647</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**vpn** *vpn-id* — Specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number

**Values** 1 to 2147483647

**Default** null (0)

**m-vpls** — Specifies a management VPLS

**e-tree** — Specifies a VPLS service as an E-Tree VPLS. E-Tree VPLS services have root and leaf-ac SAPs/SDP bindings and root-leaf-tag SAPs/SDP bindings for E-Tree interconnection. The access (AC) root SAP behaves as a normal VPLS SAP. The AC leaf SAP is restricted to communication only with root-connected services. AC leaf and root SAPs are externally normal SAPs. The AC root SDP bind behaves as a normal VPLS SDP bind. The AC leaf SDP bind is restricted to communication only with root-connected services. AC leaf and root SDP bindings are externally normal SDPs bindings.

In the E-Tree VPLS, the root-ac SAP/SDP bindings can communicate with other root-ac and leaf-ac SAP/SDP bind services locally and remotely. Root originated traffic is marked internally with a root indication and root tagged externally on tag SAP/SDP binds. The leaf-ac SAP/SDP bindings can communicate with other root SAP/SDP bindings locally and remotely. Leaf originated traffic is marked internally with a leaf indication and tagged externally on leaf tag SAP/SDP bindings.

There may be any number of AC SAPs of root or leaf up to typical SAP limits.

Network Side tag SAPs for root-leaf use additional resources. These tag SAPs used two tags one for Root and one for Leaf. Network side tag SDPs use a hard coded tag of 1 for root and 2 for leaf. AC SDP bindings are designated as root or leaf SDP bindings but carry no tags marking traffic on the egress frames.

An E-Tree SAP types are specified at creation time. To change the type of a E-Tree SAP the SAP must be removed and re-created.

**b-vpls | i-vpls** — Creates a backbone-vpls or ISID-vpls

**name** *name* — Configures an optional service name identifier, up to 64 characters, to a given service. This service name can then be used in configuration references, display, and show commands throughout the system. A defined service name can help the service provider or administrator to identify and manage services within the SR OS platforms.

To create a service, you must assign a service ID; however, after it is created, either the service ID or the service name can be used to identify and reference a service.

If a name is not specified at creation time, then SR OS assigns a string version of the *service-id* as the name.

**Values** *name*: 64 characters maximum

## allow-ip-int-bind

**Syntax** [no] **allow-ip-int-bind**

**Context** config>service>vpls

**Description** The `allow-ip-int-bind` command that sets a flag on the VPLS or I-VPLS service that enables the ability to attach an IES or VPRN IP interface to the VPLS service in order to make the VPLS service routable. When the `allow-ip-int-bind` command is not enabled, the VPLS service cannot be attached to an IP interface.

#### VPLS Configuration Constraints for Enabling `allow-ip-int-bind`

When attempting to set the `allow-ip-int-bind` VPLS flag, the system first checks to see if the correct configuration constraints exist for the VPLS service and the network ports. The following VPLS features must be disabled or not configured for the `allow-ip-int-bind` flag to set:

- SAP ingress QoS policies applied to the VPLS SAPs cannot have MAC match criteria defined
- The VPLS service type cannot be B-VPLS or M-VPLS
- MVR from Routed VPLS and to another SAP is not supported
- Enhanced and Basic Subscriber Management (ESM and BSM) features
- Network domain on SDP bindings

Once the VPLS `allow-ip-int-bind` flag is set on a VPLS service, the above features cannot be enabled on the VPLS service.

#### Network Port Hardware Constraints

The system also checks to ensure that all ports configured in network mode are associated with FlexPath2 forwarding planes. If a port is currently in network mode and the port is associated with a FlexPath1 forwarding plane, the `allow-ip-int-bind` command will fail. Once the `allow-ip-int-bind` flag is set on any VPLS service, attempting to enable network mode on a port associated with a FlexPath1 forwarding plane will fail.

#### VPLS SAP Hardware Constraints

Besides VPLS configuration and network port hardware association, the system also checks to that all SAPs within the VPLS are created on Ethernet ports and the ports are associated with FlexPath2 forwarding planes. Certain Ethernet ports and virtual Ethernet ports are not supported which include HSMDA ports and CCAG virtual ports (VSM based). If a SAP in the VPLS exists on an unsupported port type or is associated with a FlexPath1 forwarding plane, the `allow-ip-int-bind` command will fail. Once the `allow-ip-int-bind` flag is set on the VPLS service, attempting to create a VPLS SAP on the wrong port type or associated with a FlexPath1 forwarding plane will fail.

#### VPLS Service Name Bound to IP Interface without `allow-ip-int-bind` flag Set

If a service name is applied to a VPLS service and that service name is also bound to an IP interface but the `allow-ip-int-bind` flag has not been set on the VPLS service context, the system attempt to resolve the service name between the VPLS service and the IP interface will fail. After the `allow-ip-int-bind` flag is successfully set on the VPLS service, either the service name on the VPLS service must be removed and reapplied or the IP interface must be re-initialized using the **shutdown** / **no shutdown** commands. This will cause the system to reattempt the name resolution process between the IP interface and the VPLS service.

The **no** form of the command resets the allow-ip-int-bind flag on the VPLS service. If the VPLS service currently has an IP interface from an IES or VPRN service attached, the no allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is reset on the VPLS service, the configuration and hardware restrictions associated with setting the flag are removed. The port network mode hardware restrictions are also removed.

| <b>Description</b> | <p>This command enables and disables ECMP on VXLAN IPv4 destinations for R-VPLS services. When this command is enabled, packets entering a VPRN connected to an R-VPLS that is terminating on a VXLAN IPv4 destination are looked up in the routing table. If the next hop is a VXLAN IPv4 TEP, the packets are distributed based on per-flow load-balancing.</p> <p>This command can only be used in FP3- (or higher) routers. R-VPLS per-flow load-balancing for VXLAN IPv6 destinations works by default without this command.</p> <p>The <b>no</b> version of this command reverts the process to the default behavior of per-remote VTEP load-balancing.</p> |
| <b>Default</b>     | no vxlan-ipv4-tep-ecmp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command disables MAC address aging across a VPLS service or on a VPLS service SAP or spoke-SDP.</p> <p>Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the VPLS forwarding database (FDB). The <b>disable-aging</b> command turns off aging for local and remote learned MAC addresses.</p> <p>When <b>no disable-aging</b> is specified for a VPLS, it is possible to disable aging for specific SAPs and/or spoke-SDPs by entering the <b>disable-aging</b> command at the appropriate level.</p> <p>When the <b>disable-aging</b> command is entered at the VPLS level, the <b>disable-aging</b> state of individual SAPs or SDPs will be ignored.</p> <p>The <b>no</b> form of this command enables aging on the VPLS service.</p> |
| <b>Default</b>     | no disable-aging                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>When this command is enabled, the node ignores the standby-bit received from the TLDP peers for the specific spoke-SDP and performs internal tasks without taking it into account.</p> <p>This command is present at the endpoint level and the spoke-SDP level. If the spoke-SDP is part of the explicit-endpoint, this setting cannot be changed at the spoke-SDP level. The existing spoke-SDP will become part of the explicit-endpoint only if the setting is not conflicting. The newly created spoke-SDP, which is a part of the specified explicit-endpoint, will inherit this setting from the endpoint configuration.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## mac-pinning

|                    |                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mac-pinning</b>                                                                                                                                                               |
| <b>Context</b>     | config>service>vpls>spoke-sdp<br>config>service>vpls>mesh-sdp<br>config>service>vpls>sap<br>config>service>vpls>endpoint                                                              |
| <b>Description</b> | Enabling this command will disable re-learning of MAC addresses on other SAPs within the VPLS. The MAC address will remain attached to a specified SAP for duration of its age-timer. |

The age of the MAC address entry in the FDB is set by the age timer. If mac-aging is disabled on a specified VPLS service, any MAC address learned on a SAP/SDP with mac-pinning enabled will remain in the FDB on this SAP/SDP forever. Every event that would otherwise result in re-learning will be logged (MAC address; original-SAP; new-SAP).

MAC addresses learned during DHCP address assignment (DHCP snooping enabled) are not impacted by this command. MAC-pinning for such addresses is implicit.

**Default** When a SAP or spoke-SDP is part of a Residential Split Horizon Group (RSHG), MAC pinning is activated at creation of the SAP. Otherwise, MAC pinning is not enabled by default.

## max-nbr-mac-addr

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | This command indicates how the agent will handle relearn requests for protected MAC addresses, either manually added using the <code>mac-protect</code> command or automatically added using the <code>auto-learn-mac-protect</code> command. While enabled all packets entering the configured SAP, spoke-SDP, mesh-SDP, or any SAP that is part of the configured split horizon group (SHG) will be verified not to contain a protected source MAC address. If the packet is found to contain such an address, the action taken depends on the parameter specified on the <code>restrict-protected-src</code> command, namely: |

- No parameter — The packet will be discarded, an alarm will be generated and the SAP, spoke-SDP or mesh SDP will be set operationally down. The SAP, spoke-SDP or mesh-SDP must be shutdown and enabled (no shutdown) for this state to be cleared.
- alarm-only — The packet will be forwarded, an alarm will be generated but the source MAC is not learned on the SAP, spoke-SDP or mesh SDP.
- discard-frame — The packet will be discarded and an alarm generated. The frequency of alarm generation is fixed to be at most one alarm per MAC address per FP per 10 minutes in a specified VPLS service. This parameter is only applicable to automatically protected MAC addresses.

When the **restrict-protected-src** is enabled on an SHG, the action only applies to the associated SAPs (no action is taken by default for spoke-SDPs in the SHG) and is displayed in the SAP show output as the oper state unless it is overridden by the configuration of **restrict-protected-src** on the SAP itself. To enable this function for spoke-SDPs within a SHG, the **restrict-protected-src** must be enabled explicitly under the spoke-SDP. If required, **restrict-protected-src** can also be enabled explicitly under specific SAPs within the SHG.

When this command is applied or removed, with either the **alarm-only** or **discard-frame** parameters, the MAC addresses are cleared from the related object.

The use of **restrict-protected-src discard-frame** is mutually exclusive with the configuration of manually protected MAC addresses within a specified VPLS.

The **alarm-only** parameter is not supported on the 7750 SR-a, 7750 SR-1e/2e/3e, or 7950 XRS.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no restrict-protected-src                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b> | <p><b>alarm-only</b> — Specifies that the packet will be forwarded, an alarm will be generated but the source MAC is not learned on the SAP, spoke-SDP or mesh SDP</p> <p><b>discard-frame</b> — Specifies that the packet will be discarded and an alarm generated. The frequency of alarm generation is fixed to be at most one alarm per MAC address per FP per 10 minutes within a specified VPLS service</p> |

## revert-time

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>revert-time</b> <i>revert-time</i>   <b>infinite</b><br><b>no revert-time</b> |
| <b>Context</b>     | config>service>vpls>endpoint                                                     |
| <b>Description</b> | This command configures the time to wait before reverting to primary spoke-SDP.  |

In a regular endpoint the revert-time setting affects just the pseudowire defined as primary (precedence 0). For a failure of the primary pseudowire followed by restoration the revert-timer is started. After it expires the primary pseudowire takes the active role in the endpoint. This behavior does not apply for the case when both pseudowires are defined as secondary. For example, if the active secondary pseudowire fails and is restored it will stay in standby until a configuration change or a force command occurs.

- Parameters** *revert-time* — Specifies the time to wait, in seconds, before reverting back to the primary spoke-SDP defined on this service endpoint, after having failed over to a backup spoke-SDP
- Values** 0 to 600
- infinite** — Specifying this keyword makes endpoint non-revertive

## static-mac

- Syntax** **static-mac** *ieee-address* [**create**]  
**no static-mac**
- Context** config>service>vpls>endpoint
- Description** This command assigns a static MAC address to the endpoint. In the FDB, the static MAC is then associated with the active spoke-SDP.
- Default** none
- Parameters** *ieee-address* — Specifies the static MAC address to the endpoint
- Values** 6-byte mac-address (xx:xx:xx:xx:xx:xx or xx-xx-xx-xx-xx-xx) Cannot be all zeros
- create** — This keyword is mandatory while creating a static MAC

## suppress-standby-signaling

- Syntax** [**no**] **suppress-standby-signaling**
- Context** config>service>vpls>endpoint
- Description** When this command is enabled, the pseudowire standby bit (value 0x00000020) will not be sent to T-LDP peer when the specified spoke is selected as a standby. This allows faster switchover as the traffic will be sent over this SDP and discarded at the blocking side of the connection. This is particularly applicable to multicast traffic.
- Default** enabled

| <b>Description</b> | This command enables subscriber host connectivity verification on a specified SAP within a VPLS service. This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Default</b>     | no host-connectivity-verify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies an unused IP address in the same network for generation of subscriber host connectivity verification packets</p> <p><i>ieee-address</i> — Specifies the source MAC address to be used for generation of subscriber host connectivity verification packets</p> <p><i>interval</i> — Specifies the interval, in minutes, which specifies the time interval in which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p><b>Values</b> 1 to 6000<br/>A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p><b>action {remove   alarm}</b> — Defines the action taken on a subscriber host connectivity verification failure for a specified host. The <b>remove</b> keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, and so on). DHCP release will be signaled to corresponding DHCP server. Static host will be never removed. The <b>alarm</b> keyword raises an alarm indicating that the host is disconnected.</p> |

## igmp-host-tracking

|                |                           |
|----------------|---------------------------|
| <b>Syntax</b>  | <b>igmp-host-tracking</b> |
| <b>Context</b> | config>service>vpls       |

---

```
config>service>vpls>sap
```

**Description** This command enters the context to configure IGMP host tracking parameters.

## expiry-time

**Syntax** **expiry-time** *expiry-time*  
**no expiry-time**

**Context** config>service>vpls>igmp-host-tracking  
config>service>vpls>sap>igmp-host-tracking

**Description** This command configures the time that the system continues to track inactive hosts.

The **no** form of the command removes the values from the configuration.

**Default** no expiry-time

**Parameters** *expiry-time* — Specifies the time, in seconds, that this system continues to track an inactive host

**Values** 1 to 65535

## igmp-snooping

**Syntax** **igmp-snooping**

**Context** config>service>vpls  
config>service>vpls>sap  
config>service>vpls>spoke-sdp  
config>service>vpls>mesh-sdp  
config>service>vpls>bind

**Description** This command enables the Internet Group Management Protocol (IGMP) snooping context.

**Default** none

## mvr

**Syntax** **mvr**

**Context** config>service>vpls>igmp-snooping  
config>service>vpls>mld-snooping  
config>service>vpls>sap>igmp-snooping  
config>service>vpls>sap>mld-snooping

**Description** This command enters the context to configure Multicast VPLS Registration (MVR) parameters.

## group-policy

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Syntax</b>      | <b>group-policy</b> <i>policy-name</i><br><b>no group-policy</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vpls>pim-snooping<br>config>service>vpls>sap>igmp-snooping>mvr<br>config>service>vpls>mld-snooping>mvr                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command identifies filter policy of multicast groups to be applied to this VPLS entity. The sources of the multicast traffic must be a member of the VPLS.</p> <p>The <b>no</b> form of the command removes the policy association from the VPLS configuration.</p>                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>     | No group policy is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the group policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, and so on), the entire string must be enclosed within double quotes. Routing policies are configured in the config>router>policy-options context. The router policy must be defined before it can be imported. For details on IGMP policies, refer to “Enabling IGMP Group Membership Report Filtering” in the SR OS <i>Triple Play Service Delivery Architecture Guide</i> . |

## query-interval

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vpls>igmp-snooping                                   |
| <b>Description</b> | This command configures the IP source address used in IGMP queries. |

## report-src-ip

|                    |                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>report-src-ip</b> <i>address</i><br><b>no report-src-ip</b>                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vpls>igmp-snooping                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This parameter specifies the source IP address used when generating IGMP reports. According the IGMPv3 standard, a zero source address is allowed in sending IGMP reports. However, for interoperability with some multicast routers, the source IP address of IGMP group reports can be configured using this command. |
| <b>Default</b>     | 0.0.0.0                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the source IP source address in transmitted IGMP reports                                                                                                                                                                                                                                  |

## robust-count

|                |                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>If the <b>send-queries</b> command is enabled, this parameter allows tuning for the expected packet loss on a SAP or SDP. The robust-count variable allows tuning for the expected packet loss on a subnet and is comparable to a retry count. If this SAP or SDP is expected to be 'lossy', this parameter may be increased. IGMP snooping on this SAP or SDP is robust to (robust-count-1) packet losses.</p> <p>If send-queries is not enabled, this parameter will be ignored.</p> |
| <b>Default</b>     | robust-count 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Syntax</b>      | <b>[no] interface</b> <i>ip-int-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command creates a logical IP routing interface for a VPLS service. Once created, attributes such as IP address and service access points (SAP) can be associated with the IP interface.</p> <p>The interface command, under the context of services, is used to create and maintain IP routing interfaces within the VPLS service IDs. The IP interface created is associated with the VPLS management routing instance. This instance does not support routing.</p> <p>Interface names are case-sensitive and must be unique within the group of defined IP interfaces defined for the network core router instance. Interface names in the dotted decimal notation of an IP address are not allowed. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. Duplicate interface names can exist in different router instances.</p> <p>Enter a new name to create a logical router interface. When an existing interface name is entered, the user enters the router interface context for editing and configuration.</p> <p>By default, no default IP interface names are defined within the system. All VPLS IP interfaces must be explicitly defined in an enabled state.</p> <p>The no form of this command removes the IP interface and the entire associated configuration. The interface must be administratively shutdown before issuing the no interface command.</p> <p>For VPLS services, the IP interface must be shutdown before the SAP on that interface is removed.</p> <p>For VPLS service, ping and traceroute are the only applications supported.</p> |

**Parameters**    *ip-int-name* — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP.

An interface name:

- Should not be in the form of an IP address.
- Can be from 1 to 32 alphanumeric characters.
- If the string contains special characters (such as #,\$,spaces), the entire string must be enclosed within double quotes.

If *ip-int-name* already exists within the service ID, the context changes to maintain that IP interface. If *ip-int-name* already exists within another service ID, an error occurs and the context does not change to that IP interface. If *ip-int-name* does not exist, the interface is created and the context is changed to that interface for further command processing.

address

**Syntax**    **address** *ip-address[/mask] [netmask]*  
**no address**

**Context**    config>service>vpls>interface

**Description**    This command assigns an IP address, IP subnet, and broadcast address format to an IES IP router interface. Only one IP address can be associated with an IP interface.

An IP address must be assigned to each IES IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

The local subnet that the **address** command defines must be part of the services address space within the routing context using the **config router service-prefix** command. The default is to disallow the complete address space to services. Once a portion of the address space is allocated as a service prefix, that portion can be made unavailable for IP interfaces defined within the **config router interface** CLI context for network core connectivity with the **exclude** option in the **config router service-prefix** command.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down.

| Address    | Admin State | Oper State |
|------------|-------------|------------|
| No address | up          | down       |

| Address    | Admin State | Oper State |
|------------|-------------|------------|
| No address | down        | down       |
| 1.1.1.1    | up          | up         |
| 1.1.1.1    | down        | down       |

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

**Parameters** *ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP netmask

The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 to 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.

## arp-timeout

**Syntax** **arp-timeout** *seconds*  
**no arp-timeout**

**Context** config>service>vpls>interface

**Description** This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If **arp-timeout** is set to a value of zero seconds, ARP aging is disabled.

For the 7450 ESS or 7750 SR, when the **arp-populate** and **lease-populate** commands are enabled on an interface, the ARP table entries will no longer be dynamically learned, but instead by snooping DHCP ACK message from a DHCP server. In this case the configured **arp-timeout** value has no effect.

The default value for **arp-timeout** is 14400 seconds (4 hours).

The **no** form of this command restores **arp-timeout** to the default value.

**Default** 14400 seconds

---

**Parameters**     *seconds* — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.

**Values**        0 to 65535

## hold-time

**Syntax**        **hold-time**

**Context**        config>service>vpls>interface

**Description**    This command creates the CLI context to configure interface level hold-up and hold-down timers for the associated IP interface.

The **up** timer controls a delay for the associated IPv4 or IPv6 interface so that the system will delay the deactivation of the associated interface for the specified amount of time.

The **down** timer controls a delay for the associated IPv4 or IPv6 interface so that the system will delay the activation of the associated interface for the specified amount of time

## up

**Syntax**        **up ip seconds**  
**no up ip**  
**up ipv6 seconds**  
**no up ipv6**

**Context**        config>service>vpls>interface>hold-time

**Description**    This command will cause a delay in the deactivation of the associated IP interface by the specified number of seconds. The delay is invoked whenever the system attempts to bring the associated IP interface down.

The **no** form of the command removes the command from the active configuration and removes the delay in deactivating the associated IP interface. If the configuration is removed during a delay period, the currently running delay will continue until it expires.

**Parameters**    *seconds* — The time delay, in seconds, to make the interface operational.

**Values**        1 to 1200

## down

**Syntax**        **down ip seconds [init-only]**  
**no up ip**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>vpls>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command assigns a specific MAC address to a VPLS IP interface.</p> <p>For Routed Central Office (CO), a group interface has no IP address explicitly configured but inherits an address from the parent subscriber interface when needed. For example, a MAC will respond to an ARP request when an ARP is requested for one of the IPs associated with the subscriber interface through the group interface.</p> <p>The <b>no</b> form of the command returns the MAC address of the IP interface to the default value.</p> |
| <b>Default</b>     | The system chassis MAC address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p>                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. A static ARP can only be configured if it exists on the network attached to the IP interface.</p> <p>If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.</p> <p>The <b>no</b> form of the command removes a static ARP entry.</p>                                                              |
| <b>Default</b>     | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies the IP address for the static ARP in dotted decimal notation</p> <p><i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><i>unnumbered</i> — Specifies the static ARP MAC for an unnumbered interface. Unnumbered interfaces support dynamic ARP. Once this command is configured, it overrides any dynamic ARP.</p> |

## static-mac

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Context</b>     | config>service>vpls<br>config>service>vpls>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>A set of conditional static MAC addresses can be created within a VPLS supporting bgp-evpn. Conditional static macs are also supported in B-VPLS with SPBM. Conditional Static MACs are dependent on the SAP/SDP state.</p> <p>This command allows assignment of a set of conditional static MAC addresses to a SAP/spoke-SDP. In the FDB, the static MAC is then associated with the active SAP or spoke-SDP.</p> <p>Static MACs are used for PBB Epipe and I-VPLS services that may terminate external to SPBM. If this is configured under a Control B-VPLS the interface referenced will not use IS-IS for this neighbor. This may also be configured under a User B-VPLS where the corresponding interface is not supported under the Control B-VPLS.</p> <p>Static MACs configured in a bgp-evpn service are advertised as protected (EVPN will signal the mac as protected).</p> |

## unnumbered

|                    |                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>vpls                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command configures ISID policies for individual ISIDs or ISID ranges in a B-VPLS using SPBM. The ISIDs may belong to I-VPLS services or may be static-isids defined on this node. Multiple entry statements are allowed under a <b>isid-policy</b>. ISIDs that are declared as static do not require and <b>isid-policy</b> unless the ISIDs are not to be advertised.</p> <p><b>isid-policy</b> allows finer control of ISID multicast but is not typically required for SPBM operation. Use of ISID policies can cause additional flooding of multicast traffic.</p> |
| <b>Default</b>     | no default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command creates or edits an ISID policy entry. Multiple entries can be created using unique entry-id numbers within the ISID policy.</p> <p><i>entry-id</i> — Specifies an entry-id uniquely identifies a ISID range and the corresponding actions. This allows users to insert a new entry in an existing policy without requiring renumbering of all the existing entries.</p> <p>The following rules govern the usage of multiple entry statements:</p> <ul style="list-style-type: none"> <li>• overlapping values are allowed:</li> </ul> |

- isid from 301 to 310
- isid from 305 to 315
- isid 316
- the minimum and maximum values from overlapping ranges are considered and displayed. The above entries will be equivalent with “isid from 301 to 316” statement.
- there is no consistency check with the content of ISID statements from other entries. The entries will be evaluated in the order of their IDs and the first match will cause the implementation to execute the associated action for that entry.

no isid - removes all the previous statements under one entry.

no isid value | from value to higher-value - removes a specific ISID value or range. Must match a previously used positive statement: for example, if the command “isid 16 to 100” was used using “no isid 16 to 50”, it will not work but “no isid 16 to 100 will be successful.

Values 1 to 65535

|                   |                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | No entry                                                                                                                                             |
| <b>Parameters</b> | <i>range-entry-id</i> — Specifies the ID of the ISID policy to be created or edited                                                                  |
| <b>Values</b>     | 1 to 8191                                                                                                                                            |
| <b>create</b>     | — Required when first creating the configuration context. Once the context is created, one can navigate into the context without the create keyword. |

| <b>Context</b>     | config>service>vpls>isid-policy>entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | The <b>no advertise-local</b> option prevents the advertisement of any locally defined I-VPLS ISIDs or static-isids in the range in a B-VPLS. For I-VPLS services or static-isids that are primarily unicast traffic, the use-def-mcast and no advertise-local options allows the forwarding of ISID based multicast frames locally using the default multicast. The <b>no advertise-local</b> option also suppresses this range of ISIDs from being advertised in ISIS. When using the <b>use-def-mcast</b> and <b>no advertise-local</b> policies, the ISIDs configured under this <b>static-isid</b> declarations SPBM treats the ISIDs as belonging to the default tree. |
| <b>Default</b>     | advertise-local                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## range

|                |                                                |
|----------------|------------------------------------------------|
| <b>Syntax</b>  | <b>range isid [to isid]</b><br><b>no range</b> |
| <b>Context</b> | config>service>vpls>isid-policy>entry          |

---

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies an ISID or a Range of ISIDs in a B-VPLS. One range is allowed per entry.                             |
| <b>Default</b>     | no range                                                                                                                    |
| <b>Parameters</b>  | <i>isid</i> — Specifies the ISID value in 24 bits. When singular, ISID identifies a particular ISID to be used for matching |
| <b>Values</b>      | 0 to 16777215                                                                                                               |
|                    | <b>to</b> <i>isid</i> — Identifies upper value in a range of ISIDs to be used as matching criteria                          |

## load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>load-balancing</b>                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vpls<br>config>service>template>vpls-template                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command enables the load-balancing context to configure interface per-flow load balancing options that will apply to traffic entering this interface and egressing over a LAG/ECMP on system-egress. This is a per interface setting. For load-balancing options that can also be enabled on the system level, the options enabled on the interface level overwrite system level configurations. |
| <b>Default</b>     | not applicable                                                                                                                                                                                                                                                                                                                                                                                        |

## per-service-hashing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Syntax</b>      | <b>[no] per-service-hashing</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vpls>load-balancing<br>config>service>template>vpls-template>load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables on a per service basis, consistent per-service hashing for Ethernet services over LAG, over Ethernet tunnel (eth-tunnel) using loadsharing protection-type or over CCAG. Specifically, it enables the new hashing procedures for Epipe, VPLS, regular or PBB services.</p> <p>The following algorithm describes the hash-key used for hashing when the new option is enabled:</p> <ul style="list-style-type: none"> <li>• If the packet is PBB encapsulated (contains an I-TAG ethertype) at the ingress side, use the ISID value from the I-TAG</li> <li>• If the packet is not PBB encapsulated at the ingress side <ul style="list-style-type: none"> <li>– For regular (non-PBB) VPLS and Epipe services, use the related service ID</li> <li>– If the packet is originated from an ingress IVPLS or PBB Epipe SAP</li> </ul> </li> <li>• If there is an ISID configured use the related ISID value</li> </ul> |

- If there is no ISID yet configured use the related service ID
  - For BVPLS transit traffic use the related flood list id
- Transit traffic is the traffic going between BVPLS endpoints
- An example of non-PBB transit traffic in BVPLS is the OAM traffic
- The above rules apply regardless of traffic type
  - Unicast, BUM flooded without MMRP or with MMRP, IGMP snooped

The **no** form of this command implies the use of existing hashing options.

**Default** no per-service-hashing

## spi-load-balancing

**Syntax** [no] spi-load-balancing

**Context** config>service>vpls>load-balancing  
config>service>template>vpls-template>load-balancing

**Description** This command enables use of the SPI in hashing for ESP/AH encrypted IPv4/v6 traffic. This is a per interface setting.

The **no** form disables the SPI function.

**Default** no spi-load-balancing

## teid-load-balancing

**Syntax** [no] teid-load-balancing

**Context** config>service>vpls>load-balancing  
config>service>template>vpls-template>load-balancing

**Description** This command enables inclusion of TEID in hashing for GTP-U/C encapsulates traffic for GTPv1/GTPv2. The **no** form of this command ignores TEID in hashing.

**Default** no teid-load-balancing

## local-age

**Syntax** local-age *aging-timer*  
no local-age [*aging-timer*]

**Context** config>service>vpls  
config>service>template>vpls-template

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>Specifies the aging time for locally learned MAC addresses in the forwarding database (FDB) for the Virtual Private LAN Service (VPLS) instance. In a VPLS service, MAC addresses are associated with a Service Access Point (SAP) or with a Service Distribution Point (SDP). MACs associated with a SAP are classified as local MACs, and MACs associated with an SDP are remote MACs.</p> <p>Like in a Layer 2 switch, learned MACs can be aged out if no packets are sourced from the MAC address for a period of time (the aging time). In each VPLS service instance, there are independent aging timers for local learned MAC and remote learned MAC entries in the FDB. The <b>local-age</b> timer specifies the aging time for local learned MAC addresses.</p> <p>The <b>no</b> form of this command returns the local aging timer to the default value.</p> |
| <b>Default</b>     | local age 300 — Local MACs aged after 300 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>aging-timer</i> — Specifies the aging time for local MACs expressed in seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>This command enters the context to configure MAC move attributes. A sustained high re-learn rate can be a sign of a loop somewhere in the VPLS topology. Typically, STP detects loops in the topology, but for those networks that do not run STP, the mac-move feature is an alternative way to protect your network against loops.</p> <p>When enabled in a VPLS, <b>mac-move</b> monitors the re-learn rate of each MAC. If the rate exceeds the configured maximum allowed limit, it disables the SAP where the source MAC was last seen. The SAP can be disabled permanently (until a <b>shutdown/no shutdown</b> command is executed) or for a length of time that grows linearly with the number of times the specified SAP was disabled. You have the option of marking a SAP as non-blockable in the <b>config&gt;service&gt;vpls&gt;sap&gt;limit-mac-move</b> or <b>config&gt;service&gt;vpls&gt;spoke-sdp&gt;limit-mac-move</b> contexts. This means that when the re-learn rate has exceeded the limit, another (blockable) SAP will be disabled instead.</p> <p>The <b>mac-move</b> command enables the feature at the service level for SAPs and spoke-SDPs, as only those objects can be blocked by this feature. Mesh SDPs are never blocked, but their re-learn rates (sap-to-mesh/spoke-to-mesh or vice versa) are still measured.</p> <p>The operation of this feature is the same on the SAP and spoke-SDP. For example, if a MAC address moves from SAP to SAP, from SAP to spoke-SDP, or between spoke-SDPs, one will be blocked to prevent thrashing. If the MAC address moves between a SAP and mesh SDP or spoke-SDP and mesh SDP combinations, the respective SAP or spoke-SDP will be blocked.</p> |

**mac-move** will disable a VPLS port when the number of relearns detected has reached the number of relearns needed to reach the move-frequency in the 5-second interval. For example, when the move-frequency is configured to 1 (relearn per second) mac-move will disable one of the VPLS ports when 5 relearns were detected during the 5-second interval because then the average move-frequency of 1 relearn per second has been reached. This can already occur in the first second if the real relearn rate is 5 relearns per second or higher.

The **no** form of this command disables MAC move.

|                    |                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>number-retries</b> <i>number-retries</i><br><b>no number-retries</b>                                                                                                |
| <b>Context</b>     | config>service>vpls>mac-move<br>config>service>template>vpls-template>mac-move                                                                                         |
| <b>Description</b> | This command configures the number of times retries are performed for re-enabling the SAP/SDP.                                                                         |
| <b>Default</b>     | number-retries 3                                                                                                                                                       |
| <b>Parameters</b>  | <i>number-retries</i> — Specifies number of retries for re-enabling the SAP/SDP. A zero (0) value indicates unlimited number of retries.<br><br><b>Values</b> 0 to 255 |

## primary-ports

|                    |                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>primary-ports</b>                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vpls>mac-move<br>config>service>template>vpls-template>mac-move                                                                                                                                                                                                                                            |
| <b>Description</b> | This command enters the context to define primary VPLS ports. VPLS ports that were declared as secondary prior to the execution of this command will be moved from secondary port-level to primary port-level. Changing a port to the tertiary level can only be done by first removing it from the secondary port-level. |

## secondary-ports

|                    |                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-ports</b>                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vpls>mac-move<br>config>service>template>vpls-template>mac-move                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command opens configuration context for defining secondary vpls-ports. VPLS ports that were declared as primary prior to the execution of this command will be moved from primary port-level to secondary port-level. Changing a port to the tertiary level can only be done by first removing it from the primary port-level. |

## cumulative-factor

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] cumulative-factor</b> <i>factor</i>                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vpls>mac-move>primary-ports<br>config>service>vpls>mac-move>secondary-ports<br>config>service>template>vpls-template>mac-move>primary-ports<br>config>service>template>vpls-template>mac-move>secondary-ports                                                                                                                                           |
| <b>Description</b> | This command defines a factor defining how many mac-relearn measurement periods can be used to measure mac-relearn rate. The rate must be exceeded during the defined number of consecutive periods before the corresponding port is blocked by the mac-move feature. The cumulative-factor of primary ports must be higher than cumulative-factor of secondary ports. |
| <b>Default</b>     | cumulative-factor 2 — secondary ports<br><br>cumulative-factor 3 — primary ports                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>factor</i> — Specifies the factor defining the number of mac-relearn measurement periods can be used to measure mac-relearn rate                                                                                                                                                                                                                                    |
| <b>Values</b>      | 2 to 10                                                                                                                                                                                                                                                                                                                                                                |

---

## sap

|                    |                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap</b> [split-horizon-group <i>group-name</i> ] [create] [capture-sap]<br><b>no sap</b> <i>sap-id</i> |
| <b>Context</b>     | config>service>vpls>mac-move>primary-ports<br>config>service>vpls>mac-move>secondary-ports                |
| <b>Description</b> | This command declares a specified SAP as a primary (or secondary) VPLS port.                              |
| <b>Parameters</b>  | <i>sap-id</i> — Specifies the physical port identifier portion of the SAP definition                      |

## spoke-sdp

|                    |                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] spoke-sdp</b> <i>spoke-id</i>                                                                                                                                                                |
| <b>Context</b>     | config>service>vpls>mac-move>primary-ports<br>config>service>vpls>mac-move>secondary-ports                                                                                                           |
| <b>Description</b> | This command declares a specified spoke-SDP as a primary (or secondary) VPLS port.                                                                                                                   |
| <b>Parameters</b>  | <i>spoke-id</i> — Specifies the SDP ID to configure as the primary VPLS port<br><b>Values</b> 1 to 17407<br><i>vc-id</i> — Specifies the virtual circuit identifier<br><b>Values</b> 1 to 4294967295 |
