1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all DUPINT (Duplication Interface) errors in a Duplicated Option PPN, PR-MAINT (Maintenance/Tape Processor) errors in a standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 4. If the test continues to ABORT with a 2000 error code, escalate the problem.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-62. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	There is a problem with one or both power units on the tested carrier. 1. For each power unit that has all sttus LEDs OFF, check the AC input to the power unit at the power unit outlet (see Figure 11-14 and Figure 11-15). If there is no AC, then check the appropriate fuses (see Figure 11-16) for the affected power unit. If the fuses are blown out, replace the fuses (see). If the fuses blow out again or AC does not show up at the power unit outlet, then there is probably a power wiring problem in the cabinet. Follow normal escalation procedures. 2. At this point AC should be present at the power unit outlet. If the carrier being tested is the 1A or 2A carrier or the 1B carrier in a High or Critical Reliability system, refer to "Troubleshooting Control Carrier Power Units" in Chapter 5, "Routine Maintenance Procedures". Otherwise, use the **recycle carrier PC** command (where PC is the appropriate port network and carrier) in an attempt to bring back the power units for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one power unit, or both, in the tested carrier is defective. If only one power unit is defective, the status LEDs on the healthy power unit light green for a moment. When the recycle test determines that both power units are defective, the software turns off power to both the good and defective power units. This causes the status LED(s) on the good power unit to light red. 3. Unplug both power units, and wait about one minute to allow the power units to cool down. Plug in the power units. If either power unit is operating properly (that is, the status LEDs show green), then replace the defective power unit(s). See "Power Unit Replacement Procedures" in this section.

Continued on next page

Table 11-62. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	4. If the replaced power unit still does not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier may be causing an electrical load which is preventing the power unit from operating properly. Unseat all the circuit packs in the carrier and reissue the **recycle carrier** command. a. If the recycle passes, then the power units are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, replace the defective circuit pack. If the status LED still shows red, remove the Amphenol. connector on the back of the slot containing this circuit pack and reissue the **recycle carrier** command. If the status LED shows green, the problem is with one of the telephones or the wiring to one of the telephones on this slot. If the status LED still shows red, escalate the problem. b. If either power unit still shows a red status LED, check for bent pins and cable placement in the affected carrier. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that **are not** detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If no other problems can be found, escalate the problem.

Continued on next page

Table 11-62. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Both power units in the tested carrier were found to be healthy by the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system. If the status LEDs on both power units are not showing green, the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the power units. Look for and resolve any alarms on these MOs.

CARR-POW (Carrier Port Power Unit) for DC-Powered Systems

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CARR-POW	MAJOR	recycle carrier PC	Carrier Port Power Unit

1 Recycle the carrier indicated by the Port field in the Alarm Log.

Generic 1 offers two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configurations may be powered by either an external AC or DC power source.

NOTE:
For environment maintenance, the PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate MO section(s).

- For a single-carrier cabinet system, refer to the "DC-POWER (Single-Carrier Cabinet Power)" Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER (AC Power) for AC-Powered Systems", "CARR-POW (Carrier Port Power Unit) for AC-Powered Systems", or "POWER (Battery & Battery Charger) for AC-Powered Systems".
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER (AC Power) for DC-Powered Systems", "CARR-POW (Carrier Port Power Unit) for DC-Powered Systems", or "POWER (Battery & Battery Charger) for DC-Powered Systems".

Every carrier in the system must be supplied with +5 volt, -48 volt, and -5 volt DC power for the various circuit packs to operate properly. A multicarrier system can be supplied by an external AC power source or an external DC power source.

In a DC-powered system, power is supplied to the carriers as follows: DC power from an external device comes into Power Distribution Units (PDU J58890CF and PDU J58890CF-1), which distribute the power via circuit breakers (CB1-CB12 for PDU J58890CF, CB1-CB6 for J58890Cf-1) to the carrier power units. Each carrier in the system is equipped with two power units, the 644A and the 645B, which together supply the required voltages to the carrier. Figure 11-19 illustrates the position of the carrier power units and PDU J58890CF and shows which power unit each circuit breaker controls (Figure 11-19 also shows other Environment maintenance-related items that can be ignored for this section on Carrier Port Power Unit). Figure 11-20 shows the position of the circuit breakers on the PDU J58890CF. Figure 11-21 illustrates the position of the carrier power units and PDU J58890CF-1 and shows which power unit each circuit breaker controls (Figure 11-21 also shows other Environment maintenance-related items that can be ignored for this section on Carrier Port Power Unit). Figure 11-22 shows the position of the circuit breakers on the PDU J58890CF-1. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. Refer to Chapter 2 in *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test,* 555-230-104. The CARR-POW (Carrier Port Power Unit) MO represents the pair of power units for each carrier in a multicarrier cabinet system. If a problem is reported by hardware for a power unit on a port carrier, the system can recycle the pair of power units in a port carrier; however, if the problem is reported on a control carrier, the system cannot recycle the pair of power units in a control carrier. In a standard multicarrier cabinet (PPN or EPN), carrier A is the control carrier, and carriers B, C, D, and E are the port carriers. In a High or Critical Reliability system multicarrier cabinet (PPN or EPN), carriers A and B are the control carriers, and carriers C, D, and E are the port carriers. However, carrier B in the EPN can be recycled only if the Active Expansion Interface Link and Active Tone-Clock circuit pack are in the A carrier.

The carrier port power unit has one LED: the yellow LED on means operating as normal and the LED off means no external power is being supplied or that the power unit has a fault.

Loss of the 645B Carrier Port Power Unit in the active control carrier (the A carrier for a standard system and either the A or B carrier for a High or Critical Reliability system) causes loss of the administration terminal. In a High or Critical Reliability system, the Active SPE should switch to the Standby SPE if there is a CARR-POW alarm.

Recycling a carrier turns off the pair of carrier power units and turns them back on two seconds later.

WARNING:

Recycling carriers disrupts service for all circuit packs on the carrier.

Generic 1 can also support neon message waiting lamps on analog telephones. If this is required, then the carrier(s) that contains the TN769 Analog Neon circuit packs must also be supplied with 165 volt DC power to power the neon lights. The 165 volt DC power can only be supplied by a TN752 or a TN755B power unit circuit pack. The following table lists the power units and power-related circuit packs that can be used in a DC-powered system and indicates the voltages they can supply. Figure 11-23 and Figure 11-24 show a schematic of the 644A and 645B power supplies, respectively. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. Refer to Chapter 2 in *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test,* 555-230-104.

Power Supply	+5V	-48V	-5V	165V	Cabinet Position
644A	yes	no	no	no	Left Side
645B	no	yes	yes	no	Right Side
TN736	no	no	yes	no	-
TN752	no	no	yes	yes	-
TN755B	no	no	no	yes	-

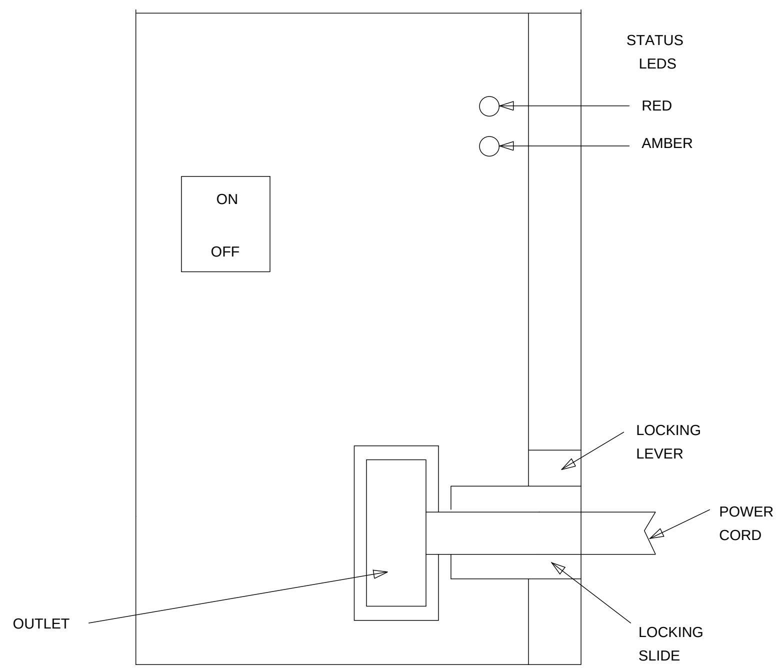

Figure 11-25. 645B Port Carrier Power Unit for DC-Powered Systems

Port Carrier Power Unit Replacement Procedures

The procedures for replacing a 644A or 645B carrier DC power unit are given below.

If the port carrier power unit to be replaced is in a control carrier of a PPN system, refer to the "Removing Power" and "Restoring Power" sections in Chapter 5, "Routine Maintenance Procedures" before replacing the port carrier power unit. To replace the port carrier power unit, follow the procedure below:

1. If this is a 645B power unit, set the power switch to OFF.
2. Unplug the power cord.
3. Move the locking slide on the power unit to the extreme left position, and unlatch the locking lever.
4. Remove the power unit from the carrier.

5. Move the locking slide on the replacement power unit to the extreme left position and open the locking lever.
6. Insert the power unit into the carrier until some resistance is felt.
7. Lift the locking lever upward until it latches.
8. Move the locking lever slide on the power unit to the extreme right position.
9. Connect the power cord.
10. If this is a 645B power unit, set the power switch to ON.

Hardware Error Log Entries and Test to Clear Values

Carrier Port Power Unit Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment P sh r 1
1(a)(b)	0 or 1	Power Unit Query Test (#127)	MAJOR	ON	test environment P r 2

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. Where P is an appropriate port network number taken for the Port field of the Error Log.

b. Run the Power Unit Query Test (#127) first using the **test environment P r 2** command. Then, if a carrier must be recycled to clear the CARR-POW alarm, use the **recycle carrier PC** command to run the Power Unit Recycle Test (#126). The Power Unit Recycle Test (#126) is not included in either the long or Short Test Sequences.

WARNING:
The Power Unit Recycle Test (#126) is destructive. For more information, refer to the description of this test.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
Power Unit Query Test (carrier E) (#127)	X	X	ND
Power Unit Query Test (carrier D) (#127)	X	X	ND
Power Unit Query Test (carrier A) (#127)	X	X	ND
Power Unit Query Test (carrier B) (#127)	X	X	ND
Power Unit Query Test (carrier C) (#127)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Temperature Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.

b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.

c. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.

e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:
This test only shows up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Power Unit Recycle Test (#126)

This test is destructive.

This test is destructive because it requires all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating or terminating on circuit packs in this carrier to be dropped. The pair of port carrier power units in the specified carrier is recycled. Both port carrier power units in the carrier are turned off for two seconds and then back on. After the port carrier power units have been turned back on, the test queries the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of the pair of port carrier power units in the specified carrier. If both port carrier power units are on and functioning, then the test passes. If both port carrier power units are not on and functioning, the test fails, and BOTH port carrier power units are turned off.

Table 11-63. TEST #126 Power Unit Recycle Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1129	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Tone-Clock for the EPN is in carrier 2B. 1. Issue the **set tone-clock 2A** command. 2. Rerun the test.
1130	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Expansion Interface Link for the EPN is in carrier 2B. 1. Issue the **set expansion-link A01** command. 2. Rerun the test.
2000	ABORT	Response to the test request was not received within the allowable time period.

Continued on next page

Table 11-63. TEST #126 Power Unit Recycle Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1 (Carrier E) 2 (Carrier D) 4 (Carrier A) 8 (Carrier B) 16 (Carrier C)	FAIL	There is a problem with one or both port carrier power units on the recycled carrier. 1. Since the Power Unit Recycle Test failed, both port carrier power supplies in the recycled carrier should have been powered off by the system software. Both port carrier power units should be showing a red status LED, instead of a green one. Since the Power Unit Query Test is a subset of the Power Unit Recycle Test, the Power Unit Query Test (#127) should also fail. Run the Power Unit Query Test by using the **test environment P** command where P is the appropriate port network number. 2. If the test fails, follow the repair procedures described for Test #127. If the problem persists, follow normal escalation procedures.
	PASS	Both port carrier power units in the recycled carrier were found to be healthy by the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system after the port carrier power units were powered-down and powered up again. If the status LEDs on both port carrier power units are not showing green, then the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the port carrier power units. Look for and resolve any alarms on these MOs.

Power Unit Query Test (#127)

This test queries the Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of the pair of port carrier power units in the specified carrier. If both port carrier units are on and functioning, the test passes. If both are not on and functioning, the test fails.

Table 11-64. TEST #127 Power Unit Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-64. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	There is a problem with one or both port carrier power units on the tested carrier. 1. For each port carrier power unit that has all status LEDs OFF, check the DC input to the port carrier power unit at the port carrier power unit outlet (see Figures 11-19 through 11-22). If there is no DC, then check the appropriate circuit breakers for the affected port carrier power unit. If the circuit breaker has tripped (that is, it is in the down position), reset the circuit breaker. If the circuit breaker trips again or DC is not present at the port carrier power unit outlet, there is probably a power wiring problem in the cabinet. Follow normal escalation procedures. 2. At this point, DC should be present at the port carrier power supply outlet. If the carrier being tested is the 1A or 2A carrier, or the 1B carrier in a High or Critical Reliability system, refer to"Troubleshooting Control Carrier Power Units"" in Chapter 5, "Routine Maintenance Procedures". Otherwise, use the **recycle carrier PC** command (where PC is the appropriate port network and carrier) in an attempt to bring back the power units for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one port carrier power unit, or both, in the tested carrier is defective. If only one port carrier power unit is defective, the status LEDs on the healthy port carrier power unit light green for a moment. When the recycle test determines that both port carrier power units are defective, the software turns off power to both the good and defective port carrier power units. This causes the status LED(s) on the good port carrier power unit to light red.

Continued on next page

Table 11-64. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	3. Unplug both port carrier power units, and wait about one-minute to allow the port carrier power units to cool down. Plug in the port carrier power units. If either port carrier power unit is operating properly (that is, the status LEDs show green), then replace the defective port carrier power unit(s). See "Port Carrier Power Unit Replacement Procedures" in this section. 4. If the replaced port carrier power unit(s) still does (do) not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier could be causing an electrical load which is preventing the port carrier power unit from operating properly. Unseat all the circuit packs in the carrier, and reissue the **recycle carrier** command. a. If the recycle passes, then the port carrier power units are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, replace the defective circuit pack. If the status LED still shows red, remove the Amphenol connector on the back of the slot containing this circuit pack and reissue the **recycle carrier** command. If the status LED shows green, the problem is with one of the telephones or the wiring to one of the telephones on this slot. If the status LED still shows red, escalate the problem. b. If either port carrier power unit still shows a red status LED, check for bent pins and cable placement in the affected carrier. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that **are not** detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If no other problems can be found, escalate the problem.

Continued on next page

Table 11-64. TEST #127 Power Unit Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Both port carrier power units in the tested carrier were found to be healthy by the Maintenance/Tape Processor in a PPN for a High or Critical Reliability system, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system. If the status LEDs on both port carrier power units are not showing green, the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the port carrier power units. Look for and resolve any alarms on these MOs.

CLSFY-BD (Call Classifier Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CLSFY-BD	MIN	test board PCSS sh	Call Classifier Circuit Pack
CLSFY-BD	WRN	test board PCSS sh	Call Classifier Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also Call Classifier Port (CLSFY-PT) Maintenance documentation for related port information.

CLSFY-PT (Call Classifier Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CLSFY-PT(a)	MAJOR	test port PCSSpp sh	Call Classifier Port Maintenance
CLSFY-PT	MINOR	test port PCSSpp sh	Call Classifier Port Maintenance
CLSFY-PT	WARNING	release port PCSSpp	Call Classifier Port Maintenance

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (e.g., A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (e.g., 01, 02, ..., etc.); and pp is the 2-digit port number (e.g.., 01).

The TN744 Call Classifier (CLSFY-BD) circuit pack is a service circuit pack that enables usage of the Outbound Call Management (OCM) and the Inbound Call Management (ICM) features. On a G3iV2-386 system, the TN744 also enables usage of R2-MFC signaling for incoming and outgoing feature operation. There are eight ports (CLSFY-PTs) on the Call Classifier circuit pack. Each port can handle call classification, touch-tone reception, or, for G3iV2-386 systems, MFC tone generation and detection or touch-tone reception.

The CLSFY-PT maintenance feature defines a set of tests to ensure that the Call Classifier circuit pack ports are capable of detecting tones for call classification, and detecting and generating necessary tones for correct MFC feature operation.

Hardware Error Log Entries and Test to Clear Values

Call Classifier Port (CLSFY-PT) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1	any	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 2
18		Port has been busied out by system technician	WARNING	OFF	release port PCSSpp
257 (b)	17666	Test (#43)	MAJOR/ MINOR(a)	ON	test port PCSSpp r 3
513 (c)	any	Tone Detection Verification Test (#42)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3

Notes:

a. There are two possible alarm levels for this error type: major alarm and minor alarm. A major alarm is raised if the total number of call classifier ports currently in-service is less than or equal to 1/2 of the administered threshold number. Otherwise, a minor alarm is raised. In either case, run the short test sequence against the port and follow the error code procedures for the individual tests.

   The threshold number of call classifier ports for service is administered using the **change system-parameters maintenance** command. For details, refer to Chapter 5, 'Routine Maintenance Procedures".

b. The call classifier port lost its translation. Testing the call classifier port is sufficient to reload its translation. If testing the call classifier port does not clear the error, then the call classifier circuit pack containing the defective call classifier port should be replaced.

c. This error indicates the call classifier port is having problems detecting system tones (DTMF, etc.) or detecting and generating necessary R2-MFC tones. This error should accompany some percentage of failed calls. If this error type is persistently logged, then the call classifier circuit pack containing the defective call classifier port should be replaced.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detection Audit/Update Test (#43)	X	X	ND

1 D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks out each port in both the touch-tone receiver mode and in the R2-MFC tone detection/generation mode. During the first half of the test, the touch-tone receiver mode is tested. In the second half of the test, each port is put into the R2-MFC mode. During this portion of the test, each port's ability to accurately detect and generate all forward and backward MFC tones is verified.

Table 11-65. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test OR there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the tones.
1001	ABORT	The system was unable to put the Call Classifier port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This situation could occur when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm [1|2]** command. Refer to the TDM-BUS (TDM Bus) Maintenance documentation for details. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-65. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a Tone-Clock circuit pack for the test connection. This situation could occur when the system is heavily loaded or if a Tone-Clock circuit pack is not present in the port network when this test is executed. 1. Verify the existence of a Tone-Clock circuit pack in the same port network. 2. If a Tone-Clock circuit pack is missing, install one in the same port network. 3. Allow approximately one minute for the Tone-Clock circuit pack maintenance to run on the newly inserted Tone-Clock circuit pack. 4. Retry the command at one minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-65. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2006	ABORT	This abort code indicates that the active Tone-Clock circuit pack might not be functioning properly. If there is more than one Tone Detector circuit pack in the system, then the problem can be either with the Tone-Clock circuit pack or the Tone Detector circuit pack. This could also be caused by the companding mode administered for the system not matching that of the Tone Detector circuit pack [G3iV2-386]. 1. [G3iV2-386] Make sure that the companding mode of the system matches that of the Tone Detector (TN748 for Mu-law systems and TN420 for A-law systems). 2. Test the active Tone-Clock circuit pack in the port network. This test is being executed via the **test tone-clock qualifier** system technician command. ("qualifier" is the carrier of the active Tone-Clock circuit pack to be tested. Valid qualifiers are: a, b, 1a, 1b, 2a, and 2b.) Refer to the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-65. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1-3	FAIL	DTMF digits were not detected correctly. This may or may not impact reception of R2-MFC calls. 1. Run the short test sequence via the **test port PCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the Call Classifier circuit pack containing the defective CLSFY-PT (Call Classifier Port).
101-122	FAIL	Forward or Backward MFC signals were not correctly generated or detected. This impacts reception of incoming MFC calls. 1. Run the short test sequence via the **test port PCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the Call Classifier circuit pack containing the defective CLSFY-PT (Call Classifier Port).
	PASS	Tone Detection Verification is successful. The Call Classifier Port (CLSFY-PT) is able to detect/generate all necessary tones.

Tone Detector Audit/Update Test (#43)

A sanity audit is performed on the CLSFY-PT (Call Classifier Port).

Table 11-66. Tone Detector Audit/Update Test (#43)

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait one-minute, and repeat the command a maximum of five times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Hardware audit failed. 1. Run the short test sequence via the **test port PCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the CLSFY-BD (Call Classifier circuit pack) containing the defective CLSFY-PT (Call Classifier Port).
	PASS	The (CLSFY-PT) Call Classifier Port has passed the sanity inquiry.

CO-BD (Central Office Trunk Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CO-BD	MIN	test board PCSS sh	Central Office Trunk Circuit Pack
CO-BD	WRN	test board PCSS sh	Central Office Trunk Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also CO-TRK (CO Trunk) Maintenance documentation for related trunk information.

CO-DS1 (DS1 CO Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
CO-DS1	MAJOR[1]	test trunk <grp/mbr> l	DS1CO Trunk
CO-DS1	MINOR	test trunk <grp/mbr> l	DS1CO Trunk
CO-DS1	WARNING	test trunk <grp/mbr>	DS1CO Trunk

1 A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

A DS1CO (central office) trunk provides a communications channel between the system and a central office switch through either a 1.544 Mbps or a 2.048 Mbps [G3iV2-386] DS1 link. A 24 channel DS1 link consists of 24 digital DS1CO trunks. A 32 channel DS1 link [G3iV2-386] consists of 30 digital DS1CO trunks. A DS1CO trunk can be used for both voice and data communication.

The DS1CO Trunk Maintenance provides a strategy in the system to maintain a CO trunk via a port on the DS1 Interface circuit pack. The TN767 and TN464 [G3iV2-386] DS1 Interface circuit packs support the low level CO trunk signaling interfaces, ground-start and loop-start. This strategy covers the in-line errors log, initialization tests, periodic tests, system technician-demanded tests, and alarm resolution and escalation.

Three trunk service states are specified in the DS1CO trunk maintenance. They are: *out-of-service* in which the trunk is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the trunk is in an activated state and can be used for both incoming and outgoing calls; *disconnect* (ready-for-service) in which the trunk is in an activated state but can only be used for an incoming call. If the DS1 Interface circuit pack is out-of-service, then all trunks on the DS1 Interface circuit pack are also in the out-of-service state, and a Warning alarm is raised for each trunk.

Hardware Error Log Entries and Test to Clear Values

DS1CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test trunk <grp>/<mbr>
1 (a)	57408				
1 (a)	57487				
15 (b)	Any	Port Audit and Update Test (#36)			
18 (c)	0	busyout trunk <grp>/<mbr>	WARNING	OFF	release trunk <grp>/<mbr>
130 (d)		None	WARNING	ON	test trunk <grp>/<mbr>
257 (e)	57392	DS1 CO Dial Tone Seizure Test (#314)	MIN/MAJ[2]	OFF	
513 (f)	57393	DS1 CO Dial Tone Seizure Test (#314)	MIN/MAJ[2]	OFF	
769 (g)	57484				
1025		DS1CO Dial Tone Seizure Test (#314)	WARNING	OFF	test trunk <grp>/<mbr>
1281		Conference Circuit Test (#7)	MAJ/MIN/ WRN[3]	ON	test trunk <grp>/<mbr> r 4
1537		NPE Crosstalk Test (#6)	MAJ/MIN/ WRN[3]	ON	test trunk <grp>/<mbr> r 3
1793 (h)				ON	test board PCSS l
2562(i))	16665				
2817(j)	52992				
3840 (k)		Port Audit and Update Test (#36)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

3 Minor alarms on this maintenance object (MO) may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this group are alarmed.

Notes:

a. Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.

   Aux Data 57487—PBX could not get "loop close" signal (TN767).

   The DS1 Interface circuit pack detected a hardware fault. These errors cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 also shows up). In this case, the trunk may be put in ready-for-service state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow its outlined procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—System Technician has busied-out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to "Facility Test Calls" section in Chapter 5, "Routine Maintenance Procedures".

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type: 57392—no external release on PBX disconnect [E030]. Escalate the problem.

f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type: 57393—belated external release on PBX disconnect [E031]. Escalate the problem.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring [E08C]. Escalate the error.

h. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for DS1-BD errors in the Hardware Error Log. Refer to the DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details.

i. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

j. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.

k. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1CO Trunk Seizure Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) resides on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-67. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-67. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to the TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-67. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Continued on next page

Table 11-67. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. **NOTE:** Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivityclears.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 11-68. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted. System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-68. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The test was aborted. The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.

Continued on next page

Table 11-68. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n.' To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 11-68. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	1. Enter the 'list configuration board UUCSS' command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later.The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see Note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSU's) have the correct administration. 6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance Documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance Documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.

Table 11-68. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. **NOTE:** Hyperactivity causes some special problems with the sequence suggested above.If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 Interface circuit pack and in the switch software.

Table 11-69. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. Issue the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a descriptionof this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.

Continued on next page

Table 11-69. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed due to internal system error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but returns to PASS. To verify that the trunk is in-service: 1. Enter **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.

Continued on next page

Table 11-69. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

DS1 CO Dial Tone Seizure Test (#314)

DS1CO Dial Tone Seizure Test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a "seizure" message to the DS1 Interface circuit pack and expects an "active" reply from the DS1 interface circuit pack. If the "active" message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a "reorder" message back to maintenance software, then the test fails.

The test **CANNOT** be run on a trunk if one of the following cases is true:

a. The trunk direction is administered as an incoming only trunk.

b. The trunk has been seized by a normal trunk call.

c. The trunk is administered with maintenance test disabled.

Table 11-70. TEST #314 DS1CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-70. TEST #314 DS1CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The test was aborted because the port was seized by a user for a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Verify the following fields on the trunk group administration screen: Is trunk direction incoming only? Is trunk the port 24 of the DS1 Interface circuit pack while common control channel signaling is specified? Is trunk group type the automatic CO (for example, FX)? 2. If the trunk has been administered using the above information, then this test should abort.
1018	ABORT	Thest is disabled via tranlsation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the **change trunk-group x** command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'. 2. Repeat the test.

Continued on next page

Table 11-70. TEST #314 DS1CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for DS1-BD errors in the Hardware Error Log. If present, refer to DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1040	ABORT	The test was aborted because this port may be an access endpoint. 1. Verify that this port is an access endpoint by issuing the **display port** command. 2. If the port has been administered as an access endpoint, then this is a normal abort.
2000	ABORT	Response to the test request was not received within the allowable time period.
2012	ABORT	The test was aborted due to an internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-70. TEST #314 DS1CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The trunk cannot be seized for an outgoing call. This could cause in-line failures to be reported against the trunk (no answer would report error type 257 with auxiliary data 57487 in the error log). 1. Verify that the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for DS1-BD/UDS1-BD errors in Hardware Error Log. If present, refer to the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 3. Retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
2000	FAIL	Response to the seizure message was not received within the allowable time period. 1. Enter the **list configuration board PCSS** command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 314 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the 'Trunk Type' field on the 'Trunk Administration' screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) maintenance documentation. 4. Retry the test at 1-minute intervals for a maximum of 5 times. 5. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-70. TEST #314 DS1CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2053	FAIL	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for these error types in the hardware error log and then follow the procedures given in the maintenance documentation that is appropriate for the error type that was found.
	PASS	The trunk can be seized for an outgoing call.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see Note below). 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. **NOTE:** Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the **list config** command but the 'Vintage' field reports that there is no board (when there really is a board), then the **busyout board** and the **release busy board** commands will not work (even though the **reset board** command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

CO-TRK (CO Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CO-TRK	MAJOR[2]	test port PCSSpp l	CO Trunk
CO-TRK	MINOR	test port PCSSpp l	CO Trunk
CO-TRK	WARNING	test port PCSSpp l	CO Trunk

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); c is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.).

2 A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

NOTE:
If ATMS testing is enabled, check the error log for ATMS Errors #3840 and #3841. If the error log indicates that measurements exceeded acceptable thresholds, and if no other trouble is found with the **test trunk** command, run the ATMS test call with the **test analog-testcall port UUCCSSpp full** command.

Central Office (CO) trunks are 2-wire analog lines to the CO which support both incoming and outgoing calls. A CO trunk circuit pack provides an interface between the 2-wire analog line from the CO and the system’s (4-wire) Time Division Multiplex (TDM) Bus. The CO Trunk circuit packs include:

- TN747B (United States), 8 port loop start or ground start CO, foreign exchange (FX), or Wide Area Telecommunications (WATS) trunks.
- TN438B (Australia), 8 port loop start.
- TN447 (United Kingdom), 8 port ground start.
- TN465 (multiple countries), 8 port loop start.
- TN2138 (Italy), 8 port loop start.
- TN2147 (multiple countries), 8 port loop start and United Kingdom Earth Calling or Loop Calling Guarded Clearing.

LOOP START AND UK LOOP CALLING GUARDED CLEARING OPERATION

Idle State - Tip _ ground, Ring = CO Battery

A. Outgoing Call

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop
   a. CO Response: DC loop current + Dial tone
2. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
   a. CO Response: CO goes to idle state (see Note)

B. Incoming Call

1. CO Applies Ringing Voltage
   a. PBX Response: Detect ringing current
2. PBX Off-Hook (Answer Message): Close loop
   a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
   a. CO Response: CO goes to idle state (see Note)

NOTE:
Except for the Netherlands Loop Start and UK Loop Calling Guarded Clearing trunks, CO does not normally provide an On-Hook (Disconnect) signal.

GROUND START AND UK EARTH CALLING OPERATION

Idle state - Tip _ open, Ring = CO Battery

A. Outgoing Call

1. PBX Off-Hook(Seize Message): Places ground on Ring
   a. CO Response: Places ground on Tip
   b. PBX Response: close the loop
   c. CO Response: provide loop current
   d. PBX response: dial out digits
2. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current
   a. CO Response: Open circuit on Tip
3. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current.
   a. PBX Response: Open Tip-Ring loop

B. Incoming Call

1. CO Off-Hook (Seizure): CO applies ground on Tip, CO applies ringing voltage
   a. PBX Response: Detect ringing, ring destination
2. PBX Off-Hook (Answer Message): Close loop
   a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current
   a. CO Response: Open circuit on Tip
4. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

Hardware Error Log Entries and Test to Clear Values

Table 11-71. CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	57347	None			
15 (b)	any	Port Audit Update Test (#36)			
18	0	busyout trunk <grp>/<mbr>	WARNING	OFF	release trunk <grp>/<mbr>

Continued on next page

Table 11-71. CO Trunk Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3073 (d)	57376	None			
3329 (d)	57408	None			
3329 (d)	57484	Dial Tone Test (#0)	MAJ/MIN/ WRN[3]	OFF	test port PCSS l r 1
3585 (d)	57424	None			
3840 (f)	8000	Analog Transmission (#844-848)		OFF	
3841 (f)		Analog Transmission (#844-848)	MINOR	OFF	test analog testcall UUCSS pp r 2

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

3 Minor alarms on this MO may be downgraded to warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

a. These are in-line errors that have no specific test associated with them. Refer to Table 11-72 for an explanation and appropriate action.

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. Aux data 57345 -- Single polarity ringing current
Aux data 57376 -- No loop current on incoming call
Aux data 57408 -- No tip ground detected on outgoing call
Aux data 57424 -- No loop current on outgoing call
Aux data 57484 -- No dial tone on outgoing call

These errors cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 also shows up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its outlined procedures.

If error count associated with this error type is very high (that is, 255) and if Alarm Status on the Hardware Error Report is "n" (not alarmed), then the existence of this error type indicates that, despite the fact that many in-line error messages have been received, all Call Seizure Tests have passed. Problems at the CO may cause this condition rather than problems with the PBX.

e. These errors are logged for all versions of the CO-TRK/CO-BD. However, no MINOR alarms are generated for Central Office Trunks [TN747B] with vintages V8 or greater. Any failures received by this test are still logged as Error type 1025/1281 as additional information for the system technician person.

   The system technician person should check for the use of MFT/Range extenders. If there are extenders present, and there are no other complaints or maintenance errors against this trunk, then there is a good chance that Test #3 failed due to excessive loop current and may be ignored.

f. Test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements that were outside the acceptable limits. Use the **list testcall detail** command to examine specific transmission parameters that are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, the limits administered on the "change trunk" screen should be changed.

Table 11-72. CO Trunk Errors with NO Tests

Error Type	Aux Data	Description and System Action	System Technician Action
1	57347	Port error. Ringing without ground. This error is detected on an incoming call on a ground-start CO trunk. The CO trunk circuit pack has not detected a Tip ground before ringing current is detected. This may indicate that the ground detector is not working. However, the call is accepted.	See Note 1 at end of table.
257	50176	Battery reversal detected. This is usually caused by the CO (often seen with step-by-step and cross-bar offices in connection with outgoing calls). This is detected if the direction of the loop current changes from normal to reverse for at least 40 msec. Could occur if the trunk was just installed and for some reason the Tip and Ring wires were reversed at the PBX. If battery reversals occur during dialing, wrong numbers may result. The CO should be asked to remove the battery reversal option.	Refer problem to CO.
513	57364	Ground detector stuck active. After several occurrences, an on-board minor alarm is generated.	Run short test. If test aborts with Error Code 1000, disconnect Tip and Ring and repeat short test. If test still aborts, replace circuit pack. If test passes, refer problem to CO. If any other error code is received, pursue that problem.
769	57392	CO not releasing after call is dropped from PBX end (off-board alarm after several occurrences), or the loop is not open after a disconnect (on-board alarm after several occurrences).	For off-board alarm, refer problem to CO. For on-board alarm, the circuit pack has an on-board problem (for example, stuck relay) and should be replaced.

Continued on next page

Table 11-72. CO Trunk Errors with NO Tests — *Continued*

Error Type	Aux Data	Description and System Action	System Technician Action
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) Another cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test also fails. The last cause could be that certain types of noise are present on the CO line during the silent period of ringing.	Check for other errors first and then see Note 4 at end of table.
2817	57360	Ground but no ringing. This error occurs on an incoming call on a ground-start trunk. If ringing is not detected within 5 seconds of the Tip being grounded, the call is still accepted. If the CO is of the No. 5ESS. switch type, ringing delays of more than 5 seconds during heavy traffic are fairly common.	Check for other errors.
2817	57393	On the TN465, the loop is opening too slowly after a disconnect. This error indicates an on-board problem, although the trunk may be functional. On the TN2138, CO released the trunk at least 4 minutes after the PBX dropped the call. This error code is log-only and causes no other testing to occur. No alarm is generated.	Check for other errors.

Continued on next page

Table 11-72. CO Trunk Errors with NO Tests — *Continued*

Error Type	Aux Data	Description and System Action	System Technician Action
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail.	Check for other errors.
3329	57408	Trunk error. No Tip ground detected on outgoing call. This error occurs when an attempt is made to seize a ground-start CO trunk for an outgoing call and Tip ground is not detected or the caller hangs up before Tip ground is detected.	See Notes 1 and 2 at end of table.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected.	See Note 3 at end of table.

Notes:

1. At the administration terminal, busyout the affected port, and run a Long Test Sequence. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be escalated or referred to the CO.
2. At the administration terminal, busyout the affected port, and run a Long Test Sequence. If Dial Tone Test #0 passes, ignore this error. Release the port.
3. At the administration terminal, busyout the affected port, and run a Long Test Sequence. If CO Demand Diagnostic Test #3 passes and this error keeps occurring, refer problems to CO. Release the port.
4. If the error count associated with this error type is very high (that is, 255) and all tests pass, then either the reverse current detector is defective or the CO line is noisy. If the CO line is suspected, Tip and Ring observations should be made. If the line is determined to be noisy, the problem should be referred to the CO. If the reverse current detector is defective, ignore this error.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
CO Demand Diagnostic Test (#3) (a)	X	X	ND
Loop Around and Conference Test (#33)		X	ND
Audit Update Test (#36) Analog Transmission Test (#844-848) (b)	X (c)	X (c)	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. A demand test of Diagnostic Test (#3) always returns a PASS indication for CO-TRK/CO-BD [TN747B] version 8 or greater. However, any errors produced as a result of this test are logged and produce no alarms.

   If errors logged by Test #3 are the only complaints against this trunk, then the system technician person should check if MFT/Range Extenders are being used. If extenders are present, then there is a good chance that there is excessive loop current, which causes Test #3 to log errors.

   However, all else being normal, these errors should not affect the customer.

b. Refer to TIE-TRK (Tie Trunk) Maintenance documentation for a description of this test.

c. ATMS test are not part of either sequence. They are run either on demand with the **test analog-testcall** command or via the ATMS schedule.

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 11-73. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the command **display port PCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test were not available. This could be due to a failure to seize the port. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-73. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Trunk has been administered as incoming-only; dial tone can only be obtained on outgoing trunks. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n". To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-73. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Test all administered outgoing ports on the board. Failure of 1 indicates a problem toward the CO. 2. If all fail, see note below. 3. Check for errors on the TONE-BD or TONE-PT. Clear any errors found, and repeat the test. 4. If the error has still not cleared, refer the problem to the CO. 5. If no service problems exist on the port, continue to use the port until the circuit pack can be replaced (as a last resort). Perform a trunk test call to see if the trunk is operable. **NOTE:** If the dial tone test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation.

Continued on next page

Table 11-73. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. If the CO Demand Diagnostic Test (#3) also failed, display the Hardware Error Log. If the CO Demand Diagnostic Test failed because it could not detect ground (indicated by Error Type 1281 in the Hardware Error Log) AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 3. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test. 4. If replacing circuit pack does not clear failure, escalate the problem.
1009	PASS	Detected tone was not pure dial tone. [G1, G3iV1.1-286] No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Continued on next page

Table 11-73. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

CO Demand Diagnostic Test (#3)

For ground start trunks only, port circuit pack relays are operated and checks are made to see if the port can detect and apply ground on the Tip lead. This test also verifies that there is no external ground on the Ring lead. In the absence of other failures, the circuit pack should be replaced only if this test fails with the CO line disconnected.

For the TN2147 World Class Central Office circuit pack, this test also checks the on-board programmable transmission circuitry that allows the circuit pack to support the transmission characteristics of several countries.

Table 11-74. TEST #3 CO Demand Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-74. TEST #3 CO Demand Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Test inapplicable to present configuration. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n". To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-74. TEST #3 CO Demand Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Failure to detect ground or faulty ground detected on Ring lead. Display the hardware errors for this trunk, to determine if the fault was on- or-off board. Look for Error Type 1025 or 1281 (if both appear in the Hardware Error Log, pick the most recent error). Error Type 1025 indicates a faulty ground detected on Ring lead (an off-board fault) and Error Type 1281 indicates failure to detect (internally generated) ground (an on-board fault). Faulty ground detected on Ring lead (Error Type 1025): **NOTE:** On TN747B vintage 8 and greater circuit packs, an incoming seizure during this test may cause it to fail with an off-board fault. 1. Repeat test. If test passes, ignore the original failure. If test aborts, follow the recommended procedures. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, refer problem to CO. Failure to detect ground (Error Type 1281): 1. Run the long test sequence. If the CO Demand Diagnostic Test fails, the Dial Tone Test (#0) fails with Error Code 2002, AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, the CO may be drawing too much current. Refer problem to CO.
57481	FAIL	On-board test of programmable transmission circuitry failed. 1. Replace the circuit pack.

Continued on next page

Table 11-74. TEST #3 CO Demand Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	This test verifies that the port is able to apply ground for outgoing calls and detect ground for incoming calls; however, it does not provide information on whether a CO line is actually connected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 11-75. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. Check the CO wiring, check for excessive loop current, and check the trunk translations. (If the trunk is translated incorrectly, this test will abort.) 2. If the port status is idle, busyout and release the trunk, and then retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test still aborts, replace the circuit pack. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-75. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-75. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop around and conference capabilities of a CO port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. Each tone is transmitted separately through the loop and checked.

Table 11-76. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
7	ABORT	Conference Circuit Test aborted.
129	ABORT	The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
131		The 1004-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
133		The 2804-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If test continues to abort, escalate the problem.

Continued on next page

Table 11-76. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 769 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized force. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-76. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test was disabled via administration. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the 'change trunk-group x' command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-76. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7,	FAIL	The conference capabilities of the port failed (Error Code 7).
129,		The reflective 404-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 129).
131, or		The reflective 1004-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 131).
133		The reflective 2804-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 133).
		FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see notes on the next page).
		1. To make sure the problem is on-board, disconnect the port from the CO and retry the test. Coordinate this with the CO, or do it after busy hours; otherwise, the CO may put the connection out of service.
		2. If the retry fails, replace the circuit pack.
		3. If the retry passes and no troubles have been reported, disable the test. If the retry passes and troubles have been reported, refer the problem to the CO.
		More information continues on the next page.

Continued on next page

Table 11-76. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7, 129, 131, or 133 *(cont'd.)*	FAIL *(cont'd.)*	**NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above.
	PASS	CO Trunk Loop Around and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 11-77. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	The port has been placed out of service, perhaps by craft busyout. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test were not available. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal system error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.

Continued on next page

Table 11-77. TEST #36 Port Audit Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Transmission Test (#844-848)

This test is non-destructive.

NOTE:
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of ''marginal'' or ''unacceptable'' thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 11-78. TEST #844-848 Transmission Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use **display port PCSSpp** to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the service state indicates that the port is in use, then the port unavailable for this test. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description all possible states). You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-78. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM bus errors. Refer to TDM Bus Maintenance to diagnose any active TDM bus errors. 1. If system has no TDM bus errors and is not handling heavy traffic, repeat test at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use status trunk to determine when the port is available for testing. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	Trunk has been administered as incoming-only; transmission tests can only be run on outgoing trunks.
1115	ABORT	The near end test line on the TN771 circuit pack could not be allocated. 1. Verify that the TN771 circuit pack is in service and that port 1 is administered and in service with the **status port** command. 2. retry the command at 1 minute intervals for a maximum of 5 retries. 3. If the test continues to abort escalate the problem.
1900	ABORT	The test completion message was not received from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-78. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1901	ABORT	This error occurs when the TN771 circuit pack uplinks a message that is not the proper response for this test. The anticipated uplink messages are seize, ring or answer. 1. Verify that the Trunk is administered properly. 2. If the test continues to abort, escalate the problem.
1905	ABORT	Intercept tone detected from far end. 1. Get the test line data from theand verify it with the far end. Dial the test number manually to see if the TTL is reached. If it is not, then either the number is wrong, or the far end is administered incorrectly. 2. If the test continues to abort escalate the problem.
1906	ABORT	Reorder tone detected from far end. 1. See actions for error code 1905.
1907	ABORT	Other unexpected tone detected from far end. 1. See actions for error code 1905.
1913	ABORT	Audible Ring detected from far end. 1. See actions for error code 1905.
1914	ABORT	Unidentified interrupted tone detected from far end. 1. See actions for error code 1905
1915	ABORT	Busy tone detected from far end. 1. Since the test line at the far end was busy. Try the test again. 2. If the test continues to abort, the problem is with the far end system.
1918	ABORT	Test progress tone not removed from far end (type 105 test line only). 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 11-78. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1919	ABORT	Unexpected far end release 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1920	ABORT	No response from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1921	ABORT	No data returned from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1922	ABORT	Steady, unidentifiable tone from far end 1. See actions for error code 1905.
1923	ABORT	Broadband energy detected from far end (such as voice or announcement). 1. See actions for error code 1905.
1924	ABORT	No test tone from far end 1. See actions for error code 1905.
1938	ABORT	Near-end self test failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1939	ABORT	Loss self check at 0dBm at 1004 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1940	ABORT	Far end noise self check failed. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 11-78. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1941	ABORT	High frequency singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1942	ABORT	Echo return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1943	ABORT	Singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1944	ABORT	Loss self check at -16 dBm at 1004 Hz failed. 1. Test the TN771 circuit packs 2. If the test continues to abort escalate the problem.
1945	ABORT	Loss self check at -16 dBm at 404 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1946	ABORT	Loss self check at -16 dBm at 2804 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1947	ABORT	Noise with tone self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
2000	ABORT	The test timed out while waiting for a response from the TN771 circuit pack. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-78. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	An internal software error occurred. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2053	ABORT	The test call could not be established, but no information on why is available. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2056	ABORT	An error occurred while trying to obtain results from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
	FAIL	Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.
8000	FAIL	Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form.

CONFIG (System Configuration)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
CONFIG	none	none	System Configuration

The System Configuration maintenance object (MO) oversees logical insertion and removal of circuit packs in the system. When Switch Control detects that a circuit pack is present in a port slot, it informs System Configuration and System Configuration queries the circuit pack to determine the type and vintage of the circuit pack. Similarly, when Switch Control detects that a circuit pack has been removed from a port slot, it informs System Configuration.

There are no alarms or tests for System Configuration, but three types of errors are logged to the Hardware Error Log (see below).

Hardware Error Log Entries and Test to Clear Values

System Configuration Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	none
2-117(a)	0-2	none			
257(b)		none			
1002-1117(c)	0-2	none			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates that a Port circuit pack in the system did not respond to a circuit pack type inquiry. Follow the procedures outlined in (b) to determine if there is an error.

b. This error indicates that less than 25% of Trunk Group is available.

c. This error indicates that a Port circuit pack in the system did not respond to a vintage inquiry.

As a result of either of these errors, a Port circuit pack may be physically inserted in a Port slot, but the system may not recognize its existence. The Error Type and Aux Data fields specify the location of the port circuit pack that caused the error as indicated in Table 11-79. If the Error Type field is greater than 1000, subtract 1000 from the Error Type field before consulting the table.

If more than one CONFIG error is logged with an Aux Data of 1 at the same time, investigate any EXP-INTF (Expansion Interface) errors before proceeding.

Once the Port circuit pack location has been determined from Table 11-79, use the **list configuration all** command to determine if the circuit pack is inserted. If not, insert the pack. If the circuit pack has already been inserted but the error persists, replace the circuit pack.

CUST-ALM (Customer-Provided Alarming Device)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
CUST-ALM	none	test customer-alarm PC	Customer-Provided Alarming Device

1 Where PC is an appropriate port network number and carrier (for a High or Critical Reliability system, specify 1a or 1b).

The system provides customers a way to connect their own alarm indication device to a switch. The CUST-ALM maintenance object represents this Customer-Provided Alarming Device (CPAD). When an alarm occurs at least to the level to which the CPAD is administered, the CPAD in the Processor Port Network (PPN) and in the Expansion Port Network (EPN) are activated. The CPAD is administered via the Maintenance-Related System Parameters Form (CPE Alarm Activation Level field). The CPAD is connected to the Maintenance/Tape Processor in the PPN (in a High or Critical Reliability system, the CPAD is connected to both Maintenance/Tape Processors) and to the EPN Maintenance circuit pack in the EPN. The valid levels to which to set the CPE Alarm Activation Level are: *none, warning, minor,* or *major.* The CPAD is also activated within a cabinet whenever Emergency Transfer is invoked within that cabinet. The CUST-ALM MO is not maintained by the system, and does not generate any alarms. If a problem is suspected with the CPAD, it may be tested using the **test customer-alarm** command, which activates the device by closing the relay on either the Maintenance/Tape Processor or the EPN Maintenance circuit pack (whichever is specified) for 1 minute. In a High or Critical Reliability system, the CPAD on the PPN is connected to the Maintenance/Tape Processor on both carrier A and carrier B, and the **test customer-alarm** command can specify which Maintenance/Tape Processor should close its relay. The repeat parameter may be used to close the relay for a longer length of time (5 minutes is the suggested repeat value).

The CPAD is also activated within a cabinet whenever Emergency Transfer is invoked within that cabinet. The CUST-ALM MO is not maintained by the system, and does not generate any alarms. If a problem is suspected with the CPAD, it may be tested using the **test customer-alarm** command, which activates the device by closing the relay on either the Maintenance/Tape Processor or the EPN Maintenance circuit pack (whichever is specified) for 1 minute. In a High or Critical Reliability system, the CPAD on the PPN is connected to the Maintenance/Tape Processor on both carrier A and carrier B, and the **test customer-alarm** command can specify which Maintenance/Tape Processor should close its relay. The repeat parameter may be used to close the relay for a longer length of time (5 minutes is the suggested repeat value).

Hardware Error Log Entries and Test to Clear Values

Customer Provided Alarming Device Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
none	none	none			

System Technician-Demanded Tests: Descriptions and Error Codes

There are no errors associated with the CPAD CUST-ALM MO. The **test customer-alarm PC** command is provided to allow a technician to check that the customer-provided alarming device is correctly installed and functional. It is recommended that this test be run at least once after both the switch and the customer alarm have been installed.

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Customer-Provided Alarming Device Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Customer-Provided Alarming Device Test (#115)	X	X	ND

1 D = Destructive; ND = Nondestructive

Customer-Provided Alarming Device Test (#115)

This test closes the relay that activates the CPAD for 1 minute only within the port network specified. If it takes longer than 1 minute to check that the CPAD has been activated, the Repeat field on the **test customer-alarm PC** command can be used to close the relay for up to 99 minutes. Note that when the repeat option is used, the results for Test #115 come back immediately and, for each test that passed, the CPAD is kept on for that many minutes. The CPAD does not go off after 1 minute and then come back on. Instead, the CPAD is kept on continuously for the entire time. If the CPAD is being activated and deactivated in a flickering fashion, there is a problem with either the CPAD, or the Maintenance/Tape Processor, or the EPN Maintenance circuit pack.

Table 11-80. TEST #115 Customer-Provided Alarming Device Test

Error Code	Test Result	Description/ Recommendation
(blank) 1000 2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The switch software successfully sent the request to the Maintenance/Tape Processor or EPN Maintenance circuit pack to turn on the CPAD. The CPAD must be physically inspected to verify that it is working. If the CPAD is working and the customer has complained that the CPAD did not indicate a system alarm when it occurred, then check the administered levels for turning on the CPAD via the Display System-Parameter Maintenance screen form. Compare these levels with the customer's specifications. If Test #115 passes, and the CPAD is not being activated, check the connection of the CPAD to the Maintenance/Tape Processor or EPN Maintenance circuit pack. If the CPAD can be activated but cannot be deactivated, first check to make sure Emergency Transfer is not activated in the affected port network via the **status system** command. Emergency Transfer can be forced to manual OFF via the Emergency Transfer switch on the Maintenance/Tape Processor or EPN Maintenance circuit pack. If Emergency Transfer is OFF and the CPAD still cannot be deactivated, check the administered levels for the CPAD via the Display System-Parameter Maintenance screen form and compare against the alarm levels currently present in the system (**display alarms** command).

DATA-BD (Network Control Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
DATA-BD	WARNING	test network-control [a | b]	Network Control Circuit Pack
DATA-BD	MINOR	test network-control [a | b]	Network Control Circuit Pack
DATA-BD	WARNING	test network-control [a | b]	Network Control Circuit Pack

The TN777 or TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four DATA-CHLs (Network Control Data Channels), the DATA-CON (Network Control Driver), and the generic hardware that interfaces with the TDM Bus (that is, DATA-BD). The generic hardware DATA-BD is described here.

All circuit packs that have an interface with the TDM Bus have a common set of generic hardware that provides the TDM Bus interface. Consequently, these circuit packs share a common set of tests that verify the integrity of the generic hardware. The circuit packs and common set of tests that they share are described in XXX-BD (Common Port Circuit Pack) Maintenance documentation. Because the Network Control circuit pack has this common set of hardware, it is classified in the XXX-BD Maintenance documentation as a service port circuit pack.

A DEFINITY system with a single SPE has a single Network Control circuit pack. A High or Critical Reliability system has two Network Control circuit packs: one that resides in the Active SPE control carrier, and one that resides in the Standby SPE control carrier. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for a description of High and Critical Reliability systems.

Because the Network Control circuit pack is a SPE circuit pack, it has two important characteristics that make maintenance on the DATA-BD MO different from the maintenance on other XXX-BD (Common Port Circuit Pack) MOs. First, because the Network Control circuit pack has the SW-CTL (Switch Control) on it, it must always be physically installed in the system. Therefore, the DATA-BD MO is always logically administered. Second, because the Network Control circuit pack is a SPE circuit pack, it has no PCSS designation. Therefore, the DATA-BD MO **cannot** be accessed by system technician via the **test board PCSS**, **reset board PCSS**, **busyout board PCSS**, or **release board PCSS** commands. The only system technician access to the DATA-BD MO is via the **test network-control [a | b] [short | long]** command.

Hardware Error Log Entries and Test to Clear Values

Network Control Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test data-module <ext> sh r 1
1 (a)	0	Data Channel Reset Test (#107)	MINOR	ON	test data-module <ext> l
23 (b)	0	None	WARNING	OFF	
257	Any	Control Channel Test (#52)	MINOR	ON	test network-control [a | b] sh r 20
257 (c)	0	None			
513 (d)	Any	None			
769 (e)	4358	None			
1025 (f)	4363	NPE Audit Test (#50)			test network-control [a | b] sh
1538 (g)		Data Channel Reset Test (#107)	MINOR	ON	test data-module <ext> l
3840 (h)	Any	None			
3841(i)	Any	None			
3999(j)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates the DATA-BD portion of the Network Control circuit pack stopped functioning. Since the Network Control circuit pack cannot be reset via the **reset board PCSS** command, the Data Channel Reset Test (#107) in the Long Test Sequence for the DATA-CHLs and DATA-CON must be used to reset it as follows:

1. Issue the **list data** command to determine if one, or more, Network Control Data Channels (DATA-CHLs) is administered.

NOTE:
A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."

2. If a Network Control Data Channel (DATA-CHL) is not administered, use the **add data-module [<ext> | next]** command to administer a DATA-CHL.
3. From the form resulting from the **list data** command, choose a Network Control Data Channel (DATA-CHL) whose port field value indicates that it is on the same carrier (A or B) as the Network Control circuit pack to be reset.
4. Issue the **test data-module <ext> long** command using the extension for the DATA-CHL chosen in Step 3.

WARNING:
Issuing this command drops all data channel extensions. See DATA-CHL (Network Control Data Channel) Maintenance documentation first.

If the red LED stays on, then replace the circuit pack.

b. The circuit pack has been logically administered but not physically installed. The alarm is cleared when the circuit pact is installed.
c. This error indicates transient communications problems with this circuit pack. This error is not service-affecting and no action is required.
d. This error indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced.
e. This error can be ignored, but look for other errors on this circuit pack.
f. This error is not service-affecting and no action is required.
g. This error indicates the DATA-BD portion of the Network Control circuit pack is out-of-service. Since the Network Control circuit pack cannot be reset via the **reset board PCSS** command, the Data Channel Reset Test (#107) in the Long Test Sequence for the DATA-CHL and DATA-CON must be used to reset it as follows:
   1. Issue the **list data** command to determine if one or more Network Control Data Channels (DATA-CHLs) are administered.

   NOTE:
   A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."

   2. If a Network Control Data Channel (DATA-CHL) is not administered, use the **add data-module [<ext> | next]** command to administer a DATA-CHL.

3. From the form resulting from the **list data** command, choose a Network Control Data Channel (DATA-CHL) whose port field value indicates that it is on the same carrier (A or B) as the Network Control circuit pack to be reset.

   - Refer to DATA-CHL (Network Control Data Channel) Maintenance documentation before issuing the **test network-control [a | b] long** command to determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and how to busyout these links prior to running destructive tests on the DATA-CHLs.
   - Refer to SW-CTL (Switch Control) Maintenance documentation before issuing the **test network-control [a | b] long** command to determine the consequences of running the Switch Control Reset Test (Test #93).

4. Issue the **test data-module <ext> long** command using the extension for the DATA-CHL chosen in Step 3.

   If the error happens again within 15 minutes, then replace the circuit pack.

h. This error is not service-affecting and no action is required.

i. In a High Critical Reliability system, the vintage number of the TN777B Network Control circuit pack must be greater than or equal to 17. The aux value for error 3841 indicates the vintage of the current TN777B installed.

j. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Audit Test (#50) (a)		X	ND
Control Channel Loop Around Test (#52)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to DATA-CHL (Network Control Data Channel) and SW-CTL (Switch Control) Maintenance documentation for other tests associated with DATA-BD maintenance.

NPE Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity information for all the NPEs on the circuit pack.

Table 11-81. TEST #50 NPE Audit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
2100	ABORT	Could not allocate the necessary system resources to run this test.
1019	ABORT	Test already in progress.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The circuit pack’s NPEs have been updated with their translation.

Control Channel Loop Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 11-82. TEST #52 Control Channel Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	Communication with this circuit pack is successful.

DATA-CHL (Network Control Data Channel)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
DATA-CHL[1]	MINOR	test data-module l <ext>	Network Control Data Channel
DATA-CHL[2]	WARNING	test data-module sh <ext>[3]	Network Control Data Channel

1 The **test data-module <ext> long** command drops all sessions on all of the Network Control ports. Refer to Data Channel Reset Test (#107).

2 <ext> is the extension of the Data Channel to be tested. The extension can be determined by issuing the **list data-module** command from the administration terminal. The resulting form provides a mapping from the 1CXXpp designation of the Data Channel to its corresponding extension, where pp indicates which one of the four Data Channels is alarmed (01, 02, 03, or 04) and C indicates the carrier on which the alarmed Data Channel resides (A for carrier A or B for carrier B).

3 The **test data-module <ext> long** command drops all sessions on all of the Network Control ports. Refer to Data Channel Reset Test (#107).

The TN777 or TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four Data Channels, the Driver, and the generic hardware that interfaces with the TDM Bus (that is, DATA-BD). The Data Channels are the subject of this section. The Driver is also described.

Together, the four DATA-CHLs and the DATA-CON provide a data communications interface that allows data terminal equipment connected to port circuit packs to communicate with software applications running on the system. The DATA-CON represents the interface to the control channel of the TDM Bus. Each DATA-CHL represents a dial-up/dial-out asynchronous communications port that interfaces to the TDM Bus. The DATA-CON supports the signaling required to establish and tear down a connection between the terminal equipment and a software application. Data is transported between the terminal equipment and the software application over the connection established over the DATA-CHL.

A system with a single SPE has a single Network Control circuit pack (DATA-BD). Thus, there is single set of four DATA-CHLs. A High or Critical Reliability system has two Network Control circuit packs: one that resides in the Active SPE control carrier, and one that resides in the Standby SPE control carrier. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for descriptions of High and Critical Reliability systems.

Network Control Data Channels (DATA-CHLs) may be used to support the following features and functions:

- Establishment of a connection over which to log CDR data to a printer or other storage unit. This connection is called PRI-CDR/SEC-CDR (PRI-CDR Link).
- Establishment of connection(s) over which to log PMS, Automatic Wakeup, and Emergency Access to Attendant data to a Journal printer. This connection is called PMS-PRINT/JRNL-PRNT (PMS Printer Link).
- Establishment of a connection to a customer-owned PMS. This connection is called the PMS-LINK.
- Establishment of a connection to system printer. This connection is called the System Printer Link (SYS-PRNT).
- Establishment of connection(s) for up to two secondary administration terminals.
- Saving announcements from the ANN-BD (Announcement Circuit Pack) to tape.
- Restoring announcements from tape to the ANN-BD (Announcement Circuit Pack).
- Maintenance testing of the DATA-CHLs and DATA-CON.

From the viewpoint of administration, the four DATA-CHLs on a Network Control circuit pack are numbered 01 through 04. In a system with a single SPE or in the Active SPE of a system with High or Critical Reliability, each DATA-CHL may be assigned a unique extension using the **add data-module [<ext> | next]** command. These extensions are called *active* extensions. When assigning an active extension to a DATA-CHL XX (where XX is 01, 02, 03, or 04) the Add Data-Module form also requires the user to assign a unique *maintenance* extension to the corresponding Standby SPE DATA-CHL XX. The maintenance extension is required even when the system does not High or Critical Reliability; that is, even when there are no Standby SPE DATA-CHLs. In a High or Critical Reliability system, a Standby SPE DATA-CHL is tested by using its maintenance extension to identify it.

NOTE:
If a DATA-CHL or the DATA-CON becomes defective on the Network Control in a system with a single SPE, the Network Control circuit pack cannot be replaced without powering down the system.

Figure 11-26 illustrates the logical decomposition of DATA-CHL (Network Control Channel) and the DATA-CON (Network Control Driver) into software and hardware components. The figure also shows the interface to the switch software via the memory bus and to terminal equipment via the TDM Bus and port circuit packs.

As indicated in the figure, DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware, and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

1. Determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and busyout these links if it is necessary to use the **test network-control [a | b] long** command.
2. Refer to SW-CTL (Switch Control) Maintenance documentation before executing the **test network-control [a | b] long** command to determine the consequences of running the Switch Control Reset Test (Test #93).

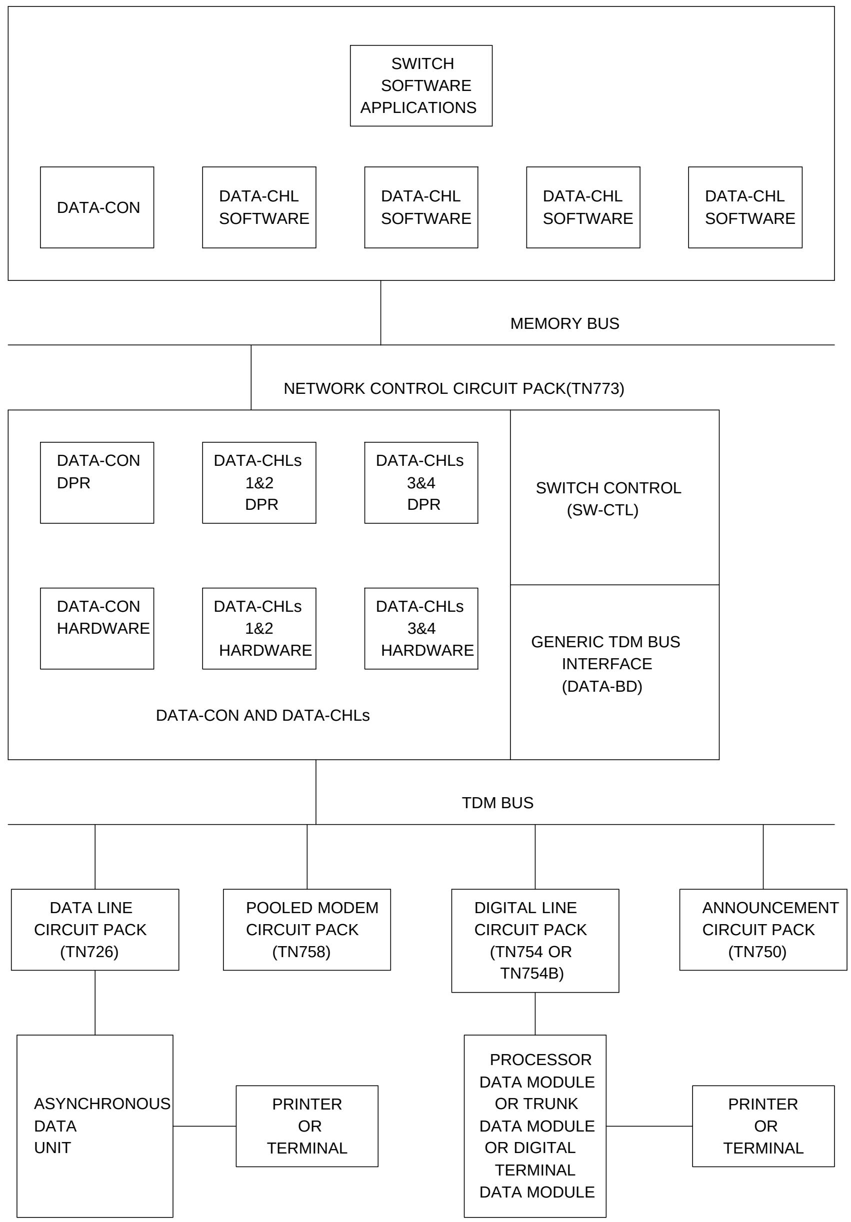

Figure 11-26. DATA-CON (Network Control Driver)

Status of Network Control Data Channels

In order to perform maintenance testing on the Network Control DATA-CHLs, the DATA-CHLs cannot be busy with one of the functions described previously. A series of system technician commands can be used to determine if the DATA-CHLs are busy and, if so, to determine the function for which they are being used. This series of system technician commands is described below and should be done before testing the DATA-CHLs.

Issue the **list data-module** command to determine the extensions for the administered Network Control Data Channels (DATA-CHLs).

NOTE:
A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."

For each Network Control Data Channel (DATA-CHL) on the Active SPE, determine if the DATA-CHL is busy by issuing the **status data-module <ext>** command using the DATA-CHL's extension. If the DATA-CHL is busy, the Service State field in the resulting form will be in service/active. However, the form does not indicate the reason the DATA-CHL is busy. This must be determined using other system technician commands.

Use the procedures below to determine whether busy Network Control Data Channels (DATA-CHLs) are being used for CDR, Journal Printer, or PMS Links. If a DATA-CHL is busy with one of these links then, in order to test the DATA-CHL, the link must be busied out using **busyout smdr-link**, **busyout journal-printer wakeup-log**, **busyout journal-printer pms-log**, or **busyout pms-link** command, respectively. Do not issue any of these busyout commands unless instructed to do so while investigating Error Codes according to the "System Technician-Demanded Tests: Descriptions and Error Codes" subsection. If one of these links must be busied out to perform maintenance testing, restore the link to service according to PRI-CDR/SEC-CDR (PRI-CDR Link), PMS-PRNT/JNL-PRNT (PMS Printer Link), and PMS-LINK Maintenance documentation, respectively.

If a DATA-CHL is busy but is not being used for one of these links, then it is being used for a secondary administration terminal connection or for maintenance testing. If it is being used for a secondary administration terminal connection, then in order to test the DATA-CHL that the connection is using, the DATA-CHL must be busied out using the **busyout data-module <ext>** command.

NOTE:
The **busyout data-module <ext>** command causes the connection over the associated DATA-CHL to be dropped. Do not issue this command unless instructed to do so.

If the DATA-CHL must be busied out in order to perform maintenance testing, the secondary administration terminal connection must be re-established by redialing the DATA-CHL.

CDR Links

1. Issue the **status smdr-link** command to see if an CDR Link has been established. If the Link State field is "Up," then the CDR Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system features** command and go to the CDR subsection on Page 2 of the resulting form. Note the values in the Primary Output Extension and Secondary Output Extension fields. If the values are extensions, then the CDR Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Primary Output Extension and Secondary Output Extension fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is an CDR Link over that DATA-CHL.

System Printer Links

1. Issue the **status sp-link** command to see if a System Printer Link has been established. If the Link State field is "Up," then the System Printer Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system features** command and go to the System Printer subsection on Page 2 of the resulting form. Note the values in the Primary Output Extension and Secondary Output Extension fields. If the values are extensions, then the System Printer Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Primary Output Extension and Secondary Output Extension fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is a System Printer Link over that DATA-CHL.

Journal Printer Links

1. Issue the **status journal-link wakeup-log** and **status journal-link pms-log** commands to see if one or both of these Journal Printer Links have been established. If the Link State field is "Up" for either of these, then that Journal Printer Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system hospitality** command and note the values in the Extension of Journal/System Printer and Extension of PMS Log Printer fields. If either of these values are extensions, then that Journal Printer Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Extension of Journal/Schedule Printer and Extension of PMS Log Printer fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is a Journal Printer Link over that DATA-CHL.

PMS Link

1. Issue the **status pms-link** command to see if a PMS Link has been established. If the Link State field is "Up," the PMS Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system hospitality** command and note the value in the Extension of the PMS field. If this value is an extension, the PMS Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For the extension in the Extension of PMS field, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate the port indicated in the Connected Ports field, and determine if that port has a "type" value of "netcon." If so, there is a PMS Link over that DATA-CHL.

Hardware Error Log Entries and Test to Clear Values

Network Control Data Channel Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1](a)	0	Any	Any	Any	test data-module <ext> sh r 1
1	Any	Local Loop Back Test (#111)	MINOR	ON	test data-module <ext> sh r 3
18 (b)	0	busyout data-module <ext>	WARNING	OFF	release data-module <ext>
130		None	WARNING	ON	test data-module <ext> sh
257	Any	Remote Maintenance Loop Around Test (#109)	MINOR	ON	test data-module <ext> sh r 5
513	Any	Crosstalk Test (#110)	MINOR	ON	test data-module <ext> sh r 3
769	Any	Dual Port RAM Test (#108)	MINOR	ON	test data-module <ext> l r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

b. In a system with the duplication option, a busyout of the DATA-CHL is preserved across an SPE interchange. When an SPE interchange occurs, and the DATA-CHL is busied out, the busyout state is transferred to the corresponding DATA-CHL on the new active SPE while the DATA-CHL on the former active SPE is released.

System Technician-Demanded Tests: Descriptions and Error Codes

There are two system technician test commands that include the Network Control Data Channels (DATA-CHLs). The **test data-module <ext> [short | long]** command tests the single DATA-CHL that has the extension specified by <ext>.

The **test network-control [a | b] [short | long]** command tests each administered DATA-CHL that resides on the Network Control circuit pack in the specified carrier.

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Data Channel Reset Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Tests for test data-module <ext> Command

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Data Channel Reset Test (#107) (a)		X	D
Data Channel Dual Port Ram Test (#108) (a)		X	D
Data Channel Remote Maintenance Loop Around Test (#109)	X	X	ND
Data Channel Local Loop Back Test (#111)	X	X	ND
Data Channel Crosstalk Test (#110)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and busyout these links if it is necessary to use the **test network-control [a | b] long** command.

Tests for test network-control [a | b] Command

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Test (Common Port Circuit Pack) (#52) (a)		X	ND
NPE Audit Test (Common Port Circuit Pack) (#50) (a)	X	X	ND
Data Channel Reset Test (#107)		X	D
Data Channel DPR Test (#108)		X	D
Data Channel Maintenance Loop Around Test (#109)	X	X	ND
Data Channel Crosstalk Test (#110)	X	X	ND
Data Channel Local Loop Back Test (#111)	X	X	ND
Switch Control Reset Test (#93) (b)		X	D
EPN Maintenance Board Interface Test (#325) (b)		X	D
Time-of-Day Clock Test (#95) (b)	X	X	ND
Control Channel Interface Test (#92) (b)	X	X	ND
Control Channel Transmission Test (#94) (b)	X	X	ND
EPN Maintenance Board Interface Test (#324) (b)	X	X	ND
12 Volt Power Supply Test (#701) (c)	X	X	ND
Memory Card Insertion Test (#695) (c)	X	X	ND
Memory Card Format and Read Test (#696) (c)	X	X	ND
Memory Card Match Test (#697) (c)	X	X	ND
Memory Card Write-Protected Test (#698) (c)	X	X	ND
Memory Card Directory Recovery Test (#699) (c)	X	X	ND
Memory Card Translation Data Integrity Test (#694) (c)		X	ND
Memory Card Erase/Write/Read Test (#693) (c)	X		ND

1 D = Destructive; ND = Nondestructive

a. Refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation for a description of these tests.

b. Refer to SW-CTL (Switch Control) Maintenance documentation for a description of these tests.

c. Refer to the CARD-MEM MO section for information on this test.

Data Channel Reset Test (#107)

This test is destructive.

This test resets the entire data communications interface provided by the DATA-CON and the four DATA-CHLs. It does this by resetting the hardware and software composing the DATA-CON and all four DATA-CHLs. All existing connections over the DATA-CHLs are dropped.

Table 11-83. TEST #107 Data Channel Reset Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2011 2012 2013 2016 2017 2020 2022 2030	ABORT	Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
2100	ABORT	System resources required for this test are unavailable.
	ABORT	An ABORT has one of two different meanings: a. System resources required to run this test are not available. b. Internal System Error.
10704	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-83. TEST #107 Data Channel Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The circuit pack failed to reset. 1. Execute the command again. 2. If the problem persists, replace the TN777 Network Control circuit pack as described in Chapter 5, "Routine Maintenance Procedures". After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. If this is a High or Critical Reliability system, set the Time-of-Day clocks as described in Chapter 8, "Reliability Systems: A Maintenance Aid", to ensure that the clocks on both Network Control circuit packs are synchronized.
	PASS	The circuit pack initializes correctly.

Data Channel Dual Port RAM Test (#108)

This test is destructive.

This is a coordinated test of the dual port RAM that is shared between the hardware and software composing the DATA-CON. Control messages and data are passed through this dual port RAM to establish and tear down connections over the DATA-CHLs. This test requests each side to read and write the dual port RAM, first one at a time and then simultaneously in alternate locations.

This test prevents any control stimuli from being received from or sent to the TDM Bus control channel preventing the establishment of new connections over the DATA-CHLs. However, existing connections are not (and cannot) be dropped.

Table 11-84. TEST #108 Data Channel Dual Port RAM Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2020	ABORT	Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
	FAIL	The DATA-CON dual port RAM is not functioning correctly. Either the software cannot correctly read from it and/or write to it or the hardware cannot correctly read from it and/or write to it. Connections cannot be established over the DATA-CHLs. 1. Execute the command again. 2. If the problem persists, replace the TN777 Network Control circuit pack. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command.
	PASS	The DATA-CON dual port RAM is functioning. Connections can be established over the DATA-CHLs.

Data Channel Remote Maintenance Loop Around Test (#109)

This test verifies the integrity of the entire DATA-CHL (that is, the software, dual port RAM, and hardware that compose it). It verifies that a connection can be established over the DATA-CHL and that the DATA-CHL can correctly send and receive data over the connection (that is, over the TDM Bus). The test actually involves two DATA-CHLs: the DATA-CHL that is the target of the test and a second, arbitrary, unbusy DATA-CHL. A connection is set up by placing a call out from the arbitrary DATA-CHL and into the target DATA-CHL. Data is looped over the connection in each direction (that is, the target DATA-CHL is tested as both a sender of data and a receiver of data). The test checks that the data received by one DATA-CHL is the same as the data that was sent by the other DATA-CHL.

Because it establishes a connection between two Network Control Data Channels (DATA-CHLs) across the TDM Bus, this test does more than just verify the integrity of the target DATA-CHL. It also verifies the integrity of the DATA-CON (by establishing the connection) and of the TDM Bus and Tone-Clock circuit pack (by sending and receiving data).

If this test aborts or fails, it is impossible to determine from this test alone whether the defective DATA-CHL is the target DATA-CHL or the arbitrarily chosen DATA-CHL, or if the problem lies with the DATA-CON, TDM Bus, or Tone-Clock circuit pack. The results of running Tests #107, #108, #110, and #111 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

NOTE:
If an Error Code is encountered recommending that an CDR, System Printer, Journal Printer, and/or PMS Link be busied out, restore each busied out link to service according to PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT (System Printer Link), JNL-PRNT (Journal Printer Link), or PMS-PRNT/JNL-PRNT (PMS Printer Link) Maintenance documentation, respectively, before concluding work on the problem.

Table 11-85. TEST #109 Data Channel Remote Maintenance Loop Around Test

Error Code	Test Result	Description/ Recommendation
4	ABORT	For this test, an Error Code of 4 can have one of two different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal System Error. Note the results of Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL. If the results of Tests #110 and #111 are both PASS, then there is a high probability that the target DATA-CHL is not defective. Proceed with the remaining steps **only if it is necessary to completely test the target DATA-CHL:** 1. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps **only if it is necessary to completely test the target DATA-CHL.** 2. If the target DATA-CHL is in use for some other function, busyout the function (CDR Link, System Printer Link, Journal Printer Link, PMS Link) or the DATA-CHL (secondary administration terminal connection **only**). 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem. 5. Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.

Error Code	Test Result	Description/ Recommendation
1016	ABORT	Resources for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	Test disabled via software patch. 1. Escalate to next tier level for instructions on enabling test.
2003	ABORT	Internal System Error.
2004	ABORT	Internal System Error. 1. Check the dial plan to make sure that the extensions of the data channel are set up as local extensions rather than remote or UDP extensions. 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
2011 2012 2013 2016 2017 2020 2022 2051	ABORT	Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.

Table 11-85. TEST #109 Data Channel Remote Maintenance Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
40 41 2000 2003 2004	FAIL	In the case of Error Codes 40 and 41, the Remote Maintenance Loop Around Test failed because the data received over the connection did not match the data sent over the connection (data was corrupted). In the case of Error Codes 2000, 2003, and 2004, the Remote Maintenance Loop Around Test failed because the data looped over the connection was not received (data was lost). However, because it involves two DATA-CHLs, the test's failure is not sufficient to indict either one of the two DATA-CHLs as defective. 1. Check the dial plan to make sure that the extensions of the data channel are set up as local extensions rather than remote or UDP extensions. 2. Determine which of the DATA-CHLs is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described in the "Status of Network Control Data Channels" section. 3. Note the test results for Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL and refer to Steps 4, 5, and/or 6 to determine the appropriate actions to take based on those results.

Table 11-85. TEST #109 Data Channel Remote Maintenance Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
40 41 2000 2003 2004 *(cont'd.)*		4. If the result of Test #110 is PASS and the result of Test #111 is PASS for the target DATA-CHL, then the most likely problem is that the arbitrarily chosen DATA-CHL is defective. ■ Run the Short Test Sequence for each DATA-CHL that is **not** in use for some other function. Note the test results for Tests #110 and #111 for each of them. ■ If the results of Tests #110 and #111 are both FAIL for at least one of the other DATA-CHLs, investigate the possibility of a defective arbitrarily chosen DATA-CHL. a. Issue the **remove data-module <ext>** for each DATA-CHL for which the results of Tests #110 and #111 were both FAIL to remove the DATA-CHL from operation. b. Repeat the test. c. Replace the Network Control circuit pack at your earliest convenience. Replace the circuit pack as described in Chapter 5, "Routine Maintenance Procedures". After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. ■ If the results of Tests #110 and #111 are not **both** FAIL for any one of the other DATA-CHLs that are not in use for some other function, investigate the possibility of a defective TDM Bus as described in Step 5.

Table 11-85. TEST #109 Data Channel Remote Maintenance Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
40 41 2000 2003 2004 *(cont'd.)*		5. If the result of Test #110 is FAIL and the result of Test #111 is PASS for the target DATA-CHL, then the most likely problem is that the TDM Bus or Tone-Clock circuit pack is defective. ■ Check for the existence of TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms. If they exist: a. Refer to the corresponding Maintenance documentation to clear the errors and alarms. b. Repeat the test. ■ If TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms do not exist, investigate the possibility that the target DATA-CHL, the DATA-CON, or the Network Control circuit pack is defective as described in Step 6.

Error Code	Test Result	Description/ Recommendation
40 41 2000 2003 2004 *(cont'd.)*		6. If the result of Test #110 is either PASS or FAIL and the result of test #111 is FAIL for the target DATA-CHL, then the most likely problem is that the target DATA-CHL is defective, the DATA-CON is defective, or the TN777 Network Control circuit pack is defective. ■ Busyout **all** functions that are using the Network Control Data Channels (DATA-CHLs). **CAUTION:** *All functions must be busied out because Test #107 is destructive and terminates all established connections over the DATA-CHLs.* ■ Issue the **test data-module <ext> long** for the target DATA-CHL. Note the test results for Test #107 and #108. a. If the result of Test #107 is FAIL, then the TN777 Network Control circuit pack is defective. ■ Replace the Network Control circuit pack immediately. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. ■ Repeat the test. b. If the result of Test #107 is PASS and the result of Test #108 is FAIL, then the DATA-CON is defective. ■ Although all DATA-CHLs are unusable, the SW-CTL is still operational. Based on the customer's use of DATA-CHLs, replace the Network Control circuit pack at the customer's convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. ■ Repeat the test.

Table 11-85. TEST #109 Data Channel Remote Maintenance Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
40 41 2000 2003 2004 *(cont'd.)*		If the result of Test #107 is PASS and the result of Test #108 is PASS, then the target DATA-CHL is defective. ■ Issue the **remove data-module <ext>** for the target DATA-CHL to remove it from operation. ■ Replace the Network Control circuit pack at your earliest convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. 7. Restore any busied out CDR, Journal Printer, System Printer, or PMS Link to service before moving on to another activity.
	PASS	The target DATA-CHL, DATA-CON, TN777 Network Control circuit pack, TDM Bus (TDM-BUS), and Tone-Clock circuit pack (TONE-BD, TONE-PT, TDM-CLK) are functioning. Connections can be established over the DATA-CHLs.

Data Channel Crosstalk Test (#110)

This test verifies the integrity of the entire DATA-CHL, that is, the software, dual port RAM, and hardware that composes it. However, unlike the Remote Maintenance Loop Around Test (#109), this test only involves the single DATA-CHL that is the target of the test. A loop around connection is established over the TDM Bus from the DATA-CHL back to itself. Data is looped over the connection in each direction, that is, the DATA-CHL is tested as both a sender of data and a receiver of data. The test checks that the data received by the DATA-CHL is the same as the data that was sent by the DATA-CHL.

Because it establishes a loop around connection from the Network Control DATA-CHL back to itself across the TDM Bus, this test does more than just verify the integrity of the target DATA-CHL. It also verifies the integrity of the DATA-CON (by establishing the connection) and of the TDM Bus and Tone-Clock circuit pack (by sending and receiving data).

If this test aborts or fails, it is impossible to determine from this test alone whether the target DATA-CHL is defective or if the problem lies with the DATA-CON, TDM Bus, or Tone-Clock circuit pack. The results of running Tests #107, #108, and #111 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common DPR and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

NOTE:
If an Error Code is encountered that recommends that an CDR Link, System Printer Link, PMS Log Printer, Wakeup-Log Printer Link, and/or PMS Link be busied out, restore each busied-out link to service according to the PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT, or PMS-LINK Maintenance documentation, respectively, before concluding work on the problem.

Table 11-86. TEST #110 Data Channel Crosstalk Test

Error Code	Test Result	Description/ Recommendation
4	ABORT	For this test, an Error Code of 4 can have one of two different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal System Error. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps **only if it is necessary to completely test the target DATA-CHL:** 1. If the target DATA-CHL is in use for some other function, busyout the function (CDR Link, System Printer Link, Journal Printer Link, PMS Link) or the DATA-CHL (secondary administration terminal connection **only<EMPH>).** 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem. 4. Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.
40 70 75	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-86. TEST #110 Data Channel Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
14 16 40 2000 2003 2004 *(cont'd.)*		3. If the result of Test #107 is PASS and the result of Test #108 is PASS, then the target DATA-CHL is defective. (a). Issue the **remove data-module <ext>** command for the target DATA-CHL to remove it from operation. (b). Replace the Network Control circuit pack at your earliest convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the **set time** command. 5. Restore any busied out function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) to service before moving on to another activity.
	PASS	The target DATA-CHL, DATA-CON, TN777 Network Control circuit pack, TDM Bus (TDM-BUS), and Tone-Clock circuit pack (TONE-BD, TONE-PT, TDM-CLK) are functioning. Connections can be established over the target DATA-CHL.

Data Channel Local Loop Back Test (#111)

This test verifies the integrity of the dual port RAM that is shared between the software and hardware that composes the DATA-CHL. The dual port RAM is placed in local loop back mode such that data to be sent by the DATA-CHL is instead looped back to be received by the DATA-CHL. The loop back is done within the dual port RAM, that is, the data is never sent over the TDM Bus. The test checks that the data received by the DATA-CHL is the same as the data that was sent by the DATA-CHL.

This test actually does more than just verify the integrity of the target DATA-CHL. Because it is the DATA-CON that actually puts the Dual Port RAM in local loop back mode and loops the data from the Dual Port RAM back into the Dual Port RAM, the test also verifies the integrity of the DATA-CON.

If this test aborts or fails, it is impossible to determine from this test alone whether the target DATA-CHL is defective or if the problem lies with the DATA-CON. The results of running Tests #107 and #108 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

NOTE:
If an Error Code is encountered that recommends that an CDR Link, System Printer Link, PMS Log Printer, Wakeup-Log Printer, and/or PMS Link be busied out, restore each busied-out link to service according to the PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT (System Printer Link), PMS-PRNT/JNL-PRNT (PMS Printer Link), or PMS-LINK (Property Management System Link) Maintenance documentation, respectively, before concluding work on the problem.

Table 11-87. TEST #111 Data Channel Local Loop Back Test

Error Code	Test Result	Description/ Recommendation
4	ABORT	For this test, an Error Code of 4 can have one of two different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal System Error. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps **only if it is necessary to completely test the target DATA-CHL.** 1. If the target DATA-CHL is in use for some other function, busyout the function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) or the DATA-CHL (secondary administration terminal connection **only**). 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem. 4. Restore any busied out PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK MOs to service before moving on to another activity.
40 70 75	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

	PASS	The target DATA-CHL and DATA-CON are functioning. Connections can be established over the target DATA-CHL.

DATA-CON (Network Control Driver)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
DATA-CON	MINOR	none	Network Control Driver

The TN777 or TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four DATA-CHLs (Data Channels), the DATA-CON (Network Control Driver), and the generic hardware that interfaces with the TDM Bus (DATA-BD). The DATA-CON (Network Control Driver) is the subject of this section. The DATA-CHLs (Network Control Channels) are also described.

Together the four DATA-CHLs and the DATA-CON provide a data communications interface that allows data terminal equipment connected to port circuit packs to communicate with software applications running on the system. The DATA-CON represents the interface to the control channel of the TDM Bus. Each DATA-CHL represents a dial-up/dial-out asynchronous communication port that interfaces to the TDM Bus. The DATA-CON supports the signaling required to establish and tear down a connection between the terminal equipment and a software application. Data is transported between the terminal equipment and the software application over the connection established over the DATA-CHL. See Figure 11-27.

A system with a single SPE has a single Network Control circuit pack. Thus, there is a single DATA-CON. A High or Critical Reliability system has two Network Control circuit packs, one in each of the two SPEs. Thus, there is a DATA-CON on the Network Control circuit pack that resides in the Active SPE control carrier and a DATA-CON on the Network Control circuit pack that resides in the Standby SPE control carrier. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for discussions of High and Critical Reliability systems.

From an external (user) point of view, the DATA-CON is not directly accessible via a system technician command; that is, there is no object command word that represents it. Instead, the DATA-CON is tested under the guise of the DATA-CHLs that it controls. The **test data-module <ext> [short | long]** command tests the DATA-CON along with the DATA-CHL designated by <ext> but all Test Results are associated with the DATA-CHL Maintenance Name.

From an internal (system software) point of view, the DATA-CON uses the same set of tests as the DATA-CHLs. Therefore, the DATA-CON assumes the same Error Type and Aux Data values as the DATA-CHLs in the Hardware Error Log. It is also alarmed at the same Alarm Level (that is, MINOR, ON BOARD) in the Alarm Log. In both logs, the Maintenance Name is DATA-CON.

Figure 11-27 illustrates the logical decomposition of DATA-CHLs (Network Control Channels) and the DATA-CON (Network Control Driver) into software and hardware components. It also shows the interface to the switch software via the memory bus and to terminal equipment via the TDM Bus and port circuit packs. As indicated in Figure 11-27, DATA-CHLs 1 and 2 share a common DPR and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

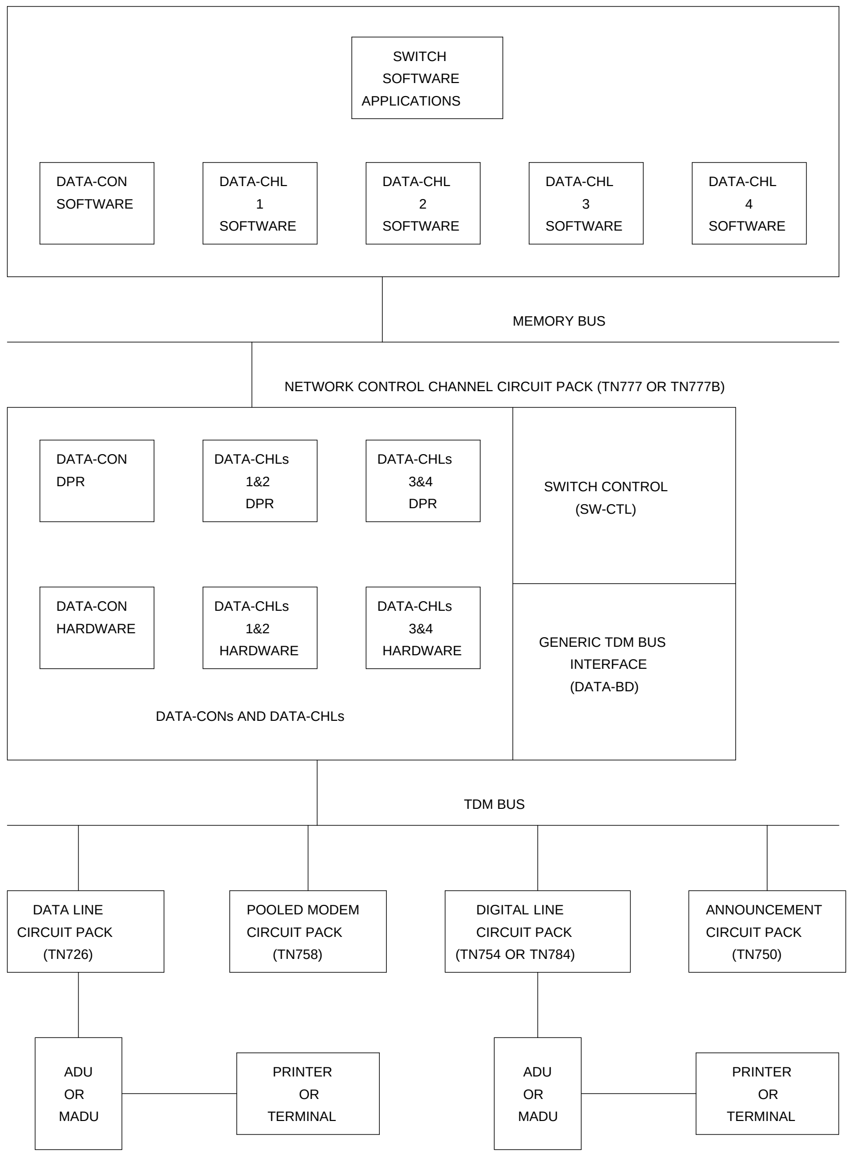

Figure 11-27. DATA-CHL (Network Control Data Channel)

Hardware Error Log Entries and Test to Clear Values

Network Control Driver Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value (a)
0[1]	0	Any	Any	Any	none
1		Local Loop Back Test (#111)	MINOR	ON	none
257	Any	Remote Maintenance Loop Around Test (#109)	MINOR	ON	none
513		Crosstalk Test (#110)	MINOR	ON	none
769	Any	Dual Port RAM Test (#108)	MINOR	ON	none

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. As previously described, the DATA-CON is not directly accessible via a system technician command so there is no Test to Clear value that can be used to directly clear errors and alarms raised against the DATA-CON. However, since the DATA-CON and the DATA-CHLs share the same set of tests (that is, test the same set of hardware, firmware, and software), DATA-CON errors and alarms are accompanied by DATA-CHL errors and alarms.

Therefore, the strategy to clear DATA-CON errors and alarms is to first clear all DATA-CHL errors and alarms. After DATA-CHL errors and alarms have been cleared, allow about 60 minutes for maintenance software to run internally and to automatically clear the DATA-CON errors and alarms.

System Technician-Demanded Tests: Descriptions and Error Codes

Because the DATA-CON uses the same set of tests as the DATA-CHLs, refer to the "System Technician-Demanded Tests: Descriptions and Error Codes" in the DATA-CHL (Network Control Data Channel) Maintenance documentation for a description of the tests and their associated error codes.

DAT-LINE (Data Line)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DAT-LINE	MINOR	test port PCSSpp l	Data Line
DAT-LINE	WARNING	test port PCSSpp sh	Data Line

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN726 Data Line circuit pack is a port circuit that provides connectivity from the system to asynchronous CPE having RS232-compatible serial interfaces. There are eight data lines (DAT-LINEs) on the Data Line circuit pack. If there are errors associated with the DT-LN-BD (Data Line Circuit Pack), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

Data Lines are administered via the administration terminal **add data-module** command. The data module type is *data-line*. The **list data-module** command lists all administered data modules in the system.

The TN750 Announcement circuit pack has one Data Line on it. The Data Line is used for saving and restoring announcements. For a description of this feature, refer to ANN-BD (Announcement Circuit Pack) Maintenance documentation. Also, if there are errors associated with the Announcement circuit pack, refer to the ANN-BD Maintenance documentation.

NOTE:
If the tests for the Data Line in question pass and there are still user-reported problems, there is probably an external problem. Test the ADU, following the procedures outlined in *User Manual Z3A Asynchronous Data Unit*, 555-401-701. If the ADU appears to be working properly, check the external wiring and, finally, check the customer equipment.

Hardware Error Log Entries and Test to Clear Value

Data Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1		Digital Loop Around Test (#171)	MINOR	ON	test port PCSSpp sh r 2
15(a)	Any	Audit Update Test (#36)			
18	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
130 (b)		None	WARNING	ON	test port PCSSpp sh
257		Conference Circuit Test (#7)	MINOR	ON	test port PCSSpp l r 2
513		NPE Crosstalk Test (#6)	MINOR	ON	test port PCSSpp l r 2
769(a)	Any (c)	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate errors (if any).

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. This error is logged when the Data Line circuit pack finds an error with the transmit/receive circuitry of an administered Data Line on circuit pack insertion. Perform the following procedure:

   1. Issue the **busyout board PCSS** command to busyout the Data Line circuit pack on which this port resides.

   2. Issue the **reset board PCSS** command. Check the Hardware Error Log to determine if Error Type 769 is logged again for the DAT-LINE MO.

      NOTE:
      When displaying errors, set the Active Alarms Only field to "n."

If Error Type 769 reappears, replace the DAT-LINE circuit pack. If Error Type 769 does not reappear, proceed to Step 3.

3. Issue the **release board PCSS** command to release the Data Line circuit pack on which this port resides.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Digital Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Loop Around Test (#171)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-88. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-88. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-88. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 11-89. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.

Continued on next page

Table 11-89. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The conference circuit test failed (possible off-board problem). 1. Busyout and release the port (data line), and then retest. 2. Replace the circuit pack if the test continues to fail.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Audit Update Test (#36)

This audit makes sure that the hardware state of the Data Line is consistent with the system translations. When this audit is run, the port is queried for the switchhook state, and the software state is updated according to the returned value. Also, the data line options are sent down to the port.

Table 11-90. TEST #36 Audit Update Test

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error.
7	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The hardware port state is consistent with the software state. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Digital Loop Around Test (#171)

The Digital Loop Around Test checks the Data Line's ability to transmit and receive data on the TDM Bus. Data is sent through Network Control Data Channel 3 (data channel port 3) over the TDM Bus, internally looped through the Data Line back onto the TDM Bus, and received again by Network Control Data Channel 3.

If data channel 3 is in use or not administered, this test aborts. This test may fail if Network Control Data Channel 3 is not functioning properly. If there are any DATA-CHL errors in the Error Log, refer to the DATA-BD (Network Control Circuit Pack) Maintenance documentation to clear them up first. This test passes regardless of any customer equipment that may be connected to the port, as long as the port is not in use by the equipment.

Table 11-91. TEST #171 Digital Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005 1007	ABORT	Network Control Data Channel 3 is not administered. This port is required to run this test. 1. Verify that data channel 3 is not administered with the **list data-module** command. Administer data channel 3 with the **add data-module** command, and run this test again. 2. If data channel 3 is administered and the test continues to abort, escalate the problem.

Continued on next page

Table 11-91. TEST #171 Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1016	ABORT	Network Control Data Channel 3 is busy. The port may be in use on a valid call. Use **status data-module** to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Reseat the circuit pack and look in the Error Log. If Error Type 769 still occurs on this port, replace the circuit pack.
2003	ABORT	Failed to receive an off-hook from the Data Line. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test still aborts, replace the circuit pack.
2004	ABORT	Failed to receive an off-hook from the Network Control Data Channel.
2005	ABORT	The handshake between the data channel and the data line port failed. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test still aborts, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-91. TEST #171 Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because the data received did not match the data sent. This would indicate that there is a fault somewhere in the transmit/receive path to the TDM Bus, which probably results in data corruption over this port. This test may fail if Network Control Data Channel 3 is not functioning properly. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Repeat this test. 3. If the test fails again, replace the Data Line circuit pack.
2000	FAIL	The test failed waiting for the transmitted data to be looped back. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Repeat this test. 3. If the test fails again, replace the Data Line circuit pack.
	PASS	The port can correctly transmit/receive data. User-reported troubles on this port should be investigated by examining the ADU, external wiring, and customer equipment.

DC-POWER (Single-Carrier Cabinet Power)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DC-POWER	MAJOR	test environment P	Single-Carrier Cabinet Power

1 Where P is an appropriate port network number determined from the PORT field of the alarm log.

DEFINITY offers two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configurations may be powered by either an external AC or DC power source.

NOTE:
For environment maintenance, the High or Critical Reliability system, PPN, or EPN cabinet configuration aspects are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate MO section(s).

- For a single-carrier cabinet system, refer to the DC-POWER (DC Power) Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following MO Maintenance documentation sections: AC-POWER (AC Power) for AC-Powered Systems, CARR-POW (Carrier Port Power Unit) for AC-Powered Systems, or POWER (Battery & Battery Charger) for AC-Powered Systems.
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following MO Maintenance documentation sections: AC-POWER (AC Power) for DC-Powered Systems, CARR-POW (Carrier Port Power Unit) for DC-Powered Systems, or POWER (Battery & Battery Charger) for DC-Powered Systems.

The DC-POWER MO represents all the environmental maintenance for a single-carrier cabinet system. It includes an external power unit and all the Carrier Port Power Units in the Port Network. The external power unit can be either a DC or an AC power source. If the external power unit is AC, then the Carrier Port Power Units must be WP-91153 power units. If the external power unit is DC, then the Carrier Port Power Units must be 676B power units. If the hardware detects a problem with any one of these elements, it reports the information to the system software through a single lead. The system software cannot differentiate between different environmental failures. All environmental alarms on a single-carrier cabinet system are logged as a major DC-POWER alarm. Therefore, it is possible to get a DC-POWER alarm when there is still power to the system. The Carrier Port Power Unit has one LED: the yellow LED on means operating as normal and the LED off means no external power being supplied or that the power unit has a fault.

NOTE:
Physically removing a Carrier Port Power Unit from a carrier in a single-carrier cabinet system does not raise a DC-POWER alarm. The removal of the power unit is equivalent to the carrier being physically absent since DC-POWER maintenance cannot distinguish between these two situations.

A single-carrier cabinet system powered by an AC external power source with WP-91153 Carrier Port Power Units has a minimal Nominal Power Holdover (NPH) for the PPN only in Standard, High, and Critical Reliability systems. There is no NPH for a DC- powered single-carrier cabinet PPN or for an AC- or DC-powered single-carrier cabinet EPN system. For a complete description of NPH, refer to the AC-POWER (AC Power) Maintenance documentation. NPH in the PPN of an AC-powered single-carrier cabinet system without High or Critical Reliability provides full powering for .25 seconds, and power to the control complex for an additional two minutes.

Hardware Error Log Entries and Test to Clear Values

Single-Carrier Cabinet Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment P sh r 1
513	0	Single-Carrier Cabinet	MAJOR	ON	test environment P r 2
		Power Query Test (#79)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Single-Carrier Cabinet Power Query Test*, for example, you may also clear errors generated from other tests in the testing sequence. Test description(s) and recommended maintenance procedures follow for all errors that can occur during system technician-demanded testing.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Single-Carrier Cabinet Power Query Test (#79)	X	X	ND
Emergency Transfer Query Test (#124) (a)	X	X	ND
External Alarm Lead Query Test (#120) (b)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

b. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

c. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:
Tests #117 and #118 only show up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Single-Carrier Cabinet Power Query Test (#79)

This test queries the Maintenance/Tape Processor (in a PPN) or the EPN Maintenance circuit pack (in an EPN) about the status of the power in a single-carrier cabinet system. This test can only detect power problems in carriers in the Port Network for which the Carrier Port Power Unit is physically present.

Table 11-92. TEST #79 Single-Carrier Cabinet Power Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test.If the test continues to ABORT with a 2000 Error Code, check for and resolve all DUPINT (Duplication Interface Circuit Pack) errors in a PPN for a High or Critical Reliability system, PR-MAINT (Maintenance/Tape Processor) errors in a Standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 3. If the test continues to ABORT with a 2000 Error Code, then escalate the problem.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-92. TEST #79 Single-Carrier Cabinet Power Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	There is currently a problem with the environment of the power system. 1. The power unit for any one of the carriers may have been lost. a. Verify and, if necessary, restore AC or DC power units for each carrier. b. Rerun the test. If the test still fails, proceed to Step 2. 2. Either the WP-91153 AC power unit or the 676B DC power unit for one of the carriers could be defective. Refer to the "Removing Power" and "Restoring Power" sections in Chapter 5, "Routine Maintenance Procedures", for instructions on replacing the power unit. a. If the WP-91153 AC power unit or the 676B DC power unit does not have its yellow status LED on, then replace the power unit. b. If the Active Tone-Clock circuit pack loses power, the system performs a Cold-2 restart to finish (the login prompt appears at the administration terminal). c. Rerun the test. If the test still fails, proceed with Step 3. 3. The PR-MAINT (Maintenance/Tape Processor), the DUPINT (Duplication Interface Circuit Pack), or the MAINT (EPN Maintenance Circuit Pack) could be incorrectly reporting this error. Resolve all alarms on these MOs, and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that **are not** detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, follow normal escalation procedures.
	PASS	The PR-MAINT (Maintenance/Tape Processor), the DUPINT (Duplication Interface Circuit Pack), or the MAINT (EPN Maintenance Circuit Pack) has reported no problem with the power.

DETR-BD

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DETR-BD	MINOR	test board PCSS	Tone Detector Circuit Pack
DETR-BD	WARNING	test board PCSS	Tone Detector Circuit Pack

1 Where P is the port network number (1 for PPN, 2 for EPN, and 3 for EPN2); C is the carrier number (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

G1, G3iV1.1-286, and those G3iV2-386 systems that use the Mu-law companding mode use TN748 Tone Detector circuit packs or TN756 combination Tone Detector-Tone-Clock circuit packs. G3iV2-386 systems that use the A-Law companding mode use TN420B (and higher suffixes) Tone Detector circuit packs. The companding mode of the DETR-BD circuit pack must match that administered for the system for proper tone detection. The companding mode is administered on the System-Parameters Country-Options form. Refer to *DEFINITY Communications System Generic 3 Implementation*, 555-230-653.

For all DETR-BD circuit pack level errors, refer to XXX-BD (Common Port Board) Maintenance documentation.

DID-BD (Direct Inward Dial Trunk Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DID-BD	MIN	test board PCSS sh	Direct Inward Dial Trunk Circuit Pack
DID-BD	WRN	test board PCSS sh	Direct Inward Dial Trunk Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or; C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DID-TRK (DID Trunk) Maintenance documentation for related trunk information.

DID-DS1 (DS1 DID Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
DID-DS1	MAJOR[1]	test trunk <grp>/<mbr> l	Direct Inward Dial Trunk
DID-DS1	MINOR	test trunk <grp>/<mbr> l	Direct Inward Dial Trunk
DID-DS1	WARNING	test trunk <grp>/<mbr>	Direct Inward Dial Trunk

1 A major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

The DID-DS1 trunk provides a digital DID trunk from a CO switch into the system through a DS1 link. A 24 channel DS1 link can support up to 24 DID-DS1 trunk calls simultaneously. A 32 channel DS1 link [G3iV2-386] can support up to 30 DID-DS1 trunk calls simultaneously. A DID-DS1 trunk can be used for both voice and data communications with appropriate DS1 signaling mode (for example, common channel signaling). Only the TN767 and TN464 [G3iV2-386] DS1 Interface circuit packs support the DID-DS1 trunk call processing signalings, wink-start, and immediate-start.

DID-DS1 trunk maintenance provides a means to maintain a DID trunk on a port of DS1 Interface circuit pack. Information included covers the in-line errors log, initialization tests, periodic tests, system technician demand tests, and alarms escalation and elimination. Two trunk service states are specified in the DID-DS1 trunk maintenance. They are: *out-of-service*, the trunk is in a deactivated state and can't be used for incoming calls; *in-service*, the trunk is in an activated state and can be used for incoming calls. If the DS1 Interface circuit pack is out-of-service, then all trunks on the DS1 Interface circuit pack are put into out-of-service state and a Warning alarm is raised.

Hardware Error Log Entries and Test to Clear Values

Direct Inward Dial Trunk Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test trunk <grp>/<mbr> sh r 1
1 (a)	Any				
15 (b)	Any	Port Audit and Update Test (#36)			
18 (c)			WARNING	OFF	release trunk <grp>/mbr>

2305(i)	50944	None	MIN/MAJ[6]	OFF	
3840 (j)		Port Audit and Update Test (#36)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

3 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

4 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

5 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

6 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

Notes:

a. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57476, on-hook before wink; 57477, on-hook before ready to receive digits; 57485, wink too short for valid signal. Escalate the error.

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate errors (if any).

c. System Technician has busied out the trunk to out-of-service state. No calls can be made on this trunk.

d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57474, rotary dial rate above 12 pulses per second; 57473, rotary dial rate below eight pulses per second. Escalate the error.

f. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57392, no external release on PBX disconnect. Escalate the error.

g. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57393, belated external release on PBX disconnect. Escalate the error.

h. DS1 Interface circuit pack is out-of-service. Look for DS1-BD errors in Hardware Error Log. Refer to the DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details.

i. Error Type 2305—This error indicates that a signaling change was detected by the PBX trunk circuit pack which is inconsistent with the present state of the trunk.

j. Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back to in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence..

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit and Update Test (#36)		X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-93. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-93. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM BUS error. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM Bus errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-93. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 11-93. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The test failed. This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-PN and/or EXP-INTF errors in the error log. If present, refer to the EXP-PN and the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD and the TONE-PT Maintenance documentation. 4. Retest when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 11-93. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **llst config** command and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passed.

Table 11-94. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-94. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at 1 minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Issue the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-94. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n'. To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 11-94. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSUs) have the correct administration. 6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the 'CARR-POW (carrier port power unit for AC-powered systems) Maintenance Documentation'. To investigate problems with a 645B DC power unit, refer to the 'CARR-POW (carrier port power unit for DC-powered systems) Maintenance Documentation'. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.

Continued on next page

Table 11-94. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring. **NOTE:** This test always passes for TN712 Analog circuit packs prior to Vintage 14 and for TN742 prior to Vintage 4.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Port Audit and Update Test (#36)

This test sends port level translation data from the switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 11-95. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The port may be busy with a valid call. Issue the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1006	ABORT	The test was aborted because the trunk is out of service. 1. Use the **status trunk** command to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. If it is OK to put the trunk back in service, issue the **release trunk** command to put the trunk back in service, and then retry the test. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-95. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate resources to run this test. 1. Retry the command at 1 minute intervals for a maximum of 5 times. If the test continues to abort, escalate the problem
	FAIL	Test failed due to Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.

Continued on next page

Table 11-95. TEST #36 Port Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

DID-TRK (DID Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DID-TRK	MAJOR[2]	test port PCSSpp l	DID Trunk
DID-TRK	MINOR	test port PCSSpp l	DID Trunk
DID-TRK	WARNING	test port PCSSpp l	DID Trunk

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

2 A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

Direct Inward Dial (DID) trunks, coming from the Central Office (CO), allow outside parties to call directly to an extension in the system. DID Trunk circuit packs include:

TN753 [G1, G3iV1.1-286, G3iV2-386]	United States
TN2146 [G3iV2-386]	Belgium and the Netherlands
TN2139 [G3iV2-386]	Italy
TN 436 [G3iV2-386]	Australia
TN459 [G3iV2-386]	United Kingdom

The DID Trunk circuit packs support eight, incoming-only, ports. Each port provides an interface between the 2-wire analog line from the CO and the DEFINITY system. The DID port receives 3 to 5 digits from the CO that is used to directly connect an outside caller to the called station without assistance from an attendant. See Figure 11-28.

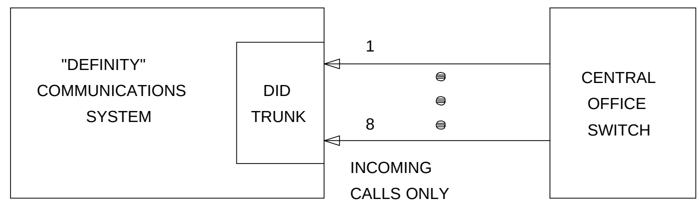

Figure 11-28. DID Trunk Interactions

For each call, the CO switch signals the system by opening and closing individual DID loops (one of the eight ports) and causing the starting or stopping of loop current.

A DID trunk operation involves three significant aspects:

1. Transmission—deals with the interface requirements regarding all AC signals. Transmission includes gain, analog to digital encoding, and digital to analog decoding.
2. Signaling—involves interpretation of DC signals appearing on Tip and Ring to and from the CO. These signals include off-hook, on-hook, and dial pulse detection.
3. Switch Connection—involves the connection between the trunk circuitry and the TDM Bus of the system. It operates the switchhook connection to the TDM Bus.

Four tests are implemented to diagnose the health of a DID trunk. All of them test on-board circuitry only. They are:

1. Loop Around and Conference Circuit Test—verifies the transmission operation of the circuit pack (loop around within the port), and checks the conference capabilities of all ports.

   This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration Test field. (This also disables the port diagnostic test).
2. NPE Crosstalk Test—verifies the switch connection operation of the circuit pack. The test also verifies that the trunk circuitry only talks on the selected time slot on the TDM Bus and never crosses over to time slots reserved for other connections.

3. Port Diagnostic Test—the battery feed circuitry is tested for hook detection.
4. Port Audit Update Test—updates the DID translation information on individual ports of the DID trunk. The port translation data consists of signaling parameters whose values depend on the CO switch connected to the trunk. These parameters include:
   - wink (signal indicating PBX is ready to receive digits) or immediate start
   - dial tone or rotary dialing trunk
   - rotary dialing inter-digit timing
   - network balance R/RC
   - disconnect timing

Additional in-line testing is performed while a call is in progress. Thus, in-line errors may occur during operation. See Error Log table for a description of these errors. These errors may be reproduced by using the trunk (that is, placing a call) and checking their occurrence in the Hardware Error Log.

Problems detected during signaling may be caused by faults off-board (in the CO switch or connections) for which a Warning alarm is raised.

Before a maintenance test can be run on a port, the port must be idle. If an incoming call seizes the port which is being tested by maintenance, the test is aborted, and the incoming call proceeds.

For transmission and signaling standard specification, refer to Digital PBX Standards document RS4648.

Hardware Error Log Entries and Test to Clear Values

DID Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	Any	None	WRN	OFF	
1 (b)	57476	None	WRN	OFF	
1 (c)	57477	None	WRN	OFF	
1 (d)	57483	None	WRN	OFF	
15 (e)	Any	Port Audit Update (#36)			
18	0	busyout trunk <grp/mbr>	WRN	OFF	release trunk <grp/mbr>
130 (f)		None	WRN	ON	test trunk <grp>/<mbr>
257 (g)	57472	None	WRN	OFF	
257 (h)	57473	None	WRN	OFF	
257 (i)	57474	None	WRN	OFF	
257 (j)	57475	None	WRN	OFF	
513 (k)	57392	None	MAJ/MIN/ WRN[2]	OFF

769	Any	Port Diagnostic (#35)	MAJ/MIN/ WRN[3]	ON	test port PCSSpp r 3
1025		Loop Around and Conference (#33)	MAJ/MIN/ WRN[4]	ON	test port PCSSpp r 3
1281		NPE Crosstalk (#6)	MAJ/MIN/ WRN[5]	ON	test port PCSSpp r 3
1537	Any	Port Diagnostic (#35)	MAJ/MIN/ WRN[6]	OFF	test port PCSSpp r 3
1793 (m)	57489	None	None		

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

3 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

4 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

5 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

6 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

A common trouble on DID trunks, which reports no errors or alarms, occurs when the CO busies out the port (disconnects port). This situation occurs when the CO thinks there are problems with the DID port. In this case, no incoming calls are possible through this port. In addition to complaints received from outside callers trying unsuccessfully to call in, this problem can be diagnosed by listing measurements on lightly used trunks. If a particular port is detected as not in use, a call to the CO is necessary to get the connection back in service.

a. This condition occurs when the tone detector times out waiting for digits.

   1 – Verify trunk administered wink/immediate-start parameter.

   2 – Verify the dial type.

   3 – Refer problem to the CO.

b. Rotary dial before wink – This condition occurs when the CO starts dialing before the PBX sends wink on a wink-start trunk. 1 – Verify trunk administered wink/immediate-start parameter.

   2 – Refer problem to CO.

c. Rotary dial too early – This condition occurs when the CO starts dialing too soon after seizure on an immediate-start trunk.

   1 – Verify trunk administered wink/immediate-start parameter.

   2 – Refer problem to CO.

d. Rotary dial pulse during wink – This condition occurs when the CO sends rotary dial digits too soon after seizure on a wink-start trunk.

   1 – Verify trunk administered wink/immediate-start parameter.

   2 – Refer problem to CO.

e. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

f. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

g. Rotary dial pulse on-hook longer than 105 msec – Break between rotary pulses is too long.

   1 – Test trunk by performing an incoming test call.

   2 – Refer problem to CO.

h. Rotary dial rate below eight pulses/sec – More than 135 msec between two successive breaks.

   1 – Verify trunk administered interdigit-timing parameters.

   2 – Refer problem to CO.

i. Rotary dial rate above 12 pulses/sec – Less than 75 msec between two successive breaks.

   1 – Verify trunk administered interdigit-timing parameters.

   2 – Refer problem to CO.

j. Digit detection – Co is starting new rotary dial digit within 150 msec of previous digit.

   1 – Verify trunk administered interdigit timing parameters.

   2 – Refer problem to CO.

k. Loop current active – CO not releasing trunk after PBX disconnect. Occurs when the PBX end drops first and the CO does not release the trunk within four minutes.

   1 – Verify the interface to the network with a hand telephone set. If calls are placed correctly, then refer problem to the CO.

   2 – If unable to place calls or this equipment is not available, check the status on port using the **status trunk** command. If active but not connected, disconnect bridging clips at the network interface. Check status on the trunk. If trunk went idle, then replace clips. If trunk is still active but unable to place calls, refer problem to the CO.

l. Late CO trunk release – This event only happens after the occurrence of Error Type 513. The CO released the trunk four minutes after the PBX dropped the call. This event decrements the severity (error count) of Error Type 513, or may mean the problem related to Error Type 513 has been fixed.

   1 – Verify that Error Type 513 does not occur again. Refer to Error 513.

m. Incomplete Dial timer expired. This error applies only to the TN459. Problem with incoming dialing stream. Refer problem to the CO.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *DID-TRK Loop Around and Conference Circuit Test,* for example, you may also clear errors generated from subsequent tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Port Diagnostic Test (#35)	X	X	ND
Loop Around and Conference Circuit Test (#33)		X	ND
Port Audit Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-96. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is active but the port is not in use (no calls), then check the Error Log for Error Type 513 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-96. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-96. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-96. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails..
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective and non-reflective loop around and conference capabilities of a DID port circuit. The test that uses 404-Hz, 1004-Hz, and 2804-Hz tones is an on-board test only. Each tone is separately transmitted to and from the port (loop around within the port) and verified.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration Test field. (This also disables the port diagnostic test.)

Table 11-97. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is active but the port is not in use (no calls), check the Error Log for Error Type 513 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.

Table 11-97. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook), if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-97. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	System resources required to run this test are not available. This may be due to the port being seized. 1. This abort code is usually associated with tone-clock (TONE-BD, TONE-PT, and TDM-CLK) resources. First, clear any tone errors in the error log. 2. Retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-97. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The nonreflective 1004 Hz tone test of the port failed. An echo was detected from the port. Poor quality transmission was detected to or from the port. The problem may be off-board.
7		The conference capabilities of the port failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
129		The reflective 404-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
131		The reflective 1004-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
133		The reflective 2804-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board. **CAUTION:** *The port may still be operational, or the fault may be off-board (connections or CO). Off-board problems also include incoming seizures or off-hook port seizures during the test and, perhaps somewhat unlikely, noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company to temporarily alleviate the alarm caused by the failure of this test. The test may be disabled from trunk administration 'Test' field. This turns off all testing for that trunk group except for tests 6 and 36.* *More information continues on the next page.*

Continued on next page

Table 11-97. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3 7 129 131 133 *(cont'd.)*	FAIL *(cont'd.)*	FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see note below). 1. To make sure the problem is on-board, disconnect the port from the far-end and retry the test. Coordinate this with the CO, or do it after busy hours. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test in the trunk group administration. If the retry passes and troubles have been reported, coordinate isolation with the CO. **NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see 'FAULT ISOLATION' above.
	PASS	DID Trunk Loop Around and Conference Test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port and refer problem to the CO.

Continued on next page

Table 11-97. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Port Diagnostic Test (#35)

This test checks a port's battery feed circuitry. The battery feed circuitry is tested for on-/off-hook detection, battery shutdown, and battery reversal (WINK) capabilities.

Table 11-98. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required to run this test were not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), then check the error log for error type 513 (refer to the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, busyout and release the trunk, and then retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, check for wiring errors toward the CO which may cause the trunk to lock up. 4. If the wiring is OK and the test continues to abort, replace the TN753.

Continued on next page

Table 11-98. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test has been disabled by trunk group administration. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-98. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
61446	FAIL	Battery feed test failed. A loop current fault was detected. This is most probably an incoming CO-line problem. This failure code is only reported by the TN2139 Italian DID circuit pack. 1. Check the incoming CO-line for loop current. If none is detected refer the problem to the CO. 2. If the CO-line checks out OK, the failure must be on the DID port. Replace the circuit pack.
61456	FAIL	Battery feed test failed. An on-board problem was detected. This port is out-of-service. 1. Replace circuit pack.
61472	FAIL	Battery feed test failed. A problem with the incoming CO-line was detected. 1. Check the incoming CO-line for proper operation. If warranted, refer the problem to the CO. 2. If the CO-line checks out OK, the failure must be on the DID port. Replace the circuit pack.
	PASS	Current flow was detected for this port. 1. User-reported troubles on this port should be investigated using other port tests and by examining connections. 2. Refer problem to the CO.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Port Audit Update Test (#36)

This test sends updates of the DID port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: wink or immediate start trunk, dial tone or rotary dialing trunk, rotary dialing inter-digit timing, Network balance R/RC, and disconnect timing.

Table 11-99. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	The port has been placed out of service, perhaps by craft busyout. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is out of service, then the port is unavailable for certain tests. You must wait until the port is in service and idle before retesting. 1. If the port status is in service and idle, then retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.

Continued on next page

Table 11-99. TEST #36 Port Audit Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	This test passed. Translation information was successfully updated on the circuit pack. 1. If signaling troubles are reported (Error Types 1, 257, or 513 in Error Log table), verify translation information for this port. 2. Refer problem to the CO. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

DIG-BD (Digital Line Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DIG-BD	MIN	test board PCSS sh	Digital Line Circuit Pack
DIG-BD	WRN	test board PCSS sh	Digital Line Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DIG-LINE (Digital Line) Maintenance documentation for related line information.

DIG-LINE (Digital Line)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DIG-LINE	MINOR	test port PCSSpp l	Digital Line
DIG-LINE	WARNING	test port PCSSpp sh	Digital Line

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

DIG-LINE maintenance monitors and tests ports on Digital Line circuit packs and the hardware connected to those ports for lines administered as a digital station. These include stations with just a digital voice terminal and stations with a digital voice terminal and a linked data module. Stand-alone data modules, and data adaptors in stand-alone mode, are covered by the PDMODULE and TDMODULE maintenance objects. Circuit pack-level maintenance is covered by DIG-BD whose strategy is described in the XXX-BD section of this chapter. The following circuit packs support digital lines:

Digital Line Circuit Packs

Code	Ports	Type	Companding	Endpoints
TN413	8	4-wire DCP	A-law	7400 series digital voice terminals, attendant consoles, 510D personal terminals, MT515 BCTs, DCP data modules
TN754	8	4-wire DCP	mu-law	
TN754B	8	4-wire DCP	A-law/mu-law	
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224	24	2-wire IDCP	A-law/mu-law	
TN2136	8	2-Wire IDCP	A-law/mu-law	Data Adaptors (DA), Italtel Digital Telephone Models 1 and 2 (IDT1/2).
TN2177	16	2-wire IDCP	A-law/mu-law	
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224	24	2-wire IDCP	A-law/mu-law	

G3r V1 systems support only TN754 and TN754B. TN413 and TN754 are found only in upgraded cabinets.

Each digital line port supports two 64 kbps information channels (primary and secondary) and one 8kbps signaling channel. Digital voice terminals always use the primary information channel. Thus only one voice terminal can be connected to each port. The secondary information channel can be used to connect a data terminal via a Digital Terminal Data Module (DTDM) or a Data Adaptor (DA). All other devices currently supported by Digital Line circuit packs communicate on the primary information channel. Figure 11-29 shows examples of digital line connectivity.

Only the TN754B or TN2136 should be used in out-of-building applications. For important information pertaining to protection required for out-of-building digital voice terminals, see *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test,* 555-230-104.

It should be noted that TN2181 and TN2224 supports both modes as shown in Figure 11-29 and Figure 11-30.

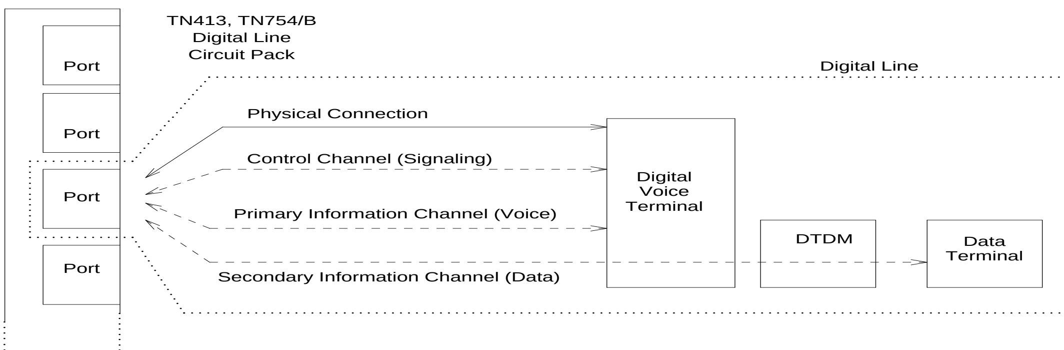

Figure 11-29. Digital Line Connectivity

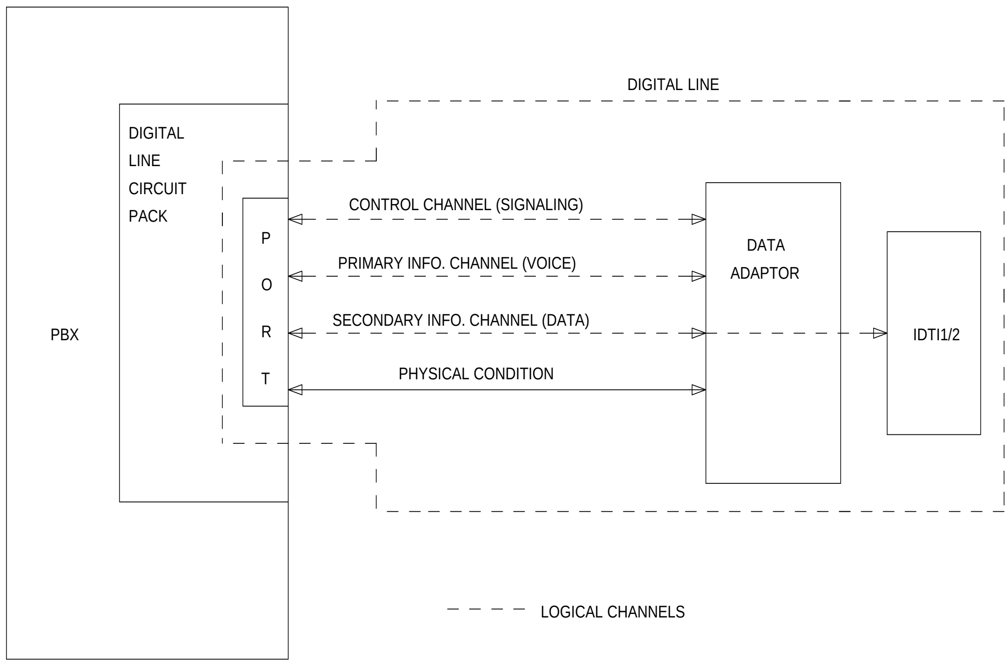

Figure 11-30. Digital Line Connectivity

Only 2-wire Italtel Digital Telephone Models 1 and 2 (IDT1/2) or DAs can be directly connected to a TN2136. AT&T DCP (4-wire) digital voice terminals and data modules can be connected to these circuit packs via Italtel's 2/4-wire adapter. DAs can operate in either of two modes which are covered by different maintenance objects:

DA Mode	Administered as:	Endpoint	Maintenance Object
Stand-alone	PDM	Data endpoint only	PDMODULE
Linked	DTDM	IDT1/2 and optional data terminal	DIG-LINE

Digital Line maintenance interacts with Digital Line circuit pack (DIG-BD) maintenance, and results of DIG-LINE testing can be affected by the health of the Digital Line circuit pack. Keep this in mind when investigating reported Digital Line problems.

There are instances where the service state of a station is mentioned. It is helpful to understand what os ment by the different service states that may exist. The different service states which apply to digital line station are explained as follows.:

Out-of-Service	The port, and thus the station, have been removed from service. Busyouts put the port in the out-of-service state.
Ready-for-Service	The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally. It can also be forced into the in-service state by going off-hook.

Downloading of Terminal Parameters

Programmable Terminals

The following information is presented as background information to help understand how maintenance software interacts with terminal parameter downloading.

Terminal Types:

The following terminals can be downloaded for Definity G3V3 and later versions:

a. 84xx multibutton digital voice terminals (8403D01A, 8410B, 8410D02A, 8434D01A) with optional expansion module.

b. 603A1 and 603D1 Callmaster terminals for telemarketing applications.

c. 302B1 attendant console.

Circuit Packs:

1. 8400x, 302B1 Terminals
   - a. TN754 (4-wire, Mu-law)

     Minimum usable vintage for 8410D and 8434D terminals - V11
   - b. TN413 (4-wire, A-law)
   - c. TN754B (4-wire, A-law/Mu-law selectable)
   - d. TN2177 (2-wire, 16-port, A-law/Mu-law selectable)
   - e. TN2181 (2-wire, 16-port, A-law/Mu-law selectable)
   - f. TN2224 (2-wire, 24-port, A-law/mu-law selectable)

2. 603A1/D1 Terminals
    a. TN754 (4-wire, Mu-law),
    b. TN413 (4-wire, A-law)
    c. TN754B (4-wire, A-law/Mu-law selectable)

Downloadable Terminal Parameters

The following parameters are downloaded to programmable terminals:

DOWNLOADABLE PARAMETERS

Parameter	Scope	Terminal
International Flags (A-law/Mu-law, Display Mode, DLI Voltage level)	System level	84xx, 603x, 302B1
Primary Levels (Transmission & Sidetone)	System level	84xx, 603x, 302B1
Adjunct Levels (Transmission & Sidetone)	System level	84xx
Handset Expander Option	System level	84xx
Administrable Options (Speakerphone & Mute Button)	Per-terminal	84xx
Administrable Softkeys	Per-terminal, System level	8410D, 8434D

Nonvolatile Memory

Nonvolatile memory is used to store downloadable parameters in programmable terminals. Therefore, once the terminal has been downloaded, it is not be necessary to download it again, even if power is removed from the terminal.

If the nonvolatile memory fails with power still present, the terminal will revert to its default factory settings except for its A-law/Mu-law companding settings which are stored in RAM. If power is removed after the nonvolatile memory fails, the terminal will revert to its factory default settings.

Mu-law companding is assigned as a default setting at the factory, so, for domestic use, a programmable terminal can place calls even though it has not been downloaded from the PBX.

Download Actions

There are several different scenarios which will cause a terminal to be downloaded. As described below, these can occur as part of background maintenance activity or on demand from the System Access Terminal or from a station.

For the background actions described below, the terminal will be downloaded automatically if a download retry flag for the terminal is set in software. This flag is set at the time translation is loaded at boot time, when translation which affects the parameters of a terminal is changed as part of system administration actions, and when a port is inserted in software as a result of board insertion or translation change.

Automatic Download Actions

1. System Reboot/Restart

   A global download action is started when periodic maintenance tests start after a system reboot/restart regardless of whether the parameters have been downloaded previously.

2. Periodic Tests

   If the download flag is still set when periodic tests are run on a terminal, a download action will occur. This operation is required in case a terminal could not be downloaded previously because it was off-hook at the time the system first booted or because the terminal was off-hook at the time translation associated with downloadable parameters was changed.

   Note that it may take more than an hour for periodic tests to reach the terminal that needs to be downloaded.

3. Terminal Administration

   A downloadable terminal is automatically downloaded when translation changes associated with downloadable parameters are made as part of system administration. As shown in Table 11-100, these changes can be for a specified terminal or may be system-wide. If the change is for system-level parameter, a background global update request is made to download all programmable terminals.

   This global update may take more than an hour for a system with several thousand programmable terminals.

4. Port Insertion

   Whenever maintenance software initiates a request to place a port into service, a terminal download action is started on that terminal if that terminal is programmable. This port insertion action occurs under the following circumstances:

   a. A digital line circuit pack that is physically inserted into the system has ports currently administered for programmable terminals.

If more than 20 port insertion requests are received within a few seconds, a global download request is started up as a background task. This action updates all programmable terminals instead of just those being inserted. This is done to avoid system overload for situations where there is massive board insertion. This could occur when connectivity to an EPN is reestablished after that EPN was down.

b. A station port is added to the system by a "**add station**" or "**change station**" command.

c. A TTI port is activated.

5. Audits

   As part of periodic maintenance, the hardware status audit test queries programmable terminals to determine which levels and/or options are being used. If the reported values are not equal to the administered values, the system will initiate a terminal download action. This audit does NOT check the parameters used for softkeys.

6. Activation of TTI

   A terminal is downloaded automatically when it is activated using the Terminal Translation Initialization feature. Therefore, no special user actions are required for TTI.

   NOTE:
   Plugging the station cord into a terminal does not automatically cause the terminal to be downloaded. If this terminal has factory defaults or if the terminal has been previously downloaded with parameters different than those desired, use one of the demand download actions described below to download the terminal.

Demand Download Actions

1. Busyout/Release Command

   A maintenance demand busyout/release request for a station will cause the terminal to be downloaded regardless of its previous download status.

2. Feature Access Code

   A Refresh Terminal Parameters Feature Access Code can be used to request a terminal download action. When this code is followed by a "#", the programmable parameters for the current terminal are downloaded when the terminal goes on hook. When this code is followed by an extension, the programmable parameters for the specified station are downloaded.

   This Refresh Terminal Parameters Feature Access Code is assigned on the second page of the "feature-access-codes" screen.

A confirmation is returned if the download request is accepted. A busy tone is returned if the request is made from a different station when the target station is off-hook.

The first three green call appearance LEDs on the 84xx 603x terminal will be turned on for three seconds if the station was successfully downloaded as a result of an entry of a Refresh Terminal Parameters Facility Access Code. This is not true for the 302B1 terminal.

There is no visible display on a station for the other background or demand download actions. As described below, the "status station" and "status attendant" screens can be used to check the download status of a specified terminal.

Status of Parameter Downloads

The "status station" and "status attendant" screens display the current download status of individual 84xx, 603, and 301B1 terminals in the Download Status field. The possible download states are:

Table 11-100. Terminal Download Status

Status	Terminal Down Load State
Complete	Terminal successfully downloaded sometime in the past.
Pending	System waiting to download the terminal. This may require the execution of a background periodic test which could take more than an hour. A demand download as described above may also be used to initiate an immediate download.
Not Applicable	Not a programmable terminal.

Possible reasons for terminal being not downloaded include:

— Terminal is off-hook.

— Terminal detected a bad checksum.

— Terminal detected a bad or missing EEPROM (refer to hardware error log).

— Terminal is busy programming data from a previous PROGRAM message.

— Terminal is in the Programming Disabled state.

— Terminal is in the Local Program Options Mode.

— Terminal is disconnected or out of service (use **status station** command).

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

3 Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

b. This Error Type and Aux Data will occur when at least 15 off-board problems have been detected with the link to the terminal. When an error with the link is detected, an on-board counter is incremented.

   The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

c. This error type is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout via the **release port UUCSS pp/PCSSpp** command.

d. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

e. Problems transmitting to the voice terminal. This problem can be caused by defective wiring. Defective wiring can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than other sets. This is usually an on-board problem and can be ignored if no user complaints are received.

f. This is an in-line event that produces this error type when a favorable response is received from running the Digital Line Electronic Power Feed Test (#11). No craft action is necessary. This alarm will be resolved with the passing of time.

g. With Aux Data 40963, this error type is a result of an unfavorable response to the Electronic Power Feed/ Positive Temperature Coefficient Test (#11). With Aux Data 40988, this error type indicates that the EPF/PTC circuit has been turned off due to an overcurrent condition.

   For TN754 vintage 13 or earlier and TN413, the EPF circuit senses an overcurrent condition at the voice terminal. Check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

   For TN754 vintage 14 or later, TN754B and TN2136, the PTC will open if there is a short on the power line for 1/2 second or longer. The voice terminal is probably not operating properly. Unplug the voice terminal for

30 seconds and then plug it back in. If the voice terminal still does not operate, then check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

Once the problem has been resolved, it may take up to 1 hour for the alarm to clear due to “leaky bucket” strategy. If the problem cannot be resolved by one of the steps above, then replace the circuit pack.

h. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

i. This indicates that the station went off-hook while it was in the ready-for-service state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No craft action is necessary.

j. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No craft action is necessary.

k. No terminal is connected to the Digital Line board. No maintenance action is required.

l. An uplink message has been logged indicating that the Electric Power Feed (EPF) is on with no load on it. No action is necessary.

m. The circuit pack’s message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.

n. Internal system error. No action is necessary.

o. There is a problem with the voice terminal EEPROM. When the voice terminal is repaired the alarm will be resolved with the passing of time.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Voice and Control Channel Local Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Terminal Remote Loop Around Test (#1201)		X	D
Voice and Control Channel Local Loop Around Test (#13)		X	ND
Digital Line NPE Crosstalk Test (#9)		X	ND
Digital Line Electronic Power Feed Test (#11)		X	ND
DIG-LINE Station Lamp Updates Test (#16)	X	X	ND
Station (Digital) Audits Test (#17)	X	X	ND

1 D = Destructive; ND = Nondestructive

Digital Terminal Remote Loop Around Test (#1201)

This test checks the integrity of the connection between the SPE and the attached Digital Terminal and the ability of the terminal and the associated port to send and receive data. This test is based, in principal, on procedure 622 used in system 85 to help isolate digital terminal problems.

A request is presented to the terminal to go into loop back mode. Then data is sent to the terminal and when received back, checked for consistency. This test is run as a part of the craft command "test long" procedure. It is not included in any error recovery strategy and generates no Error Log entries or alarms. To begin the test, Maintenance will ask Call Processing to make the associated end point and port " Maintenance Busy". This test will succeed if the endpoint is "idle". If the reserve request fails then the test will abort. If the request succeeds then the SPE sends a message to loop around both information channels for the digital terminal. First the primary information (voice, Information Channel 1 or I1) channel loop back test is run. The test is performed by sending a digital count from the Tone/Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose tone detector.

If the primary information channel test is successful, the loop around test for the secondary information (data, Information Channel 2 or I2) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered, which is also the case for a linked DA.

Only one value (Pass. Fail, or Abort) is generated as a result of the two tests run. If any test fails aborts, the sequence is stopped. Upon completion of this test the associated endpoint and port are moved back into the previous service state.

Table 11-101. TEST #1201 Digital Terminal Remote Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port**UUCSSpp/PCSSpp command to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain test. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before re-testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-101. TEST #1201 Digital Terminal Remote Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Look for TTR-LEV errors in the Error Log. If present refer to TTR-LEV (TTR-Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exist, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port**UUCSSpp command to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain test. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before resetting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The installed circuit pack does not support this operation.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-101. TEST #1201 Digital Terminal Remote Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	System resources required to run this test are not available. 1. Make sure terminal is connected and repeat test. 2. If the test continues to abort, escalate the problem. 3. If test fails replace terminal and repeat test. 4. Retry the command at 1-minute intervals a maximum of 5 times.
14	FAIL	The primary channel (voice, Information Channel 1 or I1) is not operating properly. User impact may range from noticing nothing to not being able to use the port. Check the results of "Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both test fail, and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using the **test board** UUCSS s command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit pack are functioning properly, and the tests still fail, escalate the problem. (*(Continued)*

Continued on next page

Table 11-101. TEST #1201 Digital Terminal Remote Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the station is/has not been busied out. Busy out the station with the /E3busyout station/E1 command.
16	FAIL	The secondary channel (data Information Channel 2 or I2 is not operating properly. User impact may range from noticing nothing to not being able to use this terminal. Check the results of "Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both test fail, and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using the **test board** UUCSS s command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit pack are functioning properly, and the tests still fail, escalate the problem.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of ten times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice. corrupted data transfer for data), examine the station, connections, and wiring.

Digital Line NPE Crosstalk Test (#9)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. Crosstalk testing is performed on both the primary information channel (voice) and the secondary information channel (data) associated with each digital station port. If this test fails on either channel, the station and the DTDM are taken out-of-service.

Table 11-102. TEST #9 Digital Line NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. Use the **display port** UUCSSpp command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for this test. You will have to wait until the port is idle. 2. If the port status is idle, then retry the command a 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
2	ABORT	During testing of DTDM, system resources may not have been available. Also, the port may have been busy during the test. 1. Check if port is being used. If possible, disconnect by toggling disconnect button on DTDM. Retry command after 1 minute. **WARNING:** *This action will drop the call in progress.* 2. If the test continues to abort after 5 attempts, escalate the problem.

Table 11-102. TEST #9 Digital Line NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 2	FAIL	The Network Processing Element (NPE) of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints persist, examine the station, connections, and wiring.

Continued on next page

Digital Line Electronic Power Feed/Positive Temperature Coefficient/PPF Test(#11)

For TN413, and TN754 vintage 13 or earlier, this is an Electronic Power Feed (EPF) restoral test. In this test, the processor requests that the EPF be turned on for a given port, and an attempt is made to turn on the power supply to the station. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed, there may be a short in the loop. A message is returned reporting that either the EPF was successfully turned on, or that an overcurrent condition was sensed. This test is repeated again 5 seconds later.

For TN754 vintage 14 or later, TN754B and TN2136 this is a Positive Temperature Coefficient (PTC) restoral test. In this test, the processor requests that the PTC be turned on for a given port, and an attempt is made to turn on the power supply to the station. If an overcurrent condition is sensed, there is probably a short on the power line that causing the PTC to open and disconnect the voice terminal. Since the PTC does not have self-restoral capability, the voice terminal must be manually unplugged for 30 seconds and then plugged back in to restore the PTC. A message is returned reporting that either the PTC was successfully turned on successfully with no problem or an overcurrent condition was sensed. This test is repeated again 5 seconds later.

TN2181 and TN2224 boards carry a Protected Power Feed (PPF) relays, one for each port. Therefore this will be a Protected Power Feed restoral test. The test procedure and its response is same as that of EPF. One of differences between EFP and PPF is that, if the port goes into a overcurrent state, PPF does not report this change of state because it is a transient state which will not last more than 50ms. If the over current persists the power will be shut off automatically and an EPF_off_overcurrent message is sent uplink.

Table 11-103. TEST #11 Digital Line Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use **display port** UUCSSpp/PCSSpp to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-103. TEST #11 Digital Line Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Electronic Power Feed Test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test will never actually return a FAIL result except for the **Internal System Error** described above, it will log an error indicating the real results of the test. Check the Error Log for any entries with Error Types 767 or 769 after the test completes. 2. If Error Type 767 appears in the Error Log, this should indicate that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating. 3. If Error Type 769 appears in the Error Log, this indicates some problem with the power to the station. Check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.

Voice and Control Channel Local Loop Test (#13)

These tests check the information and control channels between the Switch Processing Element (SPE) and the Digital Line port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loop back test is run. The test is performed by sending a digital count from the Tone-Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose Tone Detector.

While the primary information channel is still looped around, the Control Channel Loop Around Test is performed. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.

The Loop Around Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered.

A Conference Test is done next for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of four tests run. If any test fails or aborts, the sequence is stopped.

Table 11-104. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use **display port** UUCSSpp/PCSSpp to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-104. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use **display port** UUCSSpp/PCSSpp to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.

Continued on next page

Table 11-104. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Rerun the test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
7	FAIL	Conference Test failed on primary channel. In some cases, users may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.

Continued on next page

Table 11-104. TEST #13 Voice and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
15	FAIL	The control channel between the processor and digital circuit pack is not transmitting properly. User impact may range from noticing nothing to not being able to use the port. Could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the **test board UUCSS s/PCSS s** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice, corrupted data for data transfer), examine the station, connections, and wiring.

DIG-LINE Station Lamp Updates Test (#16)

This test lights all lamps on the terminal as specified. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

Table 11-105. TEST #16 DIG-LINE Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
3	ABORT	Station may be in ready-for-service or out-of-service state. 1. Use **status station** command to verify state of station. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-105. TEST #16 DIG-LINE Station Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use **display port** UUCSSpp/PCSSpp to determine the station extension or attendant number of the port. Use **status station** or **status attendant** to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-105. TEST #16 DIG-LINE Station Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicates that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	The message to light all of the station lamps was sent successfully to the port. 1. Observe the station lamps being lit when running the test. If all lamps do not light successfully, the other Digital Line test results may indicate related problems that will not allow the lamps to light. 2. Investigate by using other Digital Line port tests, and by examining the station, wiring, and connections.

Digital Station Audits Test (#17)

This is a series of six tests which are classified as audits. The SPE sends messages to the on-board microprocessor to perform the following tests. These audits run only if the station is in-service.

- Switchhook Inquiry Test — This is an update of the SPE records according to the circuit pack's records. This inquiry is sent all the way to the voice terminal.
- Bad Scan Inquiry Test — A message is sent uplink which contains a count that is generated due to certain events relating to the link conditions. This can be an indication of communications problems between the Processor and Digital Port circuit pack.
- EPF/PTC Inquiry Test — For a TN413 or a TN754 vintage 13 or earlier, the status of the Electronic Power Feed (EPF) is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, and EPF-no-load. For TN754 vintage 14 or later, TN754B or TN2136, TN2181, TN2224, the status of the Positive Temperature Coefficient (PTC) is sent uplink. Possible conditions are: PTC-on-ok, PTC-off, and PTC-no-load.
- ID Request Test — A request is made to the station for its status. The station sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update Test — This updates the digital telephone ringer state according to the processor records.
- DTMF Administration Update Test — This is a message to the digital station to refresh the default value which causes the station to send touch-tones only in the primary information channel. This value is set initially when the station is put in-service and every time the station's state changes from other states to in-service.

Table 11-106. TEST #17 Station (Digital) Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out.
2	ABORT	ID request fails, health bit returned from voice terminal is bad. 1. Make sure voice terminal is connected and repeat test. 2. If test fails, replace voice terminal and repeat test. 3. If the test continues to abort, escalate the problem.
3	ABORT	The EPF/PTC has detected an overcurrent condition. 1. For a TN754 vintage 13 or earlier Digital Line circuit pack, issue the **test** UUCSSpp/PCSSpp **long** command. If Test #11 passes, then the EPF/PTC condition has been cleared. Rerun the Short Test Sequence. If Test #11 does not pass, follow the repair procedures described for Test #11. 2. Look for Error Type 769 logged against DIG-LINE and follow the procedures in the associated footnote. If any additional problems are found after completion of maintenance procedures, rerun the test. 3. If the test continues to abort, escalate the problem.
4	ABORT	Internal System Error 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
5	ABORT	Ringer update aborted due to station being in ready-for-service or out-of-service state.

Continued on next page

Table 11-106. TEST #17 Station (Digital) Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
6	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, the release the port via the **release station** 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the **display port** command (the display shows that the port is a TTI port) or the **list config** command (the display shows a `t` for the port). 2. If either **list config** or **display port** indicate that the port is *not* a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	Station Audits passed. This Digital Port circuit pack is functioning properly. 1. If complaints persist, investigate by using other port tests, and by examining the station, wiring, and connections.

DIOD-DS1 (DS1 DIOD Trunk)

MO Name As It Appears In Alarm Log	Alarm Level	Initial System Technician Command To Run	Full Name of MO
DIOD-DS1	MAJOR[1]	test trunk *group# member#* l	DS1 DIOD Trunk
DIOD-DS1	MINOR	test trunk *group# member#* l	DS1 DIOD Trunk
DIOD-DS1	WARNING	test trunk *group# member#*	DS1 DIOD Trunk

1 A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. For more information on the **set options** command, see Chapter 10, "Maintenance Commands and Trouble-Clearing Aids".

NOTE:
Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 DIOD trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link
- 32-channel mode is supported only on TN464 circuit packs and on G3r V2 systems.

The DS1-DIOD maintenance object monitors and maintains a DIOD trunk port on a TN464 UDS1 Interface circuit pack. See UDS1-BD in this chapter for more information about this circuit pack. The DS1 circuit pack supports low level CO trunk signaling interfaces for both ground-start and loop-start trunks. This maintenance strategy covers the in-line errors log, initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution and escalation.

Three trunk service states are specified by DS1 DIOD trunk maintenance:

out-of-service	The trunk is in a deactivated state and cannot be used for either incoming or outgoing calls.
in-service	The trunk is in an activated state and can be used for both incoming and outgoing calls.
disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

Hardware Error Log Entries and Test to Clear Values

DS1 DIOD Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value

Continued on next page

DS1 DIOD Trunk Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2562(l)	16665				
2817(m)	52992				
3840(n)		Port Audit and Update Test (#36)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

3 Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

a. Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.

   Aux Data 57476—Rotary Dial before Wink.

   Aux Data 57477—Rotary Dial pulse too early.

   Aux Data 57485—Wink too short for a valid signal.

   Aux Data 57487—PBX could not get ‘‘loop close’’ signal.

   The DS1 Interface circuit pack detected a hardware fault. These errors will cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as ‘‘disconnected’’ by the status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow the procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—System Technician has busied out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to "Facility Test Calls" section in Chapter 5, "Routine Maintenance Procedures".

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect. Escalate the problem.

f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect. Escalate the problem.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring. Escalate the error.

h. The DS1Interface circuit pack detects a hardware fault, and the Aux Data field contains the following error type: 51200, port is unavailable. Run the Dial Tone Test (#314) and follow procedures.

i. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for UDS1-BD errors in the Hardware Error Log if the port is on a TN464 UDS1 board. Refer to the UDS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details

j. Error Type 2049—With the following Aux Data:

    Aux Data 57473—Rotary dial rate below 8 pulses per second.

    Aux Data 57474—Rotary dial rate above 12 pulses per second.

    Aux Data 57475—Rotary Dial interdigit time is too short.

   The DS1 interface circuit pack detects a hardware error on the DS1 DIOD trunk. The trunk can not communicate with the far-end because it is unable to interpret digits sent from the far-end switch. Check with the far-end switch or Operating Company for proper trunk connection.

k. Error Type 2305—Recorder message, trunk could not be seized (Aux Data 50944). Run Test #314 and follow the outlined procedures.

l. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

m. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.

n. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 Dial Tone Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) resides on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-107. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-107. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. Refer to the TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. The **list measurements tone-receiver** command will display information on the system's tone receivers. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.

Continued on next page

Table 11-107. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 11-108. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. This only applies to analog stations. 1. To enable test, set the Test field on the station administration screen for the particular analog station being tested to "y." Use the **change station extension** command.

Continued on next page

Table 11-108. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 Interface circuit pack and in the switch software.

Table 11-109. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter the **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to step 2. 2. Enter the **release trunk** command to put the trunk back into in-service. 3. Retry the test command.

DS1 CO Dial Tone Seizure Test (#314)

DS1 CO Dial Tone Seizure Test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a ‘‘seizure’’ message to the DS1 Interface circuit pack and expects an ‘‘active’’ reply from the DS1 interface circuit pack. If the ‘‘active’’ message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a ‘‘reorder’’ message back to maintenance software, then the test fails.

This test cannot be run on a trunk in any of the following conditions:

a. The trunk direction is administered as an incoming only trunk.

b. The trunk has been seized by a normal trunk call.

c. The trunk is administered with maintenance test disabled.

Table 11-110. TEST #314 DS1 CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status trunk** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Look at the trunk group administration form and see whether the trunk is incoming only, port 24 on a DS1 Interface with common control channel signaling, or an automatic CO type such as FX. Under any of these conditions this is a normal abort.

Continued on next page

Table 11-110. TEST #314 DS1 CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Test has been disabled via administration. 1. Verify that the ‘‘Maintenance Tests’’ field on the Trunk Group Form is set to ‘‘n.’’ To enable the test, issue the **change trunk-group x** command where ‘‘x’’ equals the number of the trunk group to be tested. Then change the entry in the ‘‘Maintenance Tests’’ field on the form to ‘‘y.’’ 2. Repeat the test.
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for UDS1-BD errors in the Hardware Error Log. If present, refer to the UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: ■ 1281—Loss of signal ■ 1793—Blue Alarm ■ 2049—Red Alarm ■ 2305—Yellow Alarm ■ 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 11-110. TEST #314 DS1 CO Dial Tone Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The trunk cannot be seized for an outgoing call. 1. Verify that the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for UDS1-BD errors in Hardware Error Log. If present, refer to the UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 3. Retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
	PASS	The trunk can be seized for an outgoing call.

DIOD-TRK (DIOD Trunk), DIOD-BD (DIOD Circuit Pack) [G1.2SE]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DIOD-BD[2]	MINOR	test port PCSS s	DIOD Circuit Pack

1 Where P is the port network number (1 for PPN, 2 for EPN, and 3 for the second EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.)

2 Where **1** is Long, **s** is Short, and **r** is repeat. Refer to the XXX-BD (Common Port Board) Maintenance Documentation.

DIOD-TRK (DIOD Trunk) [G1.2SE]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DIOD-TRK	MAJOR[2]	test port PCSSpp l	DIOD Trunk
DIOD-TRK	MINOR	test port PCSSpp l	DIOD Trunk
DIOD-TRK	WARNING	test port PCSSpp l	DIOD Trunk

1 Where P is the port network number (1 for PPN, 2 for EPN, and 3 for the second EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.).

2 A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

Direct Inward and Outward Dial (TN429 DIOD) trunks are 2-wire analog lines to the CO which support the following services:

- both incoming and outgoing CO calls
- DID trunk
- DID Trunk and 1-way Outgoing DIOD

The DIOD Trunk circuit pack provides eight ports for loop-start CO. The circuit pack is an interface between the 2-wire analog line from the CO and the system's (4-wire) TDM Bus.

LOOP START OPERATION

Idle State - Tip = ground, Ring = CO Battery

A. Outgoing Call

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop
   a. CO Response: DC loop current + Dial tone
2. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
   a. CO Response: CO goes to idle state (see Note)

B. Incoming Call

1. CO Applies Ringing Voltage
   a. PBX Response: Detect ringing current

2. PBX Off-Hook (Answer Message): Close loop
    a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
    a. CO Response: CO goes to idle state (see Note)

C. Direct Inward Dialing (DID)

1. CO Applies Ringing Voltage
    a. PBX Response: Detect ringing current and close loop
    b. CO Response: Send DTMF digits
    c. PBX Response: Acknowledge of Number dialed and open loop
2. PBX Off-Hook (Answer Message): Close loop
    a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
    a. CO Response: CO goes to idle state (see Note)

NOTE:
CO does not normally provide an On-Hook (Disconnect) signal.

Hardware Error Log Entries and Test to Clear Values

DIOD Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
15 (b)	any	Port Audit Update Test (#36)			
18	0	busyout trunk <grp>/<mbr>			
769 (a)	57392	None	MAJ/MIN/ WRN[2]	ON	
1537		Dial Tone Test (#0)	MAJ/MIN/ WRN[2]	ON	test port PCSS l r 2
1793		Loop Around and Conference Test (#33)	MAJ/MIN/ WRN[2]	ON	test port PCSS l r 3
2049		NPE Cross Talk Test (#6)	MAJ/MIN/ WRN[2]	ON	test port PCSS l r 3
2561 (a,d)	57345	None			
2817 (a,e)	57393	None			
3073 (a,c)	57376	None			
3073 (a,c)	57424	None			
3585 (a,c)	57424	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

a. These are in-line errors that have no specific test associated with them. Refer to the following table for an explanation and appropriate action.

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

c. Aux data 57376 - No loop current on incoming call

   Aux data 57424 - No loop current on outgoing call

   These errors cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 also shows up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its outlined procedures.

d. Single polarity ringing current - This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. This error code is only logged as an informational event and causes no other testing to occur.

e. Late CO Trunk release - This error indicates that the CO releases the trunk at least four minutes after the PBX dropped the call. This error code is only logged as an informational event and causes no other testing to occur.

Table 11-111. DIOD Trunk Errors with NO Tests

Error Type	Aux Data	Description and System Action	System Technician Action
769	57392	CO not releasing after call is dropped from PBX end (TN747B), or the loop is not open after a disconnect (TN765). After several occurrences, an off-board (TN747B) or on-board (TN465) warning alarm is generated.	Refer problem to CO.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) The other cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test also fails.	Check for other errors.

Continued on next page

Table 11-111. DIOD Trunk Errors with NO Tests — *Continued*

Error Type	Aux Data	Description and System Action	System Technician Action
2817	57393	CO released the trunk at least four minutes after the PBX dropped the call. This error code is log only and causes no other testing to occur. No alarm is generated.	Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail.	Check for other errors.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected.	See Note at end of table.

NOTE:
At the administration terminal, busyout the affected port, and run a Long test. If Dial Tone Test #0 passes, ignore this error. Release the port.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
Loop Around and Conference Test (#33)		X	ND
Audit Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 11-112. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the command **display port PCSSpp** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-112. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
1005	ABORT	Trunk has been administered as incoming-only; or DID trunk group type; dial tone can only be obtained on outgoing trunks. This is a normal condition.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Check for errors on TONE-BD or TONE-PT. Clear any errors found and repeat test. 2. If error has still not cleared, refer problem to CO.

Continued on next page

Table 11-112. TEST #0 Dial Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 2. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test. 3. If replacing circuit pack does not clear failure, escalate the problem.
1009	PASS	Detected tone was not pure dial tone. No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port’s NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port’s long test sequence and takes approximately 20 to 30 seconds to complete.

Table 11-113. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-113. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-113. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop and conference abilities of a CO port circuit. The test uses 404 Hz, 1004 Hz, and 2804 Hz tones. Each tone is transmitted separately through the loop and checked.

Table 11-114. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test.
7	ABORT	Conference Circuit Test aborted.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status trunk** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-114. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	1. Check for errors on TONE-BD or TONE-PT. If there are errors, take the appropriate actions. 2. If the Reflective Loop Around Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, check the circuit pack for a red LED. If the red LED is on, then replace the appropriate power unit circuit pack. If neither the TN736 nor the TN752 power unit circuit pack is present, then the OLS631DB AC power unit may be defective. The system may contain a TN736 or TN752 power unit circuit pack OR an OLS631DB AC power unit, BUT NOT BOTH TYPES OF POWER UNITS. **NOTE:** To investigate problems with an OLD631DB AC power source, refer to CARR-POW Maintenance documentation. 3. Rerun the test. 4. If the test fails again, replace the circuit pack.
	PASS	CO Trunk Loop Around and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack which have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 11-115. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.

DS1-BD (DS1 Interface Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
DS1-BD	MAJOR	test board PCSS sh	DS1 Interface Circuit Pack
DS1-BD	MINOR	test board PCSS l	DS1 Interface Circuit Pack
DS1-BD	WARNING	test board PCSS sh	DS1 Interface Circuit Pack

The DS1 Interface circuit pack provides an interface to the DS1 facility and is designed to support 24 DS0 channels based on a 1.544 link. These DS0 channels can be administered either as trunks to other switches or as lines to off-premises stations. The functions and maintenance strategy for the TN464 circuit packs are covered under a separate maintenance object, *UDS1-BD*.

Circuit Pack Number	24 Channel	32 Channel	Tie Trunk Signaling	CO Trunk Signaling	DID Trunk Signaling	OPS Line Signaling
TN722	x		x			
TN722B	x		x			
TN767/B/C/D/E	x		x	x	x	x
TN464B		x	x	x	x	
TN464C/D/E/F	x	x	x	x	x	x (24 channel only)

ISDN-PRI Trunk signaling (for example, Q.921, Q.931) is provided by the TN765 Processor Interface circuit pack and system software instead of by the DS1 Interface circuit pack.

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack form. The *Bit Rate* is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. The *Country Protocol* selected is used to drive layer 3 protocol decisions based on PRI specifications specific to a given country (but not on those that are relevant to specific features). This Country Protocol is independent of the *Country* parameter administered on the *System-parameters Country-options* form. Different DS1 circuit packs may be administered with different Country Protocols, thus allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations, (for instance, between two different countries). G3iV1.1-286 systems use country protocol 1. For details, see *DEFINITY Communications System Generic 3 Implementation*, 555-230-653. See *DS1/CEPT1/ISDN-PRI Reference*, 555-025-101, for more information on ISDN.

The DS1-BD maintenance strategy covers logging the in-line errors reported by the DS1 Interface circuit pack, running tests for error diagnosis and recovery, and raising or clearing maintenance alarms. The signaling over the DS1 link has to be synchronized between the transmitting and receiving ends to ensure error-free communication. Refer to SYNC (Synchronization) Maintenance documentation for details. Each trunk and line have its own maintenance strategies. However, all strategies depend on the health of the DS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1 documentation for DS1 Tie Trunk, CO-DS1 documentation for DS1 CO Trunk, DID-DS1 documentation for DS1 DID Trunk, OPS-LINE documentation for DS1 OPS Line, ISDN-TRK documentation for DS1 ISDN Trunk, and ISDN-LNK documentation for ISDN-PRI Signaling Link Port.

The TN464E/F and TN767D/E circuit packs combined with AT&T's new 120A1 CSU Module forms an Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN767E hardware and firmware, and new switch software, provides functionality equivalent to an external, stand-alone AT&T ESF T1 CSU. The 120A1 CSU Module connects to the TN767E circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module thus becomes an integrated part of the DEFINITY system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A 1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation, 555-230-193, Issue 1, December 1993*.

The TN767E and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN767E circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this DS1-BD section, but Figure 11-31 gives a high-level overview of the loopback points.

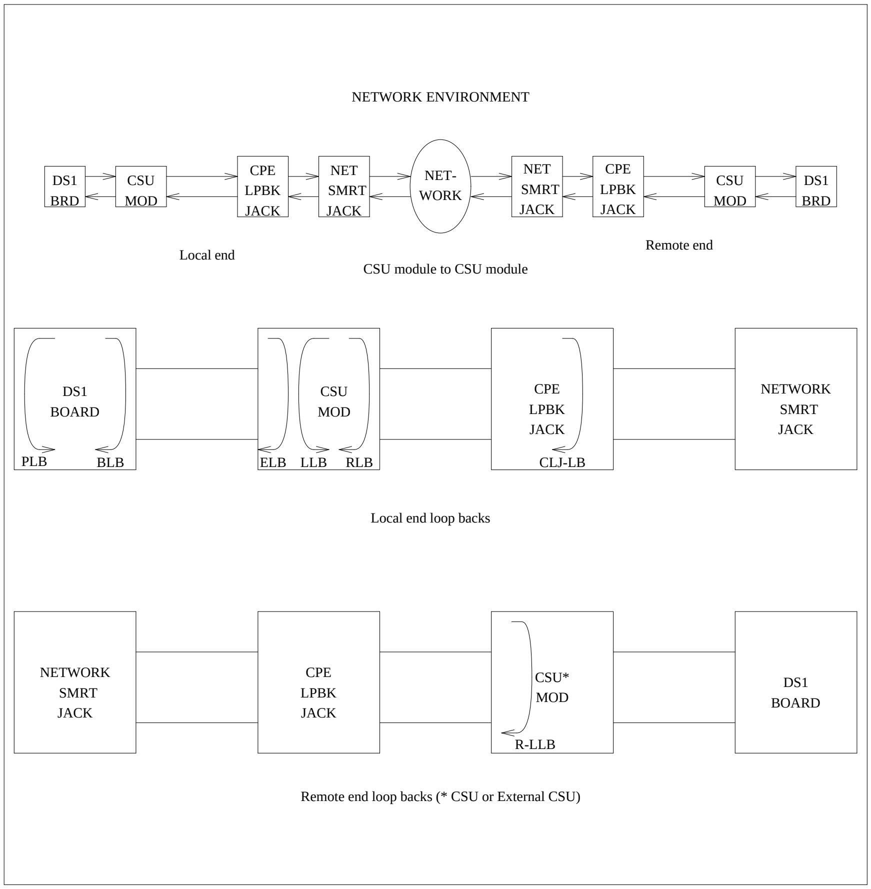

Figure 11-31. High Level Overview Of Loopback Points

The following list of acronym definitions are for Figure 11-31.

- PLB = Payload Loopback
- BLB = Board Loopback
- ELB = Equipment Loopback
- LLB = Line Loopback
- RLB = Repeater Loopback
- CLJ = CPE Loopback Jack
- R-LLB = Remote Line Loopback
- SMRT = Smart Jack
- LPBK = Loopback

Circuit Pack Administration and Options

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack form. *Bit Rate* is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. *Country Protocol* is used to drive layer 3 protocol decisions based on PRI specifications specific to a given country (not those related to specific features). This Country Protocol is independent of the *Country* parameter administered on the country-options system-parameters form. Different UDS1 circuit packs may be administered with different Country Protocols, allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations (for example, between two different countries). US systems use country protocol 1. *Near-End CSU Type* is set to *other* for no CSU installed or for an external CSU such as an AT&T ESF T1 CSU, or *integrated* for the 120A1 CSU Module. Answering *integrated* will cause additional fields to be displayed for administering the Enhanced Integrated CSU Module. In addition to the above there are numerous other fields defining such parameters as framing modes, line coding companding mode and so on. For details, see *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107.

Hardware Error Log Entries and Test to Clear Values

DS1 Interface Circuit Pack Maintenance Error Log Entries

3901(v)	Any	Far CSU Loopback Test (#1213)			
3902(w)	Any	One-Way Span Test (#1214)			
3999 (x)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.

3 Off-board minor alarms on this maintenance object (MO) may be downgraded to Warning alarms based on the values used in the **set options** command.

4 Major alarms on this MO may be downgraded to minor or warning alarms based on values set in the **set options** command.

Notes:

a. This error indicates that the circuit pack has stopped functioning or is not completely administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

To be completely administered, a DS1 circuit pack must meet all three of the following conditions:

1. Have an entry in the circuit plan via the **change circuit pack** command.
2. Be administered via the **add ds1 PCSS** command.
3. Be physically inserted in the appropriate slot.

If the circuit pack has an entry in the circuit plan, and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning DS1 circuit pack is inserted in the correct slot.

2. Completely remove the DS1-BD from the system using the following steps:

   a. Remove any administered DS1 trunks or access endpoints associated with the circuit pack from their trunk groups.

   b. Execute the **remove ds1** PCSS and **change circuit pack** PCSS commands.

If all the administration conditions are met for this circuit pack, and the red LED is still on, follow the instructions for ''LED Alarms with Error Type 1'' in Chapter 7, "LED Interpretation".

b. The DS1 Interface circuit pack has been busied out by a **busy-out board PCSS** command.

c. The DS1-BD circuit pack is not completely administered. A completely administered DS1-BD circuit pack should have an entry in the circuit plan via the **change circuit pack** command, should have been administered via the **add ds1 PCSS** command, and should have been inserted into the appropriate port slot.

d. The circuit pack in the slot does not match the type administered to that position. Either replace the circuit pack with one of the type administered, or use **change circuit-pack** to readminister the slot. This error may also indicate that the 24/32-channel selection on the DS1 administration form does not match the configuration of the circuit pack.

e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.

f. The DS1 Interface circuit pack has detected a transient hardware problem (for example, external RAM failure, internal RAM failure, internal ROM failure, or instruction set failure). This error will disappear when no faults are detected for 30 minutes. The value in the Aux Data field indicates the type of hardware problem. However, when this error is reported with Aux Data in the range of 4352 to 4358, it indicates the circuit pack has reported a hardware failure such that the circuit pack should be replaced.

g. The DS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.

h. CSU Module missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module is not physically connected (or is improperly connected) to the TN767E board on the back of the port carrier.

   If using the 120A1 CSU Module, plug (or replug) the CSU Module into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*.

If this error remains after plugging the CSU Module into the board's connector, there could be a problem with the I/O connector panel.

i. CSU Module not expected. The 120A1 CSU Module is physically connected to the TN767E board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*.

   If the 120A1 CSU Module is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier.

j. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.

k. DS1 circuit pack suffix incorrect for CSU Module. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated*, but the DS1 circuit pack is not a TN767E or later suffix DS1 board.

   If the 120A1 CSU Module is to be used, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise, use the *change ds1* command to change the *Near-End CSU Type* field to *other*.

l. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: *busyout board PCSS*, *test ds1-loop PCSS ds1/csu-loopback-tests*, and *release board PCSS*. If the BLB test continues to fail, then the TN767E circuit pack needs to be replaced.

m. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS ds1/csu-loopback-tests*, and *release board PCSS*. If the ELB test continues to fail, then either the TN767E board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by reexecuting the test by replacing one piece of hardware at a time.

n. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS ds1/csu-loopback-tests*, and *release board PCSS*. If the RLB test continues to fail, then the CSU Module needs to be replaced.

o. CPE Loopback Jack deactivation error. This error occurs when the TN767E circuit pack could not deactivate a CPE Loopback Jack loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS end-loopback/span-test*, and *release board PCSS*. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

p. Far CSU Loopback deactivation error. This error occurs when the TN767E circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS end-loopback/span-test*, and *release board PCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

q. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
   2. The tests run on the ports of this circuit pack are returning NO BOARD.
   3. A busy-out/release of the circuit pack has no affect on test results.
   4. A **list configuration** command shows that the circuit pack and ports are properly installed.

   The circuit pack is isolated from the system and all trunks of this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 Interface circuit pack is restored to normal operation. All trunks of the DS1 Interface circuit pack are then returned to the in-service state. If the error recurs after 15 minutes, then replace the circuit pack (refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures").

r. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving Slips and the AUX data shows the last Slip count that was reported.

s. For later releases of G3V4 and beyond, only error 3329 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.

t. This error is not service-affecting and can be ignored.

u. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

v. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

w. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

x. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Connection Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop Command	D/ND[1]
NPE Connection Audit Test (#50)		X			ND
Control Channel Loop Test (#52)		X			ND
Loss of Signal Alarm Inquiry	X	X			ND
Blue Alarm Inquiry Test (#139)	X	X			ND
Red Alarm Inquiry Test (#140)	X	X			ND
Yellow Alarm Inquiry Test (#141)	X	X			ND
Major Alarm Inquiry Test (#142)	X	X			ND
Minor Alarm Inquiry Test (#143)	X	X			ND
Slip Alarm Inquiry Test (#144)	X	X			ND
Misframe Alarm Inquiry Test (#145)	X	X			ND
Translation Update Test (#146)	X	X			ND
ICSU Status LEDs Test (#1227)	X	X			ND
SAKI Sanity Test (#53)			X		D
Internal Loop Around Test (#135)			X		D
DS1/CSU Loopback Tests					
DS1 Board Loopback Test (#1209)				X	D
CSU Equipment Loopback Test (#1210)				X	D
CSU Repeater Loopback Test (#1211)				X	D
CPE Loopback Jack Test (#1212)				X	D
Far CSU Loopback Test (#1213)				X	D
One-Way Span Test (#1214)				X	D
Inject Single Bit Error (#1215)				X	D
End Loopback/Span Test (#1216)				X	D

1 D = Destructive; ND = Nondestructive

NPE Connection Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 11-116. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available.
1019	ABORT	Test already in progress.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort/fail, escalate the problem.
	PASS	The circuit pack's NPEs have been updated with their translation.

Continued on next page

Table 11-116. TEST #50 NPE Connection Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Control Channel Loop Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 11-117. TEST #52 Control Channel Loop Around Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-117. TEST #52 Control Channel Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because the circuit pack did not return the circuit pack code or vintage. **NOTE:** Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as Test 138 and Test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test result. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack. 1. Retry the command for a maximum of 5 times. 2. If the problem continues, check for hyperactivity. Resolve the problem, as appropriate. 3. If there is no longer hyperactivity, retry the command for a maximum of 5 times. 4. If the test continues to fail, replace the circuit pack. 5. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-117. TEST #52 Control Channel Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Communication with this circuit pack is successful.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack.

Table 11-118. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to SYNC (Synchronization) Maintenance documentation.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute the command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute the command again. 2. If the problem persists, replace the circuit pack.

Continued on next page

Table 11-118. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Internal Loop Around Test (#135)

This test is destructive.

The Internal Loop Around Test is run by looping the transmitted DS1 bit stream back into the DS1's board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

All trunks on the DS1 Interface circuit pack must be busied out via the system technician **busy-out board** command before running the Internal Loop Around Test. When the Internal Loop Around Test is initiated, maintenance software sends appropriate messages to the DS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the DS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks of the DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-119. TEST #135 Internal Loop Around Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-119. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	Received an incoming call on a port of the DS1 circuit pack during the test. 1. Enter the **busy-out board PCSS** command to put all trunks of DS1 Interface circuit pack to out-of-service state. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on DS1 Interface circuit pack have not been busied out. 1. Enter the **busy-out board PCSS** command to put all trunks of the DS1 Interface circuit pack into out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-119. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Therefore, it cannot be reset without major system disruption. 1. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: ■ Issue the **disable synchronization-switch** command. ■ Next, issue the **set synchronization PCSS** command. ■ Lastly, issue the **enable synchronization-switch** command.

Table 11-119. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	The test was aborted. Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as Test 139 and Test 140) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-119. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack failed in the Internal Loop Around Test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 Interface circuit pack is TN767, enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. Otherwise, skip this step. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connectivity of DS1 Interface circuit packs and cable. 5. If all of the above are OK, replace the local DS1 Interface circuit pack and repeat the test. 6. Contact T1 Network Service to diagnose the remote DS1 endpoint. 7. If the test still fails, then escalate the problem.
	PASS	All administered trunks of DS1 Interface circuit pack pass the Internal Loop Around Test. The bit pattern consistency test is executed successfully over the path that covers a DS1 port, cable, and the external NCTE device.

Continued on next page

Table 11-119. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the DS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the DS1 Interface circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored.

The DS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 3 seconds. It will not retire the alarm until the signal has returned for about 16 seconds.

This test is also used to maintain the new AT&T 120A1 CSU Module. This CSU Module, when combined with the functionality provided by the TN767E circuit pack, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The combination of the TN767E and 120A1 CSU Module is known as an Enhanced Integrated CSU (I-CSU).

If a TN767E circuit pack detects certain I-CSU hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN767E board to confirm the I-CSU error. A Minor or Warning alarm will be raised depending on the severity of the I-CSU error. The trunks on the board may be taken out of service if the I-CSU error is deemed serious.

If a Loss Of Signal alarm and an I-CSU error co-exist, the Loss Of Signal alarm condition will take priority, and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the I-CSU hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other I-CSU errors or Loss Of Signal alarm exist).

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this DS1 interface circuit pack are out-of-service. If the DS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to the SYNC section in this chapter for details. 1. If the DS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 2. Check the physical connection of the DS1 Interface circuit pack and the cable. If a 120A1 CSU Module is physically connected to a TN767E board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack.
1300	FAIL	The CSU Module is missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module is not physically connected to the TN767E board on the back of the port carrier. 1. If using the 120A1 CSU Module, plug the CSU Module into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* to *other.* 2. Run the test again.

Continued on next page

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1301	FAIL	The 120A1 CSU Module is physically connected to the TN767E board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*. 1. If the 120A1 CSU Module is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier. 2. Run the test again.
1302	FAIL	Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America. 1. If the 120A1 CSU Module is to be used, physically remove the TN767E circuit pack and reconfigure for 24-channel (1.544 Mbps) operation. 2. Reinsert the circuit pack and run the test again.
1303	FAIL	The DS1 circuit pack Suffix is incorrect for CSU Module administration. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the DS1 circuit pack is not a TN767E or later suffix DS1 board. 1. If the CSU Module is to be used, and the *Near-End CSU Type* field is set to *integrated* to allow for CSU administration, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise, use the *change ds1* command to change the *Near-End CSU Type* field to *other*.
1310	FAIL	The DS1 Board Loopback (BLB) demand test (#1209) failed. 1. Repeat the test using the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the TN767E circuit pack. 3. Run this test again.

Continued on next page

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1311	FAIL	The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*. 1. Execute the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the ELB test continues to fail, then either the TN767E board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module and running the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 3. If the ELB test continues to fail, then replace the TN767E board and run the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module.
1312	FAIL	The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*. 1. Execute the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the RLB test continues to fail, then replace the CSU Module. 3. Run this test again.

Continued on next page

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1313	FAIL	The TN767E circuit pack could not deactivate a CPE Loopback Jack loopback. 1. Execute the *test ds1-loop PCSS end-loopback/span-test* command. 2. If the attempt to deactivate the CPE Loopback Jack loopback is not successful, check the cabling and investigate the problem at the CPE Loopback Jack. 3. Run the test again.
1314	FAIL	The TN767E circuit pack could not deactivate a far-end CSU loopback. 1. Execute the *test ds1-loop PCSS end-loopback/span-test* command. 2. If the attempt to deactivate the far-end CSU loopback continues to fail, then escalate the problem.
1320	FAIL	A 120A1 CSU module hardware failure or an ICSU serial interface audit failure was detected by the TN767E DS1 circuit pack. 1. Replace the CSU module, and then run the test again. 2. If the test continues to fail with this error code, replace the TN767E and run the test again. 3. If the test continues to fail with this error code, then the problem could be in the I/O cable between the backplane and the CSU module..

Continued on next page

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1321	FAIL	DTE LOS (loss of signal) was detected between the TN767E DS1 board and the 120A1 CSU Module. Either the TN767E board, the 120A1 CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. 1. Replace the CSU Module and run the test again. 2. If the test continues to fail with this error code, then replace the TN767E board and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1322	FAIL	No 5 volts power detected from the TN767E circuit pack to the 120A1 CSU Module. Problem probably due to an open fuse on the DS1 board. 1. Remove the TN767E from the system and reinsert. 2. Run the test again once the board has finished its reset. 3. If the test continues to fail with this error code, then replace the CSU Module and run the test again. 4. If the test continues to fail with this error code, then replace the TN767E board and run the test again. 5. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1323	FAIL	A service affecting CSU Module audit failure was detected by the TN767E DS1 circuit pack. All administered ports on the DS1 circuit pack are affected and maintenance software will place the ports into the out-of-service state. 1. Replace the 120A1 CSU Module.

Continued on next page

Table 11-120. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1324	FAIL	A non-service affecting CSU Module audit failure was detected by the TN767E DS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.
	PASS	DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the DS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The DS1 Interface circuit pack takes 2 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the DS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. When the switch DS1 is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Table 11-121. TEST #139 Blue Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-121. TEST #139 Blue Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Red Alarm Inquiry Test (#140)

DS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a DS1 Interface circuit pack. DS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 12 seconds to recognize and report the resolution of a Red alarm.

When the DS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the DS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks of the DS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm: If the DS1 Interface circuit pack is administered using DMI-BOS signaling, the DS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once DS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

Table 11-122. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The DS1 Interface circuit pack detects a Red alarm. An out-of-frame condition occurs on the DS1 Interface circuit pack. DS1 Interface circuit pack will transmit a Yellow alarm to the remote DS1 endpoint until the Red alarm is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. Replace the local DS1 interface circuit pack, and repeat the test. 5. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-122. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The DS1 interface circuit pack detected a loss of multiframe alarm (LMA). An out of frame condition occurred on the DS1 interface circuit pack. The DS1 interface circuit pack will transmit a remote multiframe alarm (RMA) to the remote DS1 endpoint until the LMA is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. Replace the local DS1 interface circuit pack, and repeat the test. 5. If the test continues to fail, escalate the problem.
	PASS	No Red alarm is detected on DS1 Interface circuit pack.

Table 11-122. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The DS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the DS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks on the DS1 Interface circuit pack back to their previous service state before the Yellow alarm is raised.

This Yellow Alarm corresponds to the yellow F2 state documented in CCITT recommendation I.431.

Remote Multiframe Alarm: Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition, while the DS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 State Alarm: For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

Table 11-123. TEST #141 Yellow Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
2100	ABORT	ICould not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-123. TEST #141 Yellow Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Major Alarm Inquiry Test (#142)

The Major alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 16 seconds to recognize and report a Major alarm and 16 seconds to recognize and report that a Major alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the DS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the DS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks on the circuit pack to their previous service state before a Major alarm occurs.

If the test continues to return NO BOARD, escalate the problem.

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition is cleared.

When the DS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

If the test continues to return NO BOARD, escalate the problem.

Slip Alarm Inquiry Test (144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The DS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips occurred on a DS1 link.

When the DS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on DS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the DS1 Interface circuit pack. All trunks of the DS1 Interface circuit pack are still in the in-service state. If the DS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See TDM-BUS (TDM Bus) and SYNC (Synchronization) Maintenance documentation for details.

If the test continues to return NO BOARD, escalate the problem.

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a DS1 Interface circuit pack are in error. Misframe Alarm Inquiry Test queries the total number of misframes that have occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches the threshold, a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the DS1 Interface circuit pack.

When the threshold of misframes is reached, if the DS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the DS1 Interface circuit pack is raised, but all trunks of the DS1 Interface circuit pack are still in the in-service state.

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the DS1 Interface circuit pack. Translation includes the following data administered for a DS1 Interface circuit pack (see output of **display ds1 PCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

In G3V3, if a TN767E or later DS1 circuit pack is combined with an AT&T 120A1 CSU Module to form and Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, etc.

Table 11-128. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal system software error. 1. Enter the **display ds1 PCSS** command to verify the DS1 Interface circuit pack translation. 2. If the test continues to fail, escalate the problem.
	PASS	Translation data has been downloaded to the DS1 Interface circuit pack successfully.

Continued on next page

Table 11-128. TEST #146 Translation Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN767E DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-129. TEST #1209 DS1 Board Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	DS1 Board Loopback Test cannot be executed in the current configuration. To run this Test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.

Continued on next page

Table 11-129. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Issue the **set synchronization PCSS** command. 3. Issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span tests can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop PCSS end-loopback/span-test* command in order to execute this test.

Table 11-129. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-129. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack failed the DS1 Board Loopback Test. 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the DS1 circuit pack.
	PASS	The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN767E DS1 board edge.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local AT&T 120A CSU Module and tests the connection from the TN767E DS1 board to the CSU Module (DS1 board edge, connection, and CSU Module edge). This test will only be performed if the AT&T 120A CSU Module is present, administered, and connected to a 1.544Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires that may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-130. TEST #1210 CSU Equipment Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	CSU Equipment Loopback Test cannot be executed in the current configuration. To run this test, the *Near-End CSU Type* field on the DS1 circuit pack administration form must be set to *integrated*, and the "Bit Rate" field must be set to "1.544" (24-channel operation). 1. Use the **change ds1 PCSS** command to set the *Near-End CSU Type* field on the DS1 circuit pack administration form to *integrated*, and/or change the "Bit Rate" field to "1.544" if the board is to be used in 24-channel configuration. 2. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 3. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

If the test continues to return NO BOARD, escalate the problem.

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the AT&T 120A1 CSU Module and tests the connection from the TN767E DS1 board to and including the CSU Module circuitry. This test will only be performed if the AT&T 120A1 CSU Module is present, administered, and connected to a 1.544 Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires that may not be detected by the loopback pattern itself.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN767E DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]* command. The System Technician has the choice of entering a loopback activation code on the command line or using the default code (0X47F).

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CPE Loopback Jack Test.

The CPE Loopback Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (i.e., *3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 11-132. TEST #1212 CPE Loopback Jack Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the *test ds1-loop PCSS cpe-loopback-jack-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	CPE Loopback Jack Test cannot be executed in the current configuration. To run this test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization PCSS** command. 3. Lastly, issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.

Table 11-132. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-132. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The CLJ-LB test failed because it was not set up properly. The DS1 interface pack could not successfully put the CPE loopback jack into loopback mode. 1. Rerun the **test ds1-loop PCSS cpe-loopback-jack-test-begin** command. 2. If the test continues to fail, the problem could be with the TN767E board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop PCSS ds1/csu-loopback-tests** command to determine if the loopback tests that are closer to the TN767E board are successful. If any of these tests fail, follow the maintenance strategy that is associated with the test that fails; otherwise, escalate the problem.
3	FAIL	The CPE Loopback Jack Test was not set up properly. The framed 3-in-24 test pattern, generated by the DS1 Interface circuit pack and looped back through the CPE Loopback Jack, could not be detected properly by the DS1 circuit pack. 1. Retry the *test ds1-loop PCSS cpe-loopback-jack-test-begin* command. 2. If the CSJ Loopback test continues to fail, the problem could be with the TN767E board, the CPE Loopback Jack equipment, or somewhere in between. Run the *test ds1-loop PCSS ds1/csu-loopback-tests* command to see if the loopback tests closer to the TN767E board are successful. If any of those loopback tests fail, follow the maintenance strategy associated with those loopbacks. Otherwise, escalate the problem.
	PASS	The CPE Loopback test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop PCSS end-loopback/span-test* command or the *release board PCSS* command.

Continued on next page

Table 11-132. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Far CSU Loopback Test (#1213)

This test is destructive.

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN767E DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS far-csu-loopback-test-begin* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not an AT&T 120A1 CSU Module, and the DS1 is administered for ami-zcs line coding, one's density protection must be disabled on the CSU during the test due to the large number of zeros in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (i.e., *3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 11-133. TEST #1213 Far CSU Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS far-csu-loopback-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Far CSU Loopback Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization PCSS** command. 3. Lastly, issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.

Continued on next page

Table 11-133. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop PCSS end-loopback/span-test* command in order to execute this test.
	ABORT	Internal System Error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-133. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. **NOTE:** When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-133. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The Far CSU Loopback Test was not set up properly. The DS1 Interface circuit pack could not successfully put the far-end CSU into loopback mode.
3	FAIL	The Far CSU Loopback Test was not set up properly. The framed 3-in-24 test pattern, generated by the DS1 Interface circuit pack and looped back through the far-end CSU, could not be detected properly by the DS1 circuit pack. 1. Retry the *test ds1-loop PCSS far-csu-loopback-test-begin* command. 2. If the Far CSU Loopback test continues to fail with this error code, the problem could be with the TN767E board, the far-end CSU equipment, or somewhere in between. Run the *test ds1-loop PCSS cpe-loopback-jack-test-begin* command to see if the CPE Loopback Jack test which is closer to the TN767E board is successful. (If a CPE Loopback Jack device is not being used, then run the *test ds1-loop PCSS ds1/csu-loopback-tests* command to see if these even closer loopback tests succeed). If the closer loopback test fails, follow the maintenance strategy associated with that loopback. Otherwise, escalate the problem.
	PASS	The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop PCSS end-loopback/span-test* command or the *release board PCSS* command.

Continued on next page

Table 11-133. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN767E DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS one-way-span-test-begin* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN767E DS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN767E board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show *0* until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern for the loopback/span test 9 (*Pattern* field), and whether the pattern (i.e., *3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 11-134. TEST #1214 One-Way Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the *test ds1-loop PCSS one-way-span-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	One-Way Span Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Issue the **set synchronization PCSS** command. 3. Issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.

Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

Inject Single Bit Error Test (#1215)

This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, and One-Way Span Test) are active on a TN767E circuit pack.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Table 11-135. TEST #1215 Inject Single Bit Error Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS inject-single-bit-error* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-135. TEST #1215 Inject Single Bit Error Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	A single bit error has been successfully injected into an active framed 3-in-24 test pattern.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN767E DS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL, and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS end-loopback/span-test* command. Since only one of these three different long-duration loopback/span tests can be active at a time, the TN767E circuit pack knows which loopback/span test to terminate.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state, execute the **release board** command.

Table 11-136. TEST #1216 End Loopback/Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	End Loopback/Span Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.

If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
1313	FAIL	The TN767E DS1 circuit pack could not deactivate the loopback through the Customer Loopback Jack. 1. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail with this error code, escalate the problem.

Continued on next page

Table 11-136. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1314	FAIL	The TN767E DS1 circuit pack could not deactivate the loopback through the far-end CSU. 1. Make sure that the far-end DS1 is installed if the far-end CSU is a 120A1 AT&T CSU Module. 2. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to fail with this error code, escalate the problem.
	PASS	The active long-duration loopback or span test on the TN767E circuit pack was successfully terminated.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

ICSU Status LEDs Test (#1227)

The TN767E DS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN767E board via the I/O connector panel on the back of the port carrier. The TN767E circuit pack combined with AT&T's new 120A1 CSU Module forms an Integrated CSU (ICSU).

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off, and return control of the status LEDs to the circuit pack.

This test will only be executed on TN767E or later suffix DS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 120A1 CSU Module is not physically installed, the status LEDs are always off and this test will abort.

Table 11-137. TEST #1227 ICSU Status LEDs Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	The ICSU Status LEDs test can not be executed for the current configuration. The test applies only to TN767E or later DS1 circuit packs administered for 24-channel operation (1.544 bit-rate). 1. If the circuit pack is a TN767E or later suffix DS1 circuit pack, then retry the command. 2. If the test continues to abort, escalate the problem.
1951	ABORT	The ICSU Status LEDs Test can not be executed because a 120A1 or later suffix CSU Module is not physically installed. If using a 120A1 CSU Module, physically connect it to the TN464F board on the back of the port carrier. Otherwise, ignore this abort.

Continued on next page

Table 11-137. TEST #1227 ICSU Status LEDs Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2500	ABORT	Internal System Error. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
	PASS	The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, the board should be replaced at the customer's convenience.

Continued on next page

Table 11-137. TEST #1227 ICSU Status LEDs Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **add ds1 PCSS** command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If the test continues to return NO BOARD, escalate the problem.

DT-LN-BD (Data Line Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DT-LN-BD	MIN	test board PCSS sh	Data Line Circuit Pack
DT-LN-BD	WRN	test board PCSS sh	Data Line Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DAT-LINE (Data Line Circuit Port) Maintenance documentation for related line information.

DTMR-PT [Dual Tone Multifrequency Port (TTR)]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DTMR-PT	MAJOR	test port PCSSpp sh	Dual Tone Multifrequency Receiver Port (TTR)
DTMR-PT	MINOR	test port PCSSpp sh	Dual Tone Multifrequency Receiver Port (TTR)
DTMR-PT	WARNING	release port PCSSpp	Dual Tone Multifrequency Receiver Port (TTR)

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Dual Tone Multifrequency Receiver Port (DTMR), also known as the Touch-Tone Receiver (TTR), resides on the Tone Detector circuit pack (TN748, TN420) or the TN756 Tone-Clock circuit pack. There are four Dual Tone Multifrequency Receiver (DTMR-PT) ports and two General Purpose Tone Detector (GPTD-PT) ports on a Tone Detector circuit pack. The DTMR port is used to detect touch-tone digits that are placed on the TDM bus. Examples of touch-tone digits are digits 0 through 9, digit #, and digit *. The ability of the DTMR port to detect touch-tone digits is essential for maintenance of other circuit packs (for example, Tone-Clock circuit pack) and in placing a station-to-station call. Calls originating from a hybrid station **do not** require a DTMR port.

The Dual Tone Multifrequency Receiver Port maintenance object defines a set of tests to verify that the DTMF digits detection capability of the DTMR port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

Hardware Error Log Entries and Test to Clear Values

Dual Tone Multifrequency Receiver Port (TTR) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (b)	17664	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 2
18	0	busyout port PCSSpp	WARNING	ON	release port PCSSpp
130 (d)		None	WARNING	ON	test port *PCSSpp* sh r 2
257 (c)	17666	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3
513	Any	Tone Detection Verification Test (#42)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. There are two possible alarm levels for this error: Major alarm and Minor alarm. A Major alarm is raised if the total number of DTMR ports currently in service is less than or equal to one half of the administered threshold number. Otherwise, a Minor alarm is raised. In either case, run the Short Test Sequence against the DTMR port and follow the error code procedures for the individual tests.

   The threshold number of DTMR ports for service is administered using the **change system-parameters maintenance** command.

b. This error indicates the DTMR port is having problems detecting touch-tone digits. If this error is being constantly logged, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.

c. The DTMR port lost its translation. Testing the DTMR port is sufficient to reload its translation. If testing the DTMR port does not clear the error, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.

d. This error type indicates that the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detector Audit/Update Test (#43)	X	X	ND

1 D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test verifies the "touch-tone digits detection" capability of the DTMR port is functioning properly.

Table 11-138. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the DTMR port.
1001	ABORT	The system was unable to put the DTMR port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This could happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM Bus via the **test tdm [a|b]** command. Refer to the TDM-BUS (TDM Bus) Maintenance documentation for details. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a Tone Generator for the test connection. This could happen when the system is heavily loaded or there is not a Tone-Clock circuit pack in the port network when this test is being executed. 1. Make sure there is a Tone-Clock circuit pack in the same port network. 2. If a Tone-Clock circuit pack is missing, install one in the same port network. 3. Allow about one-minute for the Tone-Clock maintenance to run on the newly inserted Tone-Clock circuit pack. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-138. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2006	ABORT	DTMF detection failed. This could be caused by the administered companding mode of the system not matching that of the Tone Detector circuit pack. 1. Make sure that companding mode of the system matches that of the Tone Detector. 2. If the test continues to abort, escalate the problem.
1-3	FAIL	DTMF digits were not correctly detected. 1. Run the Short Test Sequence: **test port PCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore the system performance to normal, replace the Tone Detector circuit pack containing the defective DTMR port.
	PASS	The DTMR port is able to detect all the touch-tone digits.

Tone Detector Audit/Update Test (#43)

The DTMR port is refreshed with all time slot information and sanity audit is performed on the DTMR port.

Table 11-139. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait one minute and try again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Hardware audit failed. 1. Run the Short Test Sequence: **test port PCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity is reduced. In order to restore the system performance to normal, replace the Tone Detector circuit pack containing the defective DTMR port.
	PASS	The DTMR port has been successfully refreshed with its translation.

DUPINT (Duplication Interface Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
DUPINT (a)	MAJOR	test duplication 1C	Duplication Interface Circuit Pack
DUPINT (a)	WARNING	test duplication 1C	Duplication Interface Circuit Pack

1 Alarms on Duplication Interface circuit pack in the A carrier are always major alarms and alarms on Duplication Interface circuit pack in the B carrier are always warning alarms. Determine the carrier to test via the PORT field from the Alarm or Error Log.

In a High or Critical Reliability PPN system, there are two Duplication Interface circuit packs: one in carrier A and one in carrier B. Together, Duplication Interface circuit pack A and Duplication Interface circuit pack B provide memory shadowing (see SHDW-CIR Maintenance documentation for a full description) and communication between software on the Active and Standby SPEs. By itself, Duplication Interface circuit pack A provides control of the duplicated 80286 Processor circuit pack, environmental maintenance monitoring and control, and administration terminal connection.

Duplication Interface circuit pack A controls a lead that lets the Tone-Clock circuit packs know which of them is supposed to be active and additional leads that control which SPE is active. The system software can request that either the SPE Select lead or Tone-Clock lead be changed.

Duplication Interface circuit pack A controls and monitors the same environment leads that the Maintenance/Tape Processor does in a PPN a system without High or Critical Reliability. Duplication Interface circuit pack A also supports the serial channel to the PPN administration terminal in a High or Critical Reliability system PPN. The administration terminal is connected to Duplication Interface circuit pack A via a connector on the back of carrier A labeled **DOT** (Terminal for High or Critical Reliability system). At any time, the administration terminal may be disconnected from Duplication Interface circuit pack A and connected directly to the active Maintenance/Tape Processor by attaching the administration terminal to the connector marked **TERM** on the active carrier. This connection should only be made if the administration terminal fails to function since a problem with the Duplication Interface circuit pack A may be present. (See Figure 11-32 on page 11-733.)

The Duplication Interface circuit packs communicate over the Inter-Carrier Cable (ICC). The ICC connects the Duplication Interface circuit packs via pin fields on the backplane. The ICC consists of two 25-pin connector cables known as ICC-A and ICC-B. (**Note:** A single-carrier cabinet system has an ICC-C also.) The pin fields where ICC-A and ICC-B are connected are clearly labeled on the backplane near the pin fields for the Duplication Interface circuit packs. The ICC carries several important leads related to maintaining a High or Critical Reliability system.

NOTE:
The ICC carries the following leads and their respective information: shadowing information and shadowing state (enabled or disabled); 80286 Processor circuit pack select lead that indicates which 80286 Processor circuit pack is active; Tone-Clock select lead that indicates which Tone-Clock circuit pack is active; SPE Select Switch State leads which indicate the position of the SPE Select Switch; Emergency Transfer leads which indicate whether Emergency Transfer is on or off in the PPN cabinet; leads to tie INADS, CDR, and Customer-Provided Alarming Device from the two Maintenance/Tape Processors together; a serial connection between Duplication Interface circuit pack B and Duplication Interface circuit pack A, and a serial connection between Duplication Interface circuit pack A and Maintenance/Tape Processor B. There is also a serial connection between Duplication Interface circuit pack A and Maintenance/Tape Processor A wired into the backplane of carrier A. The Maintenance/Tape Processor communicates with 80286 Processor circuit pack (that is, system software) over the M-BUS via special memory locations located on the TN777 Processor circuit pack. This is true in both carriers A and B. The presence of the ICC also causes ID pins on the backplane to read as a High or Critical Reliability system rather than a Standard system.

Without the ICC properly attached, the system cannot function as a High or Critical Reliability system or as a Standard system.

The Duplication Interface circuit pack uses Universal Asynchronous Receiver Transmitters (UARTs) to support the various serial links. The UARTs are physically part of the Duplication Interface circuit packs and are tested and maintained. There are four UARTs on each circuit pack. They are used to support the serial link from Duplication Interface circuit pack A to Duplication Interface circuit pack B (Inter-Dupint UART), from Duplication Interface circuit pack A to the administration terminal from Duplication Interface circuit pack A to Maintenance/Tape Processor A (SPE A UART), and from Duplication Interface circuit pack A to Maintenance/Tape Processor B (SPE B UART).

NOTE:
The Duplication Interface circuit pack B does not communicate directly with either Maintenance/Tape Processor or the administration terminal and, thus, does not use the administration terminal, SPE A, or SPE B UART. These UARTs are, however, still tested. A failure of any one of these three results in a Warning alarm.

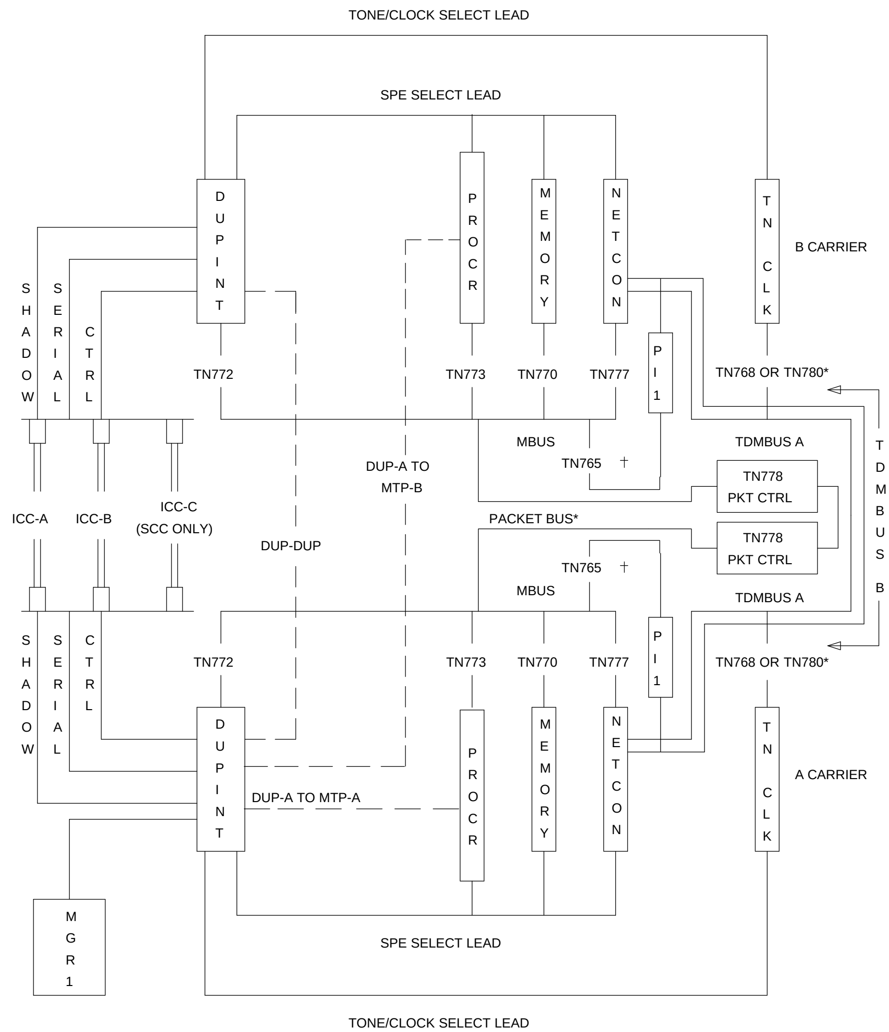
The flow of messages from 80286 Processor circuit pack A to 80286 Processor circuit pack B is as follows: from 80286 Processor circuit pack A to

Maintenance/Tape Processor A over the serial link to Duplication Interface circuit pack A over the serial link to Maintenance/Tape Processor B to 80286 Processor circuit pack B. The flow in the reverse direction is exactly the opposite.

NOTE:
The Duplication Interface circuit pack B is not involved in this communication. Duplication Interface circuit pack B is only involved in the shadowing of memory from the active to the standby carrier.

Figure 11-32 depicts the interconnection of the Duplication Interface circuit packs with the rest of the system. The dotted lines show the logical serial channel rather than actual physical implementation of the serial channel. For the sake of clarity, the UARTs are not shown. The following abbreviations are used in the figure:

- DUPINT for Duplication Interface circuit pack
- PR MAINT for Maintenance/Tape Processor
- PROCR for 80286 Processor circuit pack
- MEM BD for Memory



* G1.2 ONLY.

† MCC ONLY.

(IN A SINGLE-CARRIER CABINET CONFIGURATION, THERE CAN BE EITHER 0 or 1 PROCESSOR INTERFACE CIRCUIT PACK. IN A MULTI-CARRIER CABINET CONFIGURATION, THERE CAN BE 0, 1, OR 2 PROCESSOR INTERFACE CIRCUIT PACKS.)

Figure 11-32. Duplication Interface Circuit Pack Interactions

1793 (f)	Any	MBUS Time-Out Query Test	MAJOR/ WRN	ON	test dup 1C l r 3
		(#285)			
2049		Inter-Dupint Loop Around Test (#280)	MAJOR/ WRN	ON	test dup 1C sh r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. Alarms on Duplication Interface circuit pack in the A carrier are always Major alarms, and alarms on Duplication Interface circuit pack in the B carrier are always Warning alarms.

b. Determine the carrier to test via the Port field from either the Alarm Log or the Error Log.

c. This error indicates that an unexpected hardware reset has occurred on the Duplication Interface circuit pack. Appropriate action has been taken by the software to prevent malfunction. However, if this type error occurs with regular frequency, the DUPINT circuit pack may need to be replaced.

d. There are several possible Aux Data fields for this error, including blank. All indicate loss of contact with the indicated Duplication Interface circuit packs. The following table summarizes the Aux Data fields.

Aux	Description
1 or 3	Duplication Interface circuit pack A lost handshaking with Duplication Interface circuit pack B.
2	MTP lost handshaking with the Duplication Interface circuit pack.
221	Duplication Interface circuit pack reported the trouble.
65315 or 65503	Duplication Interface circuit pack A lost contact with Duplication Interface circuit pack B.
Blank, 65313, or 65501	If reported against Duplication Interface circuit pack A, Duplication Interface circuit pack A lost handshaking with Maintenance/Tape Processor A. If reported against Duplication Interface circuit pack B, Duplication Interface circuit pack A lost handshaking with Maintenance/Tape Processor B.

e. An Aux value of blank or 65317 is valid. The 65317 aux value means the Duplication Interface circuit pack reported the trouble, while the blank means the software detected the trouble.

f. This could be caused by mismatched numbers of Processor Interface (TN765) or Packet Control (TN778) circuit packs in the two SPEs or by a defective Duplication Interface (TN772) Circuit Pack. If the Duplication Interface Circuit Pack is defective and becomes part of the Standby SPE, then memory shadowing does not work. Follow the procedures given for the FAIL case of Common Shadow Circuit M-Bus Time-Out Query Test (#285) in the SHDW-CIR section.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Duplication Interface Circuit Pack Status Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Duplication Interface Circuit Pack StatusQuery Test (#315)	X	X	ND
Duplication Interface Circuit Pack Sanity Circuit Test (#273)(a)		X	D
Duplication Interface Circuit Pack Sanity Maze Test (#277)	X	X	ND
Duplication Interface Circuit Pack SPE A Loop Back Test (#275)	X	X	ND
Duplication Interface Circuit Pack SPE B Loop Back Test (#276)	X	X	ND
Duplication Interface Circuit Pack Administration Terminal Loop Back Test (#274)(a)	X	X	ND
Inter-Duplication Interface Circuit Pack Loop Back Test (#280)	X	X	ND
Duplication Interface Circuit Pack Background Test Query Test (#271)	X	X	ND
Duplication Interface Circuit Pack Invalid Message Query Test (#272)	X	X	ND
Common Shadow Circuit M-BUS Time-out Query Test (#285) (b)		X	ND
Common Shadow Circuit Loop Back Test (#283) (b)	X	X	ND
Common Shadow Circuit Address Decoder Test (#284) (b)	X	X	ND
SPE Select Switch Query Test (#278) (c)	X		ND

1 D = Destructive; ND = Nondestructive

Notes:

a. When running the Long Test Sequence on Duplication Interface circuit pack A, the results of Test #273 may overwrite the results of Test #274.

b. Refer to SHDW-CIR (Common Shadow Circuit) Maintenance documentation for description of this test.

c. Refer to SPE-SELEC (SPE Select Switch) Maintenance documentation for description of this test.

Duplication Interface Circuit Pack Background Test Query (#271)

This test queries the Duplication Interface circuit pack for the results of its background tests. The response indicates the results of the last time the following background tests were run:

- ROM Checksum Test: This test verifies the correctness of the Duplication Interface circuit pack firmware.
- RAM Test: This tests verifies that the RAM on the Duplication Interface circuit pack is functioning properly.

Table 11-140. TEST #271 Duplication Interface Circuit Pack Background Test Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-140. TEST #271 Duplication Interface Circuit Pack Background Test Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2008 2009 2010	FAIL	One or both background tests failed on the Duplication Interface circuit pack. Error Code 2008 means the ROM test failed. Error Code 2009 means the RAM test failed. Error Code 2010 means both tests failed. 1. Follow the procedures for replacing Common Control circuit packs and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, escalate the problem.
	NO BOARD	The Duplication Interface circuit pack has failed to reply to handshaking from either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or from Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).

Duplication Interface Circuit Pack Invalid Message Query Test (#272)

The Duplication Interface Circuit Pack Invalid Message Query Test sets the threshold for the number of bad checksum errors the Duplication Interface circuit pack detects before reporting the problem to maintenance and queries the Duplication Interface circuit pack for the number of checksum errors detected. The error threshold is set to 10. The query causes Duplication Interface circuit pack firmware to clear its bad checksum error counter. This test is run on both circuit packs, but has little meaning on Duplication Interface circuit pack B and should always pass.

Table 11-141. TEST #272 Duplication Interface Circuit Pack Invalid Message Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The Duplication Interface circuit pack is receiving an abnormal number of corrupted messages. 1. First investigate other Duplication Interface circuit pack tests that are not passing. 2. If this is the only test that fails, investigate and resolve all alarms against PR-MAINT (Maintenance/Tape Processor). 3. Rerun the test. If the test still fails, follow the procedures for replacing Common Control circuit packs and replace the Duplication Interface circuit pack. 4. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-141. TEST #272 Duplication Interface Circuit Pack Invalid Message Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The Duplication Interface circuit pack has not received any bad messages from either Maintenance/Tape Processor or the other Duplication Interface circuit pack. All serial links are operating fine.

Duplication Interface Circuit Pack Sanity Circuit Test (#273)

This test is destructive.

This test checks the sanity hardware of a Duplication Interface circuit pack. The Duplication Interface circuit pack processor is instructed to allow the on-board circuit pack sanity timer to expire, which should cause the circuit pack to reset itself. The software then allows the Duplication Interface circuit pack 15 seconds to reset. After this time, the Duplication Interface circuit pack is queried for the results of its background tests (see Test #271). If the Duplication Interface circuit pack responds to this query, then the reset passes. If performed on Duplication Interface A, this test can cause an SPE interchange to the SPE in the B carrier if the A carrier SPE was active when the test was executed. The B carrier Tone-Clock circuit pack is also selected on Duplication Interface circuit pack A processor reset. This test is run only when demanded by software and can be performed on either Duplication Interface circuit pack. There is no service-disruption when this test is run on Duplication Interface B.

Table 11-142. TEST #273 Duplication Interface Circuit Pack Sanity Circuit Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
1037	ABORT	The active Tone-Clock circuit pack is currently the one in the A carrier. If the Duplication Interface circuit pack is allowed to be reset at this time, an unscheduled tone/clock switch would take place resulting in a Cold 2 restart. 1. Check for alarms against TONE-BD in the B carrier and refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation to resolve these alarms. 2. When there are no alarms against TONE-BD in the B carrier, force the -one-Clock circuit pack to be active by issuing the **set tone-clock b** command. 3. Verify the B carrier Tone-Clock circuit pack is active by using the **status system** command. 4. Rerun the Duplication Interface circuit pack test.
2018	ABORT	Applicable only when testing Duplication Interface A. (1) Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of this error.
1185	ABORT	Only occurs when attempting to reset Duplication Interface A when SPE A is active and SPE A has not been selected via the SPE Select switch. In this case, resetting Duplication Interface A causes a warm start SPE-interchange to SPE B. 1. Issue the **reset system interchange** command to make SPE A the Standby SPE. 2. Repeat the test.

Continued on next page

Table 11-142. TEST #273 Duplication Interface Circuit Pack Sanity Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
2052	ABORT	Only occurs when attempting to reset Duplication Interface A. If SPE B is not in Standby Mode, ready to take over, then this test aborts. 1. Look for and resolve all STBY-SPE errors and alarms. 2. Use the **refresh spe** command to place SPE B in Standby Mode. 3. Repeat the test.
2000	FAIL	The software timed out waiting for Duplication Interface circuit pack to respond to the background test query. 1. Rerun the test. 2. If the test fails with a 2000 again, then deal with the Duplication Interface Circuit Pack Status Query Test (#315) results first.
	FAIL	The sanity timer circuit on the Duplication Interface circuit pack is defective. The Duplication Interface circuit pack should be replaced. 1. Follow the procedure for replacing Common Control circuit packs, and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-142. TEST #273 Duplication Interface Circuit Pack Sanity Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The Duplication Interface circuit pack successfully reset. The Duplication Interface circuit pack may still have problems related to any of the other Duplication Interface circuit pack tests. Follow up on any other test failures.

Duplication Interface Circuit Pack Administration Terminal Loop Back Test (#274)

This test loops back data through the UART used to communicate with administration terminal. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Table 11-143. TEST #274 Duplication Interface Circuit Pack Administration Terminal Loop Back Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The tested UART on the Duplication Interface circuit pack is defective. 1. If this is Duplication Interface circuit pack A, then the circuit pack must be replaced to restore duplication. If this is Duplication Interface circuit pack B, then this failure has no real impact on the system. However, since this Duplication Interface circuit pack can never be used in the A carrier, it should be replaced at some point. 2. Follow the procedures for replacing Common Control circuit packs, and replace the Duplication Interface circuit pack. 3. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-143. TEST #274 Duplication Interface Circuit Pack Administration Terminal Loop Back Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The administration terminal UART on the Duplication Interface circuit pack is good. This implies that Duplication Interface circuit pack A should be able to communicate with the administration terminal. This implies that Duplication Interface circuit pack B has a good UART. If there are problems bringing up the administration terminal, check the following: 1. Verify the terminal is connected to the connector labeled **DOT** on the back of carrier A and that the connector is securely fastened. 2. Verify the terminal is set up for 9600 baud. 3. If the terminal still does not work, replace the administration terminal.

Duplication Interface Circuit Pack SPE A Loop Back Test (#275)

This test loops data back through the UART used to communicate with Maintenance/Tape Processor A. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Table 11-144. TEST #275 Duplication Interface Circuit Pack SPE A Loop Back Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The tested UART on the Duplication Interface circuit pack is defective. 1. If this is Duplication Interface circuit pack A, then the circuit pack must be replaced to restore duplication. If this is Duplication Interface circuit pack B, then this failure has no real impact on the system. However, since this Duplication Interface circuit pack can never be used in the A carrier, it should be replaced at some point. 2. Follow general procedures for replacing Common Control circuit packs, and replace the Duplication Interface circuit pack. 3. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-144. TEST #275 Duplication Interface Circuit Pack SPE A Loop Back Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The SPE A UART on the Duplication Interface circuit pack is good. This implies that Duplication Interface circuit pack A should be able to communicate with SPE A. This implies that Duplication Interface circuit pack B has a good UART.

Duplication Interface Circuit Pack SPE B Loop Back Test (#276)

This test loops back data through the UART used to communicate with Maintenance/Tape Processor B. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Table 11-145. TEST #276 Duplication Interface Circuit Pack SPE B Loop Back Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The tested UART on the Duplication Interface circuit pack is defective. 1. If this is Duplication Interface circuit pack A, then the circuit pack must be replaced to restore duplication. If this is Duplication Interface circuit pack B, then this failure has no real impact on the system. However, since this Duplication Interface circuit pack can never be used in the A carrier, it should be replaced at some point. 2. Follow general procedures for replacing Common Control circuit packs, and replace the Duplication Interface circuit pack. 3. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-145. TEST #276 Duplication Interface Circuit Pack SPE B Loop Back Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or with Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The SPE B UART on the Duplication Interface circuit pack is good. This implies that Duplication Interface circuit pack A should be able to communicate with SPE B. This implies that Duplication Interface circuit pack B has a good UART.

Duplication Interface Circuit Pack Sanity Maze Test (#277)

This test tests the Duplication Interface circuit pack processor's ability to write through the maze circuit. The Sanity Maze is a piece of circuitry on the Duplication Interface circuit pack that the Duplication Interface circuit pack Processor must write through to get access to leads controlled by the Duplication Interface circuit pack (Tone-Clock Select Lead, 80286 Processor circuit pack Select Leads, etc.). This maze circuitry ensures that the processor on the Duplication Interface circuit pack is sane before any of these leads are changed. The Duplication Interface processor is instructed to write bit patterns through the maze circuit. The Duplication Interface processor examines the output of the maze circuit and compares it with the input.

Table 11-146. TEST #277 Duplication Interface Circuit Pack Sanity Maze Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The Sanity Maze Circuit or the processor on the Duplication Interface circuit pack is defective, which implies the Duplication Interface circuit pack can no longer be relied upon to control and support a High or Critical Reliability system. The Duplication Interface circuit pack needs to be replaced. 1. Follow general procedures for replacing Common Control circuit packs and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-146. TEST #277 Duplication Interface Circuit Pack Sanity Maze Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or with Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The Duplication Interface circuit pack Sanity Maze is good. This implies that Duplication Interface circuit pack can correctly control the SPE Select and Tone-Clock Lead.

Inter-Duplication Interface Circuit Pack Loop Back Test (#280)

This test loops back data through the UART used to communicate with the other Duplication Interface circuit pack. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Table 11-147. TEST #280 Inter-Duplication Interface Circuit Pack Loop Back Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The tested UART on the Duplication Interface circuit pack is defective. 1. Follow general procedures for replacing Common Control circuit packs and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, follow normal escalation procedures.
	NO BOARD	The Duplication Interface circuit pack B has failed to reply to handshaking either from Duplication Interface circuit pack A. 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).
	PASS	The Inter-DUPINT UART on the tested Duplication Interface circuit pack is good.

Duplication Interface Circuit Pack Status Query Test (#315)

This test is used to detect the presence of Duplication Interface circuit pack A and Duplication Interface circuit pack B. Duplication Interface circuit pack A handshakes with each Maintenance/Tape Processor and with Duplication Interface circuit pack B. To determine the status of Duplication Interface circuit pack B, a query is sent to the Duplication Interface circuit pack A. To determine the status of Duplication Interface circuit pack A, a query is sent to the Maintenance/Tape Processor on the active carrier. The response to either query indicates the status of the handshake to the appropriate Duplication Interface circuit pack.

Table 11-148. TEST #315 Duplication Interface Circuit Pack Status Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
2000	ABORT	The software timed out waiting for the reply message. 1. Rerun the test. 2. If the message times out again, then continue to the next step. If the query fails with a NO BOARD, then refer to NO BOARD on the next page of this table. 3. No response is being received from the Duplication Interface circuit pack or Maintenance/Tape Processor. If Duplication Interface circuit pack A is under-test, then check for and resolve all alarms against the active PR-MAINT (Maintenance/Tape Processor). If Duplication Interface circuit pack B is under test, then enter the **test dup a** system technician command and resolve problems with Test #315 for Duplication Interface circuit pack A first. 4. Rerun the test. If it still aborts, then a problem may exist with one of the serial links. If carrier B is active or Duplication Interface circuit pack B is under test, then the serial link to get to Duplication Interface circuit pack B is being carried by the ICC. Check for damage to the ICC, and verify that all four connectors for the ICC are plugged in. If the ICC has to be replaced, the system must be powered down. 5. If the ICC is not the problem, then that portion of the serial link wired into carrier A and/or carrier B may be defective, and the carrier pack may need to be replaced.

Continued on next page

Table 11-148. TEST #315 Duplication Interface Circuit Pack Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-148. TEST #315 Duplication Interface Circuit Pack Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The handshake to one of the Duplication Interface circuit packs has stopped. The circuit pack may be defective or communication to the circuit pack is hampered. 1. Look in the Hardware Error Log for error types against TAPE. If TAPE error types are present, resolve them since TAPE error types can cause Test #315 to fail. Refer to TAPE Maintenance documentation for recommended repair strategy. 2. After any TAPE error types are resolved, issue the **test duplication-interface** command on the suspect Duplication Interface circuit pack. If Test #315 fails on Duplication Interface A, Duplication Interface A is defective. Replace the Duplication Interface A circuit pack. If Test #315 fails on Duplication Interface B, Duplication Interface circuit pack A or Duplication Interface circuit pack B may be defective. In this case, it is necessary to determine which Duplication Interface circuit pack (A or B) is the defective one. To do this, issue the **test duplication-interface A** command. If Test #280 fails on Duplication Interface A, (and Test #315 has just failed on Duplication Interface B), Duplication Interface circuit pack A is defective and should be replaced. If Test #280 passes on Duplication Interface A (and Test #315 has just failed on Duplication Interface B), replace the Duplication Interface circuit pack B. 3. Reissue the **test duplication-interface** command on the Duplication Interface circuit pack that was replaced. If Test #315 still fails, check for problems with the Inter-Carrier Cables (ICCs). If any of the ICCs is defective, replace it. 4. Rerun the test. If Test #315 still fails, escalate the problem.

Continued on next page

Table 11-148. TEST #315 Duplication Interface Circuit Pack Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or with Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Follow the FAIL directions above.
	PASS	The tested Duplication Interface circuit pack is present and sane enough to handshake.

EMG-XFER (Emergency Transfer)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
EMG-XFER	MAJOR	test environment P	Emergency Transfer
EMG-XFER	WARNING	test environment P	Emergency Transfer

1 Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

The system provides the ability to cut designated analog phones through to CO trunks if the switch cannot provide even minimal phone service. This ability is known as Emergency Transfer. Each port network PPN and EPN can have a separate Emergency Transfer capability. The EMG-XFER MO tracks the control of Emergency Transfer. There is one EMG-XFER MO for each port network. Emergency Transfer can be controlled by the system or can be manually controlled within each port network via the Emergency Transfer switch(es) which is (are) located on the 80286 Processor circuit pack and the EPN Maintenance circuit pack. If the Emergency Transfer switch or switches in a High or Critical Reliability system on the 80286 Processor circuit pack or EPN Maintenance circuit pack are in a manual position, the system cannot change the state of Emergency Transfer within that port network. A manual ON position (to the right) generates a Major alarm. A manual OFF position (to the left) generates a Warning alarm. Unless a technician is currently working on the switch, the switches should be left in the auto position (). On a High or Critical Reliability system, the switches on BOTH 80286 Processor circuit packs must be in the ON position to manually invoke Emergency Transfer. However, if EITHER switch is in the OFF position, Emergency Transfer cannot be controlled by the system and is in the manual OFF state. The **status system** system technician command displays the current state of the Emergency Transfer switches in the system. Valid states for the switches are: *manual ON, manual OFF, auto ON* (the switch is in the auto position and the system has invoked Emergency Transfer), or (the switch is in the auto position and the system has invoked Emergency Transfer), or *auto OFF* (the switch is in the auto position and the system has not invoked Emergency Transfer).

Hardware Error Log Entries and Test to Clear Values

Emergency Transfer Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment P sh r 1
1	Any	Emergency Transfer Query (#124)	MAJOR	ON	test environment P r 3
257	0	Emergency Transfer Query (#124)	WARNING	ON	test environment P r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Multicarrier System

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
Power Unit Query Test (Carrier E) (#127) (c)	X	X	ND
Power Unit Query Test (Carrier D) (#127) (c)	X	X	ND
Power Unit Query Test (Carrier A) (#127) (c)	X	X	ND
Power Unit Query Test (Carrier B) (#127) (c)	X	X	ND
Power Unit Query Test (Carrier C) (#127) (c)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.

b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.

c. Refer to CARR-POW (Carrier Port Power Unit for AC-Powered Systems) Maintenance documentation for a description of this test.

d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.

e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:
These tests only show up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Single-Carrier System

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Power Query Test (#79) (a)	X	X	ND
Emergency Transfer Query Test (#124)	X	X	ND
External Alarm Lead Query Test (#120) (b)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to DC-POWER (Single-Carrier Cabinet Power) Maintenance documentation for a description of this test.

b. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

c. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:
These tests only show up in the test sequence if there is a TN768 Tone-Clock Board in the port network being tested.

Emergency Transfer Query Test (#124)

This test queries the hardware for the state of the Emergency Transfer switch (or switches in a High or Critical Reliability system) and reports the result. If the switch(es) is (are) in a position where the system software can control Emergency Transfer, then the test passes. If the switch(es) is (are) in a position where the system software cannot control Emergency Transfer, then the test fails. In the PPN, the Maintenance/Tape Processor controls Emergency Transfer and, in the EPN, the EPN Maintenance circuit pack controls Emergency Transfer. The system software does not have control of Emergency Transfer within a cabinet if the switch(es) is (are) in the manual ON or manual OFF state for that cabinet.

Table 11-149. TEST #124 Emergency Transfer Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all DUPINT (Duplication Interface) errors in a PPN for a High or Critical Reliability system, PR-MAINT (Maintenance/Tape Processor) errors in a Standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 4. If the test continues to ABORT with a 2000 error code, escalate the problem.

Continued on next page

Table 11-149. TEST #124 Emergency Transfer Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	Emergency Transfer is manually turned OFF via the Emergency Transfer switch(es).
2	FAIL	Emergency Transfer is manually turned ON via the Emergency Transfer switch(es). 1. Place the switch (or switches in a PPN for a High or Critical Reliability system) in the AUTO position.
	PASS	The system software has control of Emergency Transfer within this port network. If Emergency Transfer is invoked, then there can be a Major alarm in the system that is invoking Emergency Transfer. The following table lists the error types and MOs that may cause Emergency Transfer. If any or all of these errors appear in the log, then refer to the appropriate Maintenance documentation and resolve those problems first. If none of these errors appear in the log, then check the Emergency Transfer hardware. Specifically, on the EPN, if Emergency Transfer is invoked while call processing is permitted, verify that the current limiter card (982LS) is in the correct slot on the backplane. If the current limiter card is not in the correct slot, move it to the correct location and rerun this test.

Test #124 Error Log Entries That Cause Emergency Transfer

MO Name	Error Type	Aux Data
TAPE	3329	0
SW-CTL	1	
SW-CTL	2	
TONE-BD	1	0
TONE-BD	2305	0

EPN-SNTY (EPN Sanity Audit)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
EPN-SNTY	None	None	EPN Sanity Audit

The EPN Sanity Audit feature enhances the system's ability to recover from failure conditions that disable an entire EPN. In such situations, not only is the affected EPN unable to provide service to the system, but the system itself has not detected the condition. The EPN Sanity Audit feature recognizes an EPN as unable to provide service when the software cannot receive control messages from EPN circuit packs. When such a failure is detected by the EPN Sanity Audit, a sequence of recovery actions is triggered to restore the EPN to service.

For a Standard system, the recovery sequence is as follows:

1. TDM Bus Switch
2. EPN Reset

For a duplicated system, the recovery sequence is as follows:

1. TDM Bus Switch
2. Expansion Interface Link Switch
3. Tone/Clock Switch within the EPN
4. EPN Reset

The EPN Sanity Audit feature activates only when all existing maintenance operations have failed to detect the EPN problem. Therefore, the EPN Sanity Audit serves as a safety net for the EPN.

NOTE:
It is not clear why certain types of EPN problems activate this feature. Thus, error log entries related to these problems do not specify which hardware to replace. The error log entries only indicate that some drastic recovery action occurred due to an unknown problem. However, clues as to the root cause of the EPN outage may be present in the Error Logs and the Alarm Logs of the following MOs: Switch Control (SW-CTL), TDM Bus (TDM-BUS), Expansion Interface (EXP-INTF), and TDM Bus Clock (TDM-CLK). Therefore, it is recommended that you refer to these maintenance sections during trouble shooting operations.

Hardware Error Log Entries and Test to Clear Values

EPN-SNTY Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any			None
8801 (a)	Any	None			
8802 (b)	Any	None			
8803 (c)	Any	None			
8804 (d)	Any	None			
9901 (e)	Any	None			
9902 (f)	Any	None			
9903 (g)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error occurs whenever the EPN is unable to send up-link control messages and the control channel of the TDM Bus in the EPN has been switched as part of the recovery procedure.

b. This error occurs whenever the EPN is unable to send up-link control messages and an EI link switch has been invoked as part of the recovery procedure.

c. This error occurs each time whenever the EPN is unable to send up-link control messages and the EPN Tone-Clock has been switched as part of the recovery procedure.

d. This error occurs whenever the EPN is unable to send up-link control messages and the EPN has been reset as part of the recovery procedure.

e. This error occurs whenever the EPN is unable to send up-link control messages, but recovers after the control channels of the TDM Bus in the EPN are switched.

f. This error occurs whenever EPN is unable to send up-link control messages, but recovers after the Expansion Interface Links to the EPN are switched.

g. This error occurs whenever the EPN is unable to send up-link control messages, but recovers after the active Tone-Clock in the EPN is switched.

ERR-LOG (Error Log)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
ERR-LOG	none	none	Error Log

Functional Description

The ERR-LOG MO is responsible for the sanity of the Alarm Log, the Hardware Error Log, and the Software Error Log. If an inconsistency is detected in any one of these logs, all logs are re-initialized and a hardware error is logged against ERR-LOG indicating the time of inconsistency. There are no tests and no alarms for the Error Log MO. This MO exists solely for the purpose of allowing errors to be logged against it.

Hardware Error Log Entries and Test to Clear Values

Error Log Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	Any	Any	Any	Any	none
510 (a)	Any	none	none	none	none

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates that an inconsistency was detected in either the Alarm Log, the Hardware Error Log, or the Software Error Log. To recover from this error, all of the logs were cleared and re-initialized. Any alarms that were active at the time of this error have been cleared. There is no associated test for this error. If the error persists, escalate the problem.

   The Aux data value indicates when the inconsistency was found:

0	Found during a periodic audit of the Error Log
1	Found after an extended reboot

Continued on next page

2	Found after a reboot
3	Found after a Reset System 3 (Cold_1)
4	Found after a Reset System 2 (Cold_2)
16	Found after a Warm Start
100	Found after an internal software audit

ETR-PT (Enhanced Tone Receiver Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
ETR-PT(a)	MAJOR	test port PCSSpp sh	Enhanced Tone Receiver Port
ETR-PT	MINOR	test port PCSSpp sh	Enhanced Tone Receiver Port
ETR-PT	WARNING	test port PCSSpp sh	Enhanced Tone Receiver Port

1 P is the port network number (1 for PPN, 2 - 3 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

NOTE:
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The TN2182 is a combined Tone Generator/Tone Detector board. It provides 8 Enhanced Tone receiver (ETR) ports. Each of these ports provides the functions previously found individually on DTMR-PTs, GPTD-PTs and CLAS-PTs ports. Thus each port on the TN2182 may be used for any tone detection function that was previously done by TN748, TN420 or TN744 Tone detection boards.

The TN2182 provides Mu-law or A-law tone detection capability.

Since the TN2182 also provides Tone/Clock function only one (or two if your system is duplicated) TN2182 circuit packs may be present in a port network. Thus if more tone detection resources are needed, the additional resources must be provided by TN748, TN420 or TN744 circuit packs.

Hardware Error Log Entries and Test to Clear Values

Enhanced Tone Receiver Port (ETR-PT) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1	any	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 2
18		busyout port	WARNING	OFF	release port PCSSpp
257 (b)	17666	Tone Detection Audit Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3
513 (c)	any	Tone Detection Verification Test (#42)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3

Notes:

a. There are two possible alarm levels for this error type: major alarm and minor alarm. These alarm levels are dependent on the administered thresholds for TTR, CPTR and CCTR. Each ETR port is capable of operating an any of these.

   A major alarm is raised if the total number of ports capable of TTR, CPTR or CCTR detection currently in-service is less than or equal to 1/2 of the administered TTR, CPTR or CCTR threshold number.

   Otherwise, a minor alarm is raised. In either case, run the short test sequence against the port (ETR-PT) and follow the error code procedures for the individual tests.

   The threshold number of ports for service is administered using the **change system-parameters maintenance** command. For details, refer to "Chapter 5, ''Routine Maintenance Procedures''.

b. The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, then the TN2182 circuit pack containing the defective ETR port should be replaced at a time when it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.

c. This error indicates the (ETR-PT) Enhanced Tone Receiver port is having problems detecting touch tones, call progress or MFC tones. If this error type is persistently logged, then the TN2182 circuit pack containing the defective ETR-PT should be replaced at a time it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.

d. The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, then the TN2182 circuit pack containing the defective ETR port should be replaced at a time when it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detection Audit/Update Test (#43)	X	X	ND

1 D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks out a single ETR port in the touch-tone receiver mode MFC tone detection/generation mode and general purpose tone detection mode. During the first portion of the test, the touch-tone receiver mode is tested. Then general purpose call progress and maintenance tones are tested and lastly MFC tones are tested.

Table 11-150. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test OR there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the tones.
1001	ABORT	The system was unable to put the ETR-PT in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This situation could occur when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm** command. Refer to TDM-BUS for details. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a Tone-Clock for the test connection. This may be caused by a heavy load on the system or by a faulted Tone-Clock. 1. Check to see if there are any alarms against the Tone-Clock in the port network where the test aborted. If so refer to the recommended procedures for TONE-BD or TONE-PT. 2. If a new Tone-Clock has been inserted, allow about 1 minute for maintenance to run on the newly inserted circuit pack. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-150. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Circuit Pack's response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2006	ABORT	This abort code indicates that the active Tone-Clock circuit pack or a Tone Detector circuit pack may not be functioning properly. On G3r V2 systems, this abort can also be caused by a mismatch between the companding mode administered for the system and that of the Tone Detector circuit pack. 1. [G3r V2] Make sure that the companding mode of the system matches that of the Tone Detector: mu-law for TN748; A-law for TN420. 2. Test the *active* Tone-Clock circuit pack in the port network with the **test tone-clock** PC command and refer to the TONE-BD section for failures. 3. Retry the command at 1-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1-122	FAIL	DTMF digits were not detected correctly. 1. Run the short test sequence via the **test port** PCSSpp **sh r 1** command. 2. If the problem persists, the system is still operating properly but capacity will be reduced. To restore performance to normal, replace the circuit pack containing the defective ETR-PT (Enhanced Tone Receiver Port). Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.

Continued on next page

Table 11-150. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
102	FAIL	2225 Hz Modem Answer Tone was not detected correctly. This will impact call-classification operation. 1. Run the short test sequence via the **test port** PCSSpp sh r 1 command. 2. If the problem persists, the system can still operate properly but capacity will be reduced. In order to restore performance to normal, replace the circuit pack containing the defective port. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.
130	FAIL	Forward or Backward MFC signals were not correctly generated or detected. This will impact MFC calls. 1. Run the short test sequence via the **test port** PCSSpp sh r 1 command. 2. If the problem persists, the system can still operate properly but capacity will be reduced. In order to restore performance to normal, replace the TN2182 circuit pack containing the defective ETR-PT. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.
	PASS	Tone Detection Verification is successful. The ETR Port is able to detect/generate all necessary tones.

Tone Detector Audit/Update Test (#43)

A Digital Signal Processor sanity audit is performed on the ETR-PT.

Table 11-151. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait 1 minute, and repeat the command a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Hardware audit failed. 1. Run the short test sequence via the **test port PCSSpp sh r 1** command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the circuit pack containing the defective ETR-PT. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.
	PASS	The ETR Port has passed the sanity inquiry.

EXP-INTF (Expansion Interface Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
EXP-INTF	MAJOR	test board PCSS sh	Expansion Interface Circuit Pack
EXP-INTF	MINOR	test board PCSS sh	Expansion Interface Circuit Pack
EXP-INTF	WARNING	test board PCSS sh	Expansion Interface Circuit Pack

1 Where P is the port network number 1, 2 or 3, C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

CAUTION:

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems relevant to the Packet Path of the TN570 Expansion Interface. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction" in addition to the relevant MO documentation.

The TN570 or the TN776 Expansion Interface circuit pack is used in G3iV1.1-286 and G3iV2-386 systems to provide connectivity between the Processor Port Network (PPN) and either Expansion Port Network (EPN) (network 2 or 3) or between the two Expansion Port Networks. The TN776 Expansion Interface is used in G1 systems to provide connectivity between the Processor Port Network and the (single) Expansion Port Network. This connectivity is provided via a 32 mpbs fiber optic cable. The TN776 supports circuit-switched connections and the control channel to and from the EPN. The TN570 also supports packet-switched connections for those systems that use the Packet Bus. The TN776 and TN570 circuit packs must only be used in matched pairs. A TN776 circuit pack does not function if connected via fiber to a TN570 circuit pack and vice versa.

The EPN(s), if present, are always under the control of the TN777 Processor circuit pack in the PPN. Therefore, if the Expansion Interface circuit packs to the EPN are not functioning correctly, service may be unavailable in that EPN, but is available in the PPN. If the Expansion Interface circuit packs between EPNs are not functioning properly, there is service in all networks, but connectivity between EPN and EPN is not available.

A system with EPN(s) may have one or two pairs of Expansion Interface circuit packs connecting any two cabinets. If two pairs exist, one pair operates as the Active pair and provides the required connectivity. The second pair acts as a hot Standby. When a problem arises on the Active pair, the Standby pair may be called upon to take over and provide continuous service with stable calls being preserved. The Expansion Interface circuit packs must be inserted into fixed slots. In G3iV1.1-286 and G3iV2-386, the valid slots for Expansion Interface circuit packs are: 1A01, 1A02, 1B01, 1B02, 2A01, 2A02, 2B02, 2B03, 3A01, 3A02, 3B02, or 3B03; in G1 the valid slots are: 1A01, 2A01, 1B01, or 2B02. It is also a requirement that the fiber cables be connected according to the following table:

Expansion Interface Circuit Pack Connections

EXP-INTF in slot	connected to EXP-INTF in slot	Description
1A01	2A01	Network 1 to Network 2
1B01	2B02	Network 1 to Network 2 (Duplicated Link)
1A02[1]	3A01	Network 1 to Network 3
1B02[1]	3B02	Network 1 to Network 3 (Duplicated Link)
2A02[1]	3A02	Network 2 to Network 3
2B03[1]	3B03	Network 2 to Network 3 (Duplicated Link)

1 G3iV1.1-286 and G3iV2-386 only.

NOTE:
If Expansion Interface circuit packs are connected in any other way, they do not function properly.

The Active Expansion Interface Link may be selected by system technician via the **set expansion-link PCSS** command, where PCSS is the address of either Standby Expansion Interface circuit pack. System Technician may prevent the system from switching Expansion Interface Links by using the **busyout board PCSS** command, where PCSS is the address of either Standby Expansion Interface circuit pack. These two commands are described later in greater detail in the "Expansion Interface Link Switch Command" section (located at the end of this EXP-INTF Maintenance documentation).

A G3MT terminal connected to an EPN [G3i] provides the same maintenance and administrative capabilities as the local administration terminal, but at a slower transmission speed. The EPN Maintenance circuit pack also provides Emergency Transfer and environmental monitoring functions for the EPN.

The abbreviations used in Figure 11-33 and Figure 11-34 have the following meanings:

- **PROC** The TN773 Processor circuit pack (the Active TN773 Processor circuit pack in a High or Critical Reliability system)
- **NETCON** The SW-CTL portion of the Network Control circuit pack (the Active Network Control circuit pack in a High or Critical Reliability system)
- **TDM BUS** The Time Division Multiplex Bus that connects circuit packs within a cabinet
- **EXP-INTF** The Expansion Interface (EXP-INTF) circuit pack
- **FIBER** The optical fiber used to connect Expansion Interface circuit packs
- **MAINT** EPN Maintenance (MAINT) circuit pack
- **PKT-BUS** The Packet Bus used to carry ISDN-BRI signalling information
- **MGR 1** The local administration terminal

The following figures show the connectivity for a 3-port network [G3iV1.1-286, G3iV2-386, G1] system with duplicated Expansion Links.

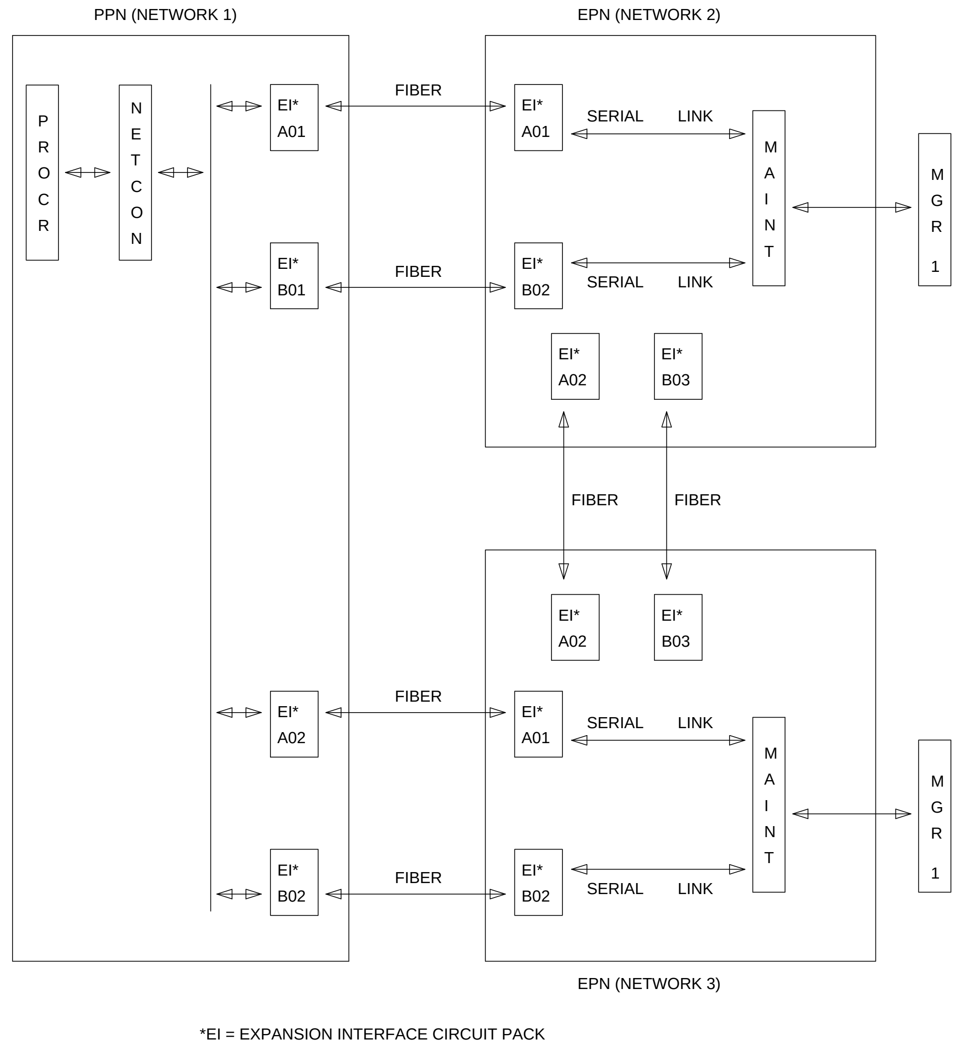

Figure 11-33. Expansion Interface Link Connectivity Between PPN and EPN(s)

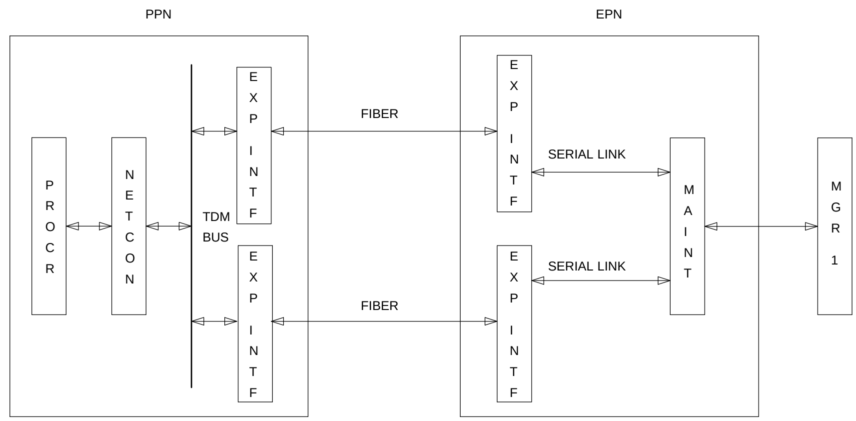

Figure 11-34. Expansion Interface Link Connectivity Between PPN and EPN [G1]

To determine which Expansion Interface Link is active and which is standby for each Expansion Interface pair, the **status system** command can be used. Alternately, visual inspection shows that the Active Expansion Interface circuit packs have the yellow LED on solid or blink a pattern two seconds on, 200 milliseconds off. See Table 11-152 for the possible Expansion Interface Yellow LED states. The Standby Expansion Interface circuit packs have the yellow LEDs off.

Table 11-152. Expansion Interface Circuit Pack Yellow LED Flashing Codes

Condition	LED on	LED off
Fiber Out-of-Frame (a)	0.1 sec	0.1 sec
In frame, No Neighbor (b)	0.5 sec	0.5 sec
Expansion Interface Active (c)	2 sec	0.2 sec
Expansion Interface Active (d)	solid on	never off
Expansion Interface Standby (e)	never on	solid off

Notes:

a. This flashing code corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes are usually accompanied by error code 1281 (no Expansion

Interface detected on opposite end of fiber). This condition may be caused by the absence of the opposite end Expansion Interface circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either Expansion Interface circuit pack.

b. This flashing code corresponds to error code 1281 from the Hardware Error Log and indicates a failure of Test #237. This condition is usually due to a failed Expansion Interface circuit pack on the opposite end of the fiber.

c. This is the normal state for an EPN Active Expansion Interface circuit pack that is also the bus master in the EPN.

d. This is the normal state for an Active Expansion Interface circuit pack that is not the bus master. It is also the state of the TN776 Expansion Interface circuit pack immediately after circuit pack initialization when the system has not yet assigned a role to it (that is, Active or Standby). To distinguish between these two situations, use the **status system** command. If the link which contains this Expansion Interface circuit pack is in-service (up), the Expansion Interface circuit pack is active; if it is out-of-service (down), the Expansion Interface circuit pack is neither active nor standby.

e. This is the normal state for a Standby Expansion Interface circuit pack. It is also the state of the TN570 Expansion Interface circuit pack immediately after circuit pack initialization when the system has not yet assigned a role to it (that is, Active or Standby). To distinguish between these two situations, use the **status system** command. If the link which contains this Expansion Interface circuit pack is in-service (up), the Expansion Interface circuit pack is standby; if it is out-of-service (down), the Expansion Interface circuit pack is neither active nor standby.

When testing Expansion Interface circuit packs to investigate problems, tests should always be run on both circuit packs of an Expansion Link. This provides a better indication of where a problem is located. Hardware errors for all Expansion Interface circuit packs (EXP-INTF) may be displayed by using the category "infc" on the Display Errors form.

In the EPN, the EPN TN775 Maintenance (MAINT) circuit pack monitors the sanity of the Expansion Interface circuit pack. If the Expansion Interface circuit pack should cycle between sane and insane several times, the Maintenance circuit pack holds the Expansion Interface circuit pack reset. If a new Expansion Interface circuit pack is installed in the EPN, the EPN Maintenance circuit pack should be removed because it may attempt to hold the new Expansion Interface circuit pack reset. The Maintenance circuit pack may be reinstalled after the Expansion Interface circuit pack has been inserted and the Expansion Interface circuit pack's red LED has gone off.

The Active Expansion Link is also involved in synchronization between the two cabinets. The Expansion Interface circuit pack reports slip errors if the two cabinets are not correctly synchronized. When diagnosing synchronization problems, the Expansion Interface circuit packs should be examined as a possible cause.

Relationship Between Expansion Interface and Tone-Clock Circuit Packs

The Expansion Interface fiber link depends on the system clock that is provided by the Active Tone-Clock circuit pack on each network. (See TDM-CLK and TONE-BD Maintenance documentation.) Each Expansion Interface circuit pack transmits over the fiber at a rate derived from the system clock on its network. If the Active Tone-Clock is defective to the point where the system clock frequency it produces is out of the specified range ("out of spec"), an Expansion Interface Link might go down even though the Expansion Interface circuit packs are healthy. In a High or Critical Reliability system, both links could go down if there is a defective Active Tone-Clock.

Whether or not a link goes down, depends on certain characteristics of the Expansion Interface circuit packs. An Expansion Interface circuit pack should not be replaced if the link on which it resides goes down because of a defective Active Tone-Clock circuit pack. The defective Tone-Clock circuit pack should be replaced instead. The Expansion Interface circuit packs are more sensitive to a defective system clock than the rest of the components of the system. Therefore, testing of the Tone-Clock circuit pack might not reveal a problem.

The symptoms of the problem in which an invalid system clock causes an Expansion Link to go down are as follows:

1. If the Active PPN Tone-Clock circuit pack is providing an invalid system clock:
   a. The EPN Expansion Interface circuit pack yellow LED blinks quickly.

      (Fiber Out-of-Frame condition from Table 11-152 on page 11-779).

      If the EPN is up, Test #238 fails on this Expansion Interface circuit pack.
   b. The PPN Expansion Interface circuit pack yellow LED blinks slowly.

      (In-frame, No Neighbor condition from Table 11-152 on page 11-779).

      Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.
2. If the EPN Tone-Clock circuit pack is providing an invalid system clock:
   a. The PPN Expansion Interface circuit pack yellow LED blinks quickly

      (Fiber Out-of-Frame condition from Table 11-152 on page 11-779).

      Test #238 fails on this Expansion Interface circuit pack.
   b. The EPN Expansion Interface circuit pack yellow LED blinks slowly

      (In-frame, No Neighbor condition from Table 11-152 on page 11-779).

If the EPN is in-service, Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.

These symptoms can also be the result of other problems (for example, one half of the fiber being unable to transmit data). If the system exhibits these symptoms, execute the following procedure:

1. Verify that the EPN stays down for at least one minute.

   If the Expansion Interface Link comes back in service after a short time, without switching the Active Tone-Clock, the problem probably was the on-line synchronization source became invalid (see SYNC Maintenance documentation for more information).

   However, if the Expansion Interface Link(s) has not come back into service after one minute, the synchronization source is not the cause of the problem. Proceed to Step 2.

2. Check for errors via the **display errors** command with the Category field set to "tone" and the Active alarms field set to "n." Some of the alarms on EPN objects might have been resolved if the EPN went down. Refer to the appropriate MO Maintenance documentation for descriptions of any of the errors occurring at about the same time as the EXP-LINK errors. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the EPN went down, the problem was probably that the synchronization on-line reference became invalid. Since reference switching was disabled, the Tone-Clock did not switch from the invalid reference. Therefore, the Tone-Clock circuit pack put out a system clock that was "out of spec." Issue the **enable synchronization-switch** command. If the EPN is down, reseat the Tone-Clock circuit packs on the EPN. This action should restore the EPN to service.

   Execute Steps 3 and 4 in the order most convenient to you and least destructive to the customer.

3. Check if the fiber optic cable is transmitting properly via the following procedure on one of the out-of-service links:

   a. Carefully record the symptoms (yellow LED pattern and tests failing) that were occurring on the PPN Expansion Interface circuit pack and the EPN Expansion Interface circuit pack. Clearly indicate which symptoms are occurring on which Expansion Interface circuit pack.

   WARNING:
   Before proceeding, note which is the current transmit fiber and which is the current receive fiber for proper reconnection.

   b. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the PPN Expansion Interface circuit pack slot (see Figure 11-35 on page 11-786).

   c. Connect what was formerly the transmit fiber to the receive jack.

d. Connect what was formerly the receive fiber to the transmit jack.

e. Perform Steps b, c, and d on the opposite end of the fiber and the lightwave transceiver on the back of the EPN Expansion Interface circuit pack slot.

NOTE:
If it is more convenient for you, execute Steps b, c, and d on the EPN Expansion Interface circuit pack first.

f. If the symptoms which were formerly occurring on the PPN Expansion Interface circuit pack are now occurring on the EPN Expansion Interface circuit pack and vice versa, the fiber is defective and should be replaced.

4. Determine if the problem is due to a defective Active Tone-Clock circuit pack. Refer to the preceding list of symptoms to decide which network contains the suspect Active Tone-Clock. See Warning.

WARNING:
If you remove the EPN Expansion Interface circuit pack that is active or that was active when the EPN was last in-service, then the 2A/3A Tone-Clock circuit pack becomes the Active Tone-Clock. This characteristic can be deceiving. Replacing or reseating the Active EPN Expansion Interface circuit pack might restore the Expansion Interface Links temporarily. However, if the 2B/3B Tone-Clock circuit pack was really the source of the problem and not the Expansion Interface circuit pack, then the Expansion Interface Link(s) goes down again the next time a Tone-Clock switch to the 2B/3B Tone-Clock is attempted (probably when the scheduled Tone-Clock switch occurs).

WARNING:
If, after all the Expansion Interface Links are restored, you suspect the problem might have been due to a defective Tone-Clock circuit pack, switch to this Tone-Clock at an appropriate time. If the Tone-Clock circuit pack was the cause of the problem and the same Expansion Interface circuit packs are in place, the same Expansion Interface Link(s) goes down again.

a. On a High or Critical Reliability system in which the network containing the suspect Tone-Clock circuit pack is in-service:

Switch to the Standby Tone-Clock on this network. If the suspect Tone-Clock circuit pack is defective, the Expansion Interface Link(s) should be restored to service at this point. Switching back to the defective Tone-Clock should make the same Expansion Interface Link(s) go out-of-service. Such a Tone-Clock circuit pack is defective and should be replaced as soon as possible. If switching Tone-Clocks does not bring up the EPN, then this Tone-Clock is not the source of the problem. Make sure to switch back to the original Tone-Clock.

WARNING:
If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch causes the same Expansion Link(s) to go out-of-service again.

b. On a system in which the EPN containing the suspect Tone-Clock circuit pack is out-of-service:

   Replace the Active Tone-Clock circuit pack on this network. In a High or Critical Reliability system, the Active Tone-Clock is the Tone-Clock circuit pack whose yellow LED is: 1) blinking and 2) blinking slower if both Tone-Clocks have blinking yellow LEDs. If the Expansion Interface Link(s) comes up after replacing this Tone-Clock circuit pack, then this Tone-Clock circuit pack should be replaced as soon as possible. See Warning.

WARNING:
If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch causes the same EPN to go out-of-service again.

   If replacing the Active Tone-Clock did not bring up the Expansion Interface Link(s), then this Tone-Clock circuit pack is not the source of the problem.

c. On a standard system in which the PPN contains the suspect Tone-Clock circuit pack:

   Replace the PPN Tone-Clock circuit pack **at a time when bringing down the system is most convenient to the customer**.

WARNING:
Replacing the PPN Tone-Clock circuit pack stops call processing on that network and also brings down stable calls. This action eventually causes a Reset System 2 (Cold 2 restart).

   If replacing the Tone-Clock circuit pack restores the Expansion Interface Link(s), then the Tone-Clock circuit pack is defective and should be replaced. Otherwise, the problem is not with the PPN Tone-Clock circuit pack.

Expansion Interface Manual Loop Back Procedure

This procedure is to be used when an Expansion Interface circuit pack cannot be tested by software. This is usually when the Expansion Interface circuit pack is in the EPN and the EPN is down. A spare length of fiber jumper cable is required for this procedure.

If this procedure is run on both Expansion Interface circuit packs of a link, and both check out fine, then the failure is most likely in the fiber itself if neither Expansion Interface circuit pack is busied out, but the link remains inactive.

1. Busyout the Expansion Interface circuit pack using the **busyout board PCSS** command.
2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the Expansion Interface circuit pack slot. **Note which is the transmit fiber and which is the receive fiber for proper reconnection at the end of this procedure.**
3. Using a spare fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in Figure 11-35 on the following page.
4. Go to the front of the cabinet and inspect the yellow LED.
   - If the yellow LED is on steady, this Expansion Interface circuit pack and the lightwave transceiver are functioning properly.
   - If the yellow LED is off, reseat the circuit pack. For the TN776, if the yellow LED comes on steady after the red LED has gone off, the Expansion Interface circuit pack and the lightwave transceiver are functioning properly. For the TN570 [G1V5], if the yellow LED is off steady after the red and green LEDs have gone off, the Expansion Interface circuit pack and the lightwave transceiver are functioning properly.
   - If the yellow LED flashes on at a rate of once per second, the Expansion Interface circuit pack or transceiver should be replaced.
   - If the yellow LED flashes on at a rate of five times per second, the Expansion Interface circuit pack or the lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the network containing this Expansion Interface circuit pack. Refer to the procedure described in the preceding "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" on page 11-781 section for further details.
5. Replace faulty component(s) and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in Step 3.
6. Release Expansion Interface circuit pack with the **release board PCSS** command.

Table 11-153. Expansion Interface Circuit Pack Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
10001 (s)	0	None			
10002 (t)	0	None			
10003 (u)	0	None			
10004 (v)	0	None			
11000 (w)	0	None			
11000 (x)	2	None			
11000 (y)	3	None			
11000 (z)	4	None			
11000 (aa)	5	None			
11000 (ab)	8	None			
11001 (ac)	0	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Expansion Interface circuit pack has been busied out by system technician.

b. Expansion Interface circuit pack has been administered on the Circuit Pack form, but has not been physically inserted into the system. Insert the circuit pack.

c. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

d. This alarm is raised after an Expansion Interface circuit pack has been removed from a slot for 11 minutes. The alarm is resolved when the Expansion Interface circuit pack is inserted into this slot. Another way to resolve or prevent this alarm is to use the **change circuit pack** command to remove the Expansion Interface circuit pack administrative entry for this slot after the Expansion Interface circuit pack has been removed from the slot. Or, if the circuit pack is in the system and the red LED is on, then follow the instructions for "Red (alarm)" in the "Control and Port Circuit Pack Status LEDs" section in Chapter 7, "LED Interpretation".

e. Error Type 257 with Aux Data 85 through 88 indicates that this Expansion Interface circuit pack is detecting incorrect data on the incoming fiber bit stream. The data is originating at the opposite Expansion Interface circuit pack. These errors could result from a bad timing reference on the network which contains the Expansion Interface circuit pack on the opposite end of the fiber. For example, if the error is logged against the 1B01 (PPN) Expansion Interface circuit pack, then the bad timing reference would be on the EPN. Look for EXP-INTF errors 2305, 769, or 770. Resolve these errors. If there are any TONE-BD, TDM-CLK, or SYNC errors, resolve these errors as well. Finally, if the errors continue to occur, perform the following procedure:

   1. If the Expansion Interface circuit pack reporting the error is part of the Active link and a Standby link exists, switch to the Standby link.
   2. Reset the Expansion Interface circuit pack at the opposite end of fiber.
   3. Issue the **test board PCSS repeat 10** command, where PCSS is the address of the EXP-INTF circuit pack reporting the error. If Tests #241 or #316 fail even once, follow the documentation procedures associated with the failures.
   4. Wait 15 minutes. Then check the Error Log to see if new errors of type 257 have been detected.
   5. If errors are present, reset the Expansion Interface circuit pack reporting the errors.
   6. Wait five minutes. Then check the Error Log to see if new errors of type 257 have been detected.
   7. If errors are present, replace the Expansion Interface circuit pack or transceiver at the opposite end of the fiber.
   8. Wait 15 minutes. Then check the Error Log to see if new errors of type 257 have been detected.
   9. If errors are present or if this error occurs intermittently (over one week’s time), replace the Expansion Interface circuit packs or transceivers on this link.

f. Error Type 513 with Aux Data 5 through 7 indicates an ON BOARD hardware failure of the circuit packs RAM or ROM. Replace the Expansion Interface circuit pack or transceiver.

g. Error Type 1538 indicates a hyperactive Expansion Interface circuit pack that is generating an abnormal amount of control messages to the TN777 Processor circuit pack. When this error was generated, the Expansion Interface was automatically reset by the system. If this system does not have duplicate Expansion Interface Links, service to the EPN is disrupted. If this system does have duplicate Expansion Interface Links, the system should have switched to the Standby Expansion Interface Link. Reset the Expansion Interface. If error 1538 is detected again, replace the Expansion Interface circuit pack or transceiver.

h. Error Type 2049 indicates that the last time the Expansion Interface circuit pack was reset, its initialization tests failed. The number in the Aux Data field is the error code with which Reset Test (#336) failed. Follow the procedure specified in the Reset Test (#336) FAIL section for this error code.

i. Error Type 2305 with aux data 118 indicates that the Expansion Interface circuit pack has detected slips on the incoming fiber data stream. Thus, the EPN and PPN are not synchronized. Examine the Error Log for any SYNC, TDM-CLK, TONE-BD, and DS1-BD errors. If these errors exist, refer to the appropriate Maintenance documentation for repair procedures. If the errors do not exist, refer to the SYNC (Synchronization) Maintenance documentation for general information on diagnosing synchronization problems. If there are no active Expansion Interface circuit pack errors with Error Types 769 and 770, Error Type 2305 is resolved when fewer than nine slips are detected in a 5- to 10-minute period (that is, Error Type 2305 is resolved within 10 minutes of the last slip.) If the Error Log has an active Expansion Interface error with type 769 or 770, then Error Type 2305 is resolved when Error Types 769 and 770 are resolved.

NOTE:
These errors may be ignored if they occur during clock interchanges.

j. Error Type 2561 indicates an on-board failure of Expansion Interface circuitry related to handling packet data from the fiber interface and from the Packet bus interface. If this error has generated a minor alarm, the Expansion Interface circuit pack or transceiver should be replaced.

k. Error Type 2817 indicates an on-board failure of Expansion Interface circuitry related to transmission of data to the fiber interface. If this error has generated a minor alarm, the Expansion Interface circuit pack or transceiver should be replaced.

l. Error Type 3074 and 3075 indicates failures of Expansion Interface circuit pack packet path tests. These packet path tests do exercise circuitry on both Expansion Interface circuit packs of the Expansion link. If Error Type 3075 is present without Error Type 3074, the fault most probably lies with the Expansion Interface circuit pack that reported the error. The Expansion Interface circuit pack or transceiver should be replaced. If Error Type 3074 exists with or without 3075, the fault is most probably on the neighbor of the Expansion Interface circuit pack that reported this error. The neighbor Expansion Interface circuit pack or transceiver should be replaced.

NOTE:
Certain Packet Bus failures can cause this error. In that case the EI is not defective. If PKT-BUS errors are also present, refer to Chapter 9, "Packet Bus Fault Isolation and Correction" and the PKT-BUS section

of Chapter 11 for fault isolation procedures. If PKT-BUS errors are not present and replacing the EI does not solve the problem this error can still be the result of a Packet Bus failure. Again, refer to Chapter 9, "Packet Bus Fault Isolation and Correction" and the PKT-BUS section of Chapter 11 for fault isolation procedures.

m. Error Type 3330 indicates a failure of a diagnostic component on the Expansion Interface circuit pack. The failed component does not impair service, but it may leave the Expansion Interface circuit pack in a state where the Expansion Interface circuit pack cannot detect errors.

n. Error Type 3585 indicates that the Expansion Interface circuit pack experienced a series of very short out-of-frame conditions within several minutes. This may indicate transmission difficulties over the fiber link. If this is a duplex system, and if no other alarms exist, the system should have switched away from the fiber link using this Expansion Interface circuit pack. If this condition ceases, the warning alarm should be resolved within 15 minutes. In the meantime, make sure all lightwave transceivers are firmly secured to the back of the cabinet. Thereafter, if the alarm is not resolved during the next four 15-minute segments, replace the following (the first after the first 15-minute segment, the second after the second 15-minute segment, etc.):

   1. Lightwave transceiver attached to the Expansion Interface reporting the alarm
   2. Lightwave transceiver on the opposite end of the fiber
   3. Expansion Interface board reporting the alarm
   4. Expansion Interface board on the opposite end of the fiber

   Since the counter is active only due to a transient condition, there is no test that can be run to clear the counter. However, the counter is automatically decremented by one every five minutes. Once the condition causing the transient Fibers Out-of-Frame (FOOFs) has been fixed, it will take 15 minutes for the counter to be cleared if the alarm was raised.

o. Error Type 3841 indicates that the Expansion Interface (TN570 only) has reported a loss of lock with the backplane system clock.

p. Error Type 3842 indicates that the test that queries the Expansion Interface (TN570 only) for the state of the lock to the system clock has failed. This means that a loss of lock condition is present. A link switch is then attempted, and the alarm is raised. When both links report this error, the link switch is not attempted because, in this case, the problem is more likely to occur with the backplane clock than with the Expansion Interface circuit pack.

q. The counter associated with Error Types 3841 and 3842 is cleared when the query for the state of the lock-to-system-clock passes. Once the alarm is raised, this test is run every five minutes. However, the test is not part of any sequence that can be run on demand.

r. Error Type 10000 is a report from the Expansion Interface circuit pack that its internal data has become corrupted. The Expansion Interface circuit pack has lost track of control messages destined for the EPN. When this error is detected, the system automatically resets the Expansion Interface circuit pack and brings the EPN down. Service to the EPN is unavailable for several minutes after detection of this error. No system technician action is required.

s. Error Type 10001 is a report that the Expansion Interface circuit pack dropped one control message to the EPN. This condition may have been observed as a call that did not complete correctly. No system technician action is required.

t. In response to Error Type 10002, the system denied all calling services for up to 10 seconds.

   If Expansion Interface Error Type 257 is logged at the same time against an Expansion Interface circuit pack on this link, first try to resolve this error. The error associated with Error Type 257 could be the cause of this error.

   If Error Type 257 is not logged at the same time as this error, then Error Type 10002 indicates that heavy call traffic was encountered involving EPN endpoints.

   No system technician action is required; however, should this error recur frequently, the system should be examined for traffic engineering. The PPN and EPNs may not be equipped with sufficient trunks and Tone Detectors for the number of stations in each cabinet.

u. Error Type 10003 indicates that heavy call traffic involving EPN endpoints has returned to normal levels. This Error Type should always appear after Error Type 10002 or 10004. No system technician action is required.

v. Error type 10004 indicates that an extreme backup of traffic was present on the Expansion Interface circuit pack. The EPN served by this link was most probably not providing service when this error was logged. If this is a High or Critical Reliability system, the system should have switched to the Standby Expansion Link in order to restore service. Error type 11000 with an Aux value of 5 should have been logged against EXP-INTF to indicate this condition.

   In a standard system, the system should have reset the EPN in order to restore service. EXP-LINK Error Type 122 with an Aux value of 6 should have been logged to indicate this condition.

w. Error Type 11000 with an Aux value of 0 appears when an Expansion Interface Link switch takes place. Data calls between the PPN and EPN may have experienced some data loss or, in severe cases, the data calls may have dropped. The link that became active is the link with the circuit pack address given in the Error Log entry. The link switch may have occurred for several reasons:

   1. System Technician demanded the Expansion Interface Link switch. This can be verified by using the **list history** command.

2. The Expansion Interface Link switch may have been scheduled. Check the Maintenance-Related System Parameters form.
3. An Expansion Interface circuit pack error may have been detected. Examine the Error Log for other Expansion Interface circuit pack errors with the same approximate time as this error.
4. An EPN Maintenance circuit pack error may have been detected. Examine the Error Log for MAINT errors with the same approximate time as this error. MAINT Error Type 2561 indicates that the Active Expansion Interface circuit pack on the EPN could not communicate with the EPN Maintenance circuit pack. MAINT Error Type 3329 means the EPN Maintenance circuit pack cannot talk to the EPN Expansion Interface circuit pack in the A carrier. MAINT Error Type 3585 means the EPN Maintenance circuit pack cannot talk to the EPN Expansion Interface circuit pack in the B carrier.
5. Synchronization (SYNC) maintenance may have detected an inability of the Active Expansion Interface Link to provide synchronization between cabinets. Examine Error Log for SYNC Error Type 2305 with the same approximate time as this error.

x. Error Type 11000 with an Aux value of 2 appears when a system technician-demanded Expansion Interface Link Switch is issued. No further action is required.

y. Error Type 11000 with an Aux value of 3 appears when a scheduled Expansion Interface Link Switch has occurred. No further action is required.

z. Error Type 11000 with an Aux value of 4 appears when an Expansion Interface Link Switch has occurred due to a Special EPN recovery strategy. The software has forced an Expansion Interface switch because the new Expansion Interface Link contains new features which support EPN recovery in case of a bad tone/clock board. This error code appears when there is a periodic/scheduled tone/clock switch.

aa. Error Type 11000 with an Aux value of 5 appears when the system has detected an excessive backup of traffic on the Active Expansion Link. This condition may have been due to communication difficulties on the Expansion link. To restore normal service, the system switched Expansion Links to the link identified in the Error Type 11000 with an Aux Data value of 5. Error Type 10004 should be present against the Expansion Interface circuit pack that reported the traffic congestion.

ab. Error type 11000 with an Aux value of 8 indicates that the Expansion Interface link was switched as part of the recovery action taken by EPN-SNTY. This error should be accompanied by EPN-SNTY error 8802 0. If EPN-SNTY error 9902 0 is also present, this indicates that the switching of the Expansion Interface link was the recovery action that restored sanity to the EPN. In this case, the fault was with the link that was switched away from. The relevant Expansion Interfaces and connections should be tested and examined to determine the cause of the problem. Look for EPN-SNTY errors in the error log, and refer to the EPN Sanity Audit (EPN-SNTY) section for more details.

ac. Error Type 11001 occurs when an Expansion Link switch was attempted but for unknown reasons could not be completed.

Expansion Interface LED Usage

The Expansion Interface circuit pack has the standard red, green, and yellow LEDs. The red and green LEDs have the traditional use, where red means some alarm condition and green indicates maintenance testing in progress. The yellow LED is used to provide useful visual status information. The state of the yellow LED is very important when executing the Expansion Interface Manual Loop Back Procedure previously described. The possible yellow LED states are shown in Table 11-152 on page 11-779.

Upon power-up, the TN776 red LED comes on and off, followed by the yellow LED coming on solid. The TN570 red and green LEDs comes on and off. The yellow LED remains off.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Expansion Interface Reset Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Expansion Interface Reset Test (#336)			D
Expansion Interface Fiber Out-of-Frame Query Test (#238)	X	X	ND
Expansion Interface Lightwave Transceiver Interface Loop Around Test (#242)		X	D
Expansion Interface Control Channel Test (#316)	X	X	ND
Expansion Interface Neighbor Query Test (#237)	X	X	ND
Expansion Interface Local Loop Around Test (#240)	X	X	ND
Expansion Interface 2-Way Transmission Test (#241)	X	X	ND
TN570 Expansion Interface Packet Interface Test (#589)	X	X	ND

1 D = Destructive; ND = Nondestructive

Expansion Interface Neighbor Query Test (#237)

The Expansion Interface Neighbor Query Test is a request to an Expansion Interface circuit pack to determine if it has established communication with the Expansion Interface circuit pack on the opposite end of the fiber.

Table 11-154. TEST #237 Expansion Interface Neighbor Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Someone may be doing something on this Port Network Interface. 1. Retry the command at 1-minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
2027	FAIL	The Expansion Interface circuit pack has contact with the opposite Expansion Interface circuit pack, but it is the incorrect Expansion Interface circuit pack. 1. Check Expansion Interface circuit packs and lightwave transceivers to verify that they are placed in the correct slots described above. 2. If working with duplicate Expansion Interface Links, check for crossed fiber pairs such as 1A01 connected to 2B02 or 1B01 connected to 2A01.

Continued on next page

Table 11-154. TEST #237 Expansion Interface Neighbor Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Expansion Interface circuit pack under test cannot make contact with opposite end Expansion Interface circuit pack. 1. If Test #238 passes (yellow LED not blinking at a rate of five times per second), the Expansion Interface circuit pack is detecting the framing signal and an Expansion Interface circuit pack is at least physically present on the opposite side. a. Reset the OPPOSITE Expansion Interface circuit pack using the **reset board PCSS** command where PCSS is the address of the OPPOSITE Expansion Interface circuit pack. b. If the reset command returns the message "EPN is unavailable," use the **change circuit-pack** command to add a TN776/TN570 Expansion Interface circuit pack to the correct EPN slot. Then, repeat the **reset board** command. c. If the reset command returns the message "Board not Assigned," the EPN Maintenance circuit pack may be holding the Expansion Interface circuit pack reset. First, try to reset the EPN Maintenance circuit pack using the **test maintenance long** command. Then, repeat the **reset board** command on the EPN Expansion Interface circuit pack. d. If the reset does not pass, refer to the Expansion Interface Reset Test (#336). e. If the reset passes, execute the **test board PCSS** command on the opposite Expansion Interface circuit pack. Resolve all problems on the opposite Expansion Interface circuit pack before proceeding. f. If this test still does not pass, try replacing the Expansion Interface circuit pack on which this test is failing. 2. If Test #238 fails (yellow LED is blinking at a rate of five times per second), refer to the procedures for Test #238.

Continued on next page

Table 11-154. TEST #237 Expansion Interface Neighbor Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Expansion Interface circuit pack has successfully established a link with the opposite Expansion Interface circuit pack. 1. If the **status system** command still indicates that this link is down, it is possible that one or both of the Expansion Interface circuit packs have been busied out. 2. If the link still does not come up, reset one or both Expansion Interface circuit packs on the link.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Fiber Out-of-Frame (FOOF) Query Test (#238)

This test is a request to an Expansion Interface circuit pack to determine if it is currently detecting the framing sequence on the incoming fiber data stream. If it cannot detect this framing signal, the Expansion Interface circuit pack is not able to establish a link with the opposite Expansion Interface circuit pack.

Table 11-155. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2026	ABORT	Expansion Interface circuit pack responded with an unknown reply. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, replace the circuit pack or transceiver.

Continued on next page

Table 11-155. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Expansion Interface circuit pack could not detect framing sequence. 1. Check if the Expansion Interface circuit pack on the opposite end of the fiber is present and if its cabinet has power. 2. Verify that the lightwave transceiver is connected to the correct slot on the back of the cabinet and that the fiber is connected to the lightwave transceiver. Verify this connection on both ends of the fiber. Check that an Expansion Interface circuit pack detects its lightwave transceiver by executing the **reset board PCSS** command, where PCSS refers to the Expansion Interface circuit pack. If the reset passes, the Expansion Interface circuit pack detects a lightwave transceiver. Refer to the description of the Expansion Interface Reset Test (#336) if the reset fails. 3. Verify that fiber transmit and receive ends have not been crossed when connected to the lightwave transceiver. 4. The problem may be due to a synchronization timing loop. Use the **status sync** command to determine which circuit pack is the synchronization reference. If the reference is a DS1 Interface circuit pack, use the **set sync** command to make a Tone-Clock circuit pack the reference. If this action causes the Expansion Interface to go into frame, synchronization must be examined for a possible timing loop. Refer to SYNC (Synchronization) Maintenance documentation for repair procedures. If the DS1 Interface circuit pack is not a reference, and the Expansion Interface circuit pack that is failing Test #238 is in the PPN, run tests on Tone-Clock circuit pack in the PPN to determine if clocks are present. If the Expansion Interface circuit pack that is failing Test #238 is in the EPN, and the red LEDs are ON on a large number of circuit packs, then reseat any Tone-Clock circuit packs in the EPN. *More information follows.*

Continued on next page

Table 11-155. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	5. Execute the **test tone-clock PC** command where P is the port network which contains the Expansion Interface circuit pack's neighbor Expansion Interface on the OPPOSITE end of the fiber and C refers to the carrier which contains the Active Tone-Clock on port network P. Also, look for SYNC errors in the Error Log. If there are any tests failing or errors found, resolve these problems and then rerun Test #238. If the test still fails and the system has a Standby Tone-Clock, switch the Active Tone-Clock on this network (**set tone-clock PC** command, where P is the port network containing the Expansion Interface circuit pack on the OPPOSITE end of the fiber and C is the carrier containing the Standby Tone-Clock). Also, if the EPN is down, replace the EPN Tone-Clock circuit pack in carrier A of the EPN. 6. Check for errors using the **display errors** command with the Category field set to "tone" and the Active alarms field set to "n." Some of the alarms on EPN objects might have been resolved if the EPN went down. Refer to the documentation for descriptions of any of the error types occurring at about same time as the EXP-LINK error types. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the EPN went down, the problem was probably that the Synchronization on-line reference became invalid. Since, reference switching was disabled, the Tone-Clock did not switch away from the invalid reference. Therefore, the Tone-Clock put out an "out-of-spec" system clock. Execute the **enable synchronization-switch** command. If the EPN is down, reseat the Tone-Clock circuit packs on the EPN. This action should restore the EPN to service. 7. Follow the procedure described in "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" near the beginning of this section if the symptoms match those described there.

Continued on next page

Table 11-155. TEST #238 Expansion Interface Fiber Out-of-Frame Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Expansion Interface circuit pack has detected the valid framing signal on the fiber. 1. Refer to errors from other Expansion Interface circuit pack tests if the link is still not functioning.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Local Loop Around Test (#240)

This test is similar to the Lightwave Transceiver Loop Around Test described in Test #242. A test tone from TDM Bus A is received by the Expansion Interface circuit pack under test, but is not transmitted out to the lightwave transceiver before being looped back onto TDM Bus A again. The test is then repeated using TDM Bus B. Thus, this loop back test is performed on each TDM Bus on the network containing the Expansion Interface circuit pack to verify that the Expansion Interface circuit pack is able to loop back data on each TDM Bus. Since this loop back is internal to the circuit pack, this test does not interfere with the normal fiber data stream.

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	ABORT	Could not allocate time slot on TDM Bus A. Loop back passed on TDM Bus B.
2	ABORT	Could not allocate time slot on TDM Bus B. Loop back passed on TDM Bus A. 1. If there is no reason to doubt that the Expansion Interface circuit pack can transfer data to or from a TDM Bus, then since the test passed on one bus, assume that the test passes on the other bus as well. 2. If EXP-INTF circuit pack Error Types 1, 2, 1537, or 1793 are present in the Error Log and/or if Expansion Interface circuit pack Tests #240, #241, or #242 have failed previously, there is reason to doubt that the Expansion Interface circuit pack can transfer data to or from a TDM Bus. To determine if the test can pass on both TDM Buses, perform the following procedure: For Error Code 1, issue the **set tdm PC** command, where P is the network containing the Expansion Interface circuit pack being tested and C is the TDM Bus A. Execute the **test board PCSS** command again. If this test passes or aborts with Error Code 2, this test is considered to have passed. For Error Code 2, issue the **set tdm PC** command, where P is the network containing the Expansion Interface circuit pack being tested and C is the TDM Bus B. Execute the **test board PCSS** again. If this test passes or aborts with error code 1, this test is considered to have passed. 3. If this test continues aborting with the same error after setting the TDM Bus as indicated in Step 2, rerun the test at one-minute intervals a maximum of five times. Apply the passing criteria for Step 2 to each result. 4. If the test still does not pass on the other TDM Bus, follow the procedure for abort error code 3.

Continued on next page

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	ABORT	The system could not allocate time slots for the test on either TDM Bus. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Enter **display errors** and follow associated repair procedures for TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 3 times. 2. If test continues to abort, follow normal escalation procedures.
1002	ABORT	The system could not allocate time slots for the test on either TDM Bus. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If these errors are present, refer to TTR-LEV (TTR Level) Maintenance documentation. Even if there are no TTR-LEV errors, there still may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If not, this test always aborts for this Expansion Interface circuit pack. This does not harm the system in any way. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1031	ABORT	A query of the Expansion Interface circuit pack aborted. The purpose of this query was to see if the Expansion Interface circuit pack could detect the framing signal. 1. If Test #238 aborted, follow the procedure associated with this abort code. 2. If Test #238 did not abort, rerun Test #240 at one-minute intervals a maximum of five times. 3. If Test #240 continues to abort without Test #238 aborting, escalate the problem.
1032	ABORT	The Expansion Interface circuit pack cannot detect the framing signal and cannot run the test. 1. Refer to the errors for Test #238 to determine why the Expansion Interface circuit pack is out-of-frame.

Continued on next page

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	Loop back on TDM Bus A failed. Loop back on TDM Bus B passed.
2	FAIL	Loop back on TDM Bus B failed. Loop back on TDM Bus A passed.
3	FAIL	Loop back on both TDM Busses failed.
12	FAIL	Loop back on TDM Bus B failed. Loop back TDM Bus A aborted because the system could not allocate time slots.
21	FAIL	Loop back on TDM Bus A failed. Loop back on TDM Bus B aborted because the system could not allocate time slots.
	FAIL	The test tone was not detected correctly after being looped through the Expansion Interface circuit pack. 1. If error type 2305 has been logged against the Expansion Interface circuit pack in the last 5 minutes, this test could have failed due to the associated slips. If this is the case, first resolve the 2305 error, and then repeat test. 2. Run the tests for the Active Tone-Clock on the Port Network that contains the indicted Expansion Interface circuit pack to verify that dial-tone is being supplied. 3. If the tone-clock is healthy, repeat the short test on the Expansion Interface circuit pack. 4. If this test continues to fail, replace Expansion Interface circuit pack.
	PASS	Test tone was correctly detected after the internal Expansion Interface loop back on both TDM Busses. 1. Refer to other Expansion Interface circuit pack tests if the Expansion Interface Link is not functioning correctly.

Continued on next page

Table 11-156. TEST #240 Expansion Interface Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface 2-Way Transmission Test (#241)

This test is a basic connectivity test between the two cabinets. The test first sends a test tone from the cabinet of the Expansion Interface circuit pack under test through the opposite Expansion Interface circuit pack to a Tone Detector in the opposite cabinet. The connections are then reversed and the tone is passed in the opposite direction. This test should be run once from each Expansion Interface circuit pack on the fiber.

Table 11-157. TEST #241 Expansion Interface 2-Way Transmission Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-157. TEST #241 Expansion Interface 2-Way Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. Even if there are no TTR-LEV errors, there still may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If there is not at least one Tone Detector, this test always aborts for this Expansion Interface circuit pack. This does not harm the system in any way. **NOTE:** G3 systems require that Tone Detector circuit packs (TN768) must be of vintage "B" or newer. If older Tone Detector circuit packs are installed in the system, this test well always abort with this abort code. 2. Look for TONE-PT errors in the Hardware Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1033	ABORT	The test cannot run because either one or both of the Expansion Interface circuit packs on this link are busied out or an Expansion Interface circuit pack is not present on the opposite end of the fiber. 1. If Expansion Interface is busied out, issue the **release board PCSS** command. 2. Examine results of Tests #237 and #238.

Continued on next page

Table 11-157. TEST #241 Expansion Interface 2-Way Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 3 retries. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals for a maximum of 3 retries. 2. If the test continues to abort, escalate the problem.
	FAIL	The test tone was not detected correctly in either direction. 1. Run the test for the Active Tone-Clocks on the Port Networks for which the Expansion Interface circuit pack under test provides a link. This will determine if the dial tone is being supplied. 2. Check for disconnected transmit or receive fiber on both ends of the fiber. Make sure both endpoint circuit packs are inserted and have no on-board alarms. 3. If this test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-157. TEST #241 Expansion Interface 2-Way Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 or 2	FAIL	The test tone was detected correctly in only one direction. 1. Run the test for the Active Tone-Clocks on the Port Networks for which the defective Expansion Interface circuit pack provides a link. This determines if the dial tone is being supplied. 2. Check for disconnected transmit or receive fibers on both ends of the fiber. 3. If Test #238 is failing, refer to procedures for Test #238. 4. If Error Type 2305 has been logged against this Expansion Interface circuit pack, or the Expansion Interface circuit pack on the opposite end of its fiber, in the last five minutes, this test may have failed due to the associated slips. If such errors exist, first resolve them, and then repeat this test. 5. Execute the **test board PCSS long** command on both Expansion Interface circuit packs and follow procedures for Test #242 to determine if the problem lies with one of the Expansion Interface circuit packs, the lightwave transceivers, or the fiber itself.
	PASS	The tone was successfully transmitted in both directions. Both Expansion Interface circuit packs and their lightwave transceivers are functioning properly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Lightwave Transceiver Loop Around Test (#242)

This test is destructive and requires that the Expansion Interface circuit pack first be busied out. Busying out an Expansion Interface circuit pack denies service to the EPN if the Expansion Interface circuit pack supports a PPN to EPN link and duplicate Expansion Interface Links are not in use. If the Expansion Interface circuit pack is part of an EPN to EPN link, service between the two EPNs are denied if duplicate Expansion Interface links are not in use. This test is NOT DESTRUCTIVE if the Expansion Interface circuit pack to be busied out is in Standby Mode.

This is a two part connectivity test. The first portion of the test applies to both TN776 and TN570 Expansion Interface circuit packs. In the first part of the test, a test tone is transmitted from the cabinet of the Expansion Interface circuit pack under test, through the Expansion Interface circuit pack under test, out to its lightwave transceiver. The connection then loops back into the lightwave transceiver through the same Expansion Interface circuit pack again and into the originating cabinet. If the test tone is detected by a tone detector, the first part of the test passes.

The second portion of the test applies only to the TN570 Expansion Interface circuit pack. In this part of the test, a data packet is sent from the TN778 Packet Control circuit pack to the Expansion Interface circuit pack under test; the packet is then looped back through the lightwave transceiver and sent back to the Packet Control circuit pack. If the Packet Control circuit pack receives the same packet it transmitted, the second part of the test passes. If the entire test has passed, the Expansion Interface circuit pack, its backplane wiring, and the electrical portion of the lightwave transceiver are healthy.

NOTE:
When the Expansion Interface circuit pack under test is an EPN, the data packet must also pass through the Active Expansion Interface circuit packs of the Active link connecting the EPN to the PPN.

This test requires the Expansion Interface circuit pack to ignore incoming data from its neighbor Expansion Interface circuit pack on the opposite end of the fiber. Thus, this test disturbs any inter-cabinet connections that currently exist and disrupts signaling between the two cabinets.

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Hardware Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. Even if there are no TTR-LEV errors, there still may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If there is not at least one Tone Detector, this test always aborts for this Expansion Interface circuit pack. This does not harm the system in any way. 2. Look for TONE-PT errors in the Hardware Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system does not allow this test to be run because the Expansion Interface circuit pack has not been busied out. 1. Busyout the Expansion Interface circuit pack. Repeat the **test board PCSS long** command.
1031	ABORT	If the Expansion Interface circuit pack is in an EPN and is active and is in slot A01 or B02, this test CANNOT be executed. If the lightwave transceiver loop around is activated, it is impossible to deactivate it. 1. If a Standby Expansion Interface circuit pack pair exists, make that pair active via the **set expansion-link PCSS** command, where PCSS is the address of a Standby Expansion Interface circuit pack. 2. If the Expansion Interface Link switch is successful, the lightwave transceiver Loop Around Test may now be executed on the original Expansion Interface circuit pack in the EPN.
1139	ABORT	The Packet Bus in an Expansion Port Network (Port Network 2 or 3) has a major alarm against it. This test needs to use the alarmed port network's Packet Bus. 1. Resolve the Packet Bus alarm. 2. Retry the command.
1141	ABORT	The Packet Control circuit pack is out-of-service. 1. Determine if the Packet Control circuit pack is busied out by checking the Hardware Error Log to see if Error Type 18 has been logged against PKT-CTRL. If Error Type 18 is present, release the circuit pack via the **release packet-control** command, and retry the command. 2. If the Packet Control circuit pack is NOT busied out, refer to PKT-CTRL (Packet Control circuit pack) Maintenance documentation for the recommended repair procedure.

Continued on next page

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1144	ABORT	The Packet Bus in the Processor Port Network has a major alarm active against it. This abort code only appears when the test is run in an EPN. 1. Resolve the alarm in the PPN. 2. Retry the command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2060	ABORT	The link on the Packet Bus being used to perform the test has failed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, check for problems with the Packet Control circuit pack (look for PKT-CTL errors). 3. If there is no problem with the Packet Control circuit pack, escalate the problem.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The test did not detect the test tone through the loop around connection. **NOTE:** If the circuit pack is a TN570, the packet portion of this test was not run since the circuit portion failed. 1. Test the Active Tone-Clock on the Port Network that contains the defective Expansion Interface circuit pack to verify that dial tone is being supplied. 2. If the Tone-Clock is healthy, issue the **test board PCSS long** command on the Expansion Interface circuit pack. 3. If this test continues to fail, replace the Expansion Interface circuit pack or transceiver. Then, reissue the **test board PCSS long** command on the new Expansion Interface circuit pack.
2	FAIL	The test tone was transmitted and detected correctly, but the correct data packet was not detected by the TN778 Packet Control circuit pack. This error only applies to the TN570 Expansion Interface circuit pack. 1. Test the TN778 Packet Control circuit pack to verify that it is functioning properly. If any tests fail, investigate those tests and repair the Packet Control circuit pack. 2. If the Packet Control circuit pack checks out OK, issue the **test board PCSS long** command on the Expansion Interface circuit pack. 3. If Test #242 continues to fail, replace the Expansion Interface circuit pack. Then, issue the **test board PCSS long** command on the new Expansion Interface circuit pack. 4. If Test #242 continues to fail, replace the lightwave transceiver, reset the circuit pack and issue the **test board PCSS long** command on the Expansion Interface circuit pack.

Continued on next page

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	**NOTE:** If the Expansion Interface is a TN570 and the system does not have the Packet Bus enabled field set to yes on the Maintenance-related system parameters form, then this test does not execute the packet bus portion of the loop around. When this test (#242) and the Expansion Interface Local Loop Around Test #240 pass, this indicates that the Expansion Interface circuit pack is functioning properly, but it does not verify that the optical portion of the lightwave transceiver is functioning properly. Remove the Expansion Interface circuit pack from the busyout state using the **release board PCSS** command. 1. If duplicate Expansion Interface Links are available, issue the **test board PCSS** command on the Standby Expansion Interface circuit packs on both ends of fiber. If this test passes from both sides, but other tests fail, such as Test #241, this condition indicates either a faulty lightwave transceiver or a faulty fiber cable. To determine if either a lightwave transceiver or the fiber itself has failed, execute the Expansion Interface Manual Loop Back Procedure described in the section preceding the "Hardware Error Log Entries and Test to Clear Values" table for this MO. **NOTE:** This test can only be run from both Expansion Interface circuit packs if they are the Standby pair, and if the Active pair is working properly.

Continued on next page

Table 11-158. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2 *(cont'd.)*	PASS *(cont'd.)*	2. If this Expansion Interface circuit pack is failing other tests, the Expansion Interface Manual Loop Back Test should be executed. If problems still exist after the Expansion Interface Manual Loop Back Procedure indicates that both Expansion Interface circuit packs and both lightwave transceivers are healthy, manually check out the building fiber. Verify that each optical fiber is connected to a transmitter at one end and a receiver at the other.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Control Channel Test (#316)

If an Expansion Interface circuit pack is a Standby Expansion Interface circuit pack (yellow LED off) or if the Expansion Interface is active in the PPN (yellow LED on), this test queries the Expansion Interface circuit pack for its circuit pack type and vintage information. If the Expansion Interface circuit pack is an Active Expansion Interface circuit pack in the EPN (yellow LED on long, off short), the Expansion Interface Control Channel Test checks to see if the Expansion Interface circuit pack can communicate with other circuit packs in the EPN using the EPNTDM Bus.

Table 11-159. TEST #316 Expansion Interface Control Channel Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Expansion Interface circuit pack responded incorrectly or, if it is the EPN Active Expansion Interface circuit pack, it could not talk to EPN circuit packs. 1. If the Active Expansion Interface circuit pack in the EPN is failing and a Standby link exists, switch to the Standby link using the **set expansion-link PCSS** command. 2. Repeat the Short Test Sequence. 3. If test continues to fail, reset the Expansion Interface circuit pack via the **reset board PCSS** command. 4. If the Expansion Interface circuit pack in the EPN is failing, check for EPN TDM-CLK, TONE-BD, or SYNC failures in the Hardware Error Log. Clear any EPN clock-related failures and repeat the Short Test Sequence. 5. If test continues to fail, replace the circuit pack or transceiver.

Continued on next page

Table 11-159. TEST #316 Expansion Interface Control Channel Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Expansion Interface circuit pack did respond correctly to the test. Communication from software to the Expansion Interface circuit pack is functioning. 1. Refer to other Expansion Interface circuit pack tests if Expansion Interface Link is not functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Reset Test (#336)

This test is potentially very destructive and requires the Expansion Interface circuit pack to be busied out prior to execution of this test.

The Expansion Interface Reset Test, which is not a part of either the Short or the Long Test Sequences, is executed via the **reset board PCSS** command where PCSS is the address of the Expansion Interface circuit pack to be reset.

If the system only has one working Expansion Interface Link between a pair of port networks and one of the Expansion Interface circuit packs must be reset, the action of busying out the desired Expansion Interface circuit pack WILL DISRUPT SERVICE TO THE EPN until the Expansion Interface circuit pack is released from the busyout state. If the Expansion Interface circuit pack is part of a PPN to EPN link, the EPN WILL BE WITHOUT SERVICE. If the Expansion Interface circuit pack is part of an EPN to EPN link CALLS BETWEEN THE TWO EPNs WILL BE DENIED.

If the system has working duplicate Expansion Interface Links, and the Expansion Interface circuit pack to be reset is part of the Active Expansion Interface Link, the system does not allow the busyout and instructs system technician to switch Expansion Interface Links via the **set expansion-link PCSS** command where PCSS is the address of either Standby Expansion Interface circuit pack on the Standby link. After executing the Expansion Interface Link switch, it is possible to busyout and then reset the original Expansion Interface circuit pack.

However, if the EPN Maintenance (MAINT) circuit pack determines that the Expansion Interface (EXP-INTF) circuit pack is cycling between sane and insane several times within several minutes, MAINT may inhibit operation of the EXP-INTF by holding the Expansion Interface circuit pack in a reset state. This condition may result in an unsuccessful reset of the Expansion Interface circuit pack.

If the reset command returns with "EPN is unavailable," execute the following steps:

1. Use the **change circuit-pack P** command where P is the port network number of the EPN.
2. For the Expansion Interface circuit pack you wish to reset, add an entry to the Circuit Pack form for the TN776 or TN570 Expansion Interface circuit pack. Be sure to enter the appropriate carrier and slot (that is, A01 or B02).
3. Enter the form.
4. Repeat the **reset board** command.

Table 11-160. TEST #336 Expansion Interface Reset Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
4	ABORT	Could not reset EPN Expansion Interface circuit pack over optical fiber since PPN Expansion Interface circuit pack on opposite end of fiber is not inserted. 1. Insert opposite Expansion Interface circuit pack and perform reset again.
1015	ABORT	The system does not allow this test to be run because the Expansion Interface circuit pack has not been busied out. 1. Busyout the Expansion Interface circuit pack. Repeat the **reset board PCSS** command.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
9999	ABORT	Expansion Interface circuit pack reset successfully. Could not perform initialization test results query because link to EPN is not up. 1. Execute **release board PCSS**. Wait one minute. Issue the **display error** command. If you see Error Type 2049 logged against this Expansion Interface circuit pack, then the Expansion Interface Reset Test has failed with an error code equal to the aux data of this entry. Otherwise, the initialization tests have passed.
12000	ABORT	Expansion Interface circuit pack reset successfully. Response to the initialization test results query was not received within the allowable time period.

Continued on next page

Table 11-160. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
12100	ABORT	Expansion Interface circuit pack reset successfully. System resources required to run initialization test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
12026	ABORT	Expansion Interface circuit pack reset successfully. It responded with an unknown reply to the query for the results of its initialization tests. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, replace the circuit pack or transceiver.
1	FAIL	The Expansion Interface did not successfully reset. 1. If the Expansion Interface circuit pack is in the EPN, the EPN Maintenance Board may be holding the Expansion Interface circuit pack reset. Attempt to rectify this condition by executing the **test maint P long** command on the maintenance board in the same EPN. 2. If Step #1 was not successful in releasing the Expansion Interface circuit pack, temporarily remove the EPN maintenance circuit pack. 3. Repeat the **reset board PCSS** command. 4. If reset continues to fail, replace circuit pack. 5. Insert EPN maintenance circuit pack if it was removed.
2	FAIL	The Expansion Interface circuit pack was successfully reset, but it did not begin running after the reset. 1. If the Expansion Interface circuit pack is in the EPN, temporarily remove the EPN maintenance circuit pack. 2. Repeat the **reset board PCSS** command. 3. Re-insert the EPN maintenance circuit pack if it was removed.

Continued on next page

Table 11-160. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The reset over the optical fiber failed. 1. Execute the **test board PCSS** command on the PPN neighbor Expansion Interface circuit pack located on the opposite end of the fiber from this Expansion Interface circuit pack. If Test #238 does not pass, follow the maintenance procedure associated with this test result. Then perform the reset again. 2. If the Expansion Interface circuit pack is in the EPN, temporarily remove the EPN Maintenance circuit pack. 3. Repeat the **reset board PCSS** command. 4. Reinsert EPN Maintenance circuit pack if it was removed. 5. Follow the procedure described in the "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" section if the symptoms match those described there. 6. Check the Hardware Error Log for the EPN Tone-Clock errors that were resolved about when the EPN went down. These EPN Tone-Clock errors may have been resolved BECAUSE the EPN went down. When there is no Tone-Clock generating the system clock on an EPN, then an Expansion Interface circuit pack can only be reset once. All subsequent reset attempts fail. It is also possible that the system itself may have already tried to reset the Expansion Interface circuit pack. Refer to the TONE-BD (Tone-Clock) Maintenance documentation for recommended maintenance strategy for Tone-Clock problems.

Continued on next page

Table 11-160. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3 *(cont'd.)*	FAIL *(cont'd.)*	7. If the reset still fails, execute the Manual Loop Back Procedure on the opposite PPN Expansion Interface circuit pack. This procedure is described in the section preceding the "Hardware Error Log Entries and Test to Clear Values" table for this MO. If the Expansion Interface circuit pack and the lightwave transceiver are healthy, the problem must lie with the Expansion Interface circuit pack and its lightwave transceiver on the EPN end of the fiber or with the fiber itself. Test the EPN Expansion Interface circuit pack with the manual loop back procedure and investigate the test results.
5001	FAIL	**Initialization failure:** Expansion Interface circuit pack reset successfully and restarted execution. But the Expansion Interface circuit pack could not synchronize itself during the self-test phase of the hardware initialization. 1. Issue the **reset board PCSS** command. If the circuit pack is on the Active link, this procedure can be very destructive. If a **test board PCSS** shows all the tests passing, and there is no Standby link to which you can switch, perform this reset at a time when service is least disrupted by losing use of the EPN. 2. If the reset fails with the same error code, execute the **test tone-clock PC** command where P is the network that contains this Expansion Interface circuit pack and C is the carrier that contains the Active Tone-Clock on network P. Also look for SYNC and TONE-BD errors. Resolve any SYNC and TONE-BD errors by following the Maintenance documentation for these MOs. Then reissue the **reset board PCSS** command. 3. If the Expansion Interface circuit pack still fails to reset with the same error code, replace the Expansion Interface circuit pack.

Continued on next page

Table 11-160. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5002	FAIL	**Initialization failure:** Expansion Interface circuit pack reset successfully and restarted execution. But the Expansion Interface circuit pack has determined that a lightwave transceiver was not attached to the backplane connector when the Expansion Interface circuit pack was last reset. If this system does not have duplicate Expansion Interface Links, all users in the EPN will be without service until this problem is resolved. If this system does have duplicate links, the backup Expansion Interface Link will be unavailable until this problem is resolved. 1. Attach lightwave transceiver to 25-pair backplane connector **in slot belonging to Expansion Interface circuit pack**. 2. Reset the circuit pack again. 3. If the reset fails with an error code other than 5002, refer to the appropriate Maintenance documentation. 4. If the reset fails again with Error Code 5002, replace the lightwave transceiver, reset the circuit pack, and execute the **reset board PCSS** command again. 5. If the reset fails again with Error Code 5002, the new lightwave transceiver may be defective, or the Expansion Interface circuit pack may need to be replaced.

Continued on next page

Table 11-160. TEST #336 Expansion Interface Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5016 5017 5018 5019 5032 5033 5048 5064 5080 5096 5112	FAIL	**Initialization failure:** Expansion Interface circuit pack reset successfully and restarted execution. But the Expansion Interface circuit pack detected communication errors during the self-test phase of the hardware initialization. The nature of the failure may prevent the Expansion Interface circuit pack from communicating with its neighbor Expansion Interface circuit pack on the opposite end of the fiber. The fault itself may be either on the Expansion Interface circuit pack or on the lightwave transceiver. 1. If all other tests on this Expansion Interface circuit pack are passing and no other errors have been logged against this circuit pack, replacement of the lightwave transceiver or the circuit pack are recommended, but not critical. 2. If all other tests on this Expansion Interface circuit pack are not passing or other errors have been logged against this circuit pack, the lightwave transceiver and/or the Expansion Interface circuit pack should be replaced.
	PASS	The Expansion Interface was successfully reset, and it did restart execution. Also, it passed all its initialization tests and detected a lightwave transceiver. Remove the Expansion Interface circuit pack from the busyout state by using the **release board PCSS** command. 1. Execute **test board PCSS short** command. Refer to errors for each test.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Packet Interface Test (#589)

This test attempts to send a data packet from the TN778 Packet Control circuit pack through any intervening Expansion Interface circuit packs and through the Expansion Interface circuit pack to be tested. The path the data packet takes is dependent on the location of the Expansion Interface circuit pack to be tested and whether the Expansion Interface circuit pack is par of the Active link or Standby link.

If the Expansion Interface circuit pack to be tested is part of an Active link from PPN to either EPN, the path shown in Figure 11-36 is used.

If the Expansion Interface circuit pack to be tested is on either EPN and is part of a Standby link from PPN to either EPN, the path shown in Figure 11-37 is used. The path in this figure is also used if the Expansion Interface circuit pack to be tested is on the PPN.

If the Expansion Interface circuit pack to be tested is part of a link from EPN to EPN, the path shown in Figure 11-38 is used.

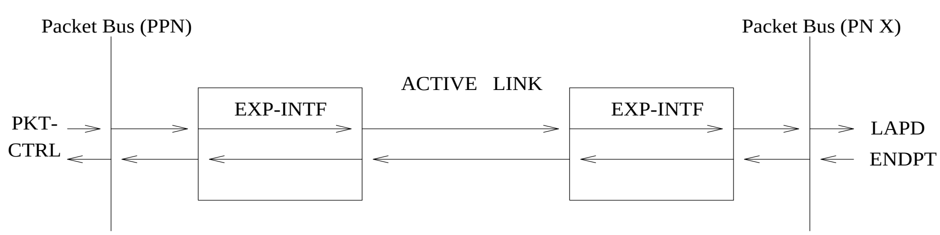

Figure 11-36. (Active EXP-INTFs on EPNs Only)

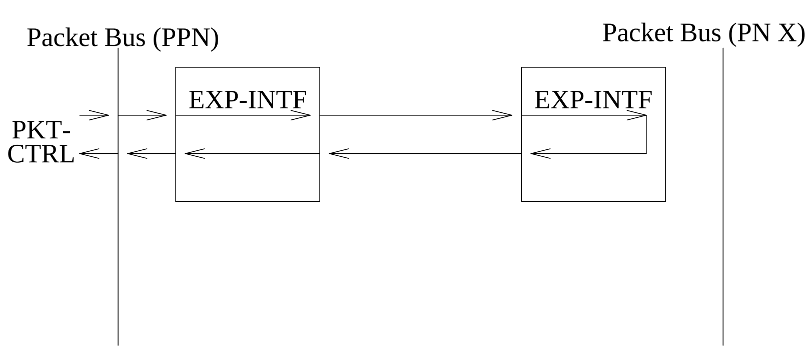

Figure 11-37. (Standby EXP-INTFs on EPNs or PPN EXP-INTFs Only)

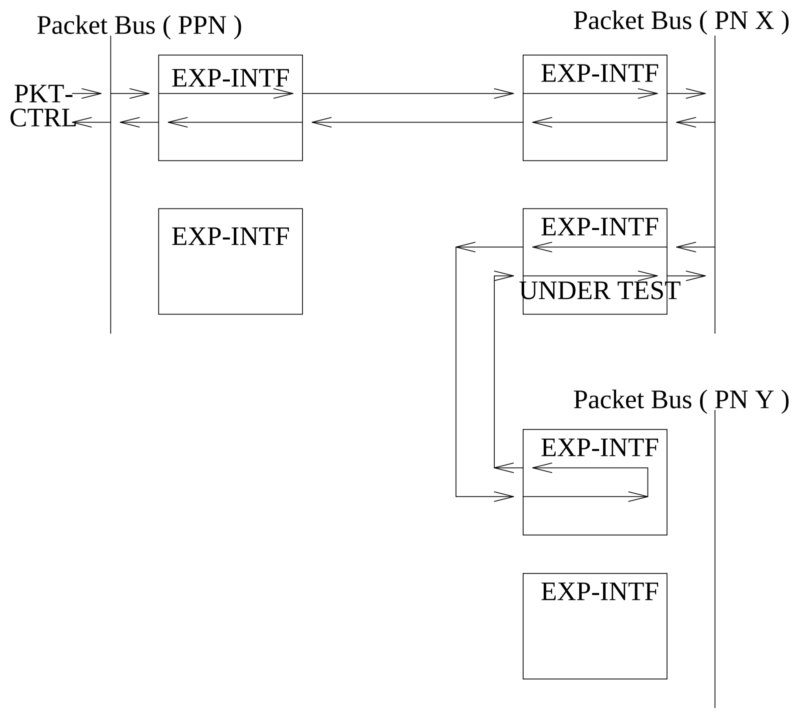

Figure 11-38. Expansion Interface Packet Interface Test—EPN to EPN

Table 11-161. TEST #589 Expansion Interface Packet Interface Test

Error Code	Test Result	Description/ Recommendation
1005	ABORT	This test does not apply to the current system configuration. Either the system is not administered to have the Packet Bus activated, the Maintenance-Related System Parameters form has the Packet Bus Enabled field set to "n," or the system is administered to have the Packet Bus activated, but there exist TN776 Expansion Interface circuit packs that prevent this test from running. The TN776 Expansion Interface circuit packs do not support Packet Bus capabilities.

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1033	ABORT	The test cannot run because either one or both of the Expansion Interface circuit packs on this link are busied out or an Exapnsion Interface circuit pack is not present on the opposite end of the fiber. 1. If Expansion Interface is busied out, issue the **release board PCSS** command. 2. Examine the results of Tests #237 and #238.
1139	ABORT	The Packet Bus in an EPN (Port Network 2 or 3) has a major alarm against it. This test needs to use the alarmed port network's packet bus. 1. Resolve the Packet Bus alarm. 2. Retry the command.
1140	ABORT	Not enough packet ports are available to complete this test. 1. If the port network being tested does not contain any packet circuit packs, ignore the results of this test. 2. If the port network being tested does contain packet circuit packs, determine if any or all of them are faulty by examining the alarm and error logs. 3. If any faulty circuit packs are found, refer to the appropriate Maintenance documentation for the recommended repair procedures and try to resolve any problems. Then, retry the command. 4. If no faulty boards are found, all of the ports are busy. Use the **busyout board PCSS** command to buyout a packet circuit pack or wait for one to become idle and retry the command.

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The Packet Control circuit pack is out-of-service. 1. Determine if the Packet Control circuit pack is busied out. (This is indicated by an Error Type 18 logged against PKT-CTRL.) If it is, release it via the **release packet-control** command, and retry the command. 2. If the Packet Control circuit pack is NOT busied out, refer to PKT-CTRL Maintenance documentation for the repair procedure for the Packet Control circuit pack.
1144	ABORT	The Packet Bus in the PPN has a major alarm active against it. 1. Resolve the alarm in the PPN. 2. Retry the command.
1195	ABORT	An EI link switched during this test. 1. Retry the command at one minute intervals a maximum of three times. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1421	ABORT	This abort code is valid and can appear only when the Expansion Interface circuit pack addressed in the test command is one which terminates the link between two the EPNs. It indicates that the test failed, but that this test was run on the EPN EI circuit pack that: a. is in the same EPN as the circuit pack under test, b. is on the active link and c. terminates the fiber from the PPN. The EI tested is probably not at fault. 1. Enter **display alarms** and follow the EXP-INTF repair procedures for the EPN EI that: a. is in the same EPN as the circuit pack just tested here b. is on the active link, and c. terminates the fiber from the PPN. 2. If there are no alarms logged against that EI, run Test #589 on it and follow procedures for this test. 3. Try this command again.
2060	ABORT	The link on the Packet Bus that is being used to perform the test has failed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, check for problems with the Packet Control circuit pack (look for PKT-CTL errors). 3. If there is no problem with the Packet Control circuit pack, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of three times. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The transmitted data packet was not received correctly by the Packet Control circuit pack. If there are any PKT-BUS errors in the Error Log, attempt to resolve those errors before investigating these test failures. PROCEDURE A Use Procedure A if the Expansion Interface circuit pack to be tested is in an EPN and is part of an Active link from the PPN to the EPN. 1. Test the Packet Control circuit pack via the **test packet-control** command. If the Packet Control circuit pack fails any tests, refer to the PKT-CTRL Maintenance documentation for recommended maintenance procedures. 2. If all Packet Control circuit pack tests pass, the failure may be in either the PPN Expansion Interface circuit pack or the connected Expansion Interface circuit pack under test or on the EPN Packet Bus. If a duplicate Expansion link exists, make that the Active link, using the **set expansion-link PCSS** command. Execute the **test board long** command on the original Expansion Interface circuit pack and the connected PPN Expansion Interface circuit pack and follow the procedures for Test #242. 3. If a duplicate link does not exist, run the Long Test Sequence on the PPN Expansion Interface circuit pack. If Test #242 fails, follow the procedures for Test #242. If Test #242 passes, the fault is in the EPN Expansion Interface circuit pack under test or on the EPN Packet Bus. *More information follows.*

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	PROCEDURE B Use Procedure B if the Expansion Interface circuit pack to be tested is in an EPN and is part of a Standby link from the PPN to the EPN or if the Expansion Interface circuit pack to be tested is in the PPN. 1. Test the Packet Control circuit pack. If the Packet Control circuit pack fails any tests, refer to the PKT-CTRL Maintenance documentation for recommended maintenance procedures. 2. If all Packet Control circuit pack tests pass, the failure may be in either the PPN Expansion Interface circuit pack or the connected EPN Expansion Interface circuit pack. If the circuit pack being tested is in the PPN and is part of an Active link from the PPN to the EPN and if a duplicate Expansion link exists, make that the Active link, using the **set expansion-link PCSS** command. Execute the **test board long** command on the original PPN Expansion Interface circuit pack and the connected EPN Expansion Interface circuit pack and follow the procedures for Test #242. Otherwise, if a duplicate link does not exist, run the Long Test Sequence on the PPN Expansion Interface circuit pack. If Test #242 fails, follow the procedures for Test #242. If Test #242 passes, the fault is in the connected EPN Expansion Interface circuit pack. 3. If the test was not run on an active PPN Expansion Interface circuit pack, issue the **test board PCSS long** command on both Standby Expansion Interface circuit packs and follow the procedures for Test #242. *More information follows.*

Continued on next page

Table 11-161. TEST #589 Expansion Interface Packet Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	PROCEDURE C Use Procedure C if the Expansion Interface circuit pack to be tested is part of any link from EPN to EPN. 1. Test the Packet Control circuit pack. If the Packet Control circuit pack fails any tests, refer to the PKT-CTRL Maintenance documentation for recommended maintenance procedures. 2. If all Packet Control circuit pack tests pass, the failure may be in the Expansion Interface circuit packs of the EPN to EPN link or on the EPN Packet Bus. 3. Issue the **test board PCSS long** command on both EPN to EPN Expansion Interface circuit packs and follow the procedures for Test #242.
	PASS	The data packet was received correctly. 1. Refer to other Expansion Interface circuit pack tests if the Expansion link is not functioning correctly.
0	NO BOARD	No board was detected by the test. 1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable. 2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the **reset board UUCSS** command. 3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. 4. Escalate if failure persists.

Expansion Interface Link Switch Command

This action is potentially destructive.

The Expansion Interface switch command enables system technician to choose which set of Expansion Interface Links should be the Active link when duplicate Expansion Interface Links are available.

The command line entry is **set expansion-link PCSS**, where PCSS is the Expansion Interface address of *either* Expansion Interface circuit pack on the Standby link. If the **status system** command indicates that the Standby link is up, the **set expansion-link** command makes the Standby link the Active link.

This action is destructive because it must temporarily disable all connections between PPN and EPN. This break in the connections is not detectable by normal voice users.

CAUTION:

Data connections lose a small amount of data. Depending on the data transmission speed, the lost data is anywhere from zero to several bytes.

It is recommended that system technician switch links when it is necessary to run the more destructive tests on Expansion Interface circuit packs. Most significantly, Test #242 requires the Expansion Interface circuit pack to be busied out and, therefore, the link with the Expansion Interface to be tested should be made the Standby link.

To prevent the system from automatically switching Expansion Interface Links during system technician-demanded tests, busyout one or both of the Standby Expansion Interface circuit packs.

CAUTION:

This introduces a small risk. If the remaining Active Expansion Link should fail while the Standby Expansion Link is busied out, service to the EPN is lost.

The **set expansion-link** command has no error codes to return. It displays one of following messages upon completion:

1. **Command completed successfully**

   Link switch was successful. This may be verified by visually inspecting the new yellow LED states as described in Table 11-152 on page 11-779 or by the **status system** command.

2. **Command did not complete successfully**

   This indicates that the system attempted to switch links, but for unknown reasons the software or hardware was unable to complete the action. The system may have switched and determined that the new link could not provide service and thus returned to the original link.

3. **Standby EXP-INTF Link is unable to take over**

   Because the Expansion Interface circuit pack pair on the Standby link has enough errors logged against it as to be unable to provide service, the system did not attempt to switch links.

4. **EXP-INTF is already on active link**

   The Expansion Interface circuit pack address given in the **set expansion-link** command is an Active Expansion Interface. The address must be a Standby Expansion Interface circuit pack in order to switch links.

5. **Address is not a valid Expansion Interface Board**

   The link switch could not be attempted because the address in the **set expansion-link** command did not correspond to any known Expansion Interface circuit pack.

EXP-LINK (Expansion Interface Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
EXP-LINK	MAJOR	display errors[1]	Expansion Interface Link

1 Display errors for "infc" category and investigate EXP-INTF errors.

The EXP-LINK (Expansion Interface Link) Maintenance strategy is covered in the EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation.

Hardware Error Log Entries and Test to Clear Values

Expansion Interface Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	disp err
122 (a)		None	MAJOR	ON	
122 (b)	None, 1-10	None	MAJOR	ON	
122 (c)	30-40	None	MAJOR	ON	
122 (d)	6	None	MAJOR	ON	
122 (e)	8	None	MAJOR	ON	

a. This alarm is used only to indicate that all Expansion Interface Links between a pair of Port Networks (PNs) are down. This condition is indicated by the EXP-LINK Error Type 122 in the Error Log. When this condition occurs, examine all EXP-INTF errors to resolve the alarm.

   The pair of PNs is specified in the port fields as follows: 1-2 (PPN to EPN1), 1-3 (PPN to EPN2), and 2-3 (EPN1 to EPN2).

b. Aux Data values of blank and 1 through 10 mean that the link is down due to a defective Expansion Interface Link. Look for and resolve Expansion Interface circuit pack errors.

c. Aux Data values of 30 through 40 mean that the EPN was reset because of a temporary loss of system timing reference on the EPN. Execute the **display errors** command with the category "tone" to determine what caused the loss or restoration of the clock.

d. The system detected an excessive backup of traffic on the Active Expansion Link. This condition may have been due to communication difficulties on the Expansion Link. To restore normal service, the system had to reset the Expansion port network served by the Expansion Link. Error type 10004 should have been logged against the Expansion Interface circuit pack that reported the traffic congestion.

e. Aux Data value of 8 means that the link is down due to the recovery feature of the EPN Sanity Audit. Look for EPN-SNTY errors in the error log, and refer to the EPN-SNTY section for more details.

EXT-DEV ADMIN? N (External Device Alarm)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
EXT-DEV	MAJOR	test environment UU	External Device Alarm
EXT-DEV	MINOR	test environment UU	External Device Alarm

1 where UU is an appropriate cabinet number determined via the PORT field from the Alarm or Error Log.

NOTE:
Use this Maintenance Object when the *External Device Alarm Admin?* field on the *change system-parameters customer-options* form is set to (**n**).

In the Standard Reliability PPN the Maintenance Processor (TN786B or TN790) in carrier (A) monitors the EXT-DEV alarm leads. In the High or Critical PPN, the Duplication Interface (TN772) circuit pack in carrier (A) monitors the EXT-DEV alarm leads, and provides status to the Maintenance processor (TN786B or TN790) in the active SPE. In the EPN the Maintenance Board (TN775) monitors the EXT-DEV alarm leads. The system only recognizes pairs connected to the 1M and 1m (ALARM MONITOR) leads. Pairs connected to the 2M, 2m, 3M, 3m, and 3w are not recognized by the system. Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111, for more details.

Hardware Error Log Entries and Test to Clear Values

Table 11-162. Hardware Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment UU r2 or 6
1 or 5	Any	External Device Alarm Test (#120)	MAJOR MINOR[2]	OFF	test environment UU r 2 or 6

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 One port generates a MAJOR alarm; the other port generates a MINOR alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* you may also clear errors generated from other tests in the testing sequence.

Multicarrier Cabinet Tests			
Order of Investigation	**Short Test Sequence**	**Long Test Sequence**	**D/ND[1]**
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
OLS Query Test (Carrier E) (#127) (c)	X	X	ND
OLS Query Test (Carrier D) (#127) (c)	X	X	ND
OLS Query Test (Carrier A) (#127) (c)	X	X	ND
OLS Query Test (Carrier B) (#127) (c)	X	X	ND
OLS Query Test (Carrier C) (#127) (c)	X	X	ND
Emergency Transfer Query Test (#124) (d)	X	X	ND
Cabinet Sensors Query Test (#122) (e)	X	X	ND
External Device Alarm Test (MAJOR port) (#120)	X	X	ND

Continued on next page

Multicarrier Cabinet Tests — *Continued*

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
External Device Alarm Test (MINOR port) (#120)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to POWER (Battery & Battery Charger) section for a description of this test.

b. Refer to AC-POWER (AC Power) section for a description of this test.

c. Refer to CARR-POW (Carrier Port Power Supply) section for a description of this test.

d. Refer to EMG-XFER (Emergency Transfer) section for a description of this test.

e. Refer to CABINET (Cabinet Sensors) section for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) section for a description of this test.

Single Carrier Cabinet Tests

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SCC Power Query Test (#79) (a)	X	X	ND
Emergency Transfer Query Test (#124) (b)	X	X	ND
External Device Alarm Test (MAJOR port) (#120)	X	X	ND
External Device Alarm Test (MINOR port) (#120)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to DC-POWER (Single Carrier Cabinet Power) section for a description of this test.

b. Refer to EMG-XFER (Emergency Transfer) section for a description of this test.

c. Refer to RING-GEN (Analog Ring Generator) section for a description of this test.

External Device Alarm Test (#120)

The External Device Alarm Test requests the state of the External Device Alarm from the Maintenance circuit pack and reports the results. The test has no effect on the external device itself.

Table 11-163. TEST #120 External Device Alarm Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 5 time. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 5 time. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet or DC-POWER alarms in a single carrier cabinet. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all SYSAM errors in a PPN or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 4. If the test continues to ABORT with a 2000 error code, then escalate the problem.
2029 2319 2320 2500	ABORT	Internal System Error 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-163. TEST #120 External Device Alarm Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The External Device Alarm has been activated by the external device. 1. Clear the major alarm on the external device, and rerun the test. 2. If the test still fails, then disconnect the External Device Alarms from the Maintenance circuit pack and rerun the test. 3. If the test still fails, then there is a problem with the Maintenance circuit pack that is reporting the alarm. This circuit pack should be replaced. There are failures that can occur on Maintenance circuit pack's that *will not* be detected by their respective maintenance, but which will cause many environment tests to fail. If many environment tests are failing, the suspect circuit pack should be replaced and the test rerun. 4. If the test still fails, escalate the problem.
	PASS	If there is a problem with the external device, but the Maintenance circuit pack connected to the device reports no alarm, then the External Device may not be properly reporting the problems or the External Device may not be properly connected to the External Device.

EXT-DEV ADMIN? Y (External Device Alarm)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
EXT-DEV	MAJOR	test eda-external-device-alrm physical location	External Device Alarm
EXT-DEV	MINOR	test eda-external-device-alrm physical location	External Device Alarm
EXT-DEV	WARNING	test eda-external-device-alrm physical location	External Device Alarm

1 where UU is an appropriate cabinet number determined via the PORT field from the Alarm or Error Log.

NOTE:
Use this Maintenance Object when the *External Device Alarm Admin?* field on the *change system-parameters customer-options* form is set to (**y**). You must have INADS or INIT login permission to administer EXT-DEV Alarm.

Generic 3i Maintenance circuit packs each have alarm leads which can be connected to external devices such as Uninterruptible Power Supplies (UPS) or adjuncts such as AUDIX. Certain conditions on the external device close the contacts on the alarm leads to notify the switch which in turn originates an EXT-DEV alarm.

The special locations UUmajor and UUminor are used to designate the major or minor maintenance board alarm connection for cabinet UU. The major/minor designation specifies the port, not the alarm level associated with the connection; *for example,* the “major” port can be administered as a major, minor, or warning alarm, and the “minor” port can be administered as a major, minor or warning alarm. In addition Analog line ports can also be administered as external device alarms.

NOTE:
An unadministered maintenance board external device alarm port, that is sensing a contact closure will have an entry in the Error Log and in the Alarm Log. INADS will not receive warning alarms.

In the Standard Reliability PPN the Maintenance Processor (TN786B or TN790) in carrier (A) monitors the EXT-DEV alarm leads. In the High or Critical PPN, the

Duplication Interface (TN772) circuit pack in carrier (A) monitors the EXT-DEV alarm leads, and provides the status to the Maintenance processor (TN786B or TN790) in the active SPE. In the EPN the Maintenance Board (TN775) monitors the EXT-DEV alarm leads. The system only recognizes pairs connected to the 1M and 1m (ALARM MONITOR) leads. Pairs connected to the 2M, 2m, 3M, 3m, and 3w are not recognized by the system. Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111, for more details.

Hardware Error Log Entries and Test to Clear Values

Table 11-164. Hardware Error Log Entries and Test to Clear Value

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0	0	Any	Any	Any	test eda-external-device-alrm physical location r 2 or 6
1 or 5	Any	External Device Alarm Test (#120)	Any	OFF	test eda-external-device-alrm physical location r 2 or 6

NOTE:
The loss of -48 volt power will prevent detection of an external device alarm. AC-POWER, CARR-POW, and DC-POWER alarms could indicate the loss of the external device alarm -48 volt power source. ALARM-PT alarms may also indicate a loss of power. When analog line ports are administered as analog line external device alarms loss of -48 volts will prevent detection of an external device alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
External Device Alarm Test (MAJOR port) (#120)	X	X	ND
External Device Alarm Test (MINOR port) (#120)	X	X	ND
External Device Alarm Test (WARNING port) (#120)	X	X	ND

1 D = Destructive; ND = Nondestructive

External Device Alarm Test (#120)

The External Device Alarm Test requests the state of the External Device Alarm from a Maintenance circuit pack and reports the results. The test has no effect on the external device itself.

Table 11-165. TEST #120 External Device Alarm Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 5 time. 2. If the test continues to abort, escalate the problem.
1035	ABORT	The Expansion Port Network containing this equipment is not available Look for and resolve all Expansion Port Network problems with this cabinet.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 5 time. 2. (Maintenance Board) If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier. Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet or DC-POWER alarms in a single carrier cabinet. Then, repeat the test. 3. (Maintenance Board) If the test continues to ABORT with a 2000 error code, check for and resolve all maintenance circuit pack errors. Then, repeat the test. 4. If the test continues to ABORT with a 2000 error code, then escalate the problem.
2029 2100 2319 2320 2500	ABORT	Internal System Error 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-165. TEST #120 External Device Alarm Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The External Device Alarm has been activated by the external device. 1. Clear the major alarm on the external device, and rerun the test. 2. If the test still fails, then disconnect the External Device Alarm Leads from the Maintenance circuit pack and rerun the test. 3. If the test still fails, then there is a problem with the analog external device alarm port or the Maintenance circuit pack that is reporting the alarm. This circuit pack should be replaced. There are failures that can occur on the Maintenance circuit pack that *will not* be detected by their respective maintenance, but which will cause many environment tests to fail. If many environment tests are failing, the suspect circuit pack should be replaced and the test rerun. 4. If the test still fails, escalate the problem.
	PASS	If there is a problem with the external device, but the administered analog line external device alarm, or the administered Maintenance circuit pack connected to the device reports no alarm, then the External Device may not be properly reporting the problems or the External Device may not be properly connected to the External Device Alarm Lead.

FL-DATA (Flash Data Consistency)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
FL-DATA	MAJOR	test card-mem a|b l	Flash Data Consistency
FL-DATA	MINOR	test card-mem a|b l	Flash Data Consistency
FL-DATA	WARNING	test card-mem a|b l	Flash Data Consistency

In systems with High or Critical Reliability, the system software and the hard patch update files are stored in the on-board flash memory in both the Active SPE and Standby SPE. The translations and announcements are stored in the memory cards in both the Active SPE and Standby SPE. Flash Data Consistency flags problems when files become mismatched by monitoring the translations, announcements, update files, and software vintage number in a High or Critical Reliability PPN system. If the software vintage numbers on both SPEs are mismatched, a MAJOR alarm is raised. If the announcement files on both memory cards are mismatched, a WARNING alarm is raised. For all other problems, a MINOR alarm is raised. The software vintage can be displayed via the **list configuration software-vintage long** command. The Flash Data Consistency Test is run on system technician command and as part of daily Standby SPE maintenance.

NOTE:
Flash Data Consistency is not applicable to Standard systems.

Hardware Error Log Entries and Test to Clear Values

Table 11-166. Flash Data Consistency Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test card-mem a/b l
8 or 16	8 or 16	Flash Data Consistency Test (#421)	WARNING	OFF	test card-mem a/b

Table 11-166. Flash Data Consistency Error Log Entries — *Continued*

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
68-70 76-78, 84-86, 132, 164, 196, 260, 292, 324, 388, 420, 452	8 or 16	Flash Data Consistency Test (#421)	MAJOR	OFF	upgrade software

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. The Aux Data field records which SPE was active at the time the Flash Data Consistency Test failed. An "8" in the log refers to carrier A and a "16" refers to carrier B.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Memory Card Insertion Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
12 Volt Power Supply Test (#701) (b)	X	X	ND
Memory Card Insertion Test (#695) (a)	X	X	ND
Memory Card Format and Read Test (#696) (a)	X	X	ND
Memory Card Match Test (#697) (a)	X	X	ND
Memory Card Write-Protected Test (#698) (a)	X	X	ND
Memory Card Directory Recovery Test (#699) (a)	X	X	ND
Memory Card Translation Data Integrity Test (#694) (a)		X	ND
Memory Card Erase/Write/Read Test (#693) (a)		X	ND
Flash Data Consistency Test (#421) (c)		X	ND

1 D = Destructive; ND = Nondestructive

a. See CARD-MEM (Memory Card) Maintenance documentation for this test description.

b. See 12V-PWR (12 Volt Power Supply) Maintenance documentation for a description of this test.

c. The Flash Data Consistency Test does not run in a Standard system.

Flash Data Consistency Check Test (#421)

The software vintage number, translation time stamps, announcement time stamps, and update file time stamps and identifiers are read off of both memory cards or SPEs and then compared. If the comparison shows any discrepancy, FL-DATA is alarmed. This test is only run in a High or Critical Reliability system. The test is run as part of the **test card-mem long** and as part of the standby PE scheduled maintenance.

Table 11-167. TEST #421 Flash Data Consistency Check Test

Error Code	Test Result	Description/ Recommendation
0	ABORT	The test timed out without completing. This error can occur when the system is heavily loaded and the test is not allocated sufficient time to run. 1. Rerun the test when the system is less busy and is not running standby maintenance. 2. If the test continues to abort, escalate the problem.
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9005	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
35498	ABORT	Difficulty was encountered trying to send information between the SPEs.
35512	ABORT	The Standby SPE cannot be put into maintenance mode. 1. Check for and resolve all DUPINT (Duplication Interface Circuit Pack), SHDW-LNK (Memory Shadowing Link), SHDW-CIR (Common Shadow Circuit), and STBY-SPE (Standby SPE) alarms. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
35514	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
35534	ABORT	Could not allocate the (active or standby) memory card drive because another memory card operation was in progress. 1. Wait 10 minutes, and retry the command.
35535	ABORT	Could not access the (active or standby) memory card. 1. The memory card may be damaged or missing. Resolve all problems with all memory card tests in the Long Test Sequence for both memory cards. 2. Repeat the test.
1	FAIL	The standby translations are out-of-date. The translations on the Standby SPE (memory card) are older than those on the Active SPE (memory card).
2	FAIL	The Active SPE translations are out-of-date. 1. Issue **save translations** command. If the translation save passes on both SPEs, go to Step 2. 2. Run **test card-mem long** again to resolve the alarms.

Continued on next page

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	The load vintages are different in both SPEs. 1. Determine the desired software release by issuing the **list configuration software long** command. Obtain the memory card of the same software release. Follow the **upgrade software** procedure to upgrade the out-of-date SPE. 2. Run the **test card-mem long** command again to resolve the alarms.
5	FAIL	The load vintages and translations are different in both SPEs. The Active SPE has the most current translations. 1. Follow the procedures for Error Code 4.
6	FAIL	The load vintages and translations are different in both SPEs. The Standby SPE has the most current translations. 1. Follow the procedures for Error Code 4. 2. Issue the **save translations** command. If the translation save passes on both SPEs, proceed to Step 3. 3. Run the **test card-mem long** command again to resolve the alarms.
8	FAIL	The announcements are different in both SPEs. The Active SPE has the most current announcements. 1. Issue the **save announcements** command to save announcements in both SPEs. If the announcement save passes on both SPEs, go to Step 2. 2. Run the **test card-mem long** again to resolve the alarms.

Continued on next page

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
9	FAIL	The translations and announcements are different in both SPEs. The Active SPE is the most current.
10	FAIL	The translations and announcements are different in both SPEs. The Standby SPE has the most current translations, and the Active SPE has the most current announcements. 1. Issue the **save translations** command to save translations in both SPEs. 2. Issue the **save announcements** command to save announcements in both SPEs. 3. If both the translation save and announcement save pass on both SPEs, run the **test card-mem long** command again to resolve the alarms.
12	FAIL	Load vintages and announcements are different in both SPEs. The Active SPE has the most current announcements. 1. Follow the procedures for Error Codes 4 and 8.
13	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Active SPE has the most current translations and announcements. 1. Follow the procedures for Error Codes 4 and 10.
14	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Standby SPE has the most current translations, and the Active SPE has the most current announcements. 1. Follow the procedures for Error Code 4. Be sure to issue the **save announcements** command.
16	FAIL	Announcements are different in both SPEs. The Standby SPE has the most current announcements. 1. Follow the procedures for Error Code 8.

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
17	FAIL	The translations and announcements are different in both SPEs. The Active SPE has the most current translations and the Standby SPE has the most current announcements.
18	FAIL	The translations and announcements are different in both SPEs. The standby SPE is the most current. 1. Follow the procedures for Error Code 9.
20	FAIL	The load vintages and announcements are different in both SPEs. The Standby SPE has the most current announcements.
21	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Active SPE has the most current translations and the Standby SPE has the most current announcements.
22	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Standby SPE has the most current translations and announcements. 1. Follow the procedures for Error Code 4. Be sure to issue the **save announcements** command.
32	FAIL	The update files are different in both SPEs. The update file on the Active SPE is most current. 1. Have INADS issue the **copy update-file** command. If the update file copy passes, go to Step 2. 2. Reissue the **test card-mem long** command to resolve the alarms.

Continued on next page

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
33	FAIL	The update files and translations are different in both SPEs. The Active SPE has the most current update file and translations.
34	FAIL	The update files and translations are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current translations. 1. Issue the **save translations** command to save translations on both SPEs. 2. Have INADS issue the **copy update-file** command to copy the update file from the Active to the Standby SPE. 3. Reissue the **test card-mem long** command to resolve the alarms.
36	FAIL	The update files and load vintages are different in both SPEs. The Active SPE has the most current update file.
37	FAIL	The update files, load vintages, and translations are different in both SPEs. The Active SPE has the most current update file and translations.
38	FAIL	The update files, load vintages, and translations are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current translations. 1. Follow the procedures for Error Code 4 to get the correct load vintage. After running the **test card-mem long** command, check for Error Codes 32 or 64. Follow the recovery procedure under the applicable error code.

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
52	FAIL	The update files, load vintages, and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current announcements.
53	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, and translations, and the Standby SPE has the most current announcements.
54	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and the Standby SPE has the most current translations and announcements. 1. Follow the procedures for Error Code 4 to get the correct load vintage. After running the **test card-mem long** command, check for Error Codes 32 or 64. Follow the recovery procedure under the applicable error code.
64	FAIL	The update files are different in both SPEs. The update file on the Standby SPE is the most current. 1. If you are on site with the switch, replace the Active SPE memory card with the Standby SPE memory card. If you are not on site with the switch, issue the **reset system interchange** command. This action causes the Standby SPE to become the Active SPE. Refer to the "Reset Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for information on the side effects of a processor interchange. 2. Have INADS issue the **copy update-file** command. If the update file copy passes, go to Step 3. 3. Reissue the **test card-mem long** command to resolve the alarms.

Table 11-167. TEST #421 Flash Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
384	ABORT	The translation memory cards are missing in both SPEs.
388	FAIL	The load vintages are different in both SPEs and the translation memory cards are missing in both SPEs. 1. Follow the procedures for Error Code 132.
416	FAIL	The update file in the Active SPE is more current, and the translation memory cards are missing in both SPEs. 1. Follow the procedures for Error Code 160.
420	FAIL	The load vintages and the update files are different in both SPEs, and the translation memory cards are missing in both SPEs. The update file in the Active SPE is more current. 1. Follow the procedures for Error Code 164.
448	FAIL	The update file in the Standby SPE is more current, and the translation memory cards are missing in both SPEs. 1. Follow the procedures for Error Code 160.
452	FAIL	The load vintages and the update files are different in both SPEs, and the translation memory cards are missing in both SPEs. The update file in the Standby SPE is more current. 1. Follow the procedures for Error Code 164.
	PASS	The load vintages, translations, announcements, and update files are the same.

GPTD-PT [General Purpose Tone Detector Port (CPTR)]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
GPTD-PT[1]	MAJOR	test port PCSSpp sh	General Purpose Tone Detector Port (CPTR)
GPTD-PT	MINOR	test port PCSSpp sh	General Purpose Tone Detector Port (CPTR)
GPTD-PT	WARNING	release port PCSSpp	General Purpose Tone Detector Port (CPTR)

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The General Purpose Tone Detector (GPTD) Port, also known as Call Progress Tone Receiver (CPTR), resides on the Tone Detector circuit pack (TN748 [all suffixes], TN420B [and greater suffixes], and TN756 combined tone detector and tone clock [all suffixes]). There are two GPTD ports and four Dual Tone Multifrequency Receiver (DTMR) ports on a Tone Detector circuit pack. The GPTD port is used to perform level measurements of test tones and to detect call progress tones. Examples of call progress tones are dial tone, ring back, busy, alert, confirmation, and recall dial. The abilities of the GPTD port to perform level measurements of test tones and to detect call progress tones are essential for maintenance of other circuit packs (for example, Tone-Clock).

The GPTD maintenance feature defines a set of tests to ensure that the general purpose tone detection capability of the GPTD port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

Hardware Error Log Entries and Test to Clear Values

General Purpose Tone Detector Port (CPTR) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (b)	17664	Tone Detector Audit/ Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 2
18	0	busyout port PCSSpp	WARNING	ON	release port PCSSpp
130 (d)		None	WARNING	ON	test port *UUCSSpp* sh r 2
257 (c)	17666	Tone Detector Audit/ Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3
513	Any	Tone Detection Verification Test (#42)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. There are two possible alarm levels for this error: Major alarm and Minor alarm. A Major alarm is raised if the total number of GPTD ports currently in service is less than or equal to one half of the administered threshold number. Otherwise, a Minor alarm is raised. In either case, run the Short Test Sequence against the GPTD port and follow the error code procedures for the individual tests.

   The threshold number of GPTD ports for service is administered using the **change system-parameters maintenance** command.

b. This error indicates the GPTD port is having problems detecting call progress tones. If this error is being constantly logged, then the Tone Detector circuit pack containing the defective GPTD port should be replaced.

c. The GPTD port lost its translation. Testing the GPTD port is sufficient to reload its translation. If testing the GPTD port does not clear the error, then the Tone Detector circuit pack containing the defective GPTD port should be replaced.

d. This error type indicates that the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented below when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tone Detection Verification Test (#42)	X	X	ND
Tone Detector Audit/Update Test (#43)	X	X	ND

1 D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test verifies that the call progress tones detection and the tone level measurement capabilities of the GPTD port are functioning properly.

Table 11-168. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the call progress tones.
1001	ABORT	The system was unable to put the GPTD port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, test the TDM-BUS via the **test tdm [1|2]** command. Refer to the TDM-BUS (TDM Bus) Maintenance documentation for details. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a Tone-Clock for the test connection. This can happen when the system is heavily loaded or there is not a Tone-Clock circuit pack in the port network when this test is being executed. 1. Make sure there is a Tone-Clock circuit pack in the same port network. 2. If a Tone-Clock circuit pack is missing, install one in the same port network. 3. Allow about one minute for the Tone-Clock maintenance to run on the newly inserted Tone-Clock circuit pack. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-168. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2006	ABORT	This abort code indicates that the active Tone-Clock circuit pack might not be functioning properly. If there is more than one Tone Detector circuit pack in the system, then the problem can be either with the Tone-Clock circuit pack or the Tone Detector circuit pack. This also could be caused by the companding mode administered for the system not matching that of the Tone Detector circuit pack. 1. Make sure that companding mode of the system matches that of the Tone Detector (TN748's for Mu-law systems and TN420's for A-law systems). 2. Test the active Tone-Clock circuit pack in the port network. This test is being executed via the **test tone-clock qualifier** system technician command. "Qualifier" is the carrier of the active Tone-Clock circuit pack to be tested. Valid qualifiers are: a, b, 1a, 1b, 2a, and 2b. Refer to the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
101-122	FAIL	1. Run the Short Test Sequence: **test port PCSSpp sh r 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore the system performance to normal, replace the Tone Detector circuit pack containing the defective GPTD port.

Continued on next page

Table 11-168. TEST #42 Tone Detection Verification Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1022	FAIL	[G3iV2-386] The system detection mode is administered to one of the broad band schemes, and the Tone Detector is not a TN420C, (the TN420C is the only circuit pack that has this capability). GPTD ports on other types of Tone Detector circuit packs are placed in the out-of -service mode since they cannot provide the administered function. 1. Change the tone detection mode administered on the system-parameters country-options form (see *DEFINITY Communications System Generic 3 Implementation*, 555-230-653). 2. Or, remove all non-TN420C tone detector circuit packs from the system.
	PASS	Tone Detection Verification is successful. The GPTD port is able to detect all call progress tones and perform level measurements of test tones.

Tone Detector Audit/Update Test (#43)

The GPTD port is refreshed with all time slot information and sanity audit is performed on the GPTD port.

Table 11-169. TEST #43 Tone Detector Audit/Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait one minute and try again.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Hardware audit failed. 1. Run the Short Test Sequence: **test port PCSSpp short repeat 1**. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. To restore the system performance to normal, replace the Tone Detector circuit pack containing the defective GPTD port.
	PASS	The GPTD port has been successfully refreshed with its translation.

HYB-BD (Hybrid Line Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
HYB-BD	MIN	test board PCSS sh	Hybrid Line Circuit Pack
HYB-BD	WRN	test board PCSS sh	Hybrid Line Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also HYB-LINE (Hybrid Line) Maintenance documentation for related line information.

HYB-LINE (Hybrid Line)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
HYB-LINE	Minor	test port PCSSpp l	Hybrid Line
HYB-LINE	Warning	test port PCSSpp l	Hybrid Line

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

Hybrid Line is the user-friendly name for Hybrid Line, which was previously used to denote the Multifunction Analog Telephone. The Hybrid Line set is also known as an SCS (Small Communications System).

The TN762B Hybrid Line circuit pack supports eight of these multifunction analog telephone sets, as shown in the following figure. The Hybrid Line sets use three pairs of wires: an analog voice pair, a transmit/receive pair, and a power pair.

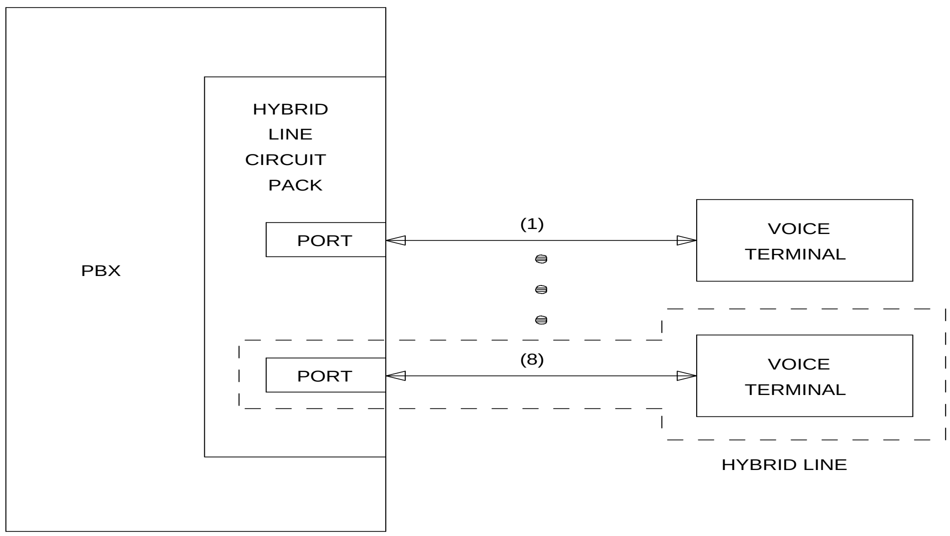

Figure 11-39. Hybrid Station Interactions

This section refers only to the HYB-LINE (Hybrid Line) maintenance that is performed. Please note that the HYB-LINE (Hybrid Line) maintenance is closely related to, and interacts with, the HYB-BD (Hybrid Line circuit pack) maintenance in some instances. Some of the results of maintenance testing of the Hybrid Line may be affected by the health of the Hybrid Line circuit pack. This interaction should be kept in mind when investigating the cause of reported Hybrid Line problems.

There are instances in this section where "service states" of a station are mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- Out-of-Service–The port, and thus the station, have been removed from service. A busyout of a port causes it to be out-of-service.
- Ready-for-Service–Once a port on the circuit pack has been put into service, the voice terminal must communicate that it is present. The time between these two events is the time when the terminal is in the ready-for-service state.
- In-Service–Once the system has received a message from the voice terminal communicating that it is present, the station is put into the in-service state. The terminal can also be forced into the in-service state if it goes off-hook while it is in the ready-for-service state.

When the **status station** command has been run, and the status screen appears, the status is reported as either out-of-service or in-service, which mean exactly as stated in the above list, or disconnect, which means the station is in the ready-for-service state.

Hardware Error Log Entries and Test to Clear Values

Table 11-170. Hybrid Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	Any	None	WARNING	OFF	
15 (b)	Any	Hybrid Audits Test (#61)			
18 (c)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
130 (d)		None	WARNING	ON	test port PCSSpp sh
257 (e)	40988	None	MIN/WRN[2]	OFF	
513 (f)	40965	Hybrid Line Audits Test (#61)	WARNING	OFF	test port PCSSpp sh r 4
769 (g)		Remote Dig Loop Around Test (#59)	WARNING	OFF	test port PCSSpp sh r 3
1025		Hybrid & Conf. Circuits Test (#57)	MIN/WRN[2]	ON	test port PCSSpp l r 3
1281 (h)		Local Digital Loop Around Test (#58)	WARNING	ON	test port PCSSpp l r 3
1537 (i)	40968	None	WARNING	OFF	
1793		TDMNPE Crosstalk Test (#6)	MIN/WRN[2]	ON	test port PCSSpp l r 3
2049 (j)	32770	None			
2049 (k)	40967	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. Indicates a defective data link. An off-board problem was detected by port circuit. Verify that the Hybrid set is connected and that the EPF test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined period of time.

b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. This error type is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout via the **release port PCSSpp** command.

d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. This indicates that the EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and make sure the voice terminal is a Hybrid set. Once the problem has been resolved, the alarm is retired after a predetermined period of time.

f. This indicates that the voice terminal has probably been disconnected or that there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.

g. Note that Error Types 769 and 1281 by themselves create Warning alarms only, but if both are present, a Minor alarm is logged.

h. This indicates that there is something wrong with the data link to the voice terminal. An in-line maintenance error has generated an off-board warning. Ignore it if there are no complaints. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack.

i. This indicates that the station went off-hook while in the disconnect state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to in-service. No system technician action is necessary.

j. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No system technician action is necessary.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Local Digital Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Local Digital Loop Around Test (#58)		X	ND
NPE Crosstalk Test (#6)		X	ND
Hybrid Electronic Power Feed Test (#56)		X	ND
Hybrid Circuit and Conference Circuit Test (#57)		X	ND
Remote Digital Loop Around Test (#59)	X	X	ND
Station Lamp Update Test (#60)	X	X	ND
Station Audits Test (#61)	X	X	ND
Ringer Update Test (#62)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-171. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-171. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-171. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. This only applies to analog stations. The default for this field is ‘y,’ so you may want to determine why it has been turned off for this station. 1. To enable test, set the Test field on the station administration screen for the particular analog station being tested to ‘y.’ Use the **change station <extension>** command.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.

Continued on next page

Table 11-171. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Retest the board when the faults from steps 1 and 2 are cleared.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Continued on next page

Table 11-171. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Electronic Power Feed Test (#56)

In this test, the software requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit from the station. If no current is being drawn, this probably indicates that the station is not connected. If an overcurrent condition is sensed (that is, too much current is being drawn), this may indicate a short in the loop or a defective voice terminal. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This test is repeated once more five seconds later. If either test is not successful, the test aborts (see first ABORT entry in the table below).

Table 11-172. TEST #56 Hybrid Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-172. TEST #56 Hybrid Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	EPF test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test never returns a FAIL result, after running this test, the Error Log should be checked for any entries with Error Type 257 to examine the real results of this test. 2. If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating. 3. If Error Type 257 appears in the Error Log, this indicates some problem with the power to the station. The system technician should check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Circuit and Conference Circuit Test (#57)

This test checks the amount of reflection from the Hybrid loop around circuitry and a Conference Test. Please be aware that if no station is connected to the port being tested, the results of the test are not valid. The Tone-Clock circuit pack places a 1004-Hz tone on a time slot that the port circuit is listening on. A GPTD is connected to another time slot that the same port circuit is talking on. The on-board microprocessor places the port in the loop around mode and the GPTD measures the level of the reflected signal.

The Conference Test is performed after the Circuit Test. The Conference Circuit Test verifies that the NPE is able to listen to several test tones and correctly conference them together. The test is executed in two parts. The first half of the test checks the operation of the NPE's first three conference channels. The NPE is put in the loop around mode and instructed to talk on a selected time slot and listen to the 1004-Hz tone using the first three Conference Channels. The signal level and noise level of the conferenced output are then measured using a GPTD and checked to verify that they are within an acceptable range.

The second half of the Conference Test checks the operation of the NPE's remaining four Conference Channels and follows the same procedure as the preceding paragraph.

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference Test failed. User may be able to use conference circuit without difficulty in some cases. In other extreme cases, conference calling will be totally restricted. The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Then, issue the **display port** and the **status station** commands to determine if the station is idle. If it is idle, issue the **test port** command for this port. 3. If test continues to fail, issue the **busyout port** and the **release port** commands, and then retest the port. 4. It is possible that the port may still be functional from a user's point of view.

Continued on next page

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
57	FAIL	Hybrid Circuit Test failed. This could result in noisy or bad connections. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the **test board PCSS short** command. 3. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 4. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Hybrid Line circuit pack. **NOTE:** If the Hybrid Circuit and Conference Circuit Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, the 631DB AC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain either a TN736 or a TN752 power unit circuit pack OR a 631DB AC power unit, *but not both types of power units.* To investigate problems with a 631DB AC power unit, refer to CARR-POW (Carrier Port Power Unit for AC-Powered Systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to CARR-POW (Carrier Port Power Unit for DC-Powered Systems) Maintenance documentation.
	PASS	Hybrid Circuit and Conference Circuit Test passed. The hybrid circuitry is transmitting properly. 1. If complaints still exist, investigate by using other port tests, and by examining the station, wiring, and connections.

Continued on next page

Table 11-173. TEST #57 Hybrid Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Local Digital Loop Around Test (#58)

This test checks the control channel between the SPE and the port's digital circuitry. The SPE sends transparent data to the on-board microprocessor and compares the data echoed back. This test is repeated three times.

Table 11-174. TEST #58 Hybrid Line Local Digital Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-174. TEST #58 Hybrid Line Local Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1,2,3	FAIL	The control channel between the processor and the port is not transmitting properly. This port is not operable. 1. Retry the test. 2. If the failure still occurs, issue the **busyout** and the **release busy** commands, and then retest. 3. If the failure is occurring on more than one port on the board, suspect the board. 4. If the failure is occurring on several boards in the same carrier, escalate the problem. 5. If the failure still occurs and appears to be isolated to one port, check all wiring to the set and all set connections. 6. Replace the circuit pack as a last resort.

Continued on next page

Table 11-174. TEST #58 Hybrid Line Local Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Hybrid Line Local Digital Loop Around Test passed. The control channel is transmitting properly. 1. If complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.

Continued on next page

Table 11-174. TEST #58 Hybrid Line Local Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Remote Digital Loop Around Test (#59)

This test checks the digital control pair from the port circuit to the terminal. The on-board microprocessor sends a message to the terminal and checks for a proper return message. This test is repeated three times, with two out of the three attempts passing being sufficient for this test to pass. [G1] This test will run if the station is in-service or out-of-service.

Table 11-175. TEST #59 Hybrid Line Remote Digital Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	ABORT	A request for a remote station audit aborted even though all internal resources were correctly allocated. 1. Look in the error log for error type 18 (port busied out) for this port. If this error type is present, release the port via the **release port UUCSSpp** command or the **release station extension** command, and then run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-175. TEST #59 Hybrid Line Remote Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1,2,3	FAIL	No response was received within the allowable time period on one of the transmissions to the terminal. This indicates that something is wrong with the data link to the voice terminal. This could be a sleeping set problem or it may be due to wiring or an unplugged or defective set. 1. Check for errors in the error log, for example, error 1537. 2. Remotely issue the **busyout** and **release busy** commands, and run the short test sequence on the port to check for other errors associated with the port or terminal. 3. Check the wiring to the set if it appears that the terminal is not responding to any tests; otherwise, replace the terminal and rerun the test. 4. If the test still fails, replace the circuit pack and reconnect the original terminal.
	PASS	Hybrid Line Remote Digital Loop Around Test passed. The hybrid circuit pack is sending and receiving proper messages to and from the voice terminal. 1. If problems still exist, investigate using other circuit pack tests and by examining the station, wiring, and connections.

Table 11-175. TEST #59 Hybrid Line Remote Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates run only if the station is in-service.

Table 11-176. TEST #60 Hybrid Line Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	A request for a remote station lamp update aborted even though all internal resources were correctly allocated. 1. Look in the error log for error type 18 (port busied out) for this port. If this error type is present, release the port via the **release port UUCSSpp** command or the **release station extension** command, and then run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
2	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
3	ABORT	The station is in a ready for service or an out of service state. This may be due to wiring or an unplugged or defective set. 1. Make sure terminal is connected and the wiring is correct. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Audits Test (#61)

This is a series of three tests that are classified as audits. These audits abort if attempted on an out-of-service station. The tests are as follows:

- Switchhook Audit - This is an update of the SPE records according to the circuit packs' records.
- Bad Scan Inquiry - A message is sent uplink that contains a count that is generated due to certain events relating to the data link conditions. This is an indication of data transmission problems between the Hybrid circuit pack and the voice terminal.
- EPF Inquiry - The status of the Electronic Power Feed is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

Table 11-177. TEST #61 Hybrid Line Audits Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error
1	ABORT	The test was aborted due to an internal system error during the switchhook audit.
2	ABORT	Internal System Error occurred during bad scan inquiry audit. 1. Make sure that the station is not in an out of service state. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
3	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, the release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Table 11-177. TEST #61 Hybrid Line Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	Hybrid Line Audits Test passed. 1. Although this test always return a PASS result, it may enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these error types in the Error Log. 2. If these errors appear in the Error Log, or if user complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Hybrid Line Ringer Update Test (#62)

In this update, a "ringer on" or a "ringer off" message is sent to the firmware to start and stop the ringer on the set.

Table 11-178. TEST #62 Hybrid Line Ringer Update Test

Error Code	Test Result	Description/ Recommendation
3	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this Error Type is present, the release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension number of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook), if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-178. TEST #62 Hybrid Line Ringer Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Hybrid Station Ringer Update passed 1. If complaints still exist, investigate using other circuit pack tests on this circuit pack, and by examining the terminal, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

INADS (INADS Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
INADS	none	test inads-link	INADS Link

The INADS Link MO represents the software and communications link required by the switch to make a call to the Initialization and Administration System (INADS). The purpose of the INADS Link MO is to check the communications link between the DEFINITY Generic 1 and INADS and verify that the alarm notification process works correctly. An INADS technician can test the process remotely to verify that alarms are reported to INADS, or a system technician may want to test the connection while on-site at installation time or during subsequent service calls.

Although the INADS Link MO is never alarmed, the errors are logged. The errors are only logged as a result of the **test inads-link** command being issued.

Hardware Error Log Entries and Test to Clear Values

The Hardware Error Log entries are described as part of the INADS Link Test description.

Short and Long Test Sequences

The **test inads-link** command is different from other test commands. This command does not have a long or short option, and the test on the INADS Link does not have an associated test number. When the

command is different from other test commands. This command does not have a long or short option, and the test on the INADS Link does not have an associated test number. When the **test inads-link** command is issued, the user immediately sees either the "Command successfully completed" or "Command failed" message.

command is issued, the user immediately sees either the "Command successfully completed" or "Command failed" message.

INADS Link Test (no test number)

The INADS Link Test attempts to place a call to INADS (in the background) to verify the communications link to INADS. When the **test inads-link** command is entered, the user immediately sees either "Command successfully completed" or "Command failed." The "Command failed" message appears when a previously run command is entered, the user immediately sees either "Command successfully completed" or "Command failed." The "Command failed" message appears when a previously run **test inads-link** command is in progress or the system has active alarms which must be reported to INADS. The "Command successfully completed" means the switch will start the attempt to call INADS in two minutes (the test still runs even if Alarm Origination is disabled). The two-minute delay allows a remote INADS technician time enough to hang up the call and thus free up the INADS line so that the switch can call INADS back. As error conditions are encountered, errors are logged against INADS. Error codes 1 through 9 can be logged if the test result was "Command successfully completed" and Error Codes 10 and 11 can be logged if the test result was "Command failed." An error is also logged against INADS if the call to INADS finally succeeds. The INADS software (release 3.2 or later) recognizes this special "test inads" type of alarm and automatically opens and then closes a trouble ticket which indicates that the reason for the trouble ticket is a command is in progress or the system has active alarms which must be reported to INADS. The "Command successfully completed" means the switch will start the attempt to call INADS in two minutes (the test still runs even if Alarm Origination is disabled). The two-minute delay allows a remote INADS technician time enough to hang up the call and thus free up the INADS line so that the switch can call INADS back. As error conditions are encountered, errors are logged against INADS. Error codes 1 through 9 can be logged if the test result was "Command successfully completed" and Error Codes 10 and 11 can be logged if the test result was "Command failed." An error is also logged against INADS if the call to INADS finally succeeds. The INADS software (release 3.2 or later) recognizes this special "test inads" type of alarm and automatically opens and then closes a trouble ticket which indicates that the reason for the trouble ticket is a **test inads-link** command. The trouble ticket alarm contains a **TESTING INADS LINK** description field.

After entering the command, it may take as long a nine minutes for the switch to place the call and for INADS to respond. The Error Log should be examined (use the category **inads**) 10 minutes after successfully entering the command to determine if the call was successful.

Use the following table to interpret the Error Log entries.

Table 11-179. INADS Link Error Log Entries Test

Error Code	Test Result	Description/ Recommendation
1	0	The call was successfully placed to INADS. No trouble found.
2	0	Informative error indicating that alarm origination was disabled at the time of the test. The test still runs even if alarm origination is disabled. 1. If Alarm Origination is desired, then enable this feature via the Maintenance-Related System Parameters Form. 2. Repeat the test.
3	0	The INADS connection is currently in use. 1. Wait 10 minutes and retry this command.
4	0	INADS did not answer the alarm origination call. 1. Verify INADS is up and running. 2. Verify the INADS phone number and switch product id are correct via the Maintenance-Related System Parameters Form. 3. Enable alarm origination via the Maintenance-Related System Parameters Form and test the PR-MAINT (Maintenance/Tape Processor) by issuing the **test processor a|b** command. If PR-MAINT Tests #102 and #103 do not pass, then refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation. 4. Retry the command.
5	0	No INADS phone number administered. 1. Administer the INADS phone number via the Maintenance-Related System Parameters Form. 2. Retry the command.

Continued on next page

Table 11-179. INADS Link Error Log Entries Test — *Continued*

Error Code	Test Result	Description/ Recommendation
6	0	INADS did not send the acknowledgment message to the "test inads alarm" message. 1. Verify the INADS phone number and switch product id are correct via the Maintenance-Related System Parameters Form. 2. Verify INADS is up and running. 3. Retry the command.
7	0	INADS sent a negative acknowledgment to the "test inads alarm" message.
8	0	Internal System Error; System received an invalid return code.
9	0	Internal System Error 1. Try the command again at 1 minute intervals up to 5 times. 2. If the test continues to abort, escalate the problem.
10	0	There is already a **test inads-link** command in progress. 1. Wait 10 minutes for the present command to finish. 2. Review the results of the present command by viewing the Error Log and selecting the category "inads-link."
11	0	The switch is trying to report alarms to INADS. The test cannot be run at this time. 1. Wait 10 minutes and retry the command.

ISDN-LNK (ISDN-PRI Signaling Link Port) [G1]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
ISDN-LNK[1]	MINOR	test port PCSS24 l	ISDN-PRI Signaling Link Port
ISDN-LNK	WARNING	test port PCSS24 sh	ISDN-PRI Signaling Link Port

1 For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.

An ISDN-PRI Signaling Link Port is known as a D-channel. The ISDN-PRI interface uses out-of-band signaling as opposed to robbed-bit, in-band signaling (Figure 11-40). The user information (for example, digitized voice, digital data) channels are known as bearer channels (B-channels); DS1 ISDN Trunks are B-channels and they simply carry the user traffic. The call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

The ISDN-PRI Signaling Link Port (ISDN-LNK) and the associated DS1 ISDN Trunk (ISDN-TRK) use ports on a TN767 DS1 Interface circuit pack (the TN722 cannot be used for this application). The DS1 ISDN Trunk, also referred to as B-channels, may use any of the first 23 ports, but the ISDN-PRI Signaling Link Port, also referred to as the D-channel, must be the 24th port. A problem with the ISDN-PRI Signaling Link Port (D-channel) has an effect on all of the associated DS1 ISDN Trunk (B-channels) since, without it, no call control information can be conveyed to the far-end switch. Stable calls may remain operational, but no new calls can be made.

The ISDN-PRI Signaling Link Port itself depends on two other entities: the TN767 DS1 Interface circuit pack it resides on and the Processor Interface Link that provides the link to the processor. If there are problems with the ISDN-PRI Signaling Link Port, also investigate the TN767 DS1 Interface circuit pack and the Processor Interface Link.

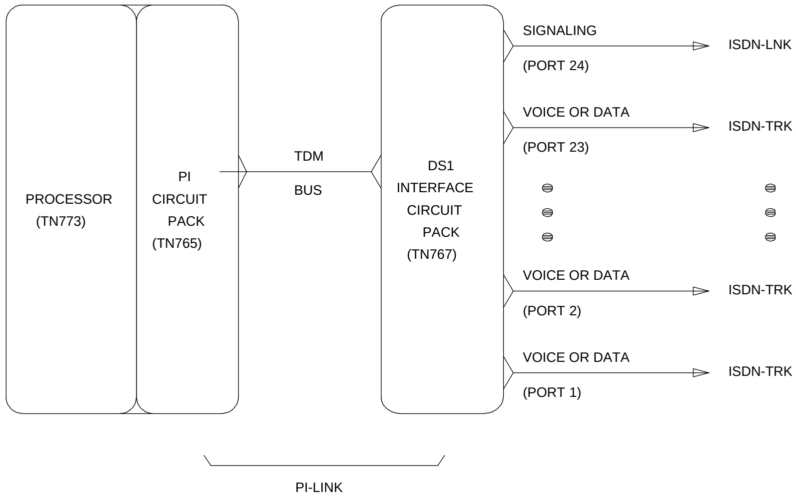

Figure 11-40. ISDN-PRI Signaling Link Port Interactions [G1]

Hardware Error Log Entries and Test to Clear Values

Table 11-180. ISDN-PRI Signaling Link Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSS24 sh r 1
1 (a)	Any	None			
18	0	busyout port PCSS24	WARNING	OFF	release port PCSS24

257 (c)	0	Signaling Link Hardware Check Test (#259)			test port PCSS24 sh r 1
769 (d)	0	Signaling Link Hardware Check Test (#259)			test port PCSS24 sh r 1
1537 (e)		NPE Crosstalk Test (#6)	MINOR	ON	test port PCSS24 l r 3
1793 (f)	Any	None			test port PCSS24 sh r 1
2049 (g)	0	None	WARNING	OFF	test port PCSS24 sh r 1
2305 (h)	Any	Remote Layer 3 Query Test (#260)			test port PCSS24 sh r 1
3840 and above (i)	port number	None			none

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This switch sent a message to the far-end switch which did not respond in the allotted time. This could be due to:

   1. link failure
   2. congestion or outage at the far-end switch

   The Aux Data field contains protocol-specific information and no action is required. It takes two and half hours to clear the alarm since this counter uses a "leaky bucket" strategy.

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. This error indicates that the link connection has been lost for more than 90 seconds. All DS1 ISDN Trunk B-channels controlled by the D-channel are moved to the maintenance/far-end state. This condition does not affect active calls, but removes these B-channels from the trunk hunt group so that they cannot be selected for new outgoing calls. Refer to ISDN-TRK (DS1 ISDN Trunk) Maintenance documentation for information on ISDN Trunk maintenance states. The switch automatically attempts to recover the link.

d. This error indicates a problem with the Processor Interface Link on which the ISDN-PRI Signaling Link Port depends. Pay particular attention to the results of Test #259 (Signaling Link Hardware Check) in the test sequence. See PI-LINK (Processor Interface Link) Maintenance documentation for details. The associated DS1 ISDN Trunk B-channels are eventually affected as well. The B-channels are moved to the maintenance/far-end state.

e. The actual alarming level depends on the options chosen via the **set options** command on the system administration terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "y" on the Set Options form).

f. This error indicates a problem with the TN767 DS1 Interface circuit pack on which the ISDN-PRI Signaling Link Port depends. Pay particular attention to Test #259 (Signaling Link Hardware Check) in the test sequence. Refer to DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation for details. The associated DS1 ISDN Trunk B-channels are eventually affected as well (calls may be dropped and the trunks may be placed in an out-of-service state).

g. This error indicates a problem with part of the Processor Interface Link. Pay particular attention to the results of Test #259 (Signaling Link Hardware Check) in the test sequence.

h. This error indicates a failure of the Remote Layer 3 Query, Test #260. A specific message was sent to the far-end switch and it did not respond within the allotted time. Investigate elements of the Processor Interface Link for both this switch and the far-end switch. If Test #260 fails twice in a row, the DS1 ISDN Trunk (B-channels) are alarmed and made unavailable for outgoing calls (although incoming calls are still accepted since B-channels are moved to the maintenance/far-end state). When Test #260 succeeds and the far-end switch starts responding properly, the DS1 ISDN Trunk (B-channels) is placed back in normal operation and its alarms are retired.

i. This error type is used to report certain error messages received by the ISDN-PRI Signaling Link Port (D-channel) for one of its associated DS1 ISDN Trunks (B-channels). The Aux Data field shows on which DS1 ISDN Trunk the message was received for (the port number).

The exact error type logged is some number greater than 3840. The error type is computed as 3840+X where X refers to a Cause Value as defined by the ISDNPRI Specification.

Note that there is no Test to Clear Value for these error types; when selected ISDN cause values are received, they are placed in the log so that the data is not lost, but no direct action or alarming is done based solely on their reception. They simply provide added data that may prove useful when tracking down obscure networking and routing problems. The following table gives more information.

Table 11-181. ISDN-PRI Signaling Link Port Error Log Entries , 3840 and above (i)

Error Type	Description	Recommendation
3842	A request has been made to use a transit network or common carrier that cannot be accessed.	1. From the circuit pack and port number (in the Aux Data field), determine the trunk group that the error was reported against. 2. Check all routing patterns containing this trunk group for validity of inter-exchange carriers requested (IXC field).
3858	Similar to Error Type 1. The switch sent an ISDN message to the far-end switch which did not respond in the allotted time.	Follow same recommendations as for Error Type 1.

Continued on next page

Table 11-181. ISDN-PRI Signaling Link Port Error Log Entries , 3840 and above (i) — *Continued*

Error Type	Description	Recommendation
3890	A request to use a network service (for example, SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.	This could be a local administration problem only, or a mismatch between the local administration and that of the network provider. 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group that the error was reported against. 2. Display the Trunk Group form. If the trunk group is Call-by-Call (Service Type is "cbc"), check all Routing Pattern forms containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field on the Trunk Group form contains the single network service purchased for this trunk. 3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.
3892	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks and no other cause can be found, escalate to next tier and provide them with this Error Log information.

Continued on next page

Table 11-181. ISDN-PRI Signaling Link Port Error Log Entries , 3840 and above (i) — *Continued*

Error Type	Description	Recommendation
3894	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	First, eliminate any transitory state mismatch problems by issuing the **test port PCSSpp** command for the trunk port shown in the Aux Data field. Test #256 (Service State Audit) is the important test in the sequence. If this passes satisfactorily, yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks and no other cause can be found, escalate to next tier and provide them with this Error Log information.
3905	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks and no other cause can be found, escalate to next tier and provide them with this Error Log information.
3906	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks and no other cause can be found, escalate to next tier and provide them with this Error Log information.

Continued on next page

Table 11-181. ISDN-PRI Signaling Link Port Error Log Entries , 3840 and above (i) — *Continued*

Error Type	Description	Recommendation
3909	A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.	Follow the recommendations for error number 3890.
3928	A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user.	This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks. Determine the trunk group from the circuit pack and port number (in the Aux Data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

REMINDER: The command line entry to test the ISDN-LNK MO is: **test port PCSS24 (sh** or **l)**

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Signaling Link Hardware Check Test (#259)	X	X	ND
Remote Layer 3 Query Test (#260)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. This test runs only if the Processor Interface link corresponding to this ISDN-LNK MO is busied out by system technician. The Processor Interface link number can be determined from the Communication-Interface Links form.

Table 11-182. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources for this test are not available. The ISDN-PRI link may be up and servicing calls. First, obtain the ISDN-PRI link number (lnk-no) from the Communication-Interface Links form by issuing the **display communication-interfaces links** command. Then, determine the status of the ISDN-PRI link via the **status link lnk-no** command. If the link is in-service, this test aborts. Therefore, to run this test, the link must be busied out. No new ISDN-PRI calls can be made while the link is in the busied-out state. 1. If the test must be run, then busyout the link. 2. Retry the command. 3. If it continues to abort with Error Code 1000, then escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-182. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.

Continued on next page

Table 11-182. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the DS1-BD Interface circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Signaling Link Hardware Check Test (#259)

This ISDN-PRI Signaling Link Port D-channel depends on the health of the TN767 DS1 Interface circuit pack and the Processor Interface Link. This test checks the hardware to ensure the basic physical connectivity of the link between the Processor Interface Link (includes the TN765 circuit pack), the TN767 DS1 Interface circuit pack, and on to the far-end switch (Figure 11-41). (The next test in the sequence, Test #260, carries this one step further and checks the link starting from the switch processor through to the far end).

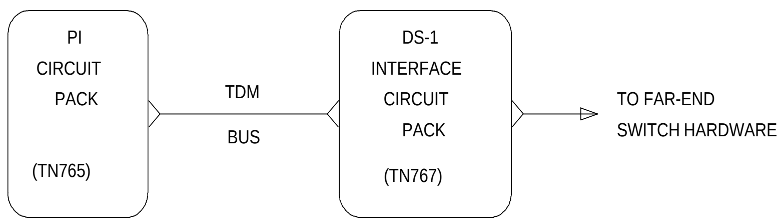

Figure 11-41. Signaling Link Hardware Check (Test #259)

Table 11-183. TEST #259 Signaling Link Hardware Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1010	ABORT	The port has been busied out and the test continues to abort until the port is put back into service. 1. Release port PCSSpp. 2. Release link lnk-no. 3. Wait five minutes until the link is back up and try again.

Continued on next page

Table 11-183. TEST #259 Signaling Link Hardware Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	There is a problem with the Processor Interface Link. No DS1 ISDN Trunk (B-channel) calls can be made until the problem is resolved. 1. The PI Signaling Link could be restarting. Wait a few minutes and then retry the test. If the test still fails, continue with Step 2. 2. Examine the Communication-Interface Links Form to determine which link is down. Find the one that matches the DS1 Interface circuit pack on which this ISDN-PRI Signaling Link Port resides. Then consult the procedures for PI-LINK (Processor Interface Link).
8	FAIL	There is a problem with the TN767 DS1 Interface circuit pack. No DS1 ISDN Trunk (B-channel) calls can be made until the problem is resolved. 1. Consult the procedures for TN767 DS1 Interface circuit pack.

Continued on next page

Table 11-183. TEST #259 Signaling Link Hardware Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
9	FAIL	There is a problem establishing or maintaining the communications connection with the far-end switch. This might simply be caused by a problem with the administration of the link, or it might be due to a failure of the transmission network. 1. Check the options chosen for the TN767 DS1 Interface circuit pack and ensure that they are compatible with those chosen for the equivalent equipment on the far-end switch. Pay particular attention to the network/user selection on the DS1 form. Also, check the CSU options. 2. Check the TN767 DS1 Interface circuit pack and measurements data. 3. Status processor (Processor Channel) provides specific information as to whether or not the link in question is up.
	PASS	The basic physical connectivity of the link between the Processor Interface Link (including the TN765 circuit pack), the TN767 DS1 Interface circuit pack, and on to the far-end switch is intact and functional. One might try this test repeatedly to ensure the link is up and uncover any transitory problems.

Remote Layer 3 Query Test (#260)

This test runs only if the previous test (#259) succeeded. If Test #259 fails, this Test (#260) aborts with an error code of 1113. The previous test checks the communications path starting at the Processor Interface Link and on to the far-end switch. This test takes it one step further by checking the communications path starting from the processor (from the processor, through the Processor Interface Link and TN767 DS1 Interface circuit pack, and on to the far-end switch) (see Figure 11-42). A special ISDN message is sent to the far-end switch, which must respond within an allotted amount of time. This test is designed to ensure that the communications path between the two switches is up and operational, and that the two switches can properly exchange ISDN control messages. The test passes if a message is successfully transmitted. The test does not fail.

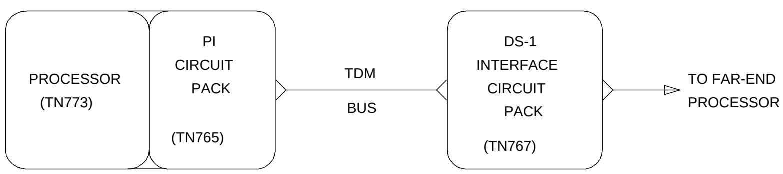

Figure 11-42. Remote Layer 3 Query (Test #260)

Table 11-184. TEST #260 Remote Layer 3 Query Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error OR Administration Problem. 1. First, check to see if any DS1 ISDN Trunks (B-channels) are administered. If there are none, then this is a NORMAL ABORT. You cannot run this test until at least one DS1 ISDN Trunk is administered. However, if at least one DS1 ISDN Trunk is administered, then there is an internal system error. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	Currently there are no associated DS1 ISDN Trunks (B-channels) in an ISDN in-service or maintenance service state. THIS IS A NORMAL ABORT. 1. Refer to PI-LINK (Processor Interface Link) or ISDN-LNK (ISDN-PRI Signaling Link Port) Maintenance documentation for reasons why the trunks are not available.
1113	ABORT	The Signaling Link is down, so messages cannot be sent to the far-end switch. 1. Examine results of Test #259 and follow recommendations provided there.

Continued on next page

Table 11-184. TEST #260 Remote Layer 3 Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	A message was composed and sent to the far-end switch. The ISDN PRI specification allows up to two minutes for a reply. Check the Error Log for this ISDN-PRI Signaling Link Port (ISDN-LNK) for errors of Type 2305 for evidence of a Remote Layer 3 Query failure. If no new errors were logged since this test was run, then this switch and the far-end switch processor can exchange call control messages. If there is still a problem with a particular DS1 ISDN Trunk (B-channel), busy it out and run the Long Test Sequence, paying particular attention to the results of Test #258 (ISDN Test Call). If the problem persists and the above action has not revealed the cause, escalate the problem.

ISDN-LNK (ISDN-PRI Signaling Link Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
ISDN-LNK[2]	MINOR	test port PCSSpp l	ISDN-PRI Signaling Link Port
ISDN-LNK	WARNING	test port PCSSpp sh	ISDN-PRI Signaling Link Port

1 Where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

2 For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack) or UDS1-BD (Universal DS1 Interface Circuit Pack) Maintenance documentation.

NOTE:
Use this Maintenance Object (ISDN-LNK) for maintenance tests , alarms, and hardware errors when the "ISDN-PRI over PACCON" option on the *system-parameters customer* form is set to a "**n**". When the ISDN PRI over PACCON is set to "**y**" use Maintenance Object ISDN-PLK.

When the ISDN-PRI over PACCON option is set to "**n**", the ISDN-PRI D-channel call control messages are transmitted over the TDM bus to the Processor Interface circuit pack and you must use this Maintenance Object for PRI Link problems.

An ISDN-PRI Signaling Link is known as a D-channel. D-channels are used to transmit call control signaling for B-channels. The call control signaling for the B-channels is combined and carried over separate ISDN-PRI D-channels. User information (for example, digitized voice, digital data) channels are known as bearer channels (B-channels); DS1 ISDN Trunks are B-channels and they carry the user traffic. PRI endpoint ports are also B-channels that can carry Wideband traffic.

The ISDN-PRI Signaling Link Port (ISDN-LNK) and the associated DS1/UDS1 ISDN Trunk (ISDN-TRK) or PRI endpoint port (PE-BCHL) use ports on a TN767 or TN464B or later DS1/UDS1 interface circuit pack (the TN722 cannot be used for this application). The TN767 is used for 24 channel 1.544 Mbps systems. The TN464B is used for 32 channel 2.048 Mbps systems. The TN464C or later can be used for either 24 or 32 channel systems. A description of these circuit packs appears in DS1-BD or UDS1-BD maintenance documentation.

In a 24 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the first 23 ports. The ISDN-PRI Signaling Link Port must be the 24th port. In certain configurations (NFAS), the 24th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

In a 32 channel system, the DS1/UDS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the ports 1-15 or 17-31, but the ISDN-PRI Signaling Link Port must be the 16th port. In certain configurations (NFAS), the 16th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

ISDN-LNK handles maintenance and recovery for the D-channel port on the DS1 carrying the signaling link. A problem with the ISDN-PRI Signaling Link Port (D-channel) has an effect on all of the associated DS1 ISDN Trunks or PRI endpoint ports (B-channels) since no call control information can be conveyed to the far-end switch without it. Stable calls may remain operational, but no new calls can be made.

The ISDN-PRI Signaling Link Port itself depends on two other entities: the DS1/UDS1 Interface circuit pack it resides on, and the Processor Interface Link that provides the link to the processor. If there are problems with the ISDN-PRI Signaling Link Port, also investigate the DS1/UDS1 interface circuit pack and the Processor Interface Link.

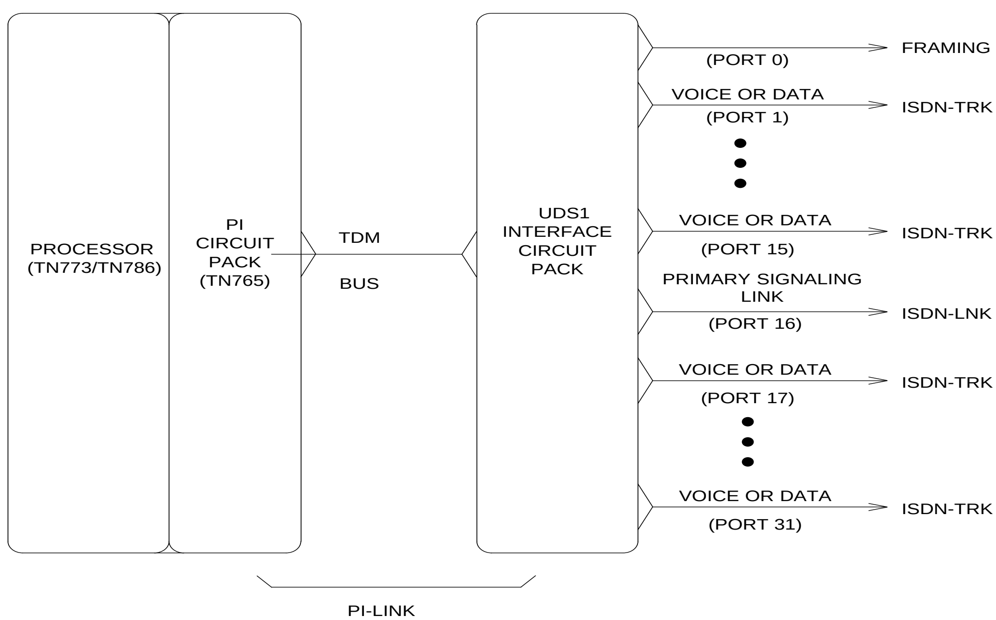

Figure 11-43. ISDN-PRI Signaling Link Port Interactions (32-Channel)

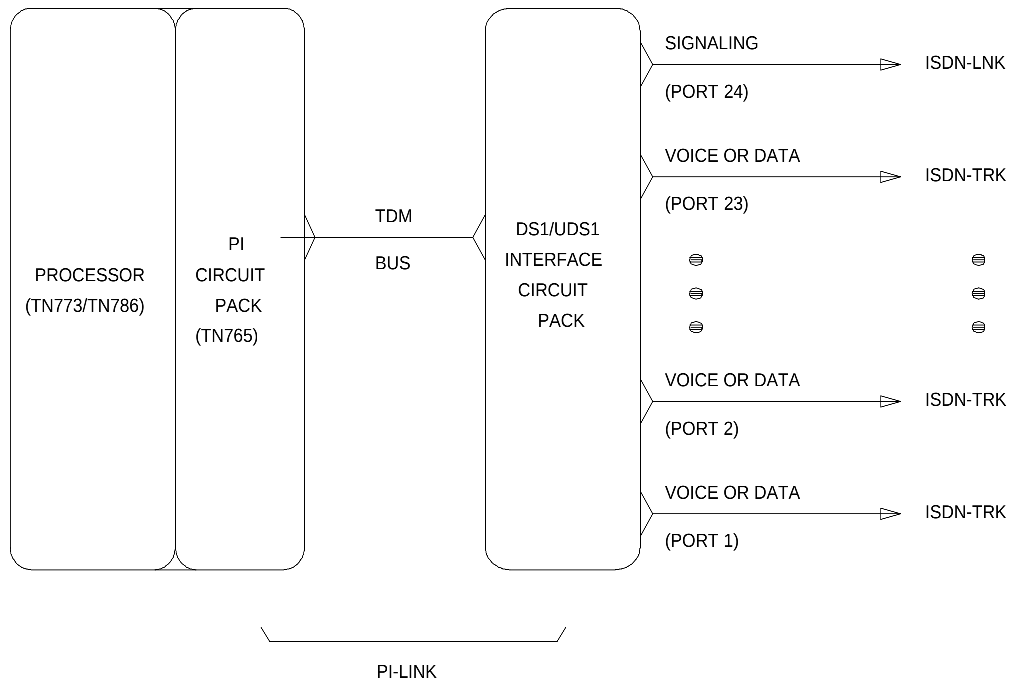

Figure 11-44. ISDN-PRI Signaling Link Port Interactions (24-Channel)

Hardware Error Log Entries and Test to Clear Values

Table 11-185. ISDN-PRI Signaling Link Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1 (c)
18	0	busyout port PCSSpp (c)	WARNING	OFF	release port PCSSpp (c)
130 (a)		None	WARNING	ON	test port PCSSpp sh (c)
1537 (b)		NPE Crosstalk Test #6	MINOR	ON	test port PCSSpp l r 3 (c)

1 Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

b. The actual alarming level depends on the options chosen via the **set options** command on the Manager terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "**y**" on the Set Options form).

c. ’pp’ is ’24’ for 24-channel interfaces, and ’16’ for 32-channel interfaces.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence. REMINDER: The command line entry to test the ISDN-LNK MO is: **test port PCSSxx (sh or l)**, where 'xx' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Signaling Link Board Check (#643)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. This test runs only if the Processor Interface link corresponding to this ISDN-LNK MO is busied out by system technician. The Processor Interface link number can be determined from the Communication-Interface Links form.

Table 11-186. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources for this test are not available. The ISDN-PRI link may be up and servicing calls. First obtain the ISDN-PRI link number (lnk-no) from the Communication-Interface Links form by issuing the **display communication-interfaces links** command. Then, determine the status of the ISDN-PRI link via the **status link lnk-no** command. If the link is in-service, this test aborts. Therefore, to run this test, the link must be busied out. No new ISDN-PRI calls can be made while the link is in the busied-out state. 1. If the test must be run, busyout the link. 2. Retry the command. 3. If it continues to abort with Error Code 1000, escalate the problem.

Continued on next page

Table 11-186. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-186. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the DS1-BD Interface circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Signaling Link Board Check (#643)

This ISDN-PRI Signaling Link Port D-channel depends on the health of the DS1 Interface circuit pack. This test checks the state of the DS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port.

Table 11-187. TEST #643 Signaling Link Board Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete test on this port, either: 1. Re-attach the disconnected PRI terminal adapter and retry test command, or 2. Disable the rollabout video feature on this circuit pack by entering **change ds1 PCSS** and set the field **"Alarm when PRI Endpoint Detached?"** to **"y."**
8	FAIL	The DS1 circuit pack is not in-service. 1. Check the Hardware Error Log for entries logged against DS1-BD and consult the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation for repair procedures.
	PASS	The DS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.

ISDN-PLK (ISDN-PRI Signaling Link Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
ISDN-PLK[2]	MINOR	test port PCSSpp l	ISDN-PRI Signaling Link Port
ISDN-PLK	WARNING	test port PCSSpp sh	ISDN-PRI Signaling Link Port

1 Where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

2 For additional repair information, see also PKT-CTRL (Packet Control), DS1-BD (DS1 Interface Circuit Pack) or UDS1-BD (Universal DS1 Interface Circuit Pack) Maintenance documentation.

NOTE:
Use this Maintenance Object (ISDN-PLK) for maintenance tests , alarms, and hardware errors when the "ISDN-PRI over PACCON" option on the *system-parameters customer* form is set to a "**y**" When the ISDN PRI over PACCON is set to "**n**" use Maintenance Object ISDN-LNK.

The ISDN-PRI over PACCON option allows the PRI Links to be carried over the PACCON (Packet Controller TN778 circuit board), increasing the system ISDN-PRI capacity to the possible number of D-channels. An ISDN-PRI Signaling Link is known as a D-channel. The D-channel is used to transmit call-control signaling for the B-channels. B-channels (User information channels) are known as bearer channels (B-channels for example, transmit digitized voice, digital data); DS1 ISDN Trunks are B-channels and they carry the user traffic. PRI endpoint ports are also B-channels that can carry Wideband traffic. The call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

The ISDN-PRI Signaling Link Port is the port on a TN464C or later UDS1 Interface circuit pack that carries D-channel messages to the processor. The ISDN-PRI interface uses out-of-band signaling as opposed to robbed-bit, in-band signaling. For G3s, and G3i, this port can be used as an interface to the TDM bus or to the Packet bus. This is controlled by the "ISDN-PRI over PACCON" option. When the option is set to "**y**" the ISDN-PRI D-channel messages are transmitted over the Packet bus to the Packet Control circuit pack. The associated maintenance object name of the UDS1 port used to carry the D-channel over the Packet Bus is ISDN-PLK.

The B-channels associated with a ISDN-PRI D-channel can use ports on the same circuit pack or ports on other TN464C or later or TN767 DS1 Interface circuit packs (the TN722 cannot be used for this application).

The TN767 DS1 interfaces is used for 24 channel 1.544 Mbps systems. The TN464C or later can be used for either 24 or 32 channel systems. The 32-channel (31 DS0 channels + 1 framing channel on a 2.048 Mbps link) are only supported on TN464 series circuit packs. A description of these circuit packs appears in DS1-BD or UDS1-BD maintenance documentation.

In a 24 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the first 23 ports. The ISDN-PRI Signaling Link Port must be the 24th port. In certain configurations (NFAS), the 24th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

In a 32 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the ports 1-15 or 17-31, but the ISDN-PRI Signaling Link Port must be the 16th port. In certain configurations (NFAS), the 16th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

ISDN-PLK handles maintenance and recovery for the D-channel port on the DS1 carrying the signaling link. A problem with the ISDN-PRI Signaling Link Port (D-channel) has an effect on all of the associated DS1 ISDN Trunks or PRI endpoint ports (B-channels) since no call control information can be conveyed to the far-end switch or Terminal Adapter without it. Stable calls may remain operational, but no new calls can be made.

The ISDN-PRI Signaling Link Port (ISDN-PLK) itself depends on two other entities: the UDS1 interface circuit pack (TN464) it resides on, and the Packet bus which provides the link to the processor. If there are problems with the ISDN-PLK, also investigate the TN464 UDS1 interface circuit pack (UDS1-BD) and the packet bus (PKT-BUS).

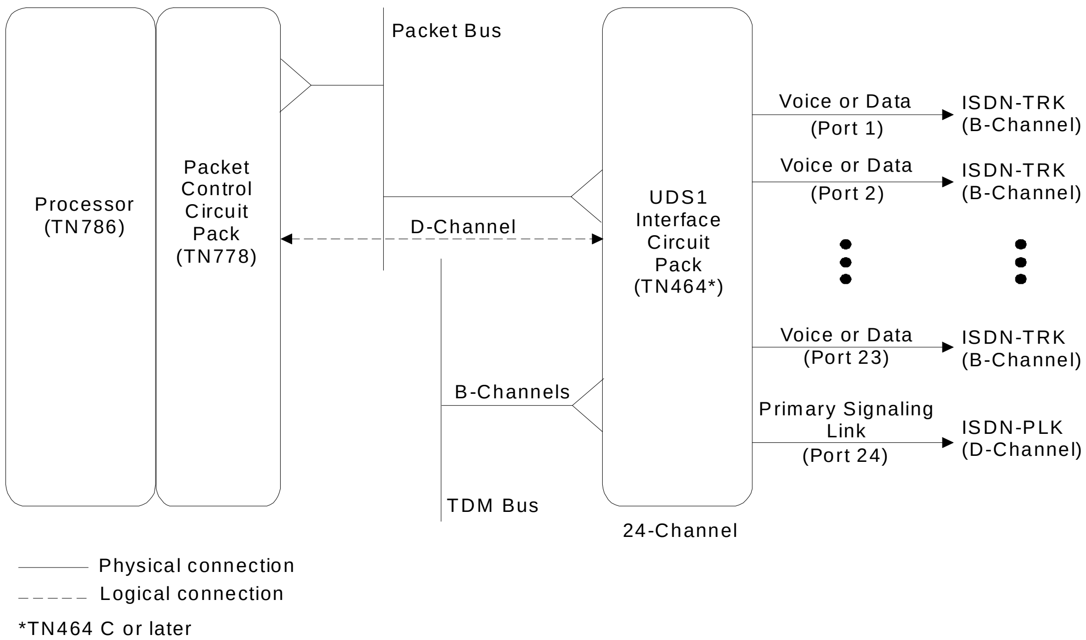

Figure 11-46. FAS ISDN-PRI Over PACCON Signaling Group (24 Channel)

Hardware Error Log Entries and Test to Clear Values

Table 11-188. ISDN-PRI Signaling Link Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp[2]
18(a)	0	busyout port PCSSpp*	WARNING	OFF	release port PCSSpp[2]
130 (b)		None	WARNING	ON	test port PCSSpp[2]
1537 (c)	46210		WARNING	OFF	
1793 (d)					test board PCSSpp[2]1
3585 (e)	46222		MINOR	ON	
3841 (f)	46211				
3842 (g)	46223				
3843 (h)		Signaling Port Packet Bus (LAN) Loopback test (#939)			test port PCSSpp[2]1

1 Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

2 pp is 24-channel interfaces and 16 for 32-channel interfaces.

Notes:

a. The D-channel is demand busied out. No calls can be made over this D-channel.

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. “Link error” This error occurs when the port receives an invalid frame over the D-channel. This error normally indicates an off-board problem usually related to transmission errors on the DS1 facility. Execute the **list measurements ds1-log** command for the UDS1 TN464 circuit pack on which the D-channel resides. If the UDS1 is reporting some errors, then the DS1 facility has experienced transmission problems which could have caused the ISDN-PLK to report a Link Error. If the UDS1 is not reporting errors, execute the long test sequence for the D-channel (ISDN-SGR). Investigate any errors, if there are none execute a long test sequence for the UDS1 circuit pack (UDS1-BD) and investigate any errors.

If this Link Error continues to be logged, follow normal escalation procedures. If no errors are reported, the Link Error is probably not affecting service.

d. The UDS1 Interface circuit pack is out-of-service. Look for and resolve UDS1-BD errors in the Hardware Error Log.

e. "Transmit FIFO Overflow error" This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. Specifically, this error occurs when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem.

   The actual alarming level depends on the options chosen via the **set options** command on the G3-MT terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "y" on the *Set Options* form).

f. "Bad DLCI error" This error occurs when a LAPD frame is received across the DS1 facility which contains a DLCI which does not have a valid entry in the on-board translation memory. This error normally indicates an off-board problem usually related to a broken endpoint or a state mismatch between a remote endpoint and the local call processing software. Maintenance will not start any testing or generate any alarms in response to this error.

g. "Receive FIFO Overflow error" This error occurs when the circuit pack detects an overflow of its receive buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch between the two end-points of a packet switched connection. LAPD should be able to recover from this problem, but it may degrade the performance of the Packet Bus. Maintenance will not start any testing or generate any alarms in response to this error.

h. This error occurs when the *Signaling Port Packet Bus Loopback Test (#939)* fails. Run the long test sequence and pay particular attention to the results of *Test #939*.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. REMINDER: The command line entry to test the ISDN-PLK MO is: **test port PCSSpp (sh or l)**, where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Signaling Port Bus Loopback Test (#939)		X	D
Signaling Link Board Check (#643)	X	X	ND

1 D = Destructive; ND = Nondestructive

Signaling Link Board Check (#643)

This test checks the state of the UDS1 Interface circuit pack (TN464C or later) transporting the ISDN-PRI Signaling Link.

Table 11-189. TEST #643 Signaling Link Board Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete test on this port, either: 1. Re-attach the disconnected PRI terminal adapter and retry test command, or 2. Disable the rollabout video feature on this circuit pack by entering **change ds1 PCCSS** and set the field **"Alarm when PRI Endpoint Detached?"** to **"y."**
8	FAIL	The UDS1 circuit pack (TN464C or later) is not in-service. 1. Check the Hardware Error Log for entries logged against UDS1-BD and consult the UDS1-BD (UDS1 Interface Circuit Pack) Maintenance documentation for repair procedures.
	PASS	The UDS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.

Signaling Port Packet Bus Loopback Test (#939)

This test verifies the connectivity of an ISDN-PRI Signaling Port (D-channel) across the Packet Bus, also known as the LAN bus. It will execute only if the port is busied out. Failure of this test indicates a fault associated with the port hardware on the circuit pack..

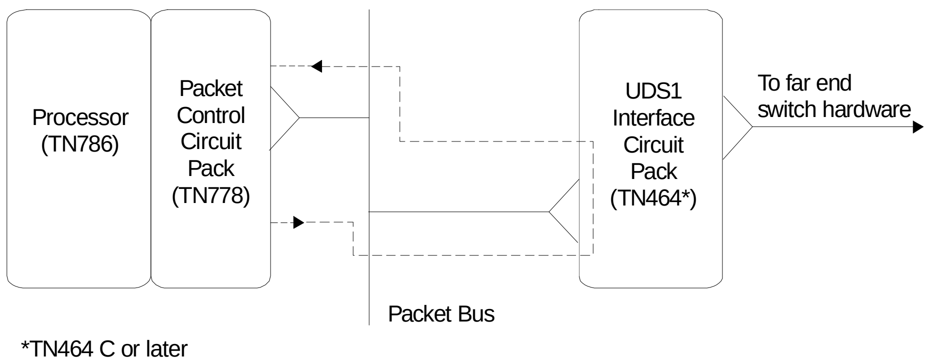

Figure 11-47. Signaling Port Packet Bus (LAN) Loopback

Table 11-190. TEST #939 Signaling Port Packet Bus Loopback

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not in the out-of-service state. Use the **busyout port PCSSpp** command to place it in the out-of-service state and repeat this test **CAUTION:** *The **busyout** will prevent new call originations on all B-channels in the signaling group until the port is released.*
1139	ABORT	The Packet Bus in this port network is out of service. 1. Follow repair procedures for the Packet Bus 2. Enter **test port PCSSpp long** and check the results of this test (939).

Continued on next page

Table 11-190. TEST #939 Signaling Port Packet Bus Loopback — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The Packet Control circuit pack is out of service. 1. Follow the repair procedures for PKT-CTRL. 2. Enter **test port PCSSpp long** and check the results of this test (939).
1144	ABORT	The Packet Bus in the PPN is out of service. 1. Follow the repair procedures for the Packet Bus. 2. Enter **test port PCSSpp long** and check the results of this test (939).
2012	ABORT	Internal system error.
2100	ABORT	Could not allocate the necessary system resources to run this test 1. Retry the command at one-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Loopback test has failed. 1. If this test fails repeatedly wait until all of the ports on the board are idle (not in use) and reset the circuit pack. To reset the circuit pack enter the commands **busyout board PCSS** and **reset PCSS**. 2. Repeat the test, and if the test continues to fail replace the circuit pack.
	PASS	1. Connectivity of the D-channel over the Packet Bus is operational.

Continued on next page

ISDN-SGR (ISDN-PRI Signaling Group)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
ISDN-SGR	MINOR	test sig-group <group>	ISDN-PRI Signaling Group
ISDN-SGR	WARNING	test sig-group <group>	ISDN-PRI Signaling Group

1 Where <group> is a number 1-8 and the test sequence can be either s (short) or l (long).

An ISDN-PRI Signaling Group is a collection of DS1/UDS1 ISDN Trunks or PRI endpoint ports (B-channels) for which a given ISDN-PRI Signaling Link Port (D-channel) carries signaling information. ISDN-PRI requires the use of one of the following DS1 interface circuit packs:

TN767	24-channel with ISDN-PRI D-channel over PI-BD
TN464B	32-channel with ISDN-PRI D-channel over PI-BD
TN464C or later	24- or 32-channel with ISDN-PRI D-channel over PI-BD or PKT-CTRL (PACCON)

See DS1-BD and UDS1-BD Maintenance documentation for a description of these circuit packs. See *DS1/CEPT1/ISDN-PRI Reference*, 55-025-101, for more information on ISDN.

NOTE:
If a ISDN-PRI over PACCON (Packet Control Circuit pack) is to be used then only the TN464C or later may be used for the D-channel Signaling.

For 24 channel interfaces, the first 23 ports on the circuit pack are used as B-channels. The 24th port may be used as a B-channel or as a D-channel depending on the type of Signaling Group used, as described below.

For 32 channel interfaces, ports 1-15 and 17-31 on the circuit pack are used as B-channels. The 16th port may be used as a B-channel or as a D-channel depending on the type of Signaling Group used, as described below.

There are two types of Signaling Groups:

- Facility Associated Signaling (FAS) (supported by all country protocols)
- Non-Facility Associated Signaling (NFAS) (supported by country protocol 1 only)

The figures following this discussion illustrate each of the configurations.

In an FAS Signaling Group, the 24th port of the DS1 Interface circuit pack (for 24 channel interfaces) or the 16th port of the DS1 Interface circuit pack (for 32 channel interfaces) is always the D-channel that carries signaling information for the other ports (B-channels) on the circuit pack. If a Packet Control circuit pack is used then only the TN464C or later circuit pack may be used.

In an NFAS Signaling Group, the 24th port of a DS1 Interface circuit pack (for 24 channel interfaces) or the 16th port of a DS1 Interface circuit pack (for 32 channel interfaces) is administered as a D-channel. The D-channel carries signaling information for the other ports (B-channels) on that circuit pack. That D-channel can also carry signaling information for any of the ports on other DS1 Interface circuit packs in the NFAS Signaling Group. As a result, the 24th port on other 24-channel DS1 Interface circuit packs and the 16th port on other 32-channel DS1 Interface circuit packs can be used as B-channels. A D-channel in an NFAS Group can signal for B-channels on a total of 20 DS1 Interface circuit packs. This configuration is known as NFAS Simplex. If a Packet Control circuit pack is used then only the TN464C or later circuit pack may be used to carry the D-channel, however other DS1/UDS1 interface circuit packs may be used to carry only B-channels.

In addition to NFAS Simplex, there is another type of NFAS Group called NFAS Duplex. This provides the user with more reliability, which is desirable because NFAS permits the D-channel to signal for so many B-channels. NFAS Duplex allows the administration of a backup D-channel, which remains in a Standby state until the Active D-channel goes down. If the Active D-channel does go down, the backup D-channel takes over and provides signaling for all the B-channels in the signaling group. In the case that a Packet Control circuit pack is used then only the TN464C or later may be used to carry the D-channels. B-channels may be carried by any DS1/UDS1 interfaces.

The ISDN-PRI Signaling Group itself depends on three other entities: the DS1 Interface circuit pack on which the D-channel(s) resides, the ISDN-PRI Signaling Link Port(s), and the interface link that provides connectivity to the processor (either the Processor Interface Link or the Packet Control circuit pack). If there are any problems with the ISDN-PRI Signaling Group, also investigate the ISDN-PRI Signaling Link Port(s), the DS1 Interface circuit pack(s), and either the Processor Interface Link or the Packet Control circuit pack.

1793 (d)	Any	Layer 2 Status (Test #647)	WARNING	OFF	test sig-group <group>
2049 (e)	Any	Layer 2 Status (Test #647)	WARNING	OFF	test sig-group <group>
2305 (f)	Any	Remote Layer 3 Query (Test #637)	MINOR	OFF	test sig-group <group>
3585 (g)	port number	none			none
3840-3928 (h)	port number				none

1 Run the Short or Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This switch sent a message to the far-end switch or terminal adapter, and the far-end did not respond in the allotted time. Possible causes include link failure and congestion or outage at the far-end. The Aux Data field contains Layer 3 protocol information used by internal counters.

If no other symptoms are not present, no action is required. If Layer 3 communication is down, there should be indications in the form of alarms and errors for link components. Check out other errors against ISDN-SGR, ISDN-TRK, and other hardware components on the link.

There is no test to clear these errors. The error counter is decremented by 1 every 15 minutes.

b. This error indicates that the primary signaling channel connection has been lost for more than 90 seconds. If a secondary signaling channel does not exist or is not in-service, the associated B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #636 (Primary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

   When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

c. This error indicates that the secondary signaling channel connection has been lost for more than 90 seconds. If the primary signaling channel is not in-service, B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #639 (Secondary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

   When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

d. This error indicates a failure of the Layer 2 Status Query Test for the primary signaling channel

e. This error indicates a failure of the Layer 2 Status Query Test for the secondary signaling channel.

f. A specific message was sent to the far-end switch, and it did not respond within the allotted time. Investigate elements of the ISDN PRI D-channel(s) (ISDN-LNK, ISDN-PLK, ISDN-SGRP, PI-LINK, PI-PT, PKT-CTRL) for both this switch and the Far-end switch. If Test #637 fails twice in a row, the B-channels will be alarmed and made unavailable for outgoing calls (although incoming calls will still be accepted). When Test #637 succeeds and the Far-end switch starts responding properly, the DS1 ISDN Trunk (B-channels) will be placed back into normal operation and their alarms will be retired.

g. A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 administration form). However, these messages are used only for duplex NFAS signaling which is supported only by country protocol 1.

   Thus, there may be a mismatch in administration between the local and far-end switches. Consult with the customer's network provider to determine whether the D-channel is set up correctly on the far-end switch.

h. These error types are used to report certain error messages received by the ISDN-PRI Signaling Group for one of its associated B-channels. The aux data field shows for which B-channel (port number) the message was received.

   The error code generated equals 3840+*x*, where *x* is a Cause Value defined by the ISDN PRI Specification. Note that there is no Test to Clear Value for these error types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. The following table provides more information:

Table 11-192. Descriptions and Recommendations for Error Types 3840-3928

Error Code	Description	Recommendation
3842	A request has been made to use a transit network or common carrier that cannot be accessed.	1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Check all routing patterns containing this trunk group for validity of interexchange carriers requested (IXC field).
3846	The far-end switch has indicated that the B-channel (trunk) is not acceptable for use in the call for which it was requested.	This could indicate an administration problem (for example, the local switch and the far-end switch have different B-channels administered), or could reflect the occurrence of a normal race condition (for example, the local switch has requested use of a B-channel which the far-end switch had just reserved for use on another call). 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Issue the **status trunk** command for the indicated trunk. 3) Refer to the ‘‘DS1 ISDN Trunk Service States’’ and ‘‘ISDN-PRI Trunk Service States’’ sections of ISDN-TRK for recovery suggestions.
3858	Similar to Error Type 1. The switch sent an ISDN message to the far-end switch or terminal adapter which did not respond in the allotted time.	Follow same recommendations as for Error Type 1.

Continued on next page

Table 11-192. Descriptions and Recommendations for Error Types 3840-3928 — *Continued*

Error Code	Description	Recommendation
3878	The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful).	1. From the circuit pack and port number (in the Aux Data field, determine the trunk group against which the error was reported. 2. Consult with the network provider to determine the nature and expected duration of the out of service condition. 3. Consider modifying all routing patterns containing this trunk group, to route calls around the network which is out of service.
3890	A request to use a network service (e.g., SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.	This could be a local administration problem only, or a mismatch between the local administration and that of the network provider. 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Display the trunk group form: If the trunk group is Call-by-Call (Service Type is ‘‘cbc’’), check all routing pattern forms containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk. 3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.

Continued on next page

Table 11-192. Descriptions and Recommendations for Error Types 3840-3928 — *Continued*

Error Code	Description	Recommendation
3892	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3894	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	First, eliminate any transitory state mismatch problems by issuing the **test port UUCSSpp** command for the trunk port shown in the aux data field. Test #256 (Service State Audit) is the important test in the sequence. If this passes satisfactorily, yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3905	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3906	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate to the problem and provide the next tier with this Error Log information.

Continued on next page

Table 11-192. Descriptions and Recommendations for Error Types 3840-3928 — *Continued*

Error Code	Description	Recommendation
3909	A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.	Follow the recommendations listed above for error type 3890.
3928	A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user itself.	This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints. Determine the trunk group from the circuit pack and port number (in the aux data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Primary Signaling Link Hardware Check*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Primary Signaling Link Hardware Check (#636)	X	X	ND
Secondary Signaling Link Hardware Check (#639)	X	X	ND
Layer 2 Query Test (#647)	X	X	ND
Remote Layer 3 Query Test (#637)	X	X	ND

1 D = Destructive; ND = Nondestructive

Primary Signaling Link Hardware Check (#636)

The ISDN-PRI Signaling Link Port itself depends on the health of the DS1/UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the DS1/UDS1 circuit pack. The ISDN-PRI Primary D-channel also depends on the health of either the Processor Interface Link or the Processor Control circuit pack providing connectivity to the DS1/UDS1 circuit pack.

If there are problems with the ISDN-PRI Signaling Link, also investigate the DS1/UDS1 circuit pack (DS1-BD/UDS1-BD) and the Processor Interface Link or Packet Control (PI-LINK/PACCON) dependant upon which is used

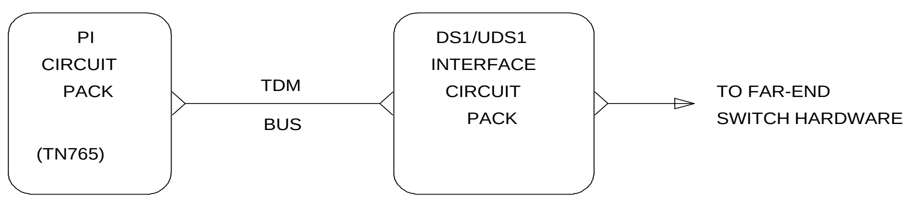

Figure 11-60. Primary Signaling Link Hardware Check (Test #636)

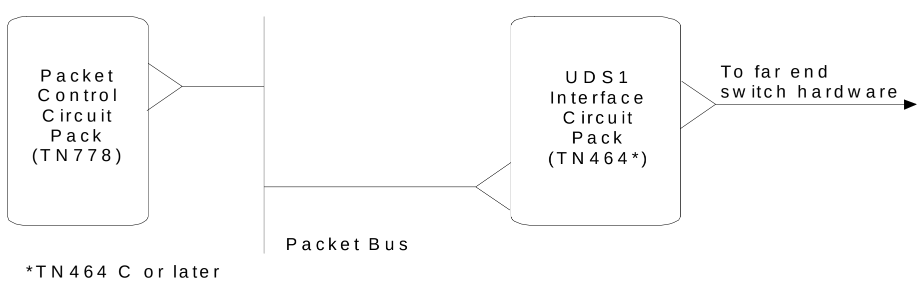

Figure 11-61. PRI over PACCON Primary Signaling Link Hardware Check (Test #636)

Table 11-193. TEST #636 Primary Signaling Link Hardware Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete test on this port, either: 1. Re-attach the disconnected PRI terminal adapter and retry test command, or 2. Disable the rollabout video feature on this circuit pack by entering **change ds1 UUCSS** and set the field **"Alarm when PRI Endpoint Detached?"** to **"y"**.
4	FAIL	There is a problem with the Processor Interface Link. No DS1 ISDN Trunk (B-channel) or wideband PRI Endpoint calls can be made until the problem is resolved. 1. Display the Communication-Interface Links Form via the to determine which link is down (find the one that matches the DS1 interface circuit pack this ISDN-PRI Signaling Link Port is on) and then consult the procedures for Processor Interface Link.
8	FAIL	There is a problem with the DS1/UDS1 Circuit Pack, or the ISDN-PRI Signaling Channel (D-channel). No DS1 ISDN Trunk (B-channel) or wideband PRI Endpoint calls can be made until the problem is resolved. 1. Consult the procedures for DS1/UDS1 Circuit Pack and the ISDN-PRI Signaling Channel (ISDN-LNK/ISDN-PLK).
	PASS	The basic physical connectivity of the primary D-channel is intact and functional. One might try this test repeatedly to ensure the link is up and to uncover any transitory problems.

Remote Layer 3 Query (#637)

This test will query the far-end switch or terminal adapter to determine if the signaling connection is functioning properly at Layer 3. It will select a B-channel in the in-service or maintenance service state and send an ISDN Layer 3 SERVice message, which requires a response from the far end (similar to performing Test #256 on an ISDN trunk. The test will not be performed if there are no B-channels in an appropriate ISDN service state (as when none are administered or they are all out of service).

> **NOTE:**
> The service state can be displayed by using the **status trunk <trunk group/trunk member>** or **status pri-endpoint** command.

As is the case with Test #256 for an ISDN trunk, a PASS only indicates that a message was composed and sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response. Check the Error Log for ISDN-SGR (ISDN-PRI Signaling Group) errors of type 2305 for evidence of a Remote Layer 3 Query failure.

Tests #639 and #636 check the health of the D-channels and DS1/UDS1 Interface Circuit Packs. As shown in the figures below, Test #637 goes one step further by checking the communication path from the processor, through the Processor Interface or Packet Control circuit pack over the TDM or Packet Bus through the DS1/UDS1 Interface circuit pack, and on to the far-end switch or terminal adapter. A special ISDN message is sent to the far-end switch or terminal adapter, which must respond within a specified amount of time. This test is designed to ensure that the communication path between the switch and the far-end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

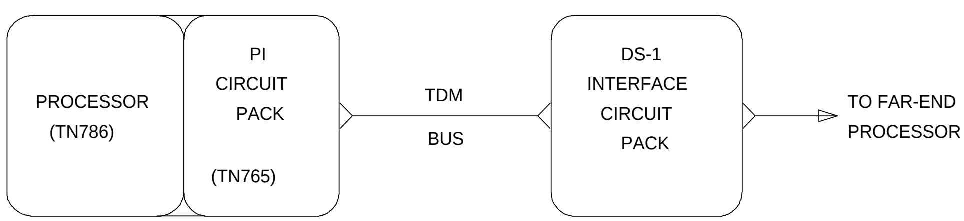

Figure 11-62. Remote Layer 3 Query (Test #637)

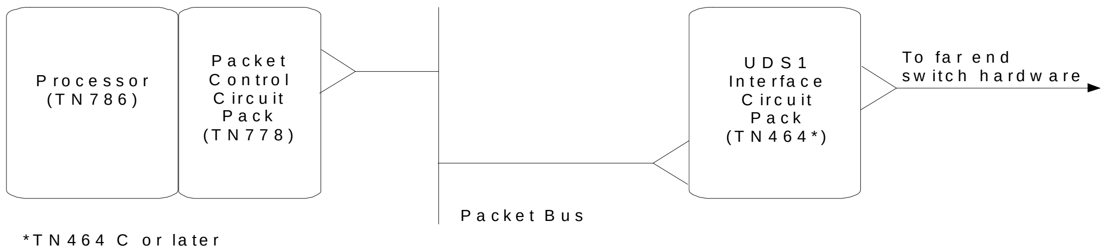

Figure 11-63. PRI Over PACON Remote Layer 3 Query (Test #637)

Table 11-194. TEST #637 Remote Layer 3 Query

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.
1006	ABORT	This is a NORMAL ABORT. For country protocol 1 interfaces (including the USA), either there are no B-channels administered in this signaling group, or all B-channels in this signaling group are either out-of-service or are in a "pending" state (PINS or PMTC, indicating that a B-channel maintenance message for that B-channel has been sent and not yet acknowledged). 1. Administer an ISDN Trunk or PRI Endpoint Port (B-channel) in this signaling group, or use the **status trunk TRK-GRP/TRK** or **status pri-endpoint <extension>** command to check the state of the ISDN Trunks or PRI Endpoint Ports associated with this signaling group. Refer to ISDN-TRK or PE-BCHL for further details regarding service state definitions and transitions. For systems not using country protocol 1 interfaces, there are no B-channels administered in this signaling group.

Continued on next page

Table 11-194. TEST #637 Remote Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1019	ABORT	There is already a Remote Layer 3 Query in progress. This is a normal ABORT. 1. Wait two minutes, then follow the procedures for when this test passes.
1113	ABORT	The Signaling Link is down. Therefore no messages can be sent to the Far-end switch. 1. Examine the results of Tests #636 and #639 and follow recommendations provided there. 2. If either test passes, it may be because the signaling link was disabled by system technician. Verify this by using the **display comm link** command. Tests #636 and #639 pass if the signaling link is not enabled. 3. If these tests pass and the signaling link is enabled, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.
2500	ABORT	Same as ABORT with no error code. 1. Follow the recommendations for ABORT with no error code.

Continued on next page

Table 11-194. TEST #637 Remote Layer 3 Query — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	FAIL	Same as ABORT with no error code. 1. Follow the recommendations for ABORT with no error code.
	PASS	A message was composed and sent to the Far-end switch. The ISDN PRI specification allows up to two minutes for a reply. 1. Check the Error Log for ISDN-SGR (ISDN-PRI Signaling Group) for errors of type 2305 for evidence of a Remote Layer 3 Query failure. If no new errors were logged since this test was run, then this switch and the Far-end switch processor can exchange call control messages. 2. If there is still a problem with a particular DS1 ISDN Trunk or PRI Endpoint Port (B-channel), busyout the trunk or port and run the long test sequence, paying particular attention to the results of Test #258 (ISDN Test Call). 3. If the problem persists and the above action has not revealed the cause, escalate the problem.

Secondary Signaling Link Hardware Check (#639)

The ISDN-PRI Signaling Group D-Channel port depends on the health of the DS1/UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the DS1/ UDS1 circuit pack. If there are problems with the ISDN-PRI Secondary Signaling Channel port (ISDN-LNK or ISDN-PLK), also investigate the DS1/UDS1 circuit pack.

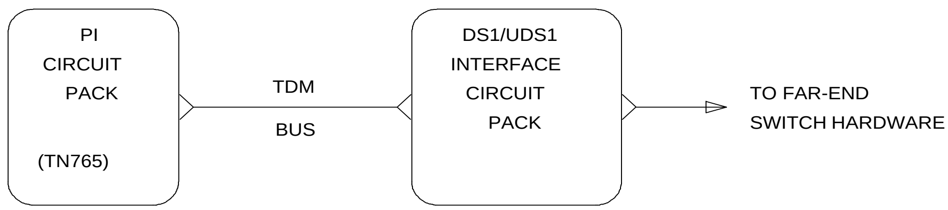

Figure 11-64. Secondary Signaling Link Hardware Check for PRI over PI (Test #639)

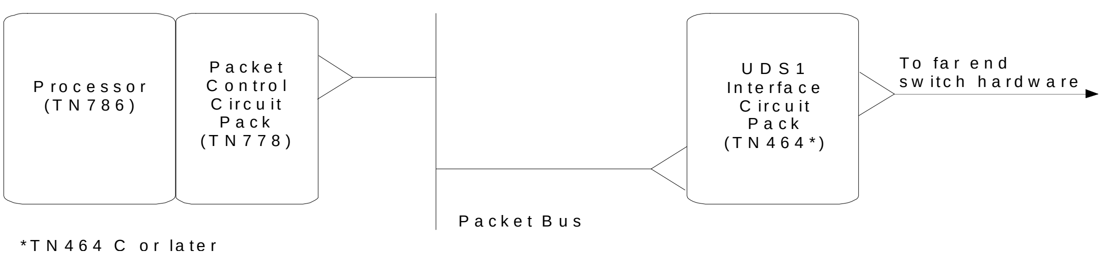

Figure 11-65. Secondary Signaling Link Hardware Check for PRI over PACCON (Test #639)

Table 11-195. TEST #639 Secondary Signaling Link Hardware Check

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.
1132	ABORT	The Secondary D-channel is not administered for this Signaling Group. This is a NORMAL ABORT. Only a Primary D-channel must be administered for a Signaling Group.
4	FAIL	There is a problem with the Processor Interface Link. No DS1 ISDN Trunk (B-channel) or Wideband PRI Endpoint calls can be made until the problem is resolved. 1. Display the Communication-Interface Links Form via the **display communication-interface** command to determine which link is down (find the one that matches the DS1 Interface circuit pack on which this ISDN-PRI Signaling Link Port resides) and then refer to the PI-LINK Processor Interface Link Maintenance documentation.
8	FAIL	There is a problem with the DS1/UDS1 Interface circuit pack or the ISDN-PRI Secondary Signaling channel (D-channel). No ISDN Trunk (B-channel) or Wideband PRI Endpoint calls can be made until the problem is resolved. 1. Refer to the DS1/UDS1 circuit pack and the ISDN-PRI Signaling channel (ISDN-LNK/ISDN-PLK) Maintenance documentation.
	PASS	The basic physical connectivity of the Signaling Group's Secondary D-channel is intact and functional. Try this test repeatedly to ensure the link is up and to uncover any transitory problems.

Layer 2 Status Test (#647)

The Layer 2 Status Test checks the layer 2 status of the ISDN-PRI Signaling Channel (D-channel). This test will fail if there is a hardware failure or a facility problem, or if the primary and secondary ISDN-PRI D-channels are not administered correctly.

The Primary and Secondary Signaling Link Hardware tests (test 636 and 639) and the Remote Layer 3 Query test (test 637) will detect most problems caused by hardware failures or incorrect administration. However, the Layer 3 test (test 637) cannot detect end-to-end transmission problems with the Standby D-channel since Layer 3 messages are not sent on the standby channel.

For G3r, the SYS-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems and for G3i/s/vs, the PI-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems (if the D-channel is connected to the Processor Interface circuit pack). However, for G3i, the PI-LINK Maintenance Object does not monitor the Layer 2 status of the ISDN-PRI D-channel when the D-channel is connected to the Packet Control circuit pack for the ISDN-PRI over PACCON feature. The Layer 2 Query test is provided to detect D-Channel Layer 2 failures and generate an associated Warning alarm independent of the hardware configuration used for the D-channels.

Table 11-196. TEST #647 Layer 2 Status Query Test

Error Code	Test Result	Description/ Recommendation
1132	ABORT	Internal System Error: The port location for the primary ISDN-PRI D-channel is not known. This condition should not be possible since an administered DS1 circuit pack must be specified when a Signaling Group is administered: 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.
1134	ABORT	Internal System Error: The associated DS1 circuit pack is not administered. This condition should not be possible since an administered DS1 circuit pack must be specified when a Signaling Group is administered. 1. Retry the command at one minute intervals a maximum of three times. 2. If the test continues to abort escalate the problem.
2500	ABORT	Internal System Error: 1. Retry the command at one minute intervals a maximum of five times. If the test continues to abort escalate the problem.

Continued on next page

Table 11-196. TEST #647 Layer 2 Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Layer 2 of the primary signaling channel is down: 1. Examine the results of the Primary Signaling Link Hardware Test (#636) and follow recommendations provided there. 2. If test #636 passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if it has been busied out. Verify that the Primary Signaling Channel (D-channel) at the far end has been administered correctly. Verify that the DS1 port used for the Primary D-channel has not been busied out at the far end. 3. If test 647 still fails, follow normal escalation procedures.
2	FAIL	Layer 2 of the secondary signaling channel is down. 1. Examine the results of Secondary Signaling Link Hardware Test (#639) and follow recommendations provided there. 2. If tests #639 passes, the Layer 2 Query test may still fail if the Signaling Channel at the far end has not been administered correctly or if the Signaling Channel has been busied out. Verify that the Secondary Signaling Channel (D-channel) at the far end has been administered correctly. Verify that the DS1 port used for the Secondary D-channel has not been busied out at the far end 3. If test 647 still fails, follow normal escalation procedures. *Continued on next page*

Table 11-196. TEST #647 Layer 2 Status Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	Both the primary and secondary Channels are down. 1. Examine the results of the Primary and SecondarySignaling Link Hardware Tests (#636 and #639) and follow recommendations provided there. 2. If tests #636 and #639 pass, the Layer 2 Query test may still fail if the Signaling Channels at the far end has not been administered correctly or if the Signaling Channels have been busied out. Verify that the Primary and Secondary Signaling Channel (D-channels) at the far end have been administered correctly. Verify that the DS1 ports used for the Primary and Secondary D-channels have not been busied out at the far end. 3. If test 647 still fails, follow normal escalation procedures.
	PASS	The Primary Signaling Channel is up and, if administered the Secondary Channel is up.

ISDN-TRK (DS1 ISDN Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
ISDN-TRK[1]	MAJOR[2]	test port PCSSpp l	DS1 ISDN Trunk
ISDN-TRK	MINOR	test port PCSSpp l	DS1 ISDN Trunk
ISDN-TRK	WARNING	test port PCSSpp sh	DS1 ISDN Trunk

1 For additional repair information, also see DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.

2 A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

A DS1 ISDN Trunk is known as a B-channel. It is a 64 kbps Bearer channel that can be used to transmit digital traffic, be it voice or data. These trunks use a separate channel for signaling (for example, for call setup); this mode of operation is known as out-of-band signaling, as opposed to in-band, robbed-bit signaling, where the signaling traffic flows over the same channel as the voice or data traffic. The separate signaling channel is called a D-channel in ISDN terminology, and it carries all the call control signaling messages for the DS1 ISDN Trunk B-channels. The D-channel for these B-channels is an ISDN-PRI (Primary Rate Interface) Signaling Link Port (ISDN-LNK/ISDN-PLK).

On 24 channel interfaces, any of the first 23 ports on the DS1/UDS1 interface circuit pack can be a B-channel. The 24th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI Signaling Group (ISDN-SGR) to which it belongs. On 32 channel interfaces, any of ports 1-15 and 17-31 on the DS1 interface circuit pack can be a B-channel. The 16th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI Signaling Group (ISDN-SGR) to which it belongs. For more details, refer to the ISDN-SGR and DS1-BD/UDS1-BD Maintenance documentation.

NOTE:

If a Packet Control circuit pack is used instead of a Processor Interface Link as the interface of the PBX SPE to the D-channel, then the signaling link port on the UDS1 circuit pack is referred to as ISDN-PLK and only the TN464C or later may be used to carry D-channel Signaling. The B-channels may be carried by any DS1/UDS1 interface circuit pack. If a Processor Interface is used for connectivity then the Signaling Link port is referred to as a ISDN-LNK and the TN767 or TN464B or later DS1 interface circuit pack may be used to carry D-channels Signaling.

For interfaces using country protocol 1 on the DS1 Circuit Pack administration form (including US), the signaling protocol used for the maintenance of the

B-channel is defined by the AT&T ISDN-PRI Specification. For interfaces using country protocols other than 1, the signaling protocol used for the maintenance of the B-channel is defined by the CCITT ISDN-PRI Specification.

There are five possible SERVICE STATES for a B-channel. The service state is negotiated with the far-end switch, changes over time, and may have a far-end or near-end component. The service state is initialized to Out-Of-Service/Far-End state and an attempt is made to negotiate it to In-Service.

NOTE:
The service state of a particular DS1 ISDN Trunk B-channel can be displayed by issuing the **status trunk <trunk_group/trunk_member>** system technician command.

If a call is present, the Specification defines the permissible CALL STATES as well. There are tests in the Short and Long Test Sequences for DS1 ISDN Trunk designed to audit these states and ensure agreement between both ends of the PRI connection.

Alarming Based on Service States

A warning alarm is logged against a DS1 ISDN B-channel trunk when it is placed in the Maintenance/Far-End or Out-Of-Service/Far-End states, during which the trunk is unusable for outgoing calls. When a warning alarm is present, use **status trunk group#/member#** command to determine the exact state. Other alarms can be diagnosed by using the short and/or long test sequences. Note that an ISDN B-channel trunk can be placed in a Far-End service state by either action taken by the far-end switch or by failure of the far-end switch to respond. For example, if the far-end does not respond to a Remote Layer 3 Query (Test #637 for ISDN-SGR), the associated DS1 ISDN trunk B-channels will be placed in the Maintenance/Far-End service state.

As a port on a DS1 circuit pack (DS1-BD or UDS1-BD), and as part of a signaling group dependent on a D-channel (ISDN-LNK/ISDN-PLK) for signaling, operation of the ISDN-TRK is dependent on the health of these other maintenance objects. The ISDN D-channel in turn depends on the Packet Bus (PKT-BUS)/Processor Interface Link (PI-LINK) (dependent on setup) for transmission through the system. Keep this hierarchy of dependencies in mind when diagnosing problems.

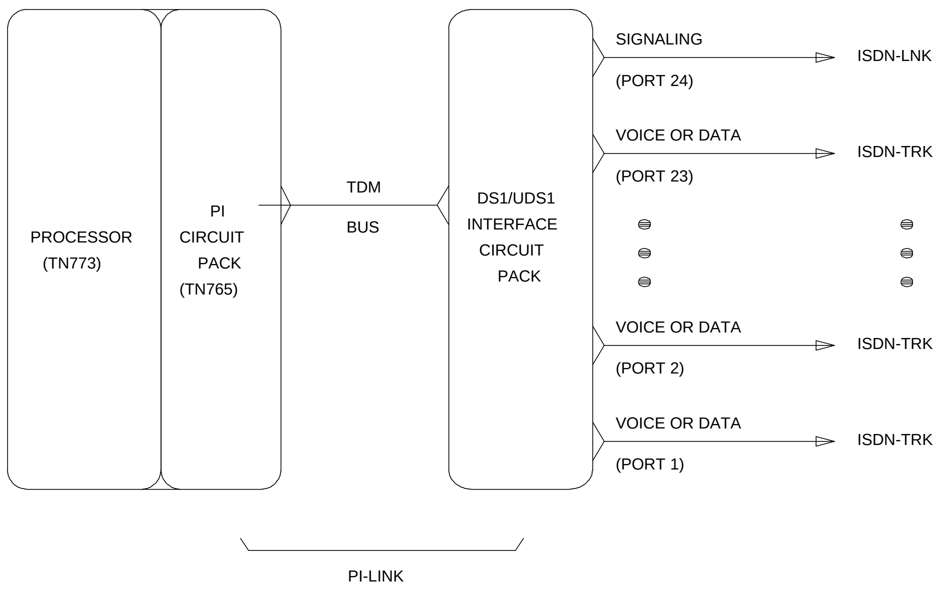

Figure 11-66. DS1 ISDN Trunk Interactions (24-channel interface)

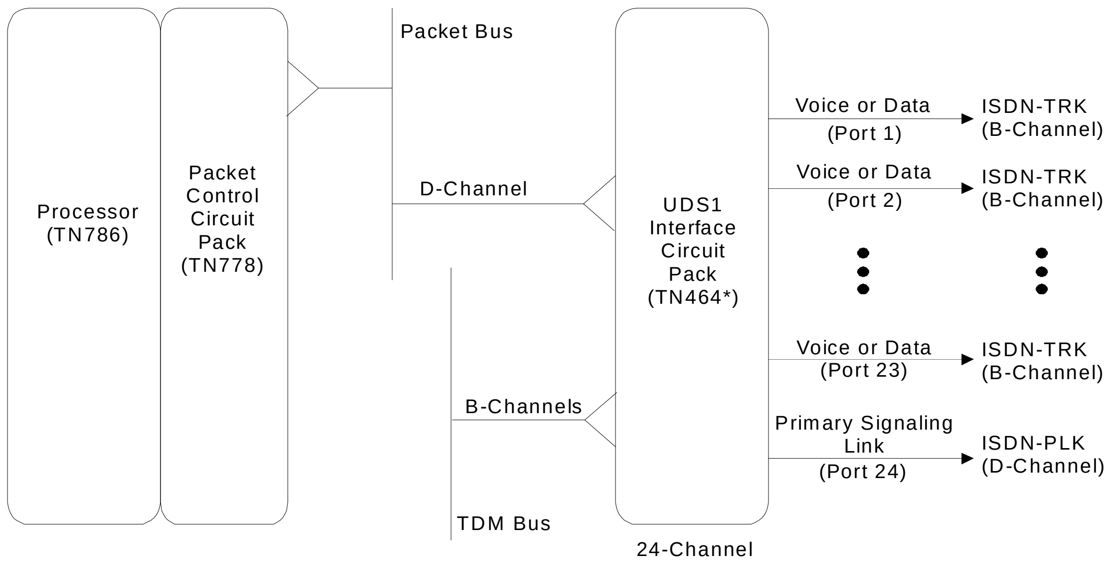

Figure 11-67. PRI Over PACCON DS1 ISDN Trunk Interactions (24-channel interface)

DS1 ISDN Trunk Service States

This section defines the possible service states of a DS1 ISDN trunk, explains the reason for each service state, and provides the recommended recovery procedures (when required).

Service States

- In-Service (INS)

  The B-channel is in its normal operating state.

- Out-of-Service/Far-end (OOS/FE)

  A B-channel is initialized to this state when administered and it may also be in this state if there is a failure on the B-channel attributed to a problem on the far-end switch. The switch sends messages to the far-end to negotiate the B-channel into service. If the far-end does not respond to the messages within a certain time period, then the service state remains out-of-service and maintenance will periodically resend the messages. The trunk is unusable for outgoing calls. On US interfaces, the trunk is unusable for incoming calls, but on non-US interfaces, incoming calls will be accepted.

- Out-of-Service/Near-end (OOS/NE)

  This is the state of the trunk when a hardware failure exists on the link, the NPE Crosstalk Test fails, or when the trunk is busied out by system technician. In this state, the trunk is unusable for incoming or outgoing calls. No messages are sent to the far-end until the signaling link comes back into service or the trunk is released by system technician.

- Maintenance/Far-end (MTC/FE)

  This state is reached when the far-end does not respond to messages sent over the signaling link for a particular trunk after a certain amount of time. This state is different from OOS/FE since the signaling link must have initially been up and the B-channels in-service. The switch will periodically send messages to the far-end to try to negotiate the trunk (B-channel) into service. The trunk is unusable for outgoing calls but will service incoming call requests from the far-end. Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in-service to MTC/FE, then stable calls are unaffected.

- Maintenance/Near-end (MTC/NE)

  The trunk (B-channel) is in this state if the signaling link (PI-LINK) is busied out by system technician. The trunk (B-channel) is also temporarily in this state if system technician has issued a **test trunk trunk_group/trunk_ member long** command. This command will execute the ISDN-PRI test call. This test will change the state of the trunk member to MTC/NE for the duration of the test unless a call request comes in from the far-end. In that case, the test would abort. Note that transitions into MTC/NE do not drop stable calls. Therefore, a system technician- demanded **busyout link lnk-no** command will not drop stable trunk calls. In this state, the B-channel is not usable for new outgoing calls, but is available for incoming calls and outgoing test calls.

- Pending States

  If the near-end is expecting a timed response from the far-end for a request to change the service state of a trunk, then the state of the trunk reflects a Pending State.

  — Pending-in-service (PINS)

    The near-end has sent a B-channel maintenance message to the far-end, requesting that the B-channel service state be transitioned to in-service. The far-end has a certain amount of time to respond to the message. The service state will be PINS until either a response is received or the timer expires.

  — Pending-maintenance (PMTC)

    This state is supported only by systems using country protocol 1 (including US). The near-end has sent a B-channel maintenance message to the far-end, requesting that the B-channel service state be transitioned to maintenance. The far-end has a certain amount of time to respond to the message. The service state will be PMTC until either a response is received or the timer expires.

— Call Activity States

In addition to the service and pending state, the state of a B-channel also reflects its call activity. If a call is connected over the B-channel, then the state of the trunk will reflect the "active" call state, for example, "in-service/active." If there is no call on the B-channel, then the trunk will reflect the "idle" call state, for example, "OOS/FE-idle."

The following diagram of the DS1 ISDN Trunk service states shows the common progression from one service state to another and the event that caused the change of state.

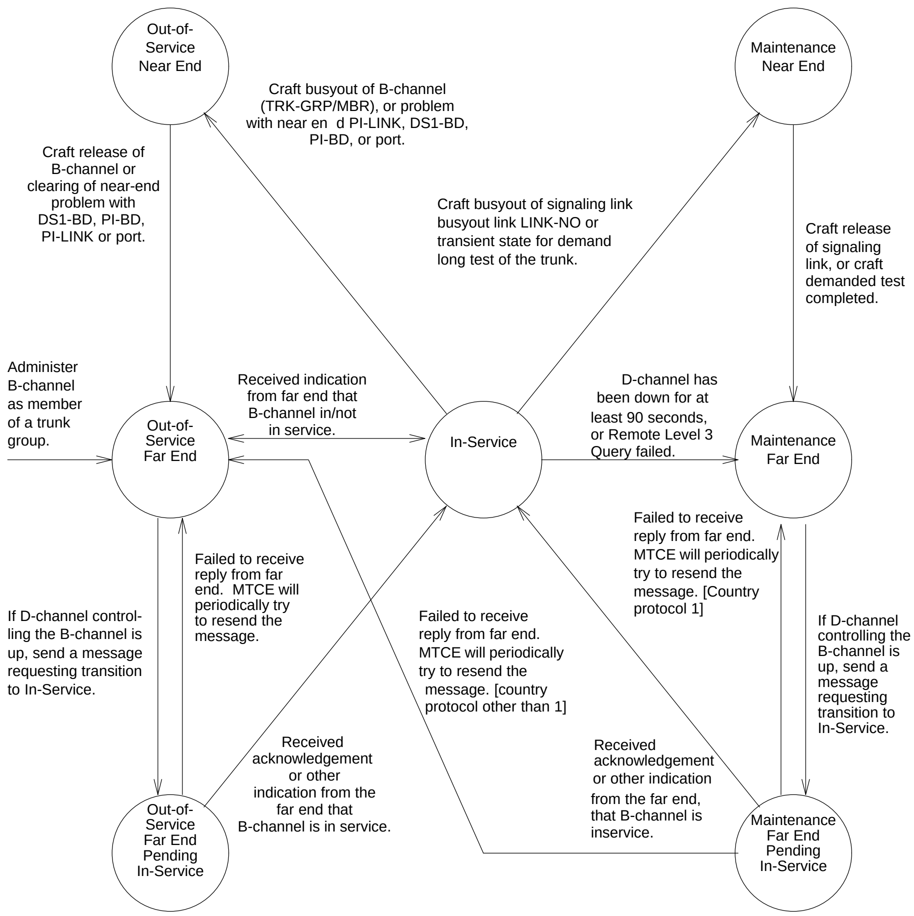

Figure 11-68. Common Progressions in Service States

ISDN-PRI Trunk Service States

The following chart summarizes each of the different DS1 ISDN Trunk service states that can result when the **status trunk <trunk_group/trunk_member>** command is issued.

NOTE:
Refer to "Troubleshooting ISDN-PRI Problems" in Chapter 5, "Routine Maintenance Procedures" for a layered approach to the processing of ISDN-PRI problems.

Table 11-197. ISDN-PRI Trunk Service States (Test #161 Loop Around Test)

Service State	Alarm*	Possible Cause	Possible Solution
out-of-service/NE	Warning	Trunk is demand busied out.	Enter **release trunk** grp#/mbr#.
	Minor	NPE Crosstalk Test (#6) failed.	Replace DS1/UDS1 circuit pack.
	None	DS1 or UDS1 circuit pack lost its signal.	Is the DS1/UDS1 circuit pack or cable removed? Is the far-end switch restarting? Check circuit pack using procedures in DS1-BD or UDS1-BD.
out-of-service/FE	Warning	Unadministered far-end	Administer corresponding trunk on far-end switch.
	Warning	The far-end trunk is busied out.	Check the status of the far-end switch.
pending-in-service, pending-maint	None	Maintenance message was sent and the switch is waiting up to 2 min. for a reply from the far-end.	Wait 2 minutes and check service state after the pending state has cleared.
maint-NE	None	ISDN test call in progress (**test trunk long** and **test isdn-testcall** commands)	Wait several minutes for test to finish and check status again.
	None	System link has been busied out by command.	Check link status. Release link with **release link** link#.

Continued on next page

Table 11-197. ISDN-PRI Trunk Service States (Test #161 Loop Around Test)

Service State	Alarm*	Possible Cause	Possible Solution
maint-FE	Warning	Signaling channel has been down for over 90 sec.	Consult ISDN-SGR and/or ISDN-LNK. Far-end signaling channel may be busied out, or the far-end switch may currently be restarting.
	Warning	Repeated failure of far end to respond to messages.	Maintenance software will periodically try to resend messages. You can speed the process with **test trunk grp#/mbr#** and/or **test signaling-gr #**.
	Warning	The far-end trunk is being tested.	Check status of the far-end switch. Wait for testing to finish.
in-service	None	Normal operating state	

Hardware Error Log Entries and Test to Clear Values

Table 11-198. DS1 ISDN Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	Any	None			test port PCSSpp sh r 1
15 (b)	Any	Audit and Update Test (#36)			
18	0	busyout trunk <grp>/<mbr>			release trunk <grp>/<mbr>
129 (c)		None	WARNING	OFF	test port PCSSpp

1793 (g)	Any	None			test port PCSSpp
3073 (h)	Any	Service State Audit (#256)			test port PCSSpp
3585 (i)	Any	None			None
3841 (j)	Any	None			None

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, then the Minor alarm will be upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

a. These error types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN *call* state of the DS1 ISDN Trunk. This switch will automatically try to recover by clearing the call, (that is, the call will be torn down). You can use the **status trunk <trunk_group/trunk_member>** command to determine the state of the trunk.

   When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

c. The far-end switch changed its ISDN *service* state to either out-of-service or maintenance. This may be a temporary condition due to testing of that trunk by the far-end *or* a hardware problem with the trunk. Outgoing calls will not be allowed over the trunk. To investigate the status of the trunk, issue the **status trunk <trunk_group/trunk_member>** command.

d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. These error types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN service state of the DS1 ISDN Trunk. This switch will automatically try to recover by performing a service state audit. You can use the **status trunk <trunk_group/trunk_member>** command to determine the state of the trunk.

   When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

f. This trunk is not recognized by the far-end switch. Investigate the trunk administration for both switches and make changes as necessary.

g. This error indicates a failure of the DS1/UDS1 Interface circuit pack. When running the Short Test Sequence, the results of the Signaling Link State Check Test (#255) are important.

h. Two Service State Audit attempts have failed (see Test #256). The trunks will not be usable for any outgoing calls (although incoming calls will be accepted) until the test passes and the trunk state is changed to in-service (use **status trunk trunk_group/trunk_member** to investigate trunk status).

i. Error Type 3585 appears when the switch receives an ISDN RESTART message for an ISDN trunk. Calls are cleared with the RESTART message. Therefore, this error type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the trunk's ISDN call state at the time the unexpected request to restart the channel was received from the remote switch. This information can be useful if dropped calls (cutoffs) are being reported by users of the ISDN-PRI trunks. The meanings of the various Aux Data values are shown below.

Aux values of concern; any others can be ignored.

0	A idle trunk receved a restart.
10	A call in a stable, talking state was cleared unexpectedly by the far-end with an ISDN RESTART message. This state is called the "active" state.
4, 7, 8 260, 263	A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far-end with an ISDN RESTART message.
1, 3, 6 9, 265	A call that has not yet reached a ringing state was cleared unexpectedly by the far-end with an ISDN RESTART message.
11, 12 19, 531, 267, 268	A call that was in the process of clearing anyway has been cleared by the far-end with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end is attempting to clear trunks that it thinks are in a "hung" state. The RESTART message brings the trunk to an idle condition.

j. An ISDN trunk selected by the near-end has been rejected 10 times by the far-end without a successful call. This may indicate a service state mismatch between the near-end and far-end for this trunk that is effecting the end user (that is, customer receives unexpected intercept tones when accessing ISDN trunks). This may indicate that the ISDN trunk is not administered on the far-end.

   The Aux field contains the physical name of the ISDN trunk in decimal. Then, verify that the far-end has this trunk administered. If problems persist, then busy-out the ISDN trunk to take it out of the hunt group.

   The Warning alarm will be retired automatically whenever an outgoing or incoming call that uses this trunk is answered by the called endpoint. If problems persist, then busy-out the ISDN trunk to take it out of the hunt group.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit and Update Test (#36)	X	X	ND
Signaling Link State Check Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND
ISDN Test Call Test (#258)		X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

NOTE:
The TN464C or later UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

Table 11-199. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status station** or **status trunk** commands to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-199. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-Bus errors. Refer to TDM-Bus Maintenance to diagnose any active TDM-Bus errors. 1. If the system has no TDM-Bus errors and is not handling heavy traffic, repeat the test at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use **status station** or **status trunk** commands to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering ‘‘y’’ in the ‘‘Maintenance Tests?’’ field on page 2 of the **change trunk-group** form.
1117	ABORT	A service state audit message is outstanding. 1. Wait two minutes and then try again.

Continued on next page

Table 11-199. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. The ISDN-TRK is moved to out-of-service/near-end state. 1. Replace the circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

NOTE:
The TN464C or later UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

Table 11-200. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status station** or **status trunk** commands to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use status station or status trunk to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Maintenance is disabled on this trunk. 1. Enable maintenance by entering “y’’ in the “Maintenance Tests?’’ field on page 2 of the **change trunk-group** form.

Continued on next page

Table 11-200. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 interface circuit pack to assure that the trunk's translation is correct. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 interface circuit pack and in the switch software.

Table 11-201. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
1018	ABORT	Maintenance is disabled on this trunk. 1. Enable maintenance by entering "y" in the "Maintenance Tests?" field on page 2 of the **change trunk-group** form.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run, but will return PASS. To verify that the trunk is in-service: 1. Enter **status-command** to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release-trunk** command to put trunk back into in-service. 3. Retry the test command.

Signaling Link State Check Test (#255)

As noted in the general description for a DS1 ISDN Trunk, it depends on the health of the DS1/UDS1 interface circuit pack and the ISDN-PRI D-channel (ISDN-LNK/ISDN-PLK) trunk for proper operation. This test checks the status of those critical elements.

Table 11-202. TEST #255 Signaling Link State Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering ‘‘y’’ in the ‘‘Maintenance Tests?’’ field on page 2 of the **change trunk-group** form.
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
4	FAIL	There is a problem with the Signaling Channel. 1. If the Packet Control circuit pack is used consult the procedures for the ISDN-PRI Signaling Group (ISDN-SGR). Further information may also be obtained by consulting the procedures for the ISDN-PRI Signaling Channel (ISDN-PLK). 2. If the Processor Interface is used consult the procedures for Processor Interface Link (PI-LINK).
8	FAIL	There is a problem with the DS1 interface circuit pack. 1. Consult the procedures for DS1 interface circuit pack (DS1-BD/UDS1-BD).
	PASS	The signaling link hardware is OK.

Service State Audit (#256)

As noted in the General description for DS1 ISDN Trunk, these trunks may be in one of several service states. This test performs a Service State Audit with the far-end switch.

For interfaces using country protocol 1 (including US), the Service State Audit executes in all trunk service states. A message is sent to the far-end switch to ensure that both sides agree on the service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that 2 minute window, the message is sent out again. If that attempt fails, an error will be logged (Error Type 3073) and the switch will then attempt another Service State Audit every 15 minutes. If the trunk was initially INS (in-service), it will then be placed in the MTC/FE (maintenance state, far-end problem) state. No outgoing calls will be placed over this trunk, but incoming calls will be accepted. If an incoming call is presented while in such a state, a Service State Audit attempt will immediately be attempted (that is, the switch will not wait for the 15-minute cycle, but will instead try to recover immediately).

For interfaces not using country protocol 1, the Service State Audit executes only if the trunk is in the OOF/FE state. A message is sent to the far-end switch to attempt to bring the trunk back into the in-service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that two minute window, the message is sent out once again. If no response is received in the next two minute window, then the trunk remains in the OOS/FE state. The switch will attempt another Service State Audit in another hour.

To investigate the service state of the DS1 ISDN Trunk, issue the **status trunk trunk-group/trunk-member** command.

Table 11-203. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be on a valid call. Use **status station** or **status trunk** to determine when trunk is available for testing. 1. Check the results of Test #255 (Signaling Link State Check).
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering "y" in the "Maintenance Tests?" field on page 2 of the **change trunk-group** form.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 (Signaling Link State Check).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1116	ABORT	The trunk is not in a service state which is appropriate for running the test. This test is only performed in the OOS/FE state.
1117	ABORT	A service state audit message is outstanding. 1. Wait two minutes and then try again.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1113	FAIL	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Consult the procedures for ISDN-LNK (ISDN-PRI Signaling Link Port) and PI-LINK (Processor Interface Link).

Continued on next page

Table 11-203. TEST #256 Service State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	Wait 4 minutes and then check the Error Log for any new errors of type 3073. If there are none, then both sides of the ISDN connection agree on the service state; the negotiation succeeded. If there is a new 3073 error, then the negotiation failed (the far-end switch twice failed to respond within 2 minutes). The switch will automatically retry every 15 minutes. If the trunk was initially in-service, it is now placed in the maintenance/far-end state. Incoming calls will be accepted, but no outgoing calls can be originated. If an incoming call is presented, another Service State Audit will be immediately performed in an attempt to put the DS1 ISDN Trunk in the proper state.

Call State Audit Test (#257)

If a call is active on the trunk, the switches on both sides of the connection should agree on the ISDN state of the call, as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end switch as to the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end switch, then **the call will be torn down.**

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end switch. The ISDN Specification allows up to two minutes for a reply. If a reply is not received within the two minute window, a protocol time-out violation will be recorded in the error log against the associated signaling channel (ISDN-PRI Signaling Link Port, which is listed in the Error Log as ISDN-LNK/ISDN-PLK; the Error Type is 1).

Table 11-204. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Maintenance is disable on this trunk. 1. Enable maintenance by entering “y’’ in the “Maintenance Tests?’’ field on page 2 of the **change trunk-group** form.
1019	ABORT	An audit is already in progress. 1. Wait two minutes and try again.
1113	ABORT	The signaling link has failed, so the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 (Signaling Link State Check).
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1116	ABORT	The trunk is in an out-of-service ISDN service state. 1. A call cannot be present if the trunk is in an ISDN out-of-service state, so a call state audit would be inappropriate. No action necessary. (Use the **status trunk**

Continued on next page

Table 11-204. TEST #257 Call State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	This switch sent a call state auditing message to the far-end switch to verify the state of the call active on this trunk. If a call state mismatch is found, then the call will be torn down within two minutes. If no call was active, then no message was sent.

ISDN Test Call Test (#258)

This test performs a far-end loop around to a far-end switch over an ISDN trunk. The trunk's service state must be in-service, maint-NE, or out-of-service/NE, and no call can be active on the trunk. The test call can be initiated as part of a long test sequence, or as an individual test, as described below. This test is valid only for systems using country protocol 1 (including US), or when the far end has loop-around capability.

A test call connection is established to a far-end switch over the ISDN trunk to be tested. The digital port on a TN711D Maintenance/Test circuit pack generates a test-pattern bit stream which is sent to the far-end switch and echoed back. The received pattern is then compared to the sent pattern and checked for errors that indicate a loss of integrity on the communications path.

If a test call is running when scheduled maintenance starts, the green LED is turned off. To determine if a test call is still running, use the **list isdn-testcall** and **status isdn-testcall** commands. A lit yellow LED on the Maintenance/Test circuit pack also indicates that a test call is running.

There are two methods available to place an outgoing ISDN-PRI test call in G3iV1.1-286 and G3iV2-386.

In the first method, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a data channel. This method is selected when no Maintenance/Test circuit pack resides in the system.

In the second method, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a digital trunk testing port on the Maintenance/Test circuit pack. The Maintenance/Test Digital Port generates a pseudo bit stream. A pictorial description of the outgoing ISDN-PRI test call connectivity is contained in the following figure.

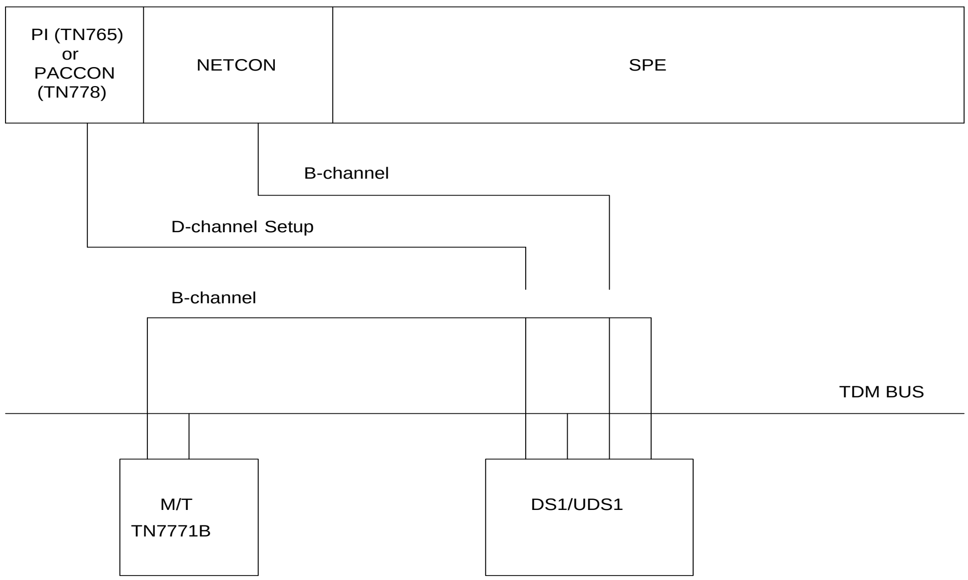

Figure 11-69. ISDN-PRI Outgoing Test Call

Synchronous Commands

You can demand a synchronous outgoing test call by using the following maintenance commands:

- **test trunk trunk-group-no/member-no long [repeat number]**
- **test board board-location long [repeat number]**
- **test port port-location long [repeat number]**

Whenever a circuit translates to an ISDN-PRI trunk during a Long Test Sequence, an outgoing test call is invoked. If the B-channel is unrestricted (B8ZS or HDB3) the default duration of the test call is 8.6 seconds. Otherwise, if the B-channel is restricted (ZCS) the default duration of the test call is 9.4 seconds. Once the test call completes, the bit error rate is retrieved from the Maintenance/Test Digital Port. A bit error rate greater than zero is reported as a failure to the Manager I terminal (MGRI). A failure indicates the need to run further diagnostics, such as the **test isdn-testcall** command.

If no Maintenance/Test circuit pack exists, the outgoing ISDN-PRI test call is established over a high speed data channel on the Network Control (NETCON) circuit pack (DATA-BD).

Asynchronous Commands

You can start, query, and stop an outgoing test call by using the following maintenance commands:

- **test isdn-testcall trunk-group-no/member-no [minutes]**

  This command enables you to start an outgoing ISDN-PRI test call for a maximum of two hours (120 minutes).

- **status isdn-testcall trunk-group-no/member-no**

  This command displays the progress of the outgoing test call by reporting the bit and block error rates of the tested B-channel specified by the "trunk group no/member no" identifier.

- **clear isdn-testcall trunk-group-no/member-no**

  This command enables you to stop an outgoing test call already in progress. The **trunk-group-no/member-no** identifier specifies the B-channel used to stop the test call. The measurements are not cleared until the next test call begins.

NOTE:
Only one trunk can be tested in a given port network, until the test call is canceled or completes.

Table 11-205. TEST #258 ISDN TEST Call

Error Code	Test Result	Description/ Recommendation
4	ABORT	There is a problem with the Processor Interface Link. 1. Refer to the PI-LINK (Processor Interface Link) Maintenance documentation.
8	ABORT	There is a problem with the DS1 interface circuit pack. 1. Refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.
1004	ABORT	B channel in use. 1. Determine if a call is active on this DS1 ISDN Trunk via the **status trunk** 2. When the service state indicates in-service/idle, retry the test.

Continued on next page

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1005	ABORT	Bad Configuration (that is, no Maintenance/Test circuit pack) Issue the **test trunk <trunk Group/trunk member>** command and make sure there is a DATA-CHL (NETCON channel) administered.
1018	ABORT	Test call is disabled. 1. Enable Maintenance on the Trunk Group form.
1019	ABORT	Another Test call is in progress. 1. Issue the **list isdn-testcall** command to locate the test call. 2. Issue the **status isdn-testcall** command to find out the duration and start time of the test call. 3. Issue the **clear isdn-testcall** command to stop the test call from running. 4. If time and duration indicate that the test call should have stopped, and the **clear isdn-testcall** command does not work, refer to M/T-DIG (Maintenance/Test Digital Port) Maintenance documentation for recommended maintenance strategy.
1020	ABORT	There is a problem with DS1 Interface Circuit Pack. 1. Refer to the DS1-BD (DS1 Trunk circuit pack) Maintenance documentation.
1024	ABORT	(M/T-DIG) Maintenance/Test Digital Port in use. 1. Wait until yellow and green LEDs are turned off on the M/T-BD (Maintenance/Test circuit pack). 2. Retry the test. If problem persists, refer to M/T-DIG (Maintenance/Test Digital Port) Maintenance documentation.
1113	ABORT	The signaling link has failed. Therefore, the system cannot send any messages on behalf of this trunk. 1. Check the results of Test #255 (Signaling Link State Check Test).

Continued on next page

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1114	ABORT	The signaling link is in a transitional state. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1116	ABORT	The switch could not appropriately change the ISDN service state. 1. Determine if a call is active on this DS1 ISDN Trunk (use the **status trunk** 2. If not, check the Error and Alarm Logs for problems with this ISDN-TRK (DS1 ISDN Trunk) MO.
1117	ABORT	ISDN B-channel maintenance message is already outstanding. 1. Wait two minutes. Then try again.
1118	ABORT	Far-end of ISDN trunk is not administered. 1. Check the administration of the far-end ISDN trunk. 2. Issue the **status trunk** 3. Try the test again.
1119	ABORT	The test call was aborted due to a normal call attempt on this trunk. The test call is performed only if the trunk is idle. 1. Either wait for the normal call to terminate normally, or force it to be dropped by using the **busyout trunk**
1120	ABORT	The DS1 ISDN Trunk is in the ISDN out-of-service/far-end state. 1. Try to change the service state via Test #256 (Service State Audit Test). Then retry this test. **However, the trunk may be in the out-of-service/far-end state due to problems at the far-end switch. If that is the case, no remedial action can be taken at this end.**
1122	ABORT	There is no test line number for the far-end switch. 1. Check the Trunk Group Administration form.

Continued on next page

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
1123	ABORT	There is no Feature Access Code administration for this Facility Test. 1. Check the Dial Plan and Feature Administration forms.
2012 None 2000	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2035	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Wait one minute and try again. 2. If the test continues to abort, escalate the problem.
2036 2037	ABORT	Internal System Error. 1. Follow the recommendation for ABORT code 2012.
2038 2039	ABORT	A problem occurred while trying to read the test data. 1. Wait one minute and then try again. 2. If the test aborts again in the same manner, there is a serious internal problem. If so, escalate the problem.
2040	ABORT	Internal System Error. 1. Follow the recommendations for ABORT code 2012.
2041	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Follow the recommendations for ABORT code 2035.
2066	ABORT	Could not establish test call. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2067	ABORT	The call has timed out, perhaps because of a lack of system resources. 1. Follow the recommendations for ABORT code 2035.

Continued on next page

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2074	ABORT	Bit and Block Error query failed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, there may be a serious internal problem with M/T-DIG (Maintenance/Test Digital Port). If this is the case, refer to the M/T-DIG (Maintenance/Test Digital Port) Maintenance documentation.
2075	ABORT	Internal System Error. 1. Follow the recommendations for ABORT code 2012.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2104	ABORT	Call dropped or could not be originated. 1. Make sure service is provisioned by the network. 2. Check the administration of the far-end test line extension on the trunk group administration form. 3. Check the administration of the test call BCC (Bearer Capability Class) on the trunk group administration form. 4. Check the reason for termination with **status isdn-testcall**. 5. For further instructions see "Troubleshooting ISDN-PRI Test Call Problems" in Chapter 5, "Routine Maintenance Procedures". 6. Try the test again. 7. If the test continues to abort, escalate the problem.

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2201 2202 2203 2204 2205	ABORT	Internal System Error. 1. Follow the recommendations for ABORT code 2012.
2206	ABORT	Could not allocate the necessary system resources to run this test. 1. Follow the recommendations for ABORT code 2100.
2208	ABORT	Internal System Error. 1. Follow the recommendations for ABORT code 2012.
2209 2210	ABORT	Could not allocate the necessary system resources to run this test. 1. Follow the recommendations for ABORT code 2100.
2211	ABORT	Internal System Error. 1. Follow the recommendations for ABORT code 2012.
2212	ABORT	Call terminated by unexpected disconnect. 1. Wait one minute and then try again.
2213	ABORT	The call has timed-out, perhaps because of a lack of system resources. 1. Follow the recommendations for ABORT code 2035.
2214	ABORT	Call terminated by unexpected disconnect. 1. Wait one minute and then try again.
2215 2216 2217 2218 2219	ABORT	Internal System Error. 1. Follow recommendations for ABORT code 2012.
2220	ABORT	Call terminated prematurely. 1. Wait one minute and try again.

Continued on next page

Table 11-205. TEST #258 ISDN TEST Call — *Continued*

Error Code	Test Result	Description/ Recommendation
2221 2222 2223 2224 2225 2226	ABORT	Internal System Error. 1. Follow recommendations for ABORT code 2012.
2227	ABORT	Could not allocate the necessary system resources to run this test. 1. Follow the recommendations for ABORT code 2100.
2042	FAIL	**This is the main purpose of the test.** The comparison of the data sent with the data received indicates a loss of integrity on the communications path. 1. The trunk should be taken out-of-service and the quality of the DS1 line should be investigated. The investigation should include an in-depth analysis of the DS1 facility including the transmission facility and any external equipment such as DACs, CSUs, etc. If the **test isdn-testcall** command is invoked, then the investigation should include getting the bit and block error rates by invoking the **status isdn-testcall** command.
	PASS	The call worked. A test pattern was sent and received properly; the communications path is OK if the synchronous test call command was issued. If the **test isdn-testcall** command was issued, a PASS indicates that the test call was established. A **status isdn-testcall** command must be invoked to query the bit and block error rates to determine if the test call passed. An in-depth analysis of the DS1 facility including the transmission facility and any external equipment such as DACs, CSUs, etc., should take place if the bit and block error rates are not acceptable.

JNL-PRNT (Journal Printer Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PMS-PRNT/JNL-PRNT	MINOR	test journal pms-log/wakeup-log	Journal Printer Link
PMS-PRNT/JNL-PRNT	WARNING	test journal pms-log/wakeup-log	Journal Printer Link

NOTE:
Since the maintenance strategy for both the JNL-PRNT (Journal Printer Link) and PMS-PRNT (PMS Printer Link) MO is the same, both of these MOs are described in the PMS-PRNT/JNL-PRNT Maintenance documentation.

LOG-SVN (Login Security Violation)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
LOG-SVN	MAJOR	enable login <login ID>	Login Security Violation

1 Where <login ID> is the AT&T services login ID for which the security violation was detected. The *Alt Name* field indicates the login ID associated with the security violation and the major alarm.

The Security Violation Notification (SVN) feature provides notification when the number of failed attempts to access the system administration/maintenance interface meets or exceeds customer administered threshold parameters.

A major alarm is logged whenever a security violation is detected involving an AT&T services login ID and that login ID has been disabled as a result of the security violation. The capability to disable a login ID following detection of a security violation involving that login ID is administrable on a per login ID basis.

Refer to *DEFINITY Communications System Generic 3 Version 5 Implementation*, Issue 1 (555-230-656) for information on administration required for the Security Violation Notification feature and the option to disable a login ID following detection of a security violation involving the affected login ID.

Hardware Error Log Entries and Test to Clear Values

Table 11-206. Hardware Error Log Entries and Test to Clear Value

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1-15	None	None	Major	OFF	enable login <login ID>

General Information about log-svn Error Log Entries

a. The number (1 - 15), that appears in the error type field, corresponds to the location the login in the internal login data structure.

b. The *Alt Name* field on the alarm report indicates the login ID associated with the security violation and major alarm.

c. These errors/alarms are associated with a number of failed attempts to access the system management/maintenance interface using an AT&T services login ID that meet or exceed the customer administered threshold parameters. The associated alarm is immediately raised as a major alarm.

d. The affected login ID will be disabled as a result of detection of the security violation, unless it is the last enabled INADS type login on the system. The provision to disable a login ID following detection of a security violation involving that login ID is administrable on a login ID basis.

e. The *enable login* command is used to both enable a login that has been disabled, and to retire any login security violation alarms associated with the login ID.

f. Use of the *enable login* command to enable a login and/or retire alarms must be executed using a login ID with greater service level hierarchy permissions.

g. Access to the *enable login* command is controlled through the Administer Permissions field on the Command Permission Categories form. This field (Administer Permissions) must be set to "y" to access the enable login command.

h. The *Port* alarm report field will set to the port where the final invalid login attempt, involving the alarmed login ID, was detected. Valid port values for G3i products include:

   — MGR1 — Dedicated manager 1 or G3 management terminal connection

   — NET-n — Network controller dial up port

   — INADS — INADS port

   — EPN — EPN maintenance EIA port

   — EIA — Other EIA port

   Valid port value for G3r products include:

   — SYSAM_LOC — Local administration port

   — YSAM_RMT — Remote administration port

   — SYS_PORT —

   — MAINT — Maintenance port

i. The *Svc State* alarm report field will be set to OUT if the login ID is in the disabled state as a result of detection of a security violation involving the login ID. Once the login ID has been enabled, the field will be set to IN.

j. The source or reason of the failed login attempts should be identified and the cause corrected prior to re-enabling a login ID and/or retiring any alarms associated with the login ID. The cause may be something as innocuous as the failure of AT&T services automatic login software, to something as insidious as a hacker attempting to gain access to the switch system management interface.

The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report.

Prior to retiring an SVN alarm and enabling the associated login ID, the *monitor security-violations login* command can be used to access information about the invalid login attempts that caused the security violation. This information can be useful in determining the source of the invalid attempts and analyzing why they occurred.

The *list logins* command provides status information about logins on the system. If a login has been disabled as a result of a security violation, the status will be "svn-disabled."

Procedure to Retire an SVN Alarm

To retire a SVN alarm:

1. Enter the command **enable login <login ID>.**

   The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report and the alarm is retired.

MAINT (EPN Maintenance Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
MAINT	MINOR	test maintenance sh	EPN Maintenance Circuit Pack
MAINT	MAJOR	test maintenance l	EPN Maintenance Circuit Pack

The EPN (Expansion Port Network) Maintenance circuit pack monitors and supports environmental maintenance for the EPNs. An EPN can be a multicarrier or a single-carrier cabinet. The EPN Maintenance circuit pack provides the switch software, a mechanism to enable and disable Emergency Transfer in the EPN (assuming the Emergency Transfer Switch is in the AUTO position). The EPN Maintenance circuit pack invokes Emergency Transfer when the EPN loses contact with the PPN or the EPN Maintenance circuit pack loses contact with all Expansion Interface circuit packs. The EPN Maintenance circuit pack handles loss of AC power in the EPN multicarrier cabinet by turning off all power to the EPN multicarrier Cabinet 15 seconds after the loss of AC power. This 15-second period is the only nominal power holdover available in an EPN multicarrier cabinet. When power fails in the EPN single-carrier cabinet, no such power holdover is available. In the event that an Expansion Interface circuit pack goes insane and is reset six times within 15 minutes, the EPN Maintenance circuit pack holds the Expansion Links reset (which prevents the Expansion Interface circuit pack from running).

The EPN Maintenance circuit pack provides system level alarm LEDs which indicate the absence or presence of Major, Minor, and Warning alarms within the entire system (PPN and EPN).

The EPN Maintenance circuit pack supports a Manager I (G1) or G3MT (G1) or G3MT terminal which runs at 9600 baud. However, the system software throttles the rate of data flow to the EPN Maintenance circuit pack for display on the Manager I (G1) or G3MT (G1) or G3MT terminal to about 1200 baud. All system commands can be executed via the EPN Manager I (G1) or G3MT terminal. However, due to the slow speed at which the software runs the EPN Manager I (G1) or G3MT terminal, it is recommended that the EPN Manager I (G1) or G3MT terminal's primary use be for system maintenance rather than system administration.

The PPN communicates with the EPN Maintenance circuit pack via the following path (messages from the EPN Maintenance circuit pack to the PPN take exactly the reverse path). From the PPN, TN773 Processor circuit pack, EPN Maintenance circuit pack messages are passed to the Switch Control on the Network Control circuit pack over the Memory Bus (MBUS) and then over the TDM Bus to the Active PPN Expansion Interface circuit pack. The Active PPN

Expansion Interface circuit pack passes the message across the fiber to the Active EPN Expansion Interface circuit pack. The Active EPN Expansion Interface circuit pack then passes the message over a serial link to the EPN Maintenance circuit pack. Figure 11-70 illustrates this path.

In Figure 11-70, PROCR stands for TN773 for a 286, TN786B for a 386, TN790 for a RISC Processor circuit pack (the Active TN773 Processor circuit pack in a High or Critical Reliability system), NETCON stands for Network Control circuit pack (TN777) (the Active Network Control circuit pack in a High or Critical Reliability system), TDM Bus stands for the Time Division Multiplex Bus that connects circuit packs within a cabinet, Expansion Interface stands for the Active Expansion Interface circuit pack, FIBER stands for the optical fiber used to connect Expansion Interface circuit pack, and MB stands for the EPN Maintenance circuit pack. Figure 11-70 shows the connectivity for a system with duplicated Expansion Interface Links.

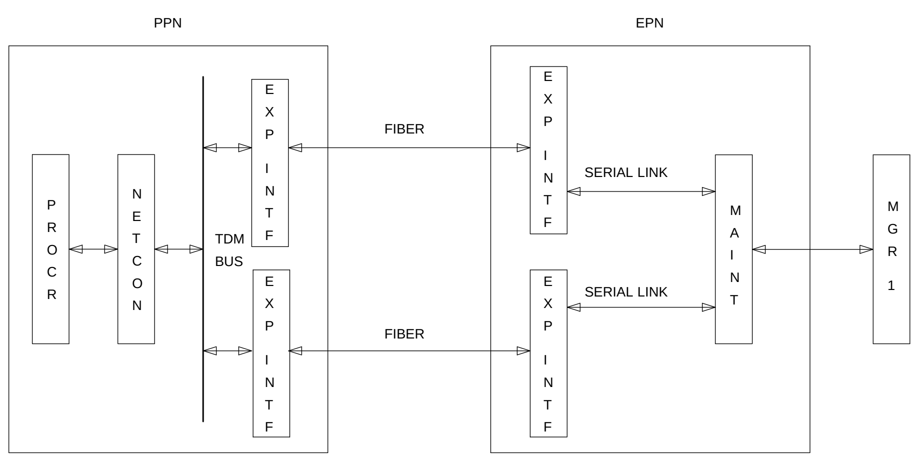

Figure 11-70. EPN Maintenance Circuit Pack Message Flow

The EPN Maintenance circuit pack must be physically inserted into the dedicated slot marked Maintenance in the A carrier of the EPN. The serial links from the EPN Maintenance circuit pack to the Expansion Links are physically connected from this dedicated slot to slots 2A01 and 2B02 (2B02 is used only if there are redundant Expansion Links). The serial link from slot 2A01 to the maintenance slot is hard-wired into the backplane of carrier A, whereas the serial link from slot 2B02 to the maintenance slot is a ribbon cable connecting the two slots. The serial link from the EPN Maintenance circuit pack to the Manager I (G1) or G3MT terminal is also a ribbon cable which plugs into a connector labeled TERM on the back of carrier A.

The maintenance strategy for the EPN Maintenance circuit pack consists of checking the integrity of the communications path to/from the EPN Maintenance circuit pack, testing individual hardware components on the EPN Maintenance circuit pack, and keeping the system level LEDs up-to-date. The individual hardware components include the serial interfaces which handle the serial links connected to the EPN Maintenance circuit pack. There are three serial interfaces, one for each possible Expansion Interface circuit pack and one for the Manager I (G1) or G3MT terminal.

Since the EPN Maintenance circuit pack supports environmental maintenance in the EPN, trouble with the EPN Maintenance circuit pack can cause environmental maintenance to falsely detect problems. In a multicarrier cabinet EPN, these environmental MOs include: POWER (Battery & Battery Charger), CARR-POW (Carrier Port Power Unit), AC-POWER (AC Power), CABINET (Cabinet Sensors), EMG-XFER (Emergency Transfer), EXT-DEV (External Alarm), and CUST-ALM (Customer-Provided Alarming Device). In a single-carrier cabinet EPN, these environmental MOs include DC-POWER (Single-Carrier Cabinet Power), EMG-XFER (Emergency Transfer), EXT-DEV (External Alarm), and CUST-ALM (Customer-Provided Alarming Device).

Since communication to the EPN Maintenance circuit pack flows through the SW-CTL (Switch Control) and the EXP-INTF (Expansion Interface) circuit packs, any problems with these MOs can prevent communication with the EPN Maintenance circuit pack.

If a repair procedure calls for the EPN Maintenance circuit pack to be replaced, and the EPN has redundant Expansion Links, the following procedure should be used to prevent an Expansion Links switch when the new EPN Maintenance circuit pack is plugged in.

1. Determine the Standby Expansion Links by using the **status system** command.
2. Busyout the Standby Expansion Links by issuing the **busyout board PCSS** command where PCSS is the 4-character circuit pack address of the Expansion Interface circuit pack in the EPN on the Standby link.
3. Replace the EPN Maintenance circuit pack.
4. Release the Standby Expansion Links by issuing the **release board PCSS** command, where PCSS is the 4-character circuit pack address of the Expansion Interface circuit pack in the EPN on the Standby link.

Hardware Error Log Entries and Test to Clear Values

EPN Maintenance Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test maintenance sh r 1
1 (a)	0 1	EPN Maintenance Circuit Pack Reset Test (#306)	MINOR	ON	test maintenance l
513 (a)	0 1	MGR I Channel Loop Test (#228)	MINOR	ON	test maintenance sh r 3
769 (b)	Any	Sanity Handshake Test (#106)			
1537 (a)	0 1	Sanity Maze Test (#303)	MINOR	ON	test maintenance sh r 3
2561 (a)	0 1	Sanity Handshake Test (#106)	MINOR	ON	test maintenance sh r 3
2817 (a)	0 (b) 1	Serial Channel Loop Test (#229)	MINOR	ON	test maintenance sh r 3
3073 (a)	0 1	Network Control Circuit Pack DPR Test (#104)	MAJOR/ WARNING[2]	OFF	test maintenance l
3329 (c)	Any	Serial Link Test (#337)	MINOR/ WARNING[2]	OFF	test maintenance sh r 3
3585 (d)	Any	Serial Link Test (#337)	MINOR/ WARNING[2]	OFF	test maintenance sh r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. A value of 0 indicates the Expansion Link in the A carrier was active when this error occurred. A value of 1 indicates the Expansion Link in the B carrier was active when this error occurred. To clear this problem, make sure the Active Expansion Link is the same as that indicated by the Aux Value.

b. Multiple values can appear in the Aux Data field. There are other errors in the log if there is a real problem. Use these other errors to troubleshoot the problem.

c. The serial link between the Expansion Link in the A carrier and the EPN Maintenance circuit pack is defective.

d. The serial link between the Expansion Link in the B carrier and the EPN Maintenance circuit pack is defective.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Sanity Handshake Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Sanity Handshake Test (#106)	X	X	ND
Network Control Circuit Pack DPR Test (#104) (a)		X	D
EPN Maintenance Circuit Pack Reset Test (#306)		X	D
Serial Channel Local Loop Around Test (#229)	X	X	ND
MGR I Channel Local Loop Around Test (#228)		X	D
EPN Maintenance Circuit Pack Sanity Maze Test (#303)	X	X	ND
EPN Maintenance Circuit Pack Serial Link Test (#337)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. If you are invoking the Long Test Sequence from the EPN Manager I (G1) or G3MT terminal, Test #104 causes the system technician terminal to be logged off, and Test #306 is not run as part of the test sequence. Test #104, however, causes Test #306 to run in an attempt to bring the EPN Maintenance circuit pack back to a known state. After the test sequence runs, the Error Log should be examined for MAINT errors of type 1 and 3073 to determine if the Network Control Circuit Pack DPR Test and EPN Maintenance Circuit Pack Reset Test failed.

If you are invoking the Long Test Sequence from the PPN, all tests listed are run and their results are displayed on the PPN Manager I (G1) or G3MT terminal. The EPN Manager I (G1) or G3MT terminal is still be logged off.

Network Control Circuit Pack Dual Port Ram (DPR) Test (#104)

This test is destructive.

When executed, this test drops the EPN Manager I (G1) or G3MT terminal login. The login prompt reappears if the test passes successfully.

The Dual Port Ram (RAM), memory shared by the TN777 Processor circuit pack and the Network Control circuit pack, is tested to ensure that it can be read from and written to. EPN Maintenance circuit pack maintenance utilizes the DPR on the Network Control circuit pack for placing messages that eventually get passed along to the Expansion Interface circuit pack in the EPN cabinet and subsequently to the EPN Maintenance circuit pack in the EPN cabinet.

Table 11-207. TEST #104 Network Control Circuit Pack Dual Port Ram (DPR) Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
1030	ABORT	Internal System Error.
2028	ABORT	Internal System Error.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
10401	ABORT	Test disabled via software patch. 1. Escalate to next tier level.
	FAIL	The test failed. 1. Since a portion of the Network Control circuit pack (the Dual Port Ram) is actually being tested here, run the Short Test Sequence against the Network Control circuit pack (SW-CTL) and follow the maintenance procedures outlined for Test #325.

Continued on next page

Table 11-207. TEST #104 Network Control Circuit Pack Dual Port Ram (DPR) Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	FAIL	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The communication to the EPN Maintenance circuit pack is good at least up to the Network Control circuit pack. If there are still problems communicating with the EPN Maintenance circuit pack, then these problems must be with either the EXP-LINK (Expansion Links), EXP-INTF (Expansion Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack.

Sanity Handshake Test (#106)

This test checks the EPN Maintenance circuit pack's ability to respond to queries. A message is sent to the EPN Maintenance circuit pack which then sends a message back. If the response message is received, then the EPN Maintenance circuit pack is queried for the EPN cabinet type (valid EPN cabinet types are single-carrier and multicarrier cabinets). The EPN Maintenance circuit pack reads pins on the backplane of carrier A that identify the type of cabinet and report this information. If a valid cabinet type is returned, then the test passes.

Table 11-208. TEST #106 Sanity Handshake Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to cabinet query was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2046	ABORT	The EPN Maintenance circuit pack reported an invalid cabinet type. Not knowing the cabinet type of the EPN prevents all EPN environment maintenance from running. 1. Retry the command. 2. If the test continues to abort with 2046, then either the EPN Maintenance circuit pack is defective, or the EPN cabinet wiring is defective. First, replace the EPN Maintenance circuit pack. 3. If the test continues to abort with 2046, then the EPN cabinet wiring is defective in the A carrier and the EPN Maintenance circuit pack cannot read the backplane pins to determine the cabinet type.
10601	ABORT	Test disabled via software patch. 1. Escalate to next tier level.

Continued on next page

Table 11-208. TEST #106 Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	EPN Maintenance circuit pack did not respond to Sanity Handshake and the test timed out. 1. Verify that the carrier A power units are good. If the -5 volt unit is defective in the A carrier, then communication with the EPN Maintenance circuit pack is not possible.

Continued on next page

Table 11-208. TEST #106 Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	2. If the -5 volt unit is good and this test continuously fails, background maintenance automatically escalates to an EPN Maintenance circuit pack Reset (Test #306). Otherwise, you can manually invoke an EPN Maintenance circuit pack Reset by issuing the **test maintenance long** command and evaluating any generated error codes from Test #306. If Test #306 passes, this test should also PASS. Otherwise, use the following steps to determine if the EPN Maintenance circuit pack, or the serial link to the EPN Maintenance circuit pack, is defective: ■ Duplicated Expansion Links: 1. Determine which serial link is the standby by issuing the **status system** system technician command. 2. Switch Expansion Links by entering **set expansion-link PCSS** where PCSS is the 4-character Expansion Interface circuit pack location for the Standby link. 3. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #106 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test. ■ Single Expansion Interface Link Switch: 1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence against it. 2. If error persists, replace the EPN Expansion Interface circuit pack, **at a time when the EPN can go down with minimal inconvenience**. 3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.

Continued on next page

Table 11-208. TEST #106 Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The communications path to and from the EPN Maintenance circuit pack is sane, and the EPN Maintenance circuit pack can read and report the correct EPN cabinet type. The EPN Maintenance circuit pack may still have problems related to Tests #228, #229, #303, or #306.

MGR I Channel Local Loop Around Test (#228)

This test is destructive.

This test checks the on-board circuitry of the EPN Maintenance circuit pack associated with the serial link for the Manager I (G1) or G3MT connection. This test does not cause the terminal to become disconnected. However, any data being displayed on the Manager I (G1) or G3MT terminal while the test is running is lost. Figure 11-71 shows the three serial interfaces on the EPN Maintenance circuit pack and is meant to clarify that only the one dealing with the EPN Manager I (G1) or G3MT terminal is being tested.

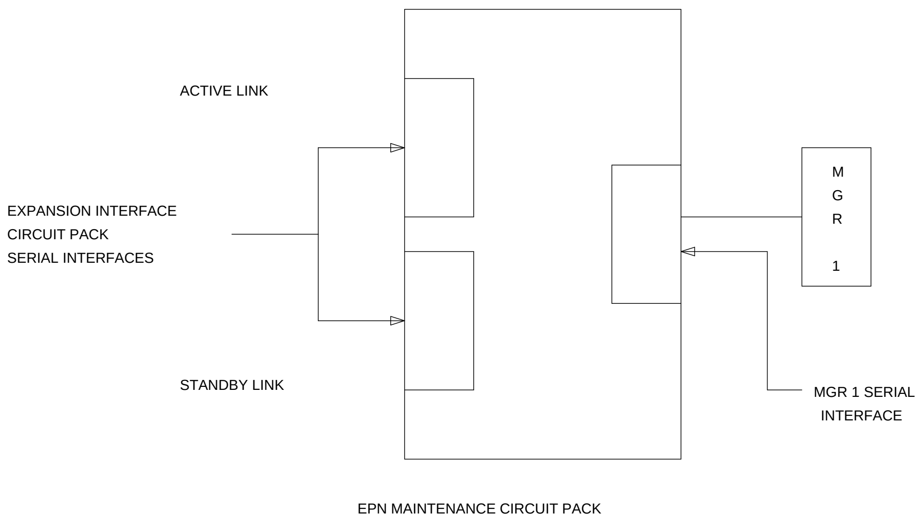

Figure 11-71. EPN Manager I (G1) or G3MT Connection

Table 11-209. TEST #228 MGR I Channel Local Loop Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2034	ABORT	Background EPN Maintenance circuit pack maintenance is running the MGR I Channel Local Loop Around Test. 1. Wait 30 seconds and retry the test a maximum of five times. 2. If the test continues to abort, escalate.
22801	ABORT	Test disabled via software patch. 1. Escalate to next tier level.

Continued on next page

Table 11-209. TEST #228 MGR I Channel Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed which means the EPN Manager I (G1) or G3MT terminal is not usable. 1. Run the test three more times. Replace the EPN Maintenance circuit pack if the test continues to fail.
	PASS	The serial interface circuitry on the EPN Maintenance circuit pack which controls the EPN Manager I (G1) or G3MT terminal is functioning properly. If there are still troubles with the EPN Manager I (G1) or G3MT terminal, the problem may be one of the following: 1. The EPN Manager I (G1) or G3MT terminal is not configured properly. The connection between the EPN Manager I (G1) or G3MT and the EPN Maintenance circuit pack must be set up at 9600 baud. 2. The serial link from the back of carrier A to the EPN Manager I (G1) or G3MT terminal may be defective. The serial link consists of the connector on the back of carrier A labeled TERM and the ribbon cable running to the EPN Manager I (G1) or G3MT terminal. 3. The EPN Manager I (G1) or G3MT terminal may be defective. Try another terminal. 4. Since this test is not 100 percent accurate, there may still be problems with the EPN Maintenance circuit pack.

Serial Channel Local Loop Around Test (#229)

This test checks the on-board circuitry of the EPN Maintenance circuit pack associated with the serial links to the Expansion Interface circuit pack. Figure 11-72 shows the three serial interfaces on the EPN Maintenance circuit pack and is meant to clarify that the two dealing with the Expansion Links are being tested. A request is sent to the EPN Maintenance circuit pack over the Active link via the Active Expansion Interface circuit pack serial interface circuitry to test the serial interface circuitry of the standby Expansion Interface circuit pack link. If a response is received, then by definition the serial interface circuitry associated with the Active link is good.

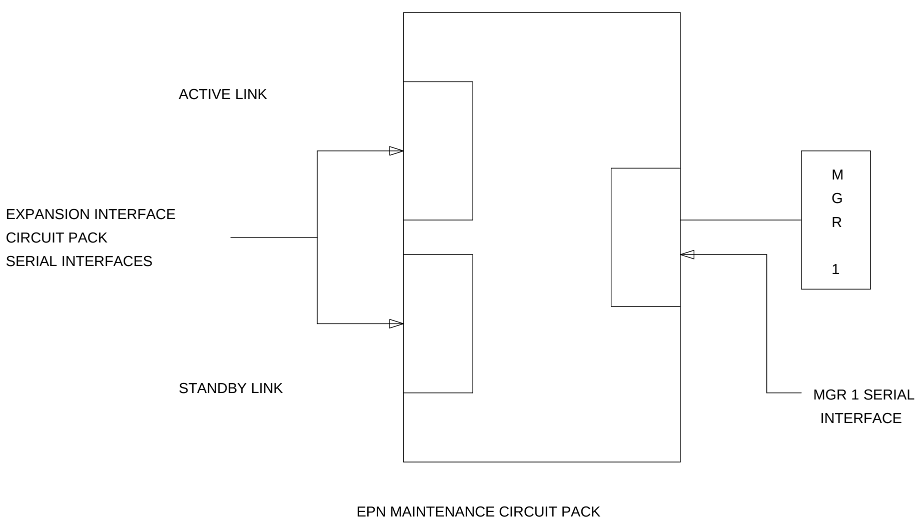

Figure 11-72. EPN Expansion Links Connections

Table 11-210. TEST #229 Serial Channel Local Loop Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.

Continued on next page

Table 11-210. TEST #229 Serial Channel Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2034	ABORT	Background EPN Maintenance circuit pack maintenance is running the Serial Channel Local Loop Around Test. 1. Wait 30 seconds, and retry the test a maximum of five times. 2. If the test continues to abort, escalate the problem.
2290 1	ABORT	Test disabled via software patch. 1. Escalate to the next tier level.

Continued on next page

Table 11-210. TEST #229 Serial Channel Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The on-board circuitry associated with the Standby serial link is defective. Since the EPN Maintenance circuit pack reported this failure, the on-board circuitry associated with the Active serial link is functional. 1. This test checks the circuitry on the EPN Maintenance circuit pack associated with the Standby Expansion Interface link. ■ In a switch without duplicated Expansion Links, current service is not affected because the circuitry failing is not being used. Nevertheless, a Minor alarm remains in the Alarm Log against MAINT. Therefore, the EPN Maintenance circuit pack must be replaced. ■ In a switch with duplicated Expansion Links, service is not affected as long as you DO NOT SWITCH LINKS; otherwise, the connection to the EPN Maintenance circuit pack is lost. Losing the EPN Maintenance circuit pack connection means loss of the EPN Manager I (G1) or G3MT and EPN Environment maintenance. If an Expansion Links switch does occur, the software probably switches the links back, based on the relative health of each link. The EPN Maintenance circuit pack must be replaced to correct this problem.

Continued on next page

Table 11-210. TEST #229 Serial Channel Local Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The on-board circuitry associated with both Expansion Interface circuit pack serial links is good. If there is still a problem communicating with the EPN Maintenance circuit pack, check the following: 1. The cable comprising the serial link (B carrier Expansion Interface circuit pack to EPN Maintenance circuit pack only) may be defective. 2. The EPN Maintenance circuit pack may actually be defective. **NOTE:** This test may not be 100 percent accurate. 3. The Expansion Interface circuit pack on the Standby link may be defective.

EPN Maintenance Circuit Pack Sanity Maze Test (#303)

The EPN Maintenance circuit pack processor has direct access to special registers in the EPN Maintenance circuit pack. These registers are tied to such things as the Expansion Interface circuit pack reset leads and Carrier Port Power Unit reset leads (which enable the EPN Maintenance circuit pack to recycle carriers). To prevent an insane EPN Maintenance circuit pack from inadvertently controlling these external devices, a special interface called the Sanity Maze is provided that must first be navigated by the EPN Maintenance circuit pack processor prior to any register access. There are two parts to the test. Part 1 involves navigating the Sanity Maze to toggle an unused lead. Part 2 attempts to toggle an unused lead without first navigating the Sanity Maze. The Sanity Maze test passes if Part 1 is successful and Part 2 fails.

Table 11-211. TEST #303 EPN Maintenance Circuit Pack Sanity Maze Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Sanity Maze of the EPN Maintenance circuit pack is defective. 1. Replace the EPN Maintenance circuit pack.
	PASS	The Sanity Maze is working properly, and the EPN Maintenance circuit pack can access the unused register. If **recycle carrier** commands (for EPN carriers) do not work, the following problems may still exist: 1. The Carrier Port Power Unit or wiring to the Carrier Port Power Unit may be defective. Refer to CARR-POW (Carrier Port Power Unit) Maintenance documentation. 2. Since this test only tests the EPN, there is a very small probability that the EPN Maintenance circuit pack cannot access those registers that deal with EPN devices. The EPN Maintenance circuit pack may need to be replaced.

EPN Maintenance Circuit Pack Reset Test (#306)

This test is destructive.

The EPN Manager I (G1) or G3MT is dropped and, if the Emergency Transfer switch is in the AUTO position, Emergency Transfer is disabled for the duration of the test.

The EPN Maintenance circuit pack is reset by the Active Expansion Interface circuit pack. After the Expansion Interface circuit pack reports that the EPN Maintenance circuit pack has reset, a handshake message is sent to the EPN Maintenance circuit pack. If the EPN Maintenance circuit pack responds to the handshake, the test passes. If not, it fails. If the test passes, the EPN Manager I (G1) or G3MT is brought back up, and Emergency Transfer is restored to its previous state.

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	Test disabled via software patch. 1. Escalate to next tier level.
2000	ABORT	Response to the reset request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, look for and resolve all problems associated with the Expansion Interface circuit pack (EXP-INTF). 3. If the test continues to abort, escalate the problem.
2028	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2030	ABORT	EPN is down. 1. Run the Short Test Sequence against the Expansion Interface circuit pack (**test board PCSS**) where PCSS is the 4-character address of the active Expansion Interface circuit pack), and refer to the maintenance procedures outlined for that circuit pack.
2031	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2032	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, replace the EPN Maintenance circuit pack.

Continued on next page

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Expansion Interface circuit pack could not reset the EPN Maintenance circuit pack. For duplicated Expansion Links in the EPN: 1. The Standby Expansion Interface circuit pack may be defective and, thereby, preventing the Active Expansion Interface circuit pack from resetting the EPN Maintenance circuit pack. Unplug the Standby Expansion Interface circuit pack, and attempt to reset the EPN Maintenance circuit pack using the **test maint long** command. If Test #306 passes, replace the Standby Expansion Interface circuit pack, and attempt the reset test again. If Test #306 fails, then replace the Standby EPN Expansion Interface circuit pack. 2. The Active Expansion Interface circuit pack may be defective and unable to reset the EPN Maintenance circuit pack. To determine which is the Standby link, enter the **status system** command from the Manager I (G1) or G3MT terminal. Switch links by entering the **set expansion-link** command followed by the 4-character Expansion Interface circuit pack location for the Standby link. Now reset the EPN Maintenance circuit pack again by using the **test maintenance long** command. If the test passes, the problem is with the known Standby Expansion Interface circuit pack. Repeat Step 2 to determine if the Standby Expansion Interface circuit pack should be replaced. 3. Replace the EPN Maintenance circuit pack, and run the test again. If the test passes, the problem is with the EPN Maintenance circuit pack. Switch Expansion Links, and run the test again. The test should pass with both Expansion Interface circuit packs being active. 4. If the B carrier Expansion Interface circuit pack is active, the ribbon cable connecting the Expansion Interface circuit pack and the EPN Maintenance circuit pack may be defective. Check the ribbon cable to make sure it is connected properly and is not damaged.

Continued on next page

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	For single Expansion Links in the EPN: 1. Replace the EPN Maintenance circuit pack, and run the test again. If it passes, the problem is with the EPN Maintenance circuit pack. 2. If the test fails, replace the Expansion Interface circuit pack. If the tests passes, the problem is with the Expansion Interface circuit pack. 3. If the test still fails, the problem is with the serial link wired into the backplane of carrier A.

Continued on next page

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2005	FAIL	EPN Maintenance Circuit Pack Reset passed, but the EPN Maintenance circuit pack did not respond to subsequent handshake message. Retry this command three more times. If it continues to fail, the EPN Maintenance circuit pack, the Active Expansion Interface circuit pack, or the serial link is defective. To determine which is defective, follow the appropriate procedures that follow. ■ Duplicated Expansion Links: 1. Determine which serial link is the Standby by issuing the **status system** system technician command. 2. Switch Expansion Links by entering **set expansion-link PCSS** where PCSS is the 4-character Expansion Interface circuit pack location for the Standby link. 3. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #306 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test Sequence. ■ Single Expansion Interface Link Switch: 1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence against it. 2. If the error persists, replace the Expansion Interface circuit pack, **at a time when the EPN can go down with minimal inconvenience**. 3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.

Continued on next page

Table 11-212. TEST #306 EPN Maintenance Circuit Pack Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Active Expansion Interface circuit pack can reset the EPN Maintenance circuit pack. This implies the EPN Maintenance circuit pack, the Active Expansion Interface circuit pack, and Active serial link are sane. There could still be a problem with the Standby Expansion Interface circuit pack and Standby serial link in a High or Critical Reliability system.

EPN Maintenance Circuit Pack Serial Link Test (#337)

This test is destructive.

This test checks the serial link from the Standby Expansion Interface circuit pack to the EPN Maintenance circuit pack. If there is no Standby link, or the Standby link is down at the time of the test, this test aborts.

NOTE:
The status of the link is changed to "down" when the Standby Expansion Interface circuit pack begins initialization tests (for example, after being reseated). The link status is then updated at the conclusion of these tests.

Table 11-213. TEST #337 EPN Maintenance Circuit Pack Serial Link Test

Error Code	Test Result	Description/ Recommendation
1030	ABORT	The active Expansion Link to the EPN Maintenance circuit pack is not running. 1. Follow up on the test results of the EPN Maintenance Circuit Pack Sanity Handshake Test (#105). 2. When problems associated with this test are resolved, rerun Test #337.
1035	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-213. TEST #337 EPN Maintenance Circuit Pack Serial Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1036	ABORT	There is no Standby Expansion Link running. Either the system only has one Expansion Link, the Standby Expansion Link is down due to Expansion Link, or the Expansion Interface circuit pack problems. 1. Issue the **status system** command and determine if the Standby Expansion Link is down or does not exist. If it does not exist, dashes are shown. Otherwise, the link status is shown. If there is no Standby link, this test always aborts. 2. If there is a Standby link and it is down, then refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation and resolve all alarms on the link. 3. Rerun the test.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Serial Link between the current Standby Expansion Interface circuit pack and the EPN Maintenance circuit pack is defective. If the Standby link is on the A carrier, errors of type 3329 are logged; however, if the Standby link is on the B carrier, errors of type 3585 are logged. 1. Replace the EPN Maintenance circuit pack. 2. Rerun the test. If the test continues to fail, replace the Standby EPN Expansion Interface circuit pack. 3. Rerun the test. If the test continues to fail and the Standby link is on the B carrier, then replace the ribbon cable that carries the serial link from Expansion Interface circuit pack B to the EPN Maintenance circuit pack. 4. Rerun the test. If the test continues to fail, escalate the problem.
	PASS	The serial link from the Standby Expansion Link to the EPN Maintenance circuit pack is working.

MEM-BD (Memory)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
MEM-BD	MAJOR	test memory l c	Memory
MEM-BD (a)	WARNING	test memory sh c	Memory
MEMORY (b)	MAJOR	test memory a/b sh c	Memory

NOTE:
For memory problems on systems with a TN790 RISC processor circuit pack see maintenance object PR-MEM.

Notes:

a. In a G3iV1.1-286 System only, this alarm occurs when a memory circuit pack of vintage 3 or greater is not used. (Refer to Notes (i) and (j) following the "Hardware Error Log Entries and Test to Clear Values" table for more information.)

b. In 386 systems [G3iV2-386, G3sV2, G3vsV2], memory is on the processor circuit pack and not on a separate memory circuit pack, as it is in a G3iV1.1-286 system. In 386 systems, the maintenance object is "MEMORY" and not "MEM-BD." However, all references to MEM-BD in this section are applicable to "MEMORY" as well.

The Memory contains the DEFINITY software and firmware. The Processor circuit pack is the most critical component of all system operations.[1]

G3iV1.1-286 systems contain two TN770 circuit packs. These circuit packs are separate from the Processor circuit pack. Memory problems may only require the replacement of the bad Memory circuit pack. However, because the circuit packs are interdependent, a Processor circuit pack should be brought to a customer's site along with the Memory circuit packs in case of memory alarms (see Figure 11-73).

386 systems contain memory that is integrated with the processor. For testing purposes, the circuit pack is logically separated into PR-MAINT, PROCR, and MEMORY. This means that a memory problem on 386 systems requires that the Processor be replaced (see Figure 11-73). 386 systems contain two types of memory: Flash ROM and DRAM. Flash ROM is permanent memory that contains the boot image, PI firmware, and PACCON firmware. This type of memory is not erased during circuit pack resets. It can be reprogrammed only via the **upgrade software** command.

1. An R1V4 DEFINITY system has all its Memory on a single TN770 circuit pack, while an R1V5 system and a G3iV1.1-286 system use two such packs for Memory. A DEFINITY 386 system has all its Memory on the Processor circuit pack (TN786B). In addition, G3iV2-386 has expansion memory on a CPP1.

DRAM is used for software data storage, and it changes constantly. DRAM loses its value during circuit pack resets. Both types of memory are present on the Processor circuit pack. The diagnostics run appropriate tests on both memories.

For all system activity, the Processor must be able to access the Memory. If the Processor cannot do this, the system goes into SPE-down mode. In SPE-down mode, fatal Memory errors may show up as Processor errors. This merely indicates that the Processor and the Memory are very closely linked as a matter of course.

If the initialization diagnostics fail, refer to the "Procedure for SPE-Down Mode" section in Chapter 4, "Initialization and Recovery".

In G3iV1.1-286, the faulty Memory circuit pack is identified in the Alt Name field on the Alarm Report Form and on the Hardware Error Report Form. A "1" in the Alt Name field refers to the Processor circuit pack, a "2" refers to the Memory, and a blank refers to both circuit packs.

In G3s/vs/ iV2-386, memory faults usually indict the CPP1 circuit pack, however the problem may be on the TN786B.

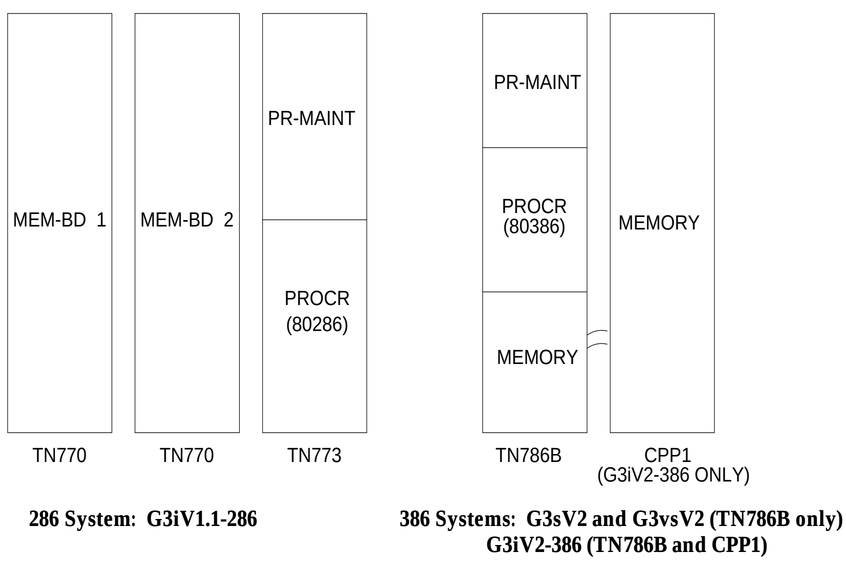

Figure 11-73. Configurations for 286 and 386 Systems

Hardware Error Log Entries and Test to Clear Values

Memory Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test memory a/b l r 1
1-256	Any	Read All Memory Test (#85)	MAJOR	ON	test memory a/b l r 5
257-512 (b)	Any	Read All Memory Test (#85)	MAJOR	ON	test memory a/b l r 1
513 (c)	0	Memory Detection/ Test (#87)	MAJOR	ON	test memory a/b r 3
769 (d)	Any	Text Checksum Test (#86)	MAJOR	OFF/ON	test memory a/b l r 2
1025 (e)	Any	Memory Functional Test (#332)	MAJOR	ON	test memory a/b l r 1
1537-1792 (f)	Any	Read All Memory (#85)	MAJOR	ON	test memory a/b l r 5
1793-2048 (g)	Any	Read All Memory (#85)	MAJOR	ON	test memory a/b l r 1
2049 (h)	0	Memory Error Detection/ Test(#87)	MAJOR	ON	test memory a/b r 3
2817 (i)	Any	Memory Board Check(#631)	WARNING	ON	test memory a/b sh

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The "clear" option can replace the "repeat" option in a **test memory** command. For a High or Critical Reliability system, the carrier (a or b) must be specified. In all other systems, there is no need to specify the carrier.

b. The Read All Memory Test (#85) failed. Refer to the FAIL section of this test. For G3iV1.1-286, the error is associated with MEM-BD 1. For all other systems, no such association is made.

c. The Memory Error Detection Test (#87) failed. Refer to the FAIL section of this test. For G3iV1.1-286, the error is associated with MEM-BD 1. For all other systems, no such association is made.

d. The Text Checksum Test (#86) failed. Refer to the FAIL section of this test. For G3iV1.1-286, the error is associated with MEM-BD 1 and is an OFF board alarm. In 386 systems, the alarm is ON board.

e. There are Functional Test errors against both the Processor circuit pack and Memory. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

f. These errors apply only to G3iV1.1-286 systems.

g. The Read ALL Memory Test (#85) failed. Refer to the FAIL section of this test. These error types apply only to MEM-BD 2 (G3iV1.1-286 systems only).

h. The Memory Error Detection (#87) failed. Refer to the FAIL section of this test. These error types apply only to MEM-BD 2 (G3iV1.1-286 systems only).

i. For G3iV1.1-286 systems only, the test is failing because the circuit pack for MEM-BD 2 is not of vintage 3 or greater. Replace the pack with one of vintage 3 or greater.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate errors in the order in which they are presented in the table that follows when you are inspecting errors in the system. By clearing error codes associated with the *Read All Memory Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Non-maskable Interrupt Test (#82)(a)	X	X	ND
Processor ROM Checksum Test (#80) (a)	X	X	ND
Processor Software Initiated Interrupt Test (#77) (a)	X	X	ND
Processor Sanity Timer Test (#83) (a)		X	D
MTP Outpulse Relay Test (#102) (b)	X	X	ND
MTP Analog Loop Around Test (#103) (b)	X	X	ND
MTP Sanity Handshake Test (#106) (b)	X	X	ND
MTPSAT Loop Around Test (#228) (b)	X	X	ND
MTP Aux Loop Around Test (#229) (b)	X	X	ND
MTP Reset Test (#101) (b)		X	D
MTP Dual Port Ram Test (#104) (b)		X	D
Read All Memory Test (#85)		X	ND
Memory Error Detection Test (#87)	X	X	ND
Text Checksum Test (#86)		X	ND
Memory Functional Test (#332) (c)		X	D
Memory Board Check Test (#631)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to PROCR (Processor) Maintenance documentation for a description of these tests [386 systems only].

b. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation for a description of these tests [386 systems only].

c. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

Read All Memory Test (#85)

This test is a nondestructive test. The test reads every memory location in memory and writes it back. A failure of this test indicates a failure in the Processor or Memory circuit pack.

Table 11-214. TEST #85 Read All Memory Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-214. TEST #85 Read All Memory Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	If the system can still provide service, this indicates that the Processor circuit pack or Memory has a problem, but can still function. The error code "1" indicates that MEM-BD 1 is failing the test. 1. In a 386 system, the PROCR (Processor circuit pack TN786B) should be replaced. If the test continues to fail, escalate the problem. **WARNING:** *If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.* 2. In a G3iV1.1-286 system, the MEM-BD 1 (Memory circuit pack 1 TN770) should be replaced. If the test still fails, the original MEM-BD 1 (TN770 Memory circuit pack 1) should be reinserted, and MEM-BD 2 (TN770 Memory circuit pack 2) should be replaced. If the test still fails, the original MEM-BD 2 (Memory circuit pack 2) should be reinserted and the PROCR (Processor circuit pack) should be replaced with a new one. If the test still continues to fail after you replace the Memory and Processor circuit packs, escalate the problem.

Continued on next page

Table 11-214. TEST #85 Read All Memory Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	If the system can still provide service, this indicates that the Processor circuit pack or Memory has a problem, but can still function. For G3iV1.1-286, the Error Code 2 indicates that MEM-BD 2 is failing the test. 1. In 386 systems, you do not get this error. Therefore, you should escalate the problem. 2. In G3iV1.1-286, the MEM-BD 2 (TN770 Memory circuit pack 2) should be replaced. If the test still fails, the original MEM-BD 2 (Memory circuit pack 2) should be reinserted, and MEM-BD 1 (TN770 Memory circuit pack 1) should be replaced. If the test still fails, the original MEM-BD 1 (Memory circuit pack 1) should be reinserted, and the PROCR (Processor circuit pack) should be replaced with a new one. If the test still continues to fail after you replace the Memory and Processor circuit packs, escalate the problem.
	PASS	The Memory is healthy.

Text Checksum Test (#86)

This test is a nondestructive test. In G3iV1.1-286, the test computes the checksum of the DEFINITY Generic 3 software text module. A failure of this test indicates corruption of the RAM. However, this failure does NOT indicate a hardware problem. **DO NOT REPLACE** the Memory circuit pack when this is the only error. However, if there are other Memory alarms, follow the maintenance procedures described in Tests #85 and #87. A system restart via the **reset system 4** command and with good tapes in the system should be implemented at the customer's earliest convenience. In a High or Critical Reliability system, an **upgrade software** command can be used with good tapes in the system. This command performs the same operation as the **reset system 4** command but is much less service-disruptive.

In 386 systems, the test computes the checksum of the DEFINITY Generic 3 software text module, and it validates the operation of the flash ROM. A failure of this test indicates corruption of the Text.

Table 11-215. TEST #86 Text Checksum Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
	FAIL	The system may or may not continue to operate correctly. The system may fail later when some action requires access to the corrupted area of the Text. 1. For G3iV1.1-286, the system should be restarted via the **reset set system 4** command. If the test continues to fail, the original PROCR (Processor circuit pack) should be reinserted, and the Memory should be replaced with a pack. If the test continues to fail, escalate the problem. If escalation does not solve the problem, a hardware problem exists, and the PROCR (Processor circuit pack) must be replaced. If the problem still persists, replace the Memory. If the test continues to fail, escalate the problem. Refer to the "Handling Control Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures", for a Standard system and to the "Repair Procedures for High and Critical Reliability" section in Chapter 8, "Reliability Systems: A Maintenance Aid", for a High or Critical Reliability system. 2. For a 386 system, the flash ROM should be reprogrammed via the **upgrade software** command. The memory card should contain the same vintage software that is currently in the system. Refer to the "Software Upgrade" section in Chapter 5, "Routine Maintenance Procedures". If the test continues to fail, escalate the problem.

Continued on next page

Table 11-215. TEST #86 Text Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2058	FAIL	**(G3iV1.1-286 system only)**. This test has two parts: a checksum of the text module only and a checksum of the initialized data. The latter is performed only on a **reset system 4** or on a **reset system 5**. 1. If Error Type 769 with an Aux Data value of 2058 occurs immediately after **reset system 4**, and if the test later passes, the checksum of the initialized data probably failed. The alarm is resolved immediately, and the system may function normally. Also, the tape may have a bad boot image on it. (There is no way to verify this except by performing a level 4 system reset.) If the system continues to operate correctly, replace the tape and save the translations. Otherwise, perform a **reset system 4** at the customer's earliest convenience after you replace the tape and save the translations. In a High or Critical Reliability system, the **upgrade software** command should be used instead of the **reset system 4** command.
	PASS	The checksum is correct.

Memory Error Detection Test (#87)

This test is a nondestructive test. In G3iV1.1-286 systems only, the test determines if the error correction circuitry on the Memory circuit packs is working. Accordingly, the test determines if single- and multiple-bit errors can be detected. Single-bit errors can be corrected.

The test is run on a few reserved locations in memory. A failure of this test indicates a failure in the Memory or Processor circuit packs.

In 386 systems only, this test determines if the parity circuitry is working. Accordingly, the test determines if parity errors can be detected. The parity circuitry is used to detect DRAM memory failures.

Table 11-216. TEST #87 Memory Error Detection Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-216. TEST #87 Memory Error Detection Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	The parity detection circuitry is not working correctly. If the system can still provide service, this indicates that the Processor circuit pack or Memory has a problem but can still function. Error Code 1 indicates that MEM-BD 1 is failing the test. 1. In 386 systems, the PROCR (Processor circuit pack TN786B) should be replaced. The failure is identifying the PROCR as being bad and only the PROCR circuit pack needs to be replaced. If the test still fails, the original PROCR circuit pack should be reinserted, and the CPP1 should be replaced. If the test continues to fail, replace the PROCR and CPP1 circuit packs. If the test still continues to fail after you replace both the PROCR and CPP1 circuit packs, escalate the problem. **WARNING:** *If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.* 2. In G3iV1.1-286, the MEM-BD 1 (Memory circuit pack 1 TN770) should be replaced. If the test still fails, the original MEM-BD 1 (TN770 Memory circuit pack 1) should be reinserted, and MEM-BD 2 (TN770 Memory circuit pack 2) should be replaced. If the test still fails, the original MEM-BD 2 (Memory circuit pack 2) should be reinserted and the PROCR (Processor circuit pack) should be replaced with a new one. If the test still continues to fail after you replace the Memory and Processor circuit packs, escalate the problem.

Continued on next page

Table 11-216. TEST #87 Memory Error Detection Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The parity detection circuitry is not working correctly. If the system can still provide service, this indicates that the Processor circuit pack or Memory has a problem but can still function. The Error Code 2 indicates that MEM-BD 2 is failing the test. 1. In a 386 system, the Processor circuit pack TN786B should be replaced. The failure is identifying the CPP1 as a "bad" circuit pack and, consequently, only the CPP1 needs to be replaced. If the test still fails, the original CPP1 should be reinserted, and the PROCR circuit pack should be replaced. If the test continues to fail, replace both the PROCR and CPP1 circuit packs. If the test still continues to fail after you replace both the PROCR and CPP1 circuit packs, escalate the problem. 2. In G3iV1.1-286, the MEM-BD 2 (TN770 Memory circuit pack 2) should be replaced. If the test still fails, the original MEM-BD 2 (Memory circuit pack 2) should be reinserted, and MEM-BD 1 (TN770 Memory circuit pack 1) should be replaced. If the test still fails, the original MEM-BD 1 (Memory circuit pack 1) should be reinserted, and the PROCR (Processor circuit pack) should be replaced with a new one. If the test still continues to fail after you replace the Memory and Processor circuit packs, escalate the problem.
	PASS	The parity detection circuitry is working.

Memory Functional Test (#332)

This test is destructive.

In G3iV1.1-286, this test ensures that each memory location can be changed independently of all other locations. Running this test wipes out any data in memory. This test is performed during a **reset system 4** command or a **reset system 5** command. Refer to the "Procedure for SPE-Down Mode" section of Chapter 4, "Initialization and Recovery", for the recommended maintenance strategy. The system cannot always isolate a fault to a specific Memory circuit pack in a system with two Memory circuit packs. The red LED on both packs is lit if the test fails. Replacing a Memory or Processor circuit pack in a Standard system first requires that the system be brought down. Thereafter, a **reset system 4** or a **reset system 5** must be performed. In a High or Critical Reliability system, it is not necessary to power down when you are replacing a control circuit pack in the Standby SPE. The health of the new circuit pack should be verified by issuing the **test memory long** command.

In 386 systems, this test ensures that every DRAM memory location can be accessed and changed independently. Running this test wipes out all data in DRAM memory. This test is performed during a **reset system 4** or **reset system 5**. If the test fails during a **reset system** command, refer to the "Procedure for SPE-Down Mode" section of Chapter 4, "Initialization and Recovery", for the recommended maintenance strategy.

Table 11-217. TEST #332 Memory Functional Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of three times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-217. TEST #332 Memory Functional Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Standby SPE Memory is defective. 1. Repeat the command at one minute intervals a maximum of five times. 2. For G3iV1.1-286, if the red LEDs on both the Processor circuit pack and the Memory are on during the test, replace the Processor circuit pack. If the test still shows a failure, the original Processor circuit pack should be reinserted, and the Memory should be replaced. For all 386 systems, the Processor circuit pack should be replaced. 3. If the test continues to fail, escalate the problem.
	PASS	The Standby SPE Memory circuit pack(s) is healthy.

Memory Board Check Test (#631)

This test is a nondestructive test. The test checks the vintage of the second memory circuit pack in G3iV1.1-286. The test verifies that the circuit pack is of vintage 3 or greater. The test PASSES if the circuit pack is of vintage 3 or greater. The test FAILS and raises a WARNING alarm if the circuit pack is not of vintage 3 or greater.

NOTE:
This test always passes for a 386 system.

Table 11-218. TEST #631 Memory Board Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Errors. 1. Retry the command at 1 minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2	FAIL	Memory 2 circuit pack must be of vintage 3 or greater. 1. Replace the circuit pack with a pack of vintage 3 or greater.
	PASS	Memory 2 circuit pack is of vintage 3 or greater.

Refer to MEM-BD (Memory Circuit Pack) Maintenance documentation for circuit pack level errors.

MET-BD (MET Line Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
MET-BD	MIN	test board PCSS sh	MET Line Circuit Pack
MET-BD	WRN	test board PCSS sh	MET Line Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also MET-LINE (MET Line) Maintenance documentation for related line information.

MET-LINE (MET Line)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
MET-LINE	MINOR	test port PCSSpp l	MET Line
MET-LINE	WARNING	test port PCSSpp sh	MET Line

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

Electronic Station is the user-friendly term to denote the MET (Multibutton Electronic Telephone) Station Set. The MET sets were originally introduced for use in earlier PBX systems but can now be used in Generic 1 switches.

The TN735 MET Line circuit pack supports four of these Multifunctional Electronic Sets. Each MET set uses three pairs of wires: an analog voice pair, a transmit pair, and a receive pair. Power is sent over the transmit and receive pairs. The MET Line circuit pack supports all 10-, 20-, and 30-button sets.

MET Line interactions are shown in Figure 11-74.

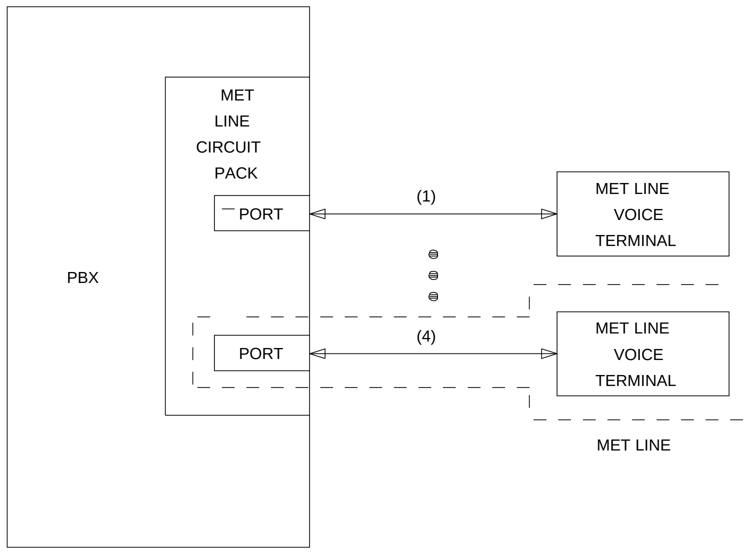

Figure 11-74. MET Line Interactions

A change in the use of the Recall button on the MET set needs to be noted. Instead of being used as it was in earlier PBX systems, the Recall button is used in this system as a self-test button and, when pressed, lights all of the lamps on the MET set and runs the ringer update.

This section refers only to the MET-LINE (MET Line) maintenance that is performed. Note that MET-LINE (MET Line) maintenance is closely related to, and interacts with, the MET-BD (MET Line circuit pack) maintenance in some instances. Some of the results of maintenance testing of the MET Line may be affected by the health of the MET Line circuit pack. This interaction should be kept in mind when investigating the cause of reports of MET Line problems.

There are instances in this section where service states of a station are mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- Out-of-Service—The port, and thus the station, have been removed from service. A busyout of a port causes it to be out-of-service.
- Ready-for-Service—Once a port on the circuit pack has been put into service, the voice terminal must communicate that it is present. The time between these two events is the time when the terminal is in the ready-for-service state.

- In Service—Once the system receives a message from the voice terminal communicating that it is present, the station is put into the in-service state. The terminal can also be forced into the in-service state if it goes off-hook while it is in the ready-for-service state.

When the **status station** command has been run, and the status screen appears, the status is reported as either out-of-service, in-service (as stated in the preceding list), or disconnect (the station is in the ready-for-service state).

Hardware Error Log Entries and Test to Clear Values

MET Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	40987	None			
18 (b)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
130 (c)		None	WARNING	ON	test port PCSSpp sh
257 (d)	40988	None	MIN/WRN[2]	OFF	
513 (e)	40965	Hybrid Line Station Audits Test (#61)	WARNING	OFF	test port PCSSpp sh r 4
769		Port Diagnostic Test (#35)	MIN/WRN[2]	ON	test port PCSSpp l r 3
1025		Hybrid & Conf. Circuits Test (#57)	MIN/WRN[2]	ON	test port PCSSpp l r 3
1537 (f)	40968	None	MIN/WRN[2]	OFF	
1793		TDMNPE Crosstalk Test (#6)	MIN/WRN[2]	ON	test port PCSSpp l r 3
2049(g)	32770				
2049(h)	40967				
3840(i)	40989				

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

a. Indicates a defective data link. An off-board problem detected by port circuit. Make sure the MET set is connected, and that the EPF test passes. If data transmission problems are experienced, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired due to the passing of time.

b. This error is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. This indicates that the EPF has been turned off due to the overcurrent condition at the voice terminal. Check for defective wiring, check for a damaged jack, and make sure the voice terminal is a MET set. Once the problem has been resolved, the alarm is retired due to the passing of time.

e. The particular station audit that causes this error type to be produced is the EPF inquiry audit. If the EPF inquiry receives an "epf-no-load" message a certain number of times, this error occurs and, if the EPF inquiry receives an "epf-on-ok" or an "epf-off-ok" message, it contributes to the resolution of this alarm.

   This indicates that the voice terminal has probably been disconnected or that there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.

f. This indicates that something is wrong with the link to the voice terminal. An in-line maintenance error has generated an off-board Minor alarm. Ignore if there are no complaints. Otherwise, verify that the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack.

g. This indicates that the station went off-hook while it was in the ready-for-service state. Use the **status system** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No action is necessary.

h. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No action is necessary.

i. An uplink message being logged that the EPF is one with no load on it. No action is necessary.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Port Diagnostic Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Port Diagnostic Test (#35)		X	ND
MFAT Electronic Power Feed Test (#56)		X	ND
Hybrid Circuit and Conference Circuit Test (#57)		X	ND
Station Lamp Update Test (#60)	X	X	ND
Station Audits Test (#61)	X	X	ND
Ringer Update Test (#62)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-219. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-219. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-219. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. This only applies to analog stations. The default for this field is 'y,' so you may want to determine why it has been turned off on this station. 1. To enable the test for the particular analog station being tested, enter the **change station extension** command and change the 'Test' field on the 'Station' form from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-219. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Continued on next page

Table 11-219. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

Port Diagnostic Test (#35)

This test checks a port's battery feed circuitry. The battery feed circuitry is tested for proper battery voltage by testing the switchhook state. In response to the test message, the on-board firmware terminates the line and checks for switch-hook presence. The termination is then removed, and a check is made for no switch-hook presence. The MET set must be on-hook for the test to execute.

Table 11-220. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-220. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. **NOTE:** The battery feed circuitry is tested for proper battery voltage by testing the switchhook state. In response to the test message, the on-board firmware terminates the line and checks for switch-hook presence. The termination is then removed, and a check is made for no switch-hook presence. The MET set must be on-hook for the test to execute. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via software patch. 1. Escalate to next tier level.
2000	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-220. TEST #35 Port Diagnostic Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Battery Feed Test failed. This port is out-of-service. 1. Other ports on this circuit pack are not affected. Place user on a different port, if available, until a replacement circuit pack can be obtained. 2. Replace circuit pack when available.
	PASS	Battery Feed Test passed. Current flow is properly detected for this port. 1. If users are reporting problems, examine connections to the port. 2. Escalate the problem.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Electronic Power Feed (#56)

In this test, the software requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit to the station. If no current is being drawn, this probably indicates that the station is not connected. If an overcurrent condition is sensed (that is, too much current is being drawn), this may indicate a short in the loop or a defective voice terminal. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This test is repeated once more five seconds later. If either test is not successful, the test aborts.

Although this test will never actually return a fail result (except for the internal system error), an error type 257 entry will be made in the error log when the test has completed if the overcurrent case is detected by the hardware.

Table 11-221. TEST #56 MET Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The test was aborted due to an internal system error on a software request to the board. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-221. TEST #56 MET Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed with an internal error while it was attempting to turn on the EPF. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	EAF Test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test never returns a FAIL result, after running this test, the Error Log should be checked for any entries with Error Type 257 to examine the real results of this test. 2. If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating. 3. If Error Type 257 appears in the Error Log, this indicates some problem with the power to the station. The system technician should check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.

Continued on next page

Table 11-221. TEST #56 MET Electronic Power Feed Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Circuit and Conference Circuit Test (#57)

The MET Circuit Test checks the amount of reflection from the MET loop around circuitry and a Conference Test. The Tone-Clock circuit pack places a 1004-Hz tone on a time slot that the port circuit is listening on. A General Purpose Tone Detector (GPTD) is connected to another time slot that the same port circuit is talking on. The on-board microprocessor places the port in the loop around mode and the GPTD measures the level of the reflected signal.

The Conference Test is performed after the Circuit Test. The Conference Circuit Test verifies that the NPE is able to listen to several test tones and correctly conference them together, and the test is executed in two parts. The first half of the test checks the operation of the NPE's first three conference channels. The NPE is put in the loop around mode and instructed to talk on a selected time slot and to listen to the 1004-Hz tone using the first three conference channels. The signal level and noise level of the conferenced output are then measured using a GPTD and checked to verify that they are within an acceptable range.

The second half of the Conference Test checks the operation of the NPE's remaining four conference channels and follows the same procedure as above.

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test were not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
7	FAIL	The conference circuit test failed. The conference circuit test is performed only if the hybrid test passes. The conference circuit test verifies that the network processing element (NPE) is able to correctly conference several test tones together. The test is executed in two parts. The first half of the test verifies the operation of the NPE's first three conference channels, while the second half verifies the NPE's remaining four conference channels. The test puts the NPE in loop around mode and instructs it to talk on a specified time slot while listening to a 1004 Hz tone, using the conference channels. A GPTD then measures the signal and noise levels of the conferenced output and reports whether or not these are within an acceptable range. The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. It is possible that the port may still be functional from a user's point of view. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT. 1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK. 2. Then, issue the **display port** and the **station status** commands to determine if the station is idle. If it is idle, issue the **test port** command for this port. 3. If test continues to fail, issue the **busyout port** and the **release port** commands, and then retest the port.

Continued on next page

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
57	FAIL	Hybrid Circuit Test failed. This could result in noisy or bad connections. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack, using **test board PCSS short** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the MET Line circuit pack. **NOTE:** If the MET Circuit and Conference Circuit Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain either a TN736 or a TN752 power unit circuit pack OR a 631DB AC power unit, **but not both types of power units.** To investigate problems with a 631DB power unit, refer to CARR-POW (Carrier Port Power Unit for AC-Powered Systems) Maintenance documentation. To investigate problems with a 645B power unit, refer to CARR-POW (Carrier Port Power Unit for DC-Powered Systems) Maintenance documentation.
	PASS	Hybrid Circuit and Conference Circuit Test passed. The hybrid circuitry is transmitting properly. 1. If complaints still exist, investigate by using other port tests, and by examining the station, wiring, and connections.

Continued on next page

Table 11-222. TEST #57 MET Circuit and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Station Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates run only if the station is in-service.

Table 11-223. TEST #60 MET Line Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
3	ABORT	Station is in ready-for-service or out-of-service state. This may be due to wiring or an unplugged or defective set. 1. Make sure terminal is connected and the wiring is correct. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	MET Line Station Lamp Updates completed successfully. 1. If complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.

Table 11-223. TEST #60 MET Line Station Lamp Updates Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Station Audits Test (#61)

This is a series of three tests that are classified as audits. These audits abort if attempted on an out-of-service station. The tests are as follows:

- Switchhook Audit—This is an update of the SPE records according to the circuit packs' records.
- Bad Scan Inquiry—A message is sent uplink that contains a count that is generated due to certain events relating to the link conditions. This is an indication of data transmission problems between the MET Line circuit pack and the voice terminal.
- EPF Inquiry—The status of the EPF is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

Although this test will never actually return a fail result (except for the internal system error), it is possible that it will enter error types 257 (over current) or 513 (open circuit) into the error log. To determine if there are any problems that do not show up in the test result, look for these error types in the error log. If these errors appear in the error log or if user complaints still exist, investigate by using other circuit pack tests and by examining the station, the wiring, and the connections.

Table 11-224. TEST #61 MET Line Station Audits Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
1	ABORT	The test was aborted due to an internal system error during the switchhook audit.
2		The test was aborted due to an internal system error during the bad scan inquiry.
3		The test was aborted due to an internal system error during the EPF audit inquiry. 1. Make sure that the station is not in an out-of-service state. 2. Retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Table 11-224. TEST #61 MET Line Station Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.

Table 11-224. TEST #61 MET Line Station Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The test failed due to an internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	Hybrid Line Station Audits passed. 1. Although this test always returns a PASS result, it may enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these error types in the Error Log. 2. If these errors appear in the Error Log, or if user complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MET Line Ringer Update Test (#62)

In this update, a "ringer on" or a "ringer off" message is sent to the firmware to start and stop the ringer on the set.

Table 11-225. TEST #62 MET Line Ringer Update Test

Error Code	Test Result	Description/ Recommendation
3	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the **release station <extension>** command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension, attendant number, or trunk group/member number of the port. Use the **status station**, **status attendant**, or **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-225. TEST #62 MET Line Ringer Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Hybrid Station Ringer Update passed. 1. If complaints still exist, investigate using other circuit pack tests, and by examining the terminal, wiring, and connections.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.

MIS (Management Information System)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
MIS	WRN	release mis	Management Information System

The Management Information System (MIS)/Call Management System (CMS) MO is used only for administering MIS translations, such as trunks and stations. There are no hardware failures associated with this MO (see Note).

NOTE:
To diagnose MIS link hardware errors and alarms, see PI-LINK (Processor Interface Link) and PI-SCI (System Communication Interface) Maintenance documentation.

The MIS/CMS is an adjunct processor that collects ACD data sent from the switch. In order to change MIS translations, a switch administrator must first enter a **busyout mis** command at the Manager I (G1) or G3MT terminal. When the MIS is busied out, the switch stops sending ACD data to the MIS, and a Warning alarm is raised.

When the switch administrator is finished, a **release mis** command should be entered at the Manager I (G1) or G3MT terminal. This clears the Warning alarm and allows the switch to send ACD data to the MIS.

Hardware Error Log Entries and Test to Clear Values

Management Information System Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	release mis
18(a)	0	busyout mis	WARNING	ON	release mis

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. When the **busyout MIS** command is issued, no data is sent to the MIS/CMS regardless of the link state. To allow data to be sent to MIS/CMS, a **release mis** command must be issued from the terminal.

MODEM-BD (Modem Pool Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
MODEM-BD	MIN	test board PCSS sh	Modem Pool Circuit Pack
MODEM-BD	WRN	test board PCSS sh	Modem Pool Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also MODEM-PT (Modem Pool Port) Maintenance documentation for related port information.

MODEM-PT (Modem Pool Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
MODEM-PT	MINOR	test port PCSSpp sh	Modem Pool Port

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Modem Pool Port provides an interface for digital and analog data communication devices or ports connected to the PBX. It may be thought of as a PBX data communications "conversion resource" because it converts analog modem signals typically used in the telephone network into digital signals that are compatible with the internal PBX network and vice versa.

There may be a number of these conversion resources available in the PBX, each assigned to one of five available Modem Pool Groups. Only one conversion resource is used per data connection. The PBX software usually adds the conversion resource into a data connection if it determines that it is necessary for the call. Typical connections that include Modem Pool conversion resources include data calls from Analog Line or Central Office Trunk ports to any digital port or Digital Line or Trunk ports to any analog port. An example of a Data Module to Central Office Trunk connection using a Modem Pool conversion resource is shown in Figure 11-75. When a local data call originates from an analog port normally used for voice service only and terminates on a digital port, a Data Origination access code must be dialed before the extension number for the Modem Pool conversion resource to be included in the connection.

Refer to Figure 11-75 on page 11-1111 while reading the following paragraph.

Each Modem Pool conversion resource contains two ports. One of these, an Analog Line Port, is connected (via the PBX network) to the Analog Line or Central Office Trunk Port that is the source of the modem signal. The second port is referred to as the digital port and is connected (again through the PBX network) to the Digital Line or Trunk port associated with the Data Module in the connection. The analog modem signals enter the analog port of the conversion resource in standard Pulse Code Modulation (PCM) format but are converted into Data Communications Protocol (DCP) format before going to the Digital Line or trunk in the connection.

There are two primary types of Modem Pool conversion resources available: an Integrated Pooled Modem and a Combined Modem Pool. The integrated TN758 Pooled Modem circuit pack contains two independent 300 or 1200 baud conversion resources. Each conversion resource contains two interfaces to the

PBX digital network: an analog port and a digital port. The analog port is connected through the PBX network to the analog line or trunk port containing the analog modem signals. The digital port connects through the PBX network to the digital line or trunk port in the call. Figure 11-75 shows a typical end-to-end connection using a conversion resource on the integrated Pooled Modem circuit pack.

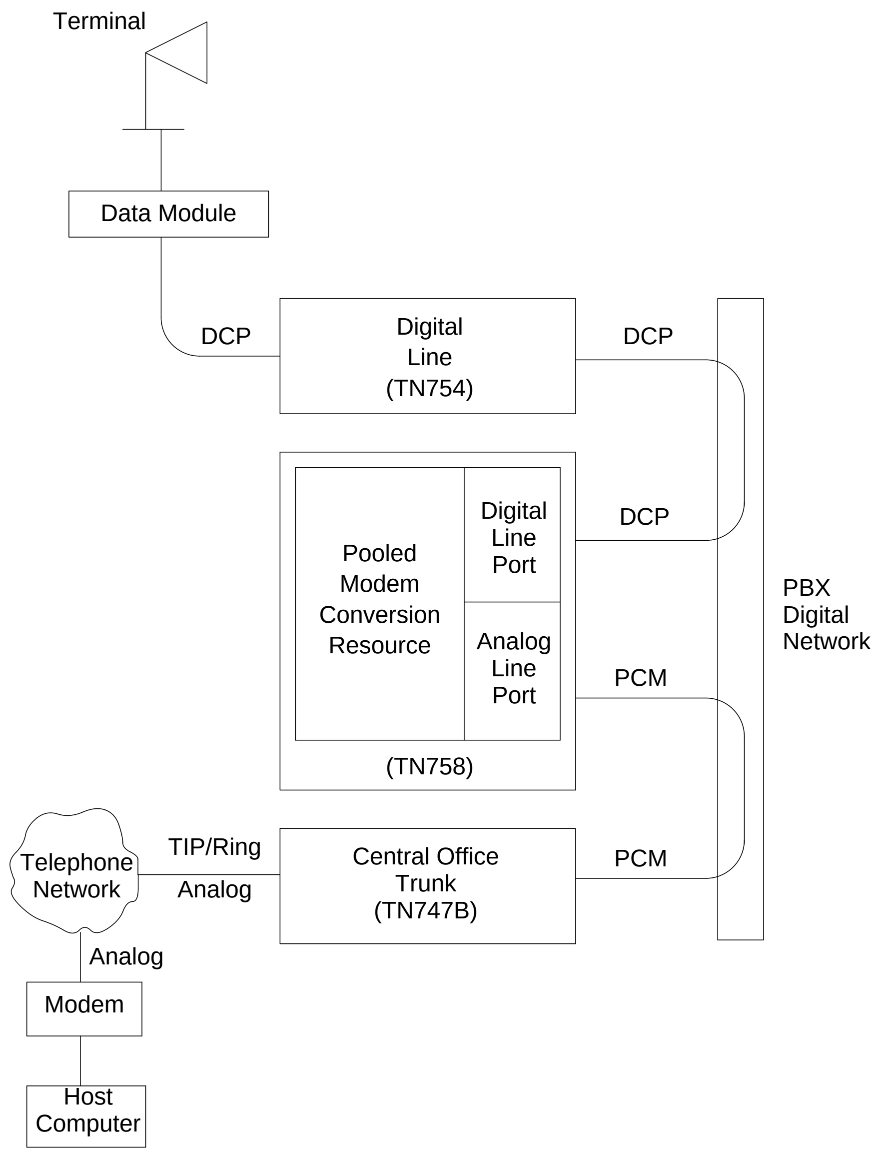

Figure 11-75. Typical Modem Pool Switched Connection with Integrated Pooled Modem

The Combined Modem Pool conversion resource is the second type available. The function served by the Combined Modem Pool is similar to that of the integrated Pooled Modem circuit pack, but the physical implementation is much different. It has the advantage of supporting any speed the external modem can support. The integrated Pooled Modem circuit pack can only support 300 or 1200 baud transmission rates. The Combined Modem Pool conversion resource consists of a port on a TN742 or TN746 Analog Line circuit pack, an external modem, a Data Module, and a port on a TN754 Digital Line circuit pack. The tip and ring interface of the Analog Line is connected to the modem, the EIA 232C interface of the modem connects to the Data Module, and the DCP interface on the Data Module is connected to the Digital Line port.

The analog modem signals pass through the Analog Line port to the modem. The modem converts these to EIA 232C signals which are passed on to the Data Module. The Data Module further converts the signals to the DCP protocol for the Digital Line port which passes the signals on to the PBX network. See Figure 11-76.

Certain customer-reported troubles may provide important information for troubleshooting Modem Pool problems. For example, if the customer tries to make a data call requiring a Modem Pool conversion resource, and the Modem Pool and Data Module speeds or other options don't match, they receive a "CHECK OPTIONS" error message on the terminal. If this happens, the Modem Pool administration and customer Data Module option settings should be checked. In addition, if the Modem Pool is a Combined type, option settings should be checked on the external Modem and Data Module making up the Combined Modem Pool. The cabling and connections between the Digital Line port, Data Module, Analog Line port, and Modem should be checked between the Combined Modem Pool components.

There are three types of commands that can be used to test Modem Pool circuits: **test port, test modem-pool #,** and **test board.** The **test port** command is generally the first test to run after the Error Log is evaluated and an entry is found for a Modem Pool port. The **test modem-pool #** command runs the same tests as the **test port short** command performed on a Modem Pool port. However, the **test modem-pool #** command can automatically test all ports in the Modem Pool group number specified in #. The **test board** command performs the same tests as **test port** and **test modem-pool #** plus additional tests for circuits common to the entire circuit pack. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for information on additional tests performed with **test board** (#50, #52, and #53).

If the Modem Pool port or group being tested with **test modem-pool #** contains Combined Modem Pools, the ports on the associated TN742 or TN746 Analog Line circuit pack and the TN754 Digital Line circuit pack are tested as a group. Note, however, that Combined Modem Pools are not tested with the tests described in this section and the repair information related to Tests # 96, 97, 98, and 99 is not applicable. The Analog port of the Combined Modem port is tested with Analog port tests (that is, Tests #6, #47, #35, #48 and #36), and the Digital port of the Combined Modem port is tested with TDMODULE/PDMODULE tests (that is, Tests #9, #13, #17 and #175). Therefore, use the repair procedures outlined in the ANL-LINE, ANL-16-L, ANL-NE-L, and TDMODULE/PDMODULE

Maintenance documentation when interpreting the results of the execution of the **test modem-pool** # command on Combined Modem Pools.

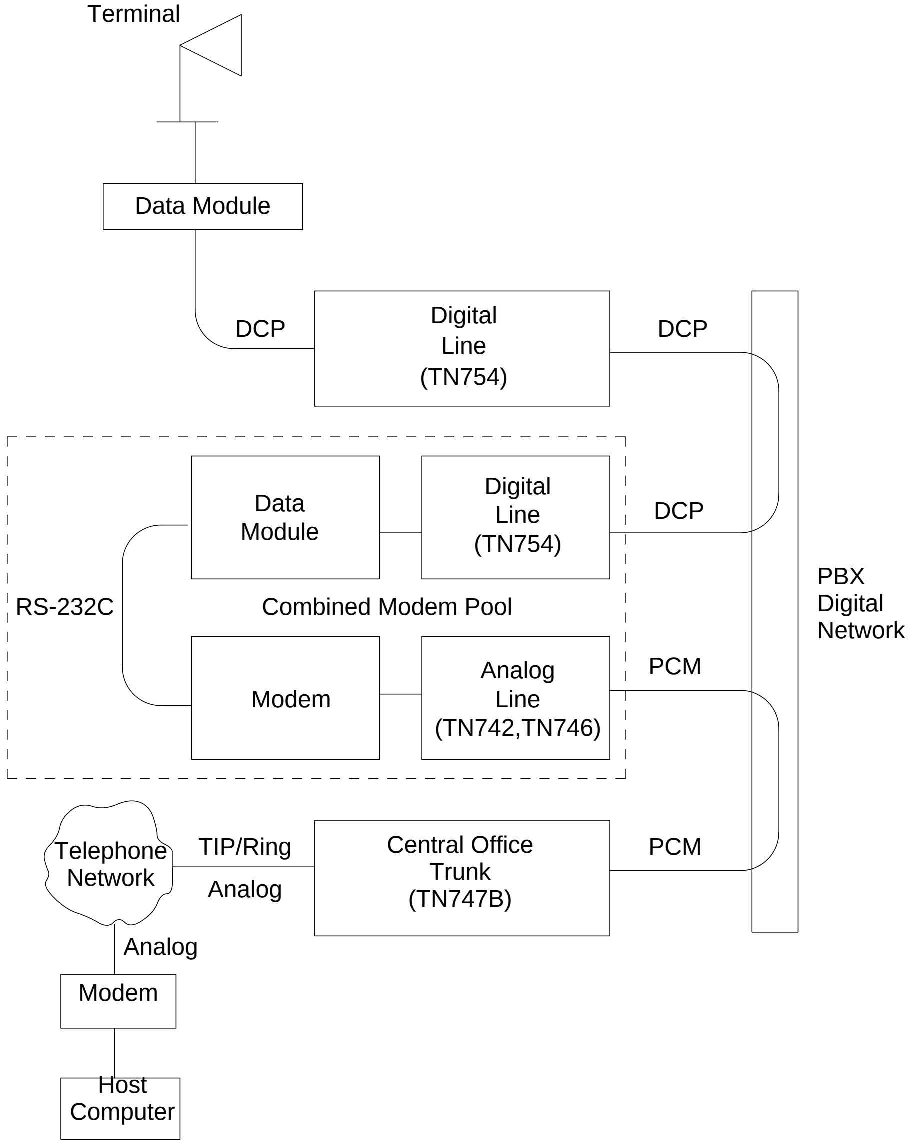

Figure 11-76. Typical Modem Pool Switched Connection with Combined Modem Pool

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

a. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Modem Pool Conference Test,* for example, you may also clear errors generated from other tests in the testing sequence. The tests in this section do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. The test descriptions for those maintenance objects (MOs) should be consulted when repairing Combined Modem Pool arrangements.

For example, you may also clear errors generated from other tests in the testing sequence. The tests in this section do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. The test descriptions for those maintenance objects (MOs) should be consulted when repairing Combined Modem Pool arrangements.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Modem Pool NPE Crosstalk Test (#96)		X	D
Modem Pool Conference Test (#97)		X	D
Modem Pool Conversion Resource Loop Around Test (#98)	X	X	ND
Modem Pool Audits Test (#99)	X	X	ND

1 D = Destructive; ND = Nondestructive

Modem Pool NPE Crosstalk Test (#96)

This test is destructive.

This NPE Crosstalk Test verifies that the NPE is connected only to the desired time slot and is not crosstalking on other time slots. This test operates exactly like Test #6 for other types of port circuits but is performed twice in order to test both NPEs in the Modem Pool Port.

Table 11-226. TEST #96 Modem Pool NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Determine whether the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-226. TEST #96 Modem Pool NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Hardware Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Hardware Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Determine whether the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1020	ABORT	The test did not run due to a previously existing error on the specific port or because of a more general circuit pack error. 1. Examine the Hardware Error Log for existing errors against this port or the circuit pack, and attempt to diagnose the previously existing errors.
2000	ABORT	A response to the test request was not received within the allowable time period. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-226. TEST #96 Modem Pool NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
6000	ABORT	System resources needed to complete the test could not be allocated for the digital section of the Modem Pool conversion resource. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait one minute and attempt the test again. 2. If it is absolutely necessary to test the conversion resource, the call must be dropped by issuing a **busyout port PCSS** command against the conversion resource. Issue the **release port PCSS** command. The busyout and release of the port drop any existing calls on that port. 3. Run the test again. 4. If the same error occurs while the conversion resource is idle, busyout and release both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under test. This action drops any existing calls on that circuit pack. 5. If the test continues to abort, replace the Pooled Modem circuit pack and retest. 6. If the test continues to abort with this error code after circuit pack replacement, escalate the problem.
6001	ABORT	System resources needed to complete the test could not be allocated for the analog section of the Modem Pool conversion resource. 1. Follow the test procedures for the previous error code.

Continued on next page

Table 11-226. TEST #96 Modem Pool NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
NONE	FAIL	The test failed. This error is internal to the Pooled Modem circuit pack and does not involve external equipment or interfaces. 1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest. 3. If the circuit pack fails after replacement, escalate the problem.
ANY	FAIL	The NPE of the tested port was found to be transmitting in error. This condition causes noisy and unreliable connections. 1. If the remaining ports are currently not in use (that is, yellow LED is off), attempt to reset the circuit pack. Then repeat the test. 2. If the test fails again, replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Modem Pool Conference Test (#97)

This test is destructive.

This test checks most of the switching and gain control functions provided by the NPE circuit in the analog section of the conversion resource. This test conferences a 1004-Hz tone through the NPE, looping it back so that it can be verified with a Tone Detector circuit.

Table 11-227. TEST #97 Modem Pool Conference Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Determine whether the port is available for testing.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM Bus errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

4000	ABORT	System resources needed to complete the test could not be allocated. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait one minute and attempt the test again. 2. If it is absolutely necessary to test the conversion resource, the call must be dropped by issuing a **busyout port PCSS** command against the conversion resource. Issue the **release port PCSS** command. The busyout and release of the port drop any existing calls on that port. 3. Run the test again. 4. If the same error occurs while the conversion resource is idle, busyout and release both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under the test. This action drops any existing calls on that circuit pack. 5. If the test continues to abort, replace the Pooled Modem circuit pack and retest. 6. If the test continues to abort with this error code after circuit pack replacement, escalate the problem.
65515	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. Issue the **test port long** command on the port on which the test aborted. If any test aborted or failed, follow recommended maintenance strategy for the appropriate port type (for example, ANL-LINE, DIG-LINE). 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-227. TEST #97 Modem Pool Conference Test — *Continued*

Error Code	Test Result	Description/ Recommendation
NONE	FAIL	The test failed. This error is internal to the Pooled Modem circuit pack and does not involve external equipment or interfaces. 1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest. 3. If the circuit pack fails after replacement, escalate the problem.
ANY	FAIL	The Network Processing Element (NPE) of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. If the remaining ports are currently not in use (that is, yellow LED is off), attempt to reset the circuit pack. Then repeat the test. 2. If the test fails again, replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Modem Pool Conversion Resource Loop Around Test (#98)

The Modem Pool Conversion Resource Loop Around Test is set up as follows:

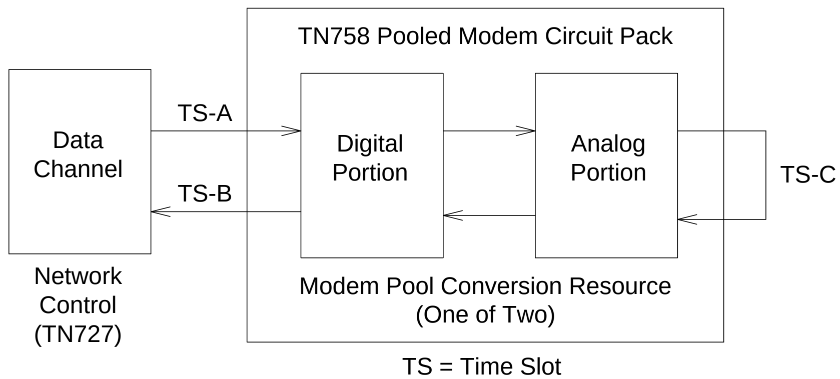

Figure 11-77. Modem Pool Conversion Resource Loop Around Test Set-up

Test data patterns are transmitted from the Network Control Channels 1 or 3 over network time slot A through the digital port, looped around through the analog port via time slot C back to the Network Control Channel circuit via time slot B where the patterns are checked for accuracy. Finally, the test forces a disconnect by breaking the connection between the Data Channel and Modem Pool Port (time slot A) and verifying that the Data Channel and Modem Pool Port go on-hook within the proper time.

This test attempts to allocate a Network Control Channel, Modem Pool Port, and other internal resources. If any of these allocation attempts fail, the test cannot be completed and a specific abort error is reported.

Table 11-228. TEST #98 Modem Pool Conversion Resource Loop Around Test

Error Code	Test Result	Description/ Recommendation
NONE	ABORT	Internal System Error. 1. Wait one-minute and try the test again. 2. If the error occurs again, escalate the problem.
5000	ABORT	System resources needed to complete the test could not be allocated for the digital section of the Modem Pool conversion resource. Ordinarily, this means the conversion resource or other hardware used during the test was in use. 1. Wait one minute and attempt the test again. 2. If it is absolutely necessary to test the conversion resource, the call must be dropped by issuing a **busyout port PCSS** command against the conversion resource. Issue the **release port PCSS** command. The busyout and release of the port drop any existing calls on that port. 3. Run the test again. 4. If the same error occurs while the conversion resource is idle, busyout and release both Modem Pool conversion resources on the TN758 Pooled Modem circuit pack containing the conversion resource under test. This action drops any existing calls on that circuit pack. 5. If the test continues to abort, replace the Pooled Modem circuit pack and retest. 6. If the test continues to abort with this error code after circuit pack replacement, escalate the problem.

Continued on next page

Table 11-228. TEST #98 Modem Pool Conversion Resource Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5001	ABORT	A Network Control Channel could not be allocated for this test. This error is more closely related to the Data Channels (1 or 3 only) on the DATA-CHL circuit pack used for this test than the TN758 Pooled Modem circuit pack itself. Therefore, any hardware testing or replacement activities focus on the DATA-CHL circuit pack. However, the Data Channels on the DATA-CHL circuit pack normally should not be busied out, tested with the **test data-module** command, or reseated in the carrier to clear this error, since this may drop other data calls that may be active at the time. The administration of Data Channels 1 and 3 should be checked if this error occurs. 1. Wait one minute and attempt the test again. 2. If the same error persists after five attempts at one-minute intervals, escalate the problem.
5002	ABORT	The Network Control Channel allocated for this test could not be set to "maintenance busy" status. 1. Follow the repair procedures for Error Code 5001.
5003	ABORT	The test was not able to establish a connection for the digital portion of the Modem Pool Port. 1. Follow the repair procedures for Error Code 5000.
5004	ABORT	The test was not able to allocate the analog portion of the Modem Pool Port. 1. Follow the repair procedures for Error Code 5000.
5005	ABORT	The test was not able to establish a connection for the analog portion of the Modem Pool Port. 1. Follow the repair procedures for Error Code 5000.

Continued on next page

Table 11-228. TEST #98 Modem Pool Conversion Resource Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5006	FIL	The Modem Pool Port did not respond to the "maintenance activate" message. This error is internal to the Modem Pool circuit pack and does not involve external equipment or interfaces. The test failed. This error is internal to the Pooled Modem circuit pack and does not involve external equipment or interfaces. 1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to fail, replace the Pooled Modem circuit pack and retest. 3. If the circuit pack fails after replacement, escalate the problem.
5007	ABORT	The Network Control Channel allocated for this test did not respond to the incoming call indication. 1. Follow the repair procedures for Error Code 5001.
5009	ABORT	The Network Control Channel allocated for this test did not handshake correctly. 1. Attempt the test again. 2. If the same error occurs, test the DATA-CHL circuit pack using the **test data-module** command (refer to the DATA-CHL maintenance strategy). 3. If the DATA-CHL circuit pack tests pass, escalate the trouble report.
5010	FAIL	The Data Loop Around Test failed, indicating a probable problem with the TN758 Pooled Modem circuit pack. 1. Follow the repair procedure for Error Code 5006.
5011	ABORT	The Network Control Channel allocated for this test did not disconnect properly. 1. Follow the repair procedures for Error Code 5001.
5012	ABORT	The digital portion of the tested Modem Pool Port did not disconnect properly. 1. Follow the repair procedures for Error Code 5000.

Continued on next page

Table 11-228. TEST #98 Modem Pool Conversion Resource Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5013	FAIL	The Modem Pool Port did not respond with an on-hook message when the connection to the Data Channel was broken, indicating a likely problem with the TN758 Pooled Modem circuit pack. 1. Follow the repair procedure for Error Code 5006.
5014	ABORT	The Network Control Channel allocated for this test did not respond correctly to the setup message sent to it after the connection was established. 1. Attempt the test again. 2. If the same error occurs, test the DATA-CHL circuit pack using the **test data-module** command (refer to the DATA-CHL maintenance strategy). 3. If the DATA-CHL circuit pack tests pass, escalate the problem.
5015	ABORT	Data Channels 1 and/or 3 have not been administered. 1. Administer the Data Channels and retest.

Modem Pool Audit Test (#99)

This audit updates the Modem Pool conversion resource status contained in the TN758 Pooled Modem circuit pack's microprocessor. It does not actually test the Pooled Modem circuit pack; therefore, there are no FAIL codes. The audit can only be performed on idle conversion resources. If the conversion resource is in use, the audit aborts.

Table 11-229. TEST #99 Modem Pool Audit Test

Error Code	Test Result	Description/ Recommendation
NONE	ABORT	The system was not able to allocate all the necessary resources to execute this test. An ABORT simply indicates that the conversion resource was in use when the audit was performed. No repair action is necessary unless it was known that the conversion resource was actually idle during the test (yellow in-use LED was off) or was busied out before the test was run. If this is the case, a TN758 failure condition may exist and the following procedure should be used: 1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource. 2. If the test continues to abort, replace the Pooled Modem circuit pack and retest. 3. If the circuit pack fails after replacement, escalate the problem.

M/T-ANL (Maintenance/Test Analog Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-ANL	Minor	test port PCSSpp l	Maintenance/Test Analog Port
M/T-ANL	Warning	release port PCSSpp	Maintenance/Test Analog Port

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The Maintenance/Test Analog Port is port number 1 on the TN771 Maintenance/Test circuit pack. This port is used by the Automatic Transmission Measurement System (ATMS) as an Originating Test Line (OTL) or Terminating Test Line (TTL) for test calls over analog trunks. Figure 11-78 shows a typical ATMS configuration.

M/T-ANL maintenance ensures that the analog trunk's testing function is operating correctly. An alarm against M/T-ANL can reduce service, but it will not block it. To accurately measure performance and health of analog trunks, the TN771 should be replaced when a new circuit pack is available.

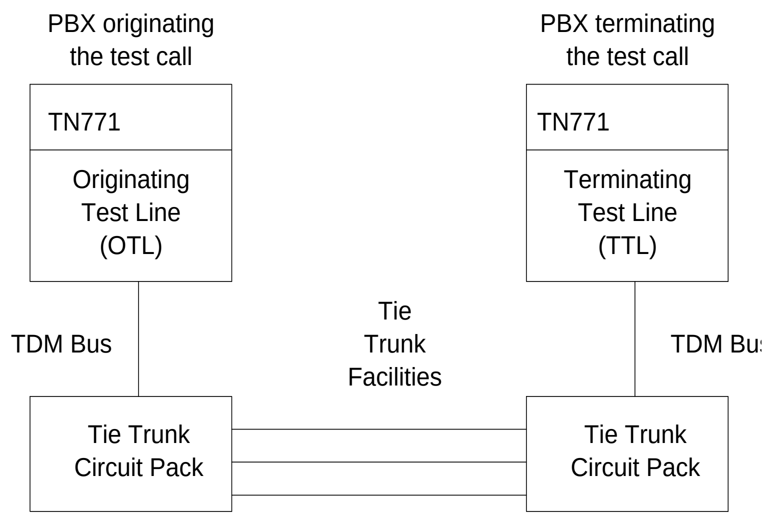

Figure 11-78. ATMS Tie Trunk Test Call

Hardware Error Log Entries and Test to Clear Values

M/T-ANL Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1] (a)	0	Any	Any	Any	test port PCSSpp
1 (b)	41018	none	MINOR	ON	test port PCSSpp l r 3
18	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
257	Any	NPE Crosstalk test (#9)	MINOR	ON	test port PCSSpp l r 3
513	Any	Analog Port Sanity Test (#963)	MINOR	ON	test port PCSS01 r 2
769	Any	Analog Port Digital Loop Around Test (#13)	MINOR	ON	test port PCSSpp r 3
3840(c)	Any	Hook State Inquiry test (#566)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error code appears in the Error Log only if the MTB circuit pack has been removed since the Error Log was last cleared. Verify that the circuit pack has been reinserted.

b. This error indicates a hardware failure on the Analog Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.

c. This error indicates that call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test Analog Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Analog Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Analog Port Sanity Test (#963)	X	X	ND
Digital Loop Around Test (#13)	X	X	ND
NPE Crosstalk Test (#9)		X	ND
Hook State Inquiry (#566)	X	X	ND
Clear Error Counters (#270)		X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections.

One or more Network Processing Elements (NPE) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete

Table 11-230. TEST #9 NPE Cross Talk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid ATMS trunk test call. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. A system is considered under heavy traffic when the Call Processing Occupancy is greater than 50% or when the System Management and the Call Processing Occupancies together exceed 65%. To view the system occupancy measurements enter the command **status system health** on the system technician terminal. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-230. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at 1 minute intervals a maximum of 3 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a valid ATMS test call. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-230. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. If the remaining ports are currently not in use (yellow LED is off), try to reset the circuit pack via the **busyout board PCSS**, **reset board PCSS**, **release board PCSS** command sequence. Then repeat the test. 2. If the test fails again, replace circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by examining station, trunk, or external wiring.

Analog Port Digital Loop Around Test (#13)

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Analog Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped

Table 11-231. TEST #13 Analog Port Digital Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The port is in use on a valid ATMS Test Call. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-231. TEST #13 Analog Port Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance to diagnose any active TDM-BUS errors. A system is considered under heavy traffic when the Call Processing Occupancy is greater than 50% or when the System Management and the Call Processing Occupancies together exceed 65%. To view the system occupancy measurements enter the command **status system health** on the system technician terminal. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the command at 1 minute intervals a maximum of 3 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid ATMS Test Call. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort and the port is not in use on a valid ATMS Test Call, escalate the problem. To determine whether the port is in use by an ATMS Test Call enter **status station ext** where **ext** is the assigned ATMS station number.

Continued on next page

Table 11-231. TEST #13 Analog Port Digital Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
7	FAIL	Conference test failed on the primary information channel. 1. Run the circuit pack tests to check the Tone/Clock (TONE-BD) circuit pack and the Tone Detector circuit pack via the **test board PCSS** command. 2. Resolve any problems that are detected on the Tone/Clock (TONE-BD) circuit pack or Tone Detector circuit pack. See the section on Tone Generator circuit pack. 3. If the Tone/Clock and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test circuit pack.
14	FAIL	The primary information channel is not transmitting properly. User may not notice any interruption in service or may not be able to use this port. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using **test board PCSS**. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. See the section on Tone Generator circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test Circuit Pack.
	PASS	The Maintenance/Test Analog Port analog trunk testing capability is operating correctly.

Clear Error Counters (#270)

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message will be sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared. This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel will send a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

Table 11-232. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
	PASS	The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Analog Port maintenance software and call processing agree on the on-/off-hook status of the Maintenance/Test Analog Port.

Table 11-233. TEST #566 Hook State Inquiry

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switch hook audit timed out. No response was received from the circuit pack for information about the switch hook state. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, replace the circuit pack and repeat the test. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	Internal System Error 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to fail reset the circuit pack via the **busyout board PCSS**, **reset board PCSS**, **release board PCSS** command sequence. 3. Retry the command at 1 minute intervals a maximum of 3 times. 4. If the test continues to fail, escalate the problem.
	PASS	Call processing and Maintenance/Test Analog Port maintenance software agree on the Maintenance/Test Analog Port hook state.

Analog Port Sanity Test (#963)

This test verifies that the port circuitry involved in the analog trunk testing on the Maintenance/Test Analog Port is functioning properly.

This test will abort if an ATMS Test Call is in progress on the Maintenance/Test Analog Port when the test is requested.

Table 11-234. TEST #963 Analog Port Sanity Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at 1 minute intervals a maximum of 3 times. 2. If the test continues to fail, escalate the problem.
50	FAIL	The switch was unable to communicate with the port circuitry used for analog trunk testing. 1. Reset the circuit pack via the **busyout board PCSS**, **reset board PCSS**, **release board PCSS** command sequence. 2. Test the port again via the **test port PCSS01 l** command. 3. If the test fails again, replace the circuit pack.
	PASS	The Maintenance/Test Analog Port analog trunk testing capability is operating correctly.

M/T-BD (Maintenance/Test Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-BD	MIN	test board PCSS l	Maintenance Test Circuit Pack
M/T-BD	WRN	release board PCSS	Maintenance/Test Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

CAUTION:

In G3iV1.1-286 and G3iV2-386, a TN771D (or later vintage) Maintenance/Test circuit pack must be used.

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also M/T-DIG (Maintenance/Test Digital Port) and M/T-PKT (Maintenance/Test Packet Bus Port) Maintenance documentation for related digital port and Packet Bus port information, respectively.

M/T-DIG (Maintenance/Test Digital Port) [G3iV1-1.286, G3iV2-386]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-DIG	Minor	test port PCSSpp l	Maintenance/Test Digital Port
M/T-DIG	Warning	release port PCSSpp	Maintenance/Test Digital Port

1 Where P is the port network number (1 for PPN, 2 or, 3 for EPN-1 and 3 for EPN-2); C is the carrier designation (A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Maintenance/Test Digital Port is a port on the TN771D (or later vintage) Maintenance/Test circuit pack, which is required for G3iV1.1-286 or G3iV2-386. Ports 2 and 3 are Digital Ports. The Maintenance/Test Digital Port provides the ability to perform digital (that is, ISDN-PRI) trunk testing via the TDM Bus. For an ISDN-PRI test call, connections are set up in the system as shown in Figure 11-79.

When the Maintenance/Test Digital Port is participating in an ISDN-PRI test call, the port sends a stream of pseudo-random data along the connected B-channel. The far end loops back this data, and the Maintenance/Test Digital Port compares the data to that which was sent. Errors are recorded on a bit and block basis. Refer to ISDN-TRK (DS1ISDN Trunk) Maintenance documentation for more information on ISDN-PRI test calls.

The Maintenance/Test Digital Port maintenance ensures that the digital trunk testing function is operating correctly. The Maintenance/Test Digital Port is alarmed if maintenance determines that the digital port is operating incorrectly.

NOTE:
An alarm on the Maintenance/Test Digital Port reduces service, but does not block it since the ISDN-TRK has other means to determine the health of the ISDN-PRI trunk facility. However, to accurately measure the error performance and to ensure accuracy of the health of the ISDN-PRI trunk, the Maintenance/Test circuit pack should be replaced when a new circuit pack is available.

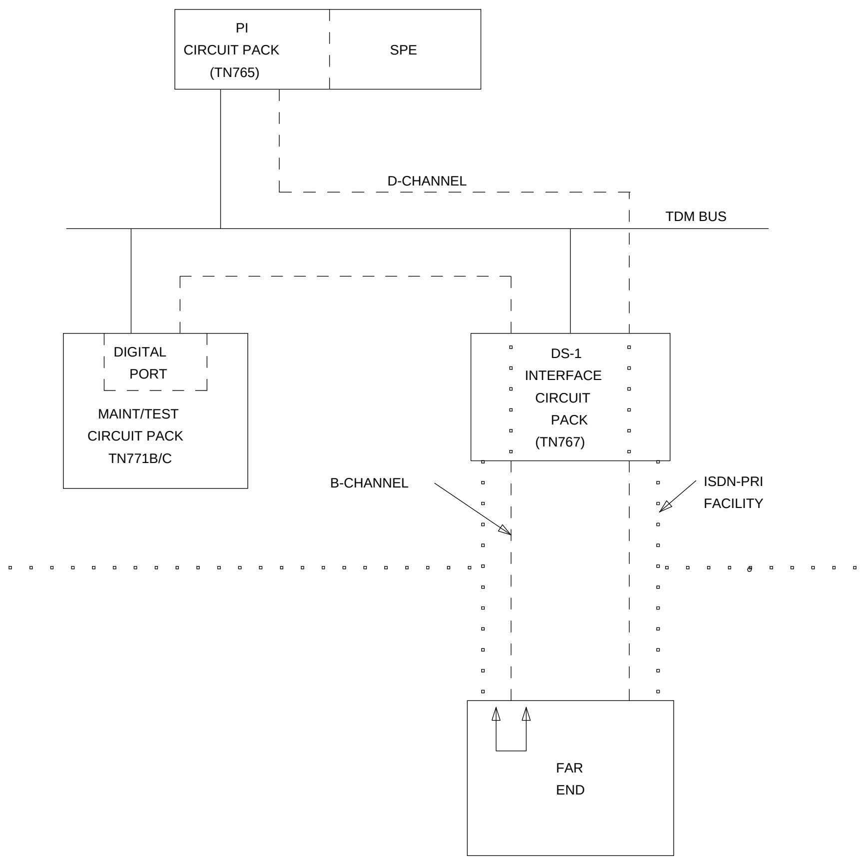

Figure 11-79. ISDN-PRI Outgoing Test Call

Hardware Error Log Entries and Test to Clear Values

M/T-DIG Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp
1 (a)	41018	none	MINOR	ON	test port PCSSpp l r 3
18 (b)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
257 (c)	Any	NPE Crosstalk Test (#9)	MINOR	ON	test port PCSSpp l r 3
513 (d)	Any	Digital Port Sanity Test (#565)	MINOR	ON	test port PCSS02 r 2
769 (e)	Any	Digital Port Loop Around Test (#13)	MINOR	ON	test port PCSSpp r 3
3840 (f)	Any	Hook State Inquiry Test (#566)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates a hardware failure on the Digital Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.

b. The port has been busied out via the **busyout port PCSSpp** command.

c. This error indicates that Maintenance/Test Digital Port is talking on more than just its assigned time slot. Replace the Maintenance/Test circuit pack.

d. This error indicates that the Maintenance/Test Digital Port has failed its self-test. Since the Digital Port Sanity Test runs only on Port 2, but tests both Ports 2 and 3, both ports are alarmed when the test fails. Note that the command above indicates to test Port 2, even if the error is logged against Port 3.

e. This error indicates that the Maintenance/Test Digital Port has been unable to successfully loop data from a tone generator to a tone detector.

f. This error indicated that call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test Digital Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Digital Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Digital Port Sanity Test (#565)	X	X	ND
Digital Port Loop Around Test (#13)	X	X	ND
NPE Crosstalk Test (#9)		X	ND
Hook State Inquiry (#566)	X	X	ND
Clear Error Counters (#270)		X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance.

One or more NPE reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete. This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance.

Table 11-235. TEST #9 NPE Cross Talk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid ISDN-PRI test call. Use the **list isdn-testcall** command to determine if the port is in use (if the port is listed in the M/T Port column). If it is in use, either wait for the test call to complete (as indicated in the Start Time and Duration fields in the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where **tg/mem** is determined from the B-channel field of the above display. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-235. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out of service due to TDM-BUS errors. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a valid ISDN-PRI test call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where tg/mem is determined from the B-channel field of the above display. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.

Continued on next page

Table 11-235. TEST #9 NPE Cross Talk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. If the remaining ports are currently not in use (yellow LED is off), try to reset the circuit pack. Then repeat the test. 2. If the test fails again, replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Digital Port Loop Around Test (#13)

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Digital Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped.

Table 11-236. TEST #13 Digital Port Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The port is in use on a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields in the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where tg/mem is determined from the B-channel field of the above display. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-236. TEST #13 Digital Port Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where tg/mem is determined from the B-channel field of the above display. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.

Continued on next page

Table 11-236. TEST #13 Digital Port Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
7	FAIL	Conference test failed on the primary information channel. In most cases, the user may not notice a disruption in service. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack via the **test board PCSS** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test circuit pack.

Continued on next page

Table 11-236. TEST #13 Digital Port Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
14	FAIL	The primary information channel is not transmitting properly. User impact may range from nothing to not being able to use this port. 1. Run the circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using **test board PCSS**. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test Circuit Pack.
	PASS	The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message is sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared.

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel sends a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

Table 11-237. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.

Digital Port Sanity Test (#565)

This test verifies that the port circuitry involved in the digital trunk testing on the Maintenance/Test Digital Port is functioning properly. This circuitry is common to both Maintenance/Test Digital Ports on the Maintenance/Test circuit pack. Therefore, this test is only run for Port 2. The test aborts when run on Port 3, as described in Table 11-238.

This test operates by connecting the two Maintenance/Test Digital Ports on the TDM Bus so that they talk and listen to each other. Then four self-tests are attempted: (a) sending data from Port 2 to Port 3 in asynchronous mode; (b) sending data from Port 3 to Port 2 in asynchronous mode; (c) sending data from Port 2 to Port 3 in synchronous mode; and (d) sending data from Port 3 to Port 2 in synchronous mode. The test passes if all four of these self-tests are successful. The test stops as soon as any one of these self-tests fails.

This test aborts if an ISDN Test Call is in progress on either Maintenance/Test Digital Port when the test is requested, or if an ISDN Test Call is initiated while the Digital Port Sanity Test is in progress.

Table 11-238. TEST #161 Loop Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	One of the Maintenance/Test Digital Ports is busy with background maintenance. 1. Either wait for the port to become idle, or busyout both Maintenance/Test Digital Ports on the Maintenance/Test circuit pack via the **busyout port PCSS02** and **busyout port PCSS03** commands, respectively. 2. Release the ports (if they were busied out) via the **release port PCSS02** and **release port PCSS03** commands, respectively. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-238. TEST #161 Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. Refer to the TDM-BUS Maintenance documentation to diagnose any active TDM Bus errors. 1. If the system has no TDM-BUS errors, and if not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid ISDN-PRI Test Call. Use the **list isdn-testcall** command to determine which call is using the port (from the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where **tg/mem** is determined from the B-channel field of the above display.
1019	ABORT	An ISDN Test Call is in progress using this Maintenance/Test circuit pack. The Maintenance/Test circuit pack cannot perform a self-test on one of its Digital Ports while an ISDN Test Call is using either of the Digital Ports. Use the **list isdn-testcall** command to determine which call is using the port (form the M/T Port column). Either wait for the test call to complete (as indicated in the Start Time and Duration fields of the above display), or abort the test call with the **clear isdn-testcall tg/mem** command, where **tg/mem** is determined from the B-channel field of the above display. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1138	ABORT	This test does not run on Port 3 of the Maintenance/Test circuit pack. This test runs only on Port 2. Look at the results of the Digital Port Sanity Test for Port 2. 1. Run the command again for Port 2 via the **test port PCSS02** or **test port PCSS02 l** command.

Continued on next page

Table 11-238. TEST #161 Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-238. TEST #161 Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
50	FAIL	The switch was unable to communicate with the port circuitry used for digital trunk testing.
100	FAIL	Data was not sent from Port 2 to Port 3 successfully in asynchronous mode.
101	FAIL	Data was not sent from Port 3 to Port 2 successfully in asynchronous mode.
102	FAIL	Data was not sent from Port 2 to Port 3 successfully in synchronous mode.
103	FAIL	Data was not sent from Port 3 to Port 2 successfully in synchronous mode. 1. Reset the circuit pack via the **busyout board PCSS**, **reset board PCSS**, **release board PCSS** command sequence. 2. Test the port again via the **test port PCSS02 l** command. 3. If the test fails again, replace the circuit pack.
	PASS	The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Digital Port maintenance software and call processing agree on the on-/off-hook status of the Maintenance/Test Digital Port.

Table 11-239. TEST #161 Loop Around Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switch hook audit timed out. No response was received from the circuit pack for information about the switch hook state. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, replace the circuit pack and repeat the test. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	Internal System Error. This test should never return a failure. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail reset the circuit pack via the **busyout board PCSS**, **reset board PCSS**, **release board PCSS** command sequence. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to fail, escalate the problem.
	PASS	Call processing and Maintenance/Test Digital Port maintenance software agree on the Maintenance/Test Digital Port hook state.

M/T-PKT (Maintenance/Test Packet Bus Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
M/T-PKT	Minor	test port PCSSpp l	Maintenance/Test Packet Bus Port
M/T-PKT	Warning	release port PCSSpp	Maintenance/Test Packet Bus Port

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Maintenance/Test Packet Bus Port is a port (always Port #4) on the TN771D (or later vintage) Maintenance/Test circuit pack, which is required for G3iV1.1-286 or G3iV2-386. The Packet Bus port provides the following Packet Bus maintenance functions:

- Packet Bus fault detection - the ability to detect faults (for example, shorts, open leads) on the Packet Bus autonomously (that is, without SPE involvement).
- Packet Bus reconfiguration - the ability to swap faulty leads with spare leads autonomously so that the Packet Bus remains operational. This is accomplished by sending messages to all Packet circuit packs [for example, ISDN-BRI (TN556)] telling them which spare leads to use on the Packet Bus.

Maintenance/Test Packet Bus Port maintenance ensures that these maintenance functions are operating correctly. The Maintenance/Test Packet Bus Port is alarmed if maintenance determines that the port's maintenance functions are operating incorrectly.

When Maintenance/Test Packet Bus Port maintenance determines that the Packet Bus Port is defective, the Packet Bus fault detection and Packet Bus reconfiguration functions provided by the port are turned off.

Maintenance/Test Packet Bus Port maintenance interacts with Packet Bus maintenance. Therefore, there may be alarms on the Packet Bus when there is a fault on the Maintenance/Test Packet Bus Port. Refer to PKT-BUS (Packet Bus) Maintenance documentation for further information.

Hardware Error Log Entries and Test to Clear Values

M/T-PKT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp
1 (a)	41018	none	MINOR	ON	test port PCSSpp l r 3
18 (b)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
257 (c)	Any	none	MINOR	ON	
513 (d)	Any	Packet Bus Port Health Inquiry Test (#567)	MINOR	ON	test port PCSSpp r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error indicates a hardware failure with the port circuitry which provides the Packet Bus maintenance functions. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the test command above.

b. The port has been busied out via the **busyout port PCSSpp** command.

c. This error indicates that the Maintenance/Test Packet Bus Port has reconfigured the Packet Bus (that is, swapped a bad lead to a spare). Note that this error is sent up whenever the Maintenance/Test Packet Bus Port is initialized (since the Packet Bus Port reconfigures the Packet Bus to whatever state it determines the Packet Bus is in). This occurs if the circuit pack is inserted, if the system is restarted, or if the port is released from a busyout state. Therefore, it is normal for this error to be present in the error log.

   If the Maintenance/Test Packet Bus Port reconfigures the Packet Bus 12 times within 15 minutes, a Minor alarm is raised. When the Minor alarm is raised, this is an indication that the Packet Bus maintenance functions are not operating correctly, or that many changes are taking place on the Packet Bus (that is, circuit pack insertion or removal). If the system has been in a stable state for more than 15 minutes, try the following procedures:

   1. Reset the Maintenance/Test circuit pack from the Manager I terminal, as follows:

      ■ Enter the **busyout board PCSS** command.

- Enter the **reset board PCSS** command.
- Enter the **release board PCSS** command.

2. Wait 15 minutes.
3. If the error recurs, replace the Maintenance/Test circuit pack.

When this alarm is active, the yellow LED is in one of three states:

- If there is no activity on the Maintenance/Test circuit pack, the yellow LED is off. It is OK to replace the Maintenance/Test circuit pack.
- If there is an indication of an uncorrectable fault on the Packet Bus, the yellow LED will be blinking at a rate of 1 Hz. It is OK to replace the Maintenance/Test circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
- If there is other activity on the Maintenance/Test circuit pack (that is, ISDN Test Call), or if there is an indication of a correctable fault on the Packet Bus, the yellow LED will be on steady. If there is an ISDN Test Call in progress, it must be halted via the **clear isdn-testcall grp/member** command prior to replacing the circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.

d. This error indicates a failure of the Packet Bus Port Health Inquiry Test. Either the Packet Bus Port has reported a self-test failure, or the SPE is able to communicate with the Maintenance/Test Circuit Pack but not with the Maintenance/Test Circuit Pack Packet Bus Port. Refer to the description of the Packet Bus Port Health Inquiry Test, and follow the instructions indicated for the failure code that matches the Aux Data field.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Packet Bus Port Health Inquiry Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Bus Port Health Inquiry Test (#567)	X	X	ND
Clear Error Counters (#270)		X	ND

1 D = Destructive; ND = Nondestructive

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that CCMS (Control Channel Message Set) messages are not continuously sent uplink. Using this method, the message are sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared.

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel sends a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test circuit pack. Therefore, this test should never abort or fail.

Table 11-240. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.

Packet Bus Port Health Inquiry Test (#567)

This test verifies that the Packet Bus fault detection maintenance function of the Maintenance/Test Packet Bus Port is functioning properly. This is done by having the Maintenance/Test Packet Bus Port perform a self-test. If this self-test passes, then the Packet Bus Port Health Inquiry Test passes. If the self-test fails, or the SPE cannot communicate with the Maintenance/Test Packet Bus Port, then the test fails.

Table 11-241. TEST #567 Packet Bus Port Health Inquiry Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources necessary to run this test are not available.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2059	FAIL	The Maintenance/Test Packet Bus Port has reported a failure of the on-board self-test.
2060	FAIL	The Maintenance/Test Packet Bus Port has reported an invalid state for the Packet Bus.
2061	FAIL	The SPE cannot communicate with the Maintenance/Test Packet Bus Port, but is able to communicate with the Maintenance/Test Circuit Pack. 1. Retry the command. 2. If the test continues to fail, replace the Maintenance/Test circuit pack and retry the command. 3. If the test continues to fail, refer to PKT-BUS Maintenance documentation to determine if the M/T-PKT failure is being caused by a Packet Bus fault.
	PASS	The Maintenance/Test Packet Bus Port Packet Bus fault detection capability is operating correctly.

OPS-LINE (DS1 OPS Line)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
OPS-LINE	MINOR	test station <ext> l	DS1OPS Line
OPS-LINE	WARNING	test station <ext>	DS1OPS Line

An analog Off-Premises Station (OPS) can be connected to the system through a DS1 link. A TN767 DS1 Interface circuit pack supports up to 24 DS1OPSs. Since the DS1OPS is an analog telephone set, a channel multiplexer is necessary as the remote DS1 endpoint that converts the digital signal of a DS1 port to the OPS Line and vice versa. See Figure 11-80 for details.

The DS1OPS Line Maintenance provides a strategy to maintain an OPS Line via a port of the DS1 Interface circuit pack. The strategy covers initialization tests, periodic tests, system technician-demanded tests, and alarm resolution and escalation. Two service states are specified in a DS1OPS Line maintenance. They are: *out-of-service* in which the line is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the line is in an activated state and can be used for both incoming and outgoing calls. If the DS1 Interface circuit pack is out-of-service, then all lines on the DS1 Interface circuit pack are put into the out-of-service state, and a Warning alarm is raised.

For maintenance of the remote DS1 endpoint (for example, Channel Division Multiplexer, D4 Channel Bank), refer to the maintenance documentation from its vendor for details.

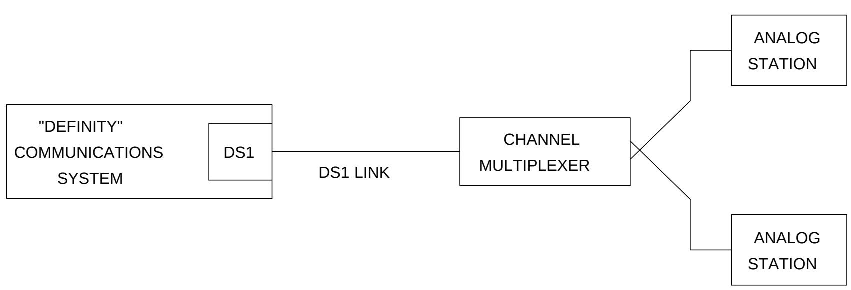

Figure 11-80. DS1 OPS Line Interactions

Hardware Error Log Entries and Test to Clear Values

DS1 OPS Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test station <ext> sh r 1
15 (a)	Any	Audit and Update Test (#36)			
18 (b)	0	busyout station <ext>	WARNING	OFF	release station <ext>
130 (c)		None	WARNING	ON	test station <ext>
1281		Conference Circuit Test (#7)	MINOR	ON	test station <ext> l
1537		NPE Crosstalk Test (#6)	MINOR	ON	test station <ext> l
1793 (d)					test circuit pack PCSS l

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

b. The DS1OPS Line has been busied out by a **busyout station <ext>** command. No calls can be made on this line.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. Error Type 1793 indicates a problem with the DS1 Interface circuit pack. Since there is no error against the OPS-LINE port, no alarm is raised against the OPS-LINE port. However, there should be errors logged against the DS1 Interface circuit pack. Look for DS1-BD errors in the Hardware Error Log and follow procedures provided in the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1OPS Switchhook Inquiry Test (#312)	X	X	ND
Audit and Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-242. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test or an internal system error (software) occurred. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-242. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The test was aborted because the port was seized by a user for a valid call. Use **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an an already existing error on the specific port or due to a more general error on the circuit pack. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. (Error code 1793 indicates a problem with the DS1 interface board, and any problems on the associated DS1-BD or UDS1-BD should be resolved first.)

Continued on next page

Table 11-242. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The test failed. This can be due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and to the TONE-PT Maintenance documentation. 2. Retest when the faults from step 1 are cleared.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 11-242. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 11-243. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1002	ABORT	The test was aborted because the system could not allocate time slots for the test. The system might be under heavy traffic conditions, or it might have time slots out of service due to TDM-BUS errors. (The **status health** command may be used to determine whether the system is experiencing heavy traffic.) Refer to the TDM-BUS (TDM bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors, is not handling heavy traffic, and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-243. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use **status station** or **status trunk** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1018	ABORT	The test was disabled via translation. 1. You may want to determine why the test has been disabled before you enable it. 2. To enable the test for the particular analog station being tested, enter the 'change station extension' command, and then change the 'Test' field on the 'Station' form from 'n' to 'y.'

Continued on next page

Table 11-243. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to an already existing error on the specific port or due to a more general error on the circuit pack. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. (Error code 1793 indicates a problem with the DS1 interface board, and any problems on the associated DS1-BD or UDS1-BD should be resolved first.)
2000	ABORT	The test was aborted because response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-243. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the **list configuration board PCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the far-end PBX. Make sure that the near-end and far-end switches and any NTCE equipment (the CSUs) have the correct administration.

Continued on next page

Table 11-243. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(con't.)*	6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Table 11-243. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 11-244. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the station extension of the port. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port is idle, retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-244. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The test was aborted because the station is out of service. This condition may be accompanied by an error type 18 entry in the error log. You may want to determine why the station was taken out of service. (When stations are taken out of service by maintenance software, the problems that preceded that point must be cleared.) 1. Use the **status station** command to check the service state of the port. If the port is indeed out of service, enter the **release station** command to bring the station back into service. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort and the service state indicates that the station is in service and idle, escalate the problem.
2000	ABORT	The test was aborted because response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first. 3. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-244. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7 or 8	FAIL	Test failed due to internal system error. Do not replace port board. ■ Error code 7: the failure occurred during station translation download (to DS1 Interface circuit pack). ■ Error code 8: the failure occurred during station ringer update. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

DS1 OPS Switchhook Inquiry Test (#312)

This test initiates the Switchhook Audit Test. The test queries the switchhook state of the Off-Premises-Station in switch software. If the state in switch software disagrees with the state on the DS1 Interface circuit pack. The state in the switch software is updated to match the state on the DS1 Interface circuit pack.

Table 11-245. TEST #312 DS1OPS Switchhook Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status station** command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1005	ABORT	Test failed due to incompatible configuration administered in station administration. 1. Verify the station administration is the station assigned to Port 24 of the DS1 Interface circuit pack while common channel signaling is specified.
1006	ABORT	The test was aborted because the station is out of service. This condition may be accompanied by an error type 18 entry in the error log. You may want to determine why the station was taken out of service. (When stations are taken out of service by maintenance software, the problems that led up to that must be cleared.) 1. Use the **status station** command to check the state of the port. If the port is indeed out of service, enter the **release station** command to bring the station back into service. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, and the station is in the in-service/idle state, escalate the problem.

Continued on next page

Table 11-245. TEST #312 DS1OPS Switchhook Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for DS1-BD errors in Hardware Error Log. If present, refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
2000	ABORT	The test was aborted because response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test aborts with error code 2000 again, run short test sequence on the associated DS1-BD or UDS1-BD. If tests 138 through 145 on the associated DS1-BD or UDS1-BD are also aborting with error code 2000, hyperactivity on the board or facility is indicated. In this case, the hyperactivity problem should be dealt with first. 3. If the test continues to abort and the board is OK, escalate the problem.
2012	ABORT	The test was aborted due to a system error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-245. TEST #312 DS1OPS Switchhook Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Internal System Error. 1. Look for DS1-BD errors in the Hardware Error Log. If present, refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation. 2. If a channel multiplexer is used as the remote DS1 endpoint to which the station connects, refer to the multiplexer vendor's maintenance document for diagnosis. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to fail, escalate the problem.
	PASS	The station hook states in both switch software and DS1 Interface circuit pack are consistent.
0 2012	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

PDMODULE, TDMODULE (Data Module)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
PDMODULE[2,3]	MINOR	test port PCSSpp l	Processor Data Module
PDMODULE	WARNING	test port PCSSpp sh	Processor Data Module
TDMODULE[2,3]	MINOR	test port PCSSpp l	Trunk Data Module
TDMODULE	WARNING	test port PCSSpp sh	Trunk Data Module

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

2 The DTDM is considered to be part of the DIG-LINE MO. Refer to the Digital Line testing section for DTDM or linked Data Adapter (DA) failures.

3 Some of the alarms that are logged due to PDMODULE and TDMODULE test failures may be related to circuit pack problems reported during the Common Port Circuit Pack testing phase. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for information about testing the Digital Line circuit packs.

As illustrated in Figure 11-81, data modules provide an interface between the system TN754, TN784, TN413 [G3iV2-386], or TN754 [G3iV2-386] Digital Line circuit pack and data equipment such as terminals, host computers, and modems. Data modules are used for both dial-up and permanent circuit-switched data calls. DA data modules provide this interface when the system uses a TN2136 [G3iV2-386] Digital Line circuit pack.

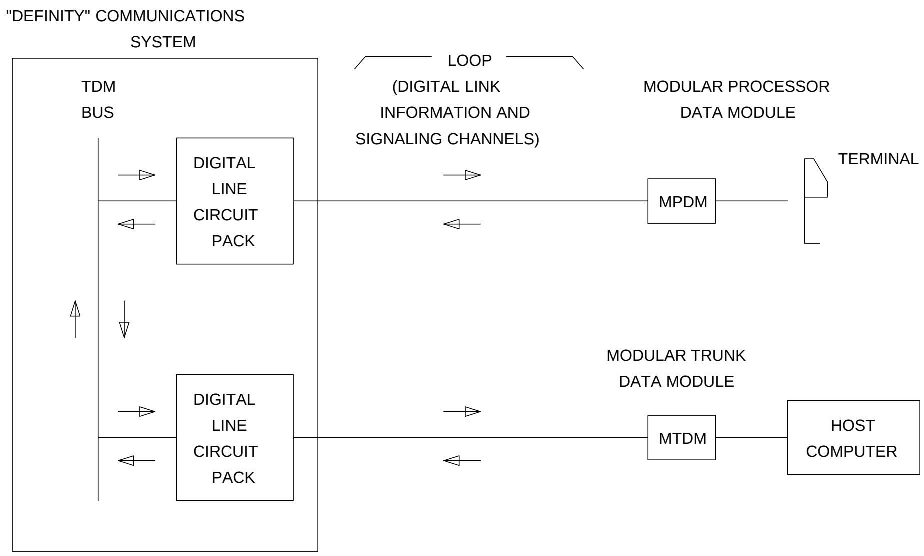

Figure 11-81. Typical Data Module Application

The MPDM provides an interface for Data Terminal Equipment (terminals), and the MTDM (see Note) provides an interface for Data Communications Equipment (transmission equipment such as modems).

NOTE:
Early versions of these data modules were referred to as PDMs and TDMs, respectively. Later models are designed to provide various customer interfaces through the use of interchangeable interface modules and, therefore, are called modular data modules. Both versions are supported by the tests described in this section.

The PBX loop or digital link between a data module and the Digital Line port supports two logical information channels and one signaling channel. MPDMs and MTDMs use the primary information channel for data communications and the signaling channel for dialing and call supervision. The secondary information channel can be used to support a second data module on a shared digital port.

Data modules are not only used for data calls between terminals, computers, and data communications equipment, but are also used as interfaces to equipment associated with system features such as System Administration, CDR, MCS, ACD, DCS, and AUDIX. Maintenance tests for data modules associated with those services are covered by tests other than those described here. (See PI-LINK, PMS-PRNT/JNL-PRNT, and PMS-LINK Maintenance documentation.)

Maintenance of MPDMs and MTDMs is closely related to, and interacts with, the Digital Line circuit pack maintenance in some instances and some of the results of testing MPDMs and MTDMs may be affected by the health of the Digital Line circuit pack. This interaction should be kept in mind when investigating the cause of reported data module problems.

Data modules provide a variety of option switches to allow the customer to select data rates, parity, keyboard dialing, local, and remote loop back, etc. An incorrect setting of those switches does not affect error and alarm information or test results described in this section, but it may result in an inoperable condition. Refer to the Installation Manual provided with the data module for more information about those options.

The DA data module provides an AT (Hayes) type interface that allows the customer to select data rates, parity, local, interface mode (**linked** to digital phone or **stand-alone**), and remote loop back, etc. An incorrect selection does not affect error and alarm information or test results described in this section, but it may result in an inoperable condition.

There are instances in this document where the service state of a data module is mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- Out-of-Service—The port, and thus the data module, have been removed from service. A busyout of a port or removal of the associated Digital Line circuit pack causes the data module to be placed in the out-of-service state. Failure of the NPE Crosstalk Test (Test #9) also takes a port out-of-service.
- Disconnected—The port is administered but the associated digital link does not respond. An administered port is put in a disconnected state after system booting or circuit pack insertion, until a "link reset pass" message is received from firmware on the associated circuit pack.
- In-Service—Once the PBX software has received a "link reset pass" message from the Digital Line port, the port is placed in the in-service state. In case the "link reset pass" message is missed, and an off-hook message is received while the port is in the disconnected state, maintenance software runs an ID request test and the port is put back in service if a correct response is received.

  If the link is disconnected, the port returns to the disconnect state. Note that it takes a few minutes (less than five) for the state of a data module port to change from in-service to disconnected after the data module is disconnected from the local PBX loop.

Hardware Error Log Entries and Test to Clear Values

PDMODULE and TDMODULE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	40987	None	WARNING	OFF	
1 (b)	1 to 20	None	WARNING	OFF	
15 (c)	Any	None			
18 (d)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
257 (e)	40971	None			
513[2]	0	Data Module Audits Test (#17)	WARNING (j)	OFF	test port PCSSpp sh r 6
769 (f)	40988	None	WARNING	OFF	
1281	Any	Data Module Audits Test (#17)	WARNING	OFF	test port PCSSpp sh r 4
1537 (g)	40968	None	WARNING	OFF	
1793		Information Channel and Control Channel Loop Around Test (#13)	MINOR	ON	test port PCSSpp l r 3
2049		NPE Crosstalk Test (#9)	MINOR	ON	test port PCSSpp l r 3
2305 (h)	32770	None			
2305 (i)	40967	None			
2561		Data Module Internal Loop Around Test (#175)	WARNING	OFF	test port PCSSpp l r 5
2817 (k)		Link GPP Loop (183) Against Links	MAJOR	ON	
3841 (l)		NONE			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 G3iV1.1-286 and G3iV2-386 only.

Notes:

a. Could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for faulty wiring, check for a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 60 minutes.

   The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

   NOTE:
   Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111.

b. This error type and auxiliary data occur when at least 15 off-board problems have been detected with the link to the data module. When an error with the link is detected, an on-board counter is incremented.

   The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for faulty wiring, check for a faulty data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see the next Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 60 minutes.

   The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

   NOTE:
   Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111.

c. This is an internal type error that occurs when an audit request fails.

d. This error type is logged when the port in question is busied out by maintenance personnel. Make sure that the port is released from busyout.

e. There are problems with transmitting to the data module. This is usually an on-board problem and can be ignored if no user complaints are received. Otherwise, check for faulty wiring.

f. This error indicates that EPF has been turned off due to the overcurrent condition at the data module. Make sure that the data module is connected. Look for faulty wiring or a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see Note). If the problem still exists, it may be due to the fact that the PTC is in the "tripped" position due to a short on the power line. This can be corrected by removing the short, unplugging the data module from the wall for about 30 seconds, and plugging it back in. If the problem persists, replace the Digital Line circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined period of time since this counter uses a "leaky bucket" strategy.

   The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

   NOTE:
   Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111.

g. An in-line maintenance error has generated an off-board warning due to some problem with the link to the data module. This can be ignored if no user complaints are received. Otherwise, make sure the data module is connected, check for faulty wiring, check for a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire, see Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 90 minutes.

   The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

   NOTE:
   Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring,* 555-204-111.

h. This indicates that the data equipment went off-hook while the associated link was being initialized (in a disconnected state). Use the **status data-module** command to determine the state of the data module. The off-hook should have changed the service state to in-service. No system technician action is necessary.

i. This is the resulting code that is generated when the link between the circuit pack and the data module is successfully reset. The link is normally reset when the circuit pack associated with an administered port is first plugged in (assuming that the data module is already in place and connected to the associated port), when a port is first administered (assuming the associated circuit pack is plugged in and that the data module is connected to the associated port), or when a data module is first connected to an administered port. No system technician action is necessary.

j. This warning off-board alarm occurs only for G3iV1.1-286 or G3iV2-386. The alarm occurs when it appears to the system that a DCP endpoint has been disconnected.

k. A DCP endpoint may have been disconnected.

l. This endpoint is part of processor link. Link initialization has failed (or demand test for #183 for PI links has failed) and is indicating the associated PDM as the cause. Check the PDM, the wiring to the PDM and the link to the far end (i.e. AUDIX DCS, etc.) to resolve the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Data Module Internal Loop Around Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Data Module Internal Loop Around Test (#175)		X	ND
Network Processing Element Crosstalk Test (#9)		X	ND
Information and Control Channel Loop Around Test (#13)		X	ND
Data Module Audits Test (#17)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. If a secondary data module is assigned, it is tested after the primary data module. If either test fails, both data modules are taken out of service This test usually runs only during the Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-246. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. 1. Check the port status. Use the **display port PCSSpp** command to determine the station extension of the port. Use the **station status** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for this test. You must wait until the port is idle. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the extension of the data module port. Use the **status data-module** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states). You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-246. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	System resources to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-246. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port may be busy with a valid call. Use the **display port PCSSpp** command to determine the extension of the data module port. Use the **status data-module** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states). You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	Test disabled via background testing. Use **status data-module** command to determine when the data module is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.
2020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-246. TEST #9 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
1,2	FAIL	The NPE of the tested port was found to be transmitting in Error Log. This causes noisy and unreliable connections. Failure Code 1 indicates that the Crosstalk Test failed on the primary channel. Failure Code 2 indicates that the Crosstalk Test failed on the secondary channel. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times and verify that it continues to pass. 2. If complaints still exist, examine the data module, connections, and wiring.

Information and Control Channel Local Loop Test (#13)

This is a set of four tests that check the operation of the information and control channels used between the SPE and the Digital Line port circuit.

NOTE:
This is an Internal Loop Around test only and does not check building wiring. Use Test #175 for external loop around tests to the data module.

1. The SPE first sends a message to the on-board microprocessor to loop around both the information and control channels for the port. Then, the primary information channel loop back test is run. The test is performed by sending a digital count from the Tone-Clock circuit pack on the primary channel time slot and receiving the same digital count with a GPTD. The digital count looks like transparent data to the on-board microprocessor.
2. With the port still in loop around mode, the S channel Loop Around Test is performed next. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.
3. The third test is a Loop Around Test for the secondary (alternate) channel. It is not performed for data modules since this channel is not used by MPDMs, MTDMs, and stand-alone DA's [G3iV2-386].
4. A Conference Test is done next for the primary channel. This test is the same as the Analog Line Terminal/Port Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of four tests run. If any test fails or aborts, the sequence is stopped.

Table 11-247. TEST #13 Information and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-247. TEST #13 Information and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the command at one-minute intervals for a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the data module extension. Then use **status data module** command with the extension number to determine the service state of the data module. If the service state indicates that the data module is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-247. TEST #13 Information and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2001	ABORT	System resources required to run this test are not available. 1. Retry the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Rerun the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2500	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
15	FAIL	The control channel between the processor and Digital Line circuit pack is not transmitting properly. This can cause a wide range of effects. The user may notice nothing or the port may be totally unusable. This could also disrupt other users. 1. Run circuit pack tests to check the Tone Generator and the Tone Detector circuit packs using the **test board UUCSS short** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.

Continued on next page

Table 11-247. TEST #13 Information and Control Channel Local Loop Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference test failed on the primary information channel. In some cases, user may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary information channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.
15	FAIL	The control channel between the processor and Digital Line circuit pack is not transmitting properly. This can cause a wide range of effects. The user may notice nothing or the port may be totally unusable. This could also disrupt other users. 1. Run circuit pack tests to check the Tone Generator and the Tone Detector circuit packs using the **test board UUCSS short** command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.
16	FAIL	The secondary information is not transmitting properly. This can cause a wide range of effects. The user may notice nothing or the port may be totally unusable. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist (poor data transmission), examine the data module, connections, and wiring.
	PASS	Information and Control Channel Local Loop Test passed. All channels are transmitting properly.

Data Module Audits Test (#17)

This is a series of six tests that are classified as hardware audits. The processor sends messages to the on-board microprocessor to perform the following tests. [G1] The audits run only if the station is in-service.

- Switchhook Inquiry — This is an update of the processor's software records based on the on-hook/off-hook status of the data module.
- Bad Scan Inquiry — A message is sent uplink that contains a count generated by certain events relating to the digital loop's (link) conditions. This could be an indication of communication problems between the processor and digital port circuit pack.
- EPF inquiry — The status of the EPF is sent uplink. EPF is not used for data modules.
- ID Request — A request is made to the data module for its status. The data module sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update — This updates the data module's ringer state according to processor records.
- Translation Update — This is a message normally used with digital stations to refresh the default value that causes the station to send touch-tones only in the primary information channel. This test is not used with data modules.

Table 11-248. TEST #17 Data Module Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out. 1. Verify the data module is connected to the PBX and repeat the test. 2. If the test aborts, replace the data module and repeat the test. 3. If the test continues to abort, replace the circuit pack and repeat the test. 4. If the test continues to abort, escalate the problem.
2	ABORT	ID request fails, health bit is defective, or no response from on-board microprocessor. 1. Verify that the correct data module type (PDM versus TDM) is administered. 2. If the test aborts, replace the data module and repeat the test. 3. If the test aborts, replace the circuit pack and repeat the test. 4. If the test continues to abort, escalate the problem.
3	ABORT	No response from EPF audit.
4	ABORT	Internal System Error. 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-248. TEST #17 Data Module Audits Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5	ABORT	Ringer update aborted (data module not in the in-service state). 1. Verify that the data module is powered (power LED on). 2. Make sure data module is connected to the building wiring, check for faulty wiring, check for faulty data module. 3. Retry the command at one-minute intervals a maximum of five times. 4. Replace the Data Module and repeat the test. 5. If the test continues to abort, replace the Digital Line circuit pack and repeat the test. 6. If the test continues to abort, escalate the problem.
6	ABORT	Data module translation update aborted. 1. Verify the data module is connected to the PBX. 2. Retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	Data Module Audits passed. This digital port circuit pack is functioning properly. 1. If complaints still exist, investigate by using other port tests, and by examining the data module options, wiring, and connections.

Data Module Internal Loop Around Test (#175)

This test verifies that a data message can be sent from the PBX, through the building wiring, through an internal looparound path in the data module under test, and back to the PBX. Figure 11-82 shows the hardware configuration used for this test.

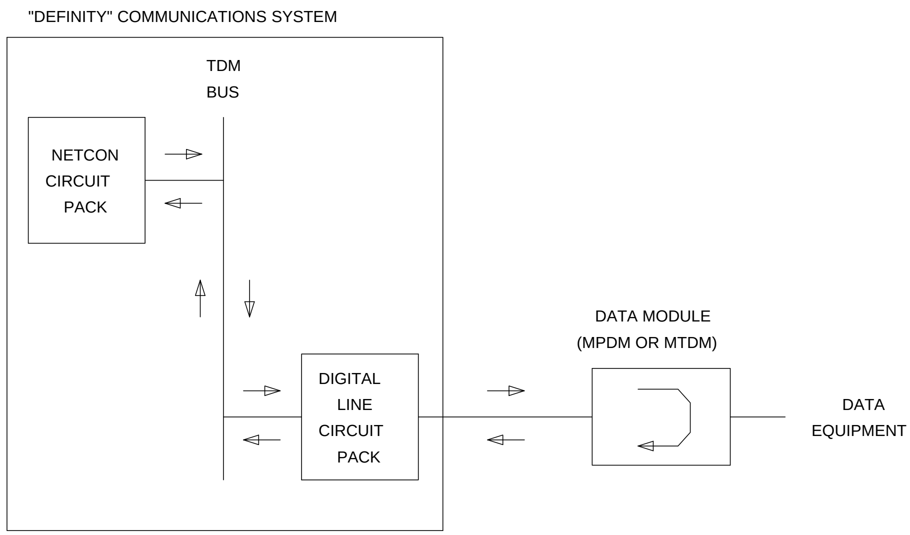

Figure 11-82. Internal Loop Around Test

A signaling message is sent through the digital port circuit pack to the data module under test to request it to enter loop around mode. A test pattern is then sent from the SPE through the Network Control circuit pack (Netcon), over the TDM Bus, through the digital port circuit pack, to the data module where the message is looped around, and sent back through the digital port circuit pack, the TDM Bus, the Network Control circuit pack, and to the SPE where it is checked for consistency.

This test aborts if no terminal or communications equipment is connected to the data module. It also aborts if a number of local PBX resources are not available. These resources include a network control channel from the Network Control circuit pack (there are a maximum of four channels administered as Netcon-type data modules), two TDM time slots (one for each direction of the loop around message), and an idle digital port circuit associated with the data module under test. Failure to allocate any of these resources causes the test to abort with a specific error code for that resource.

A "yes/no" parameter on each data module (MPDM, MTDM, or stand-alone DA only) administration form is required to specify if the Data Module remote Loop Around Test is supported by the data module endpoint. If the parameter is "n" (no), the test does not run.

Table 11-249. TEST #175 Data Module Internal Loop Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	Could not get translation information for port. 1. Verify that port circuit is administered. 2. Wait one minute and attempt the test again. 3. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not applicable to the given hardware configuration. 1. This abort message can be ignored.
1020	ABORT	Internal Software Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1030	ABORT	Internal software group identifier for data module not valid. 1. Verify that port circuit is administered correctly. 2. If administration data correct, escalate the problem.
1031	ABORT	Extension number not valid.
1032	ABORT	Extension number not correct length. 1. Verify that the data module extension is administered correctly. 2. If the administration data is correct, escalate the problem.

Continued on next page

Table 11-249. TEST #175 Data Module Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1071	ABORT	No auxiliary port on Netcon circuit pack available to test with. 1. Check that the Netcon data channels are administered (the **list data-modules** command should show at least one Netcon-type data module). 2. Test the Network Control (Netcon) circuit pack using the **test data-module** command for the Netcon circuit pack. 3. If administration data is correct, escalate the problem.
2000	ABORT	Data module disconnected. 1. Verify that the data module is powered (power LED on). 2. Make sure data module is connected to the building wiring. Check for faulty wiring and faulty data module. 3. Retry the command at one-minute intervals a maximum of five times. 4. Replace the Data Module and repeat the test. 5. If the test continues to abort, replace the Digital Line circuit pack and repeat the test. 6. If the test continues to abort, escalate the problem.
2500	ABORT	Internal System Error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-249. TEST #175 Data Module Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3004	ABORT	1. This error could be caused by the switch setting of the PDM. Verify that the switch on the PDM is set to the "remote loop" position. When the remote loop around test is completed, return the switch to the "off" position. 2. This error could be caused by the Network Control Data Channel. Look for DATA-CHL errors in the Hardware Error Log. 3. This error could also result if no data equipment is connected to the data module. Verify that (a) the data equipment is properly connected to the data module, (b) that power is available to the data equipment, and that (c) the data equipment is powered on. 4. This error could also occur if the baud rate of the data module is set to 19.2 Kbps since the Network Control circuit pack used by this test does not support baud rates greater than 9600 bps. Verify that the baud rate of the data module is set to 9600 bps or less.
1040	FAIL	Data received from remote loop back does not match data sent. 1. Check for faulty wiring. 2. Replace the data module and repeat the test. 3. If the test fails, replace the Digital Line circuit pack associated with the data module and repeat the test. 4. If the test continues to fail, escalate the problem.
1070	FAIL	Internal software response. 1. Wait one minute and attempt the test again. 2. If the same error persists after five attempts in one-minute intervals, escalate the problem.

Continued on next page

Table 11-249. TEST #175 Data Module Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1072	FAIL	Poor response from auxiliary channel. 1. Test the Network Control (Netcon) circuit pack using the **test data-module** command. 2. If the test fails, replace the Digital Line circuit pack. 3. If the test continues to fail, escalate the problem.
1073	FAIL	Internal System Error. 1. Wait one minute and attempt the test again. 2. If the same error persists after five attempts in one-minute intervals, escalate the problem.
1074	FAIL	Internal System Error. 1. Make sure that the data equipment connected to the data module is powered. 2. For an (M)PDM, verify that the Data Terminal "Ready" LED is ON, or for an (M)TDM, verify that the Data Set Ready LED is ON. If it is not on, check the cable from the data equipment to the data module. 3. If the test continues to fail, escalate the problem.
1075	FAIL	Unknown message received during test. 1. Attempt the test again. 2. If the same error occurs, test the Network Control Data Channel using the **test data-module** command and a known working data module. 3. Replace the Digital Line circuit pack and repeat the test. 4. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-249. TEST #175 Data Module Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2040	FAIL	Internal System Error.
2095	FAIL	Internal System Error. 1. Repeat the test. 2. If the test continues to fail, escalate the problem.
	PASS	Data Module Loop Around Test passed. This digital port circuit pack is functioning properly. 1. If problems persist, investigate by using other port tests and by examining the data module options, wiring, and connections.

PE-BCHL (PRI Endpoint Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PE-BCHL[1]	MINOR	test port PCSSpp l	PRI Endpoint Port
PE-BCHL	WARNING	test port PCSSpp sh	PRI Endpoint Port

1 For additional repair information, see also UDS1-BD (UDS1 Interface Circuit Pack) Maintenance documentation and "Troubleshooting PRI Endpoint Problems" in Chapter 5, "Routine Maintenance Procedures".

A PRI Endpoint provides ISDN-PRI (Primary Rate Interface) connections for customers with application equipment or terminal adapters that terminate ISDN-PRI. The equipment or terminal adapters are connected to the switch via the UDS1 interface circuit pack. PRI Endpoint Port (PE-BCHL) maintenance provides a strategy to maintain PRI Endpoint Port hardware circuitry on the UDS1 circuit pack. The maintenance strategy involves logging PRI Endpoint Port hardware errors, running tests for port initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution.

Wideband Switching

The Wideband Switching capability supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

The Wideband Switching capability is designed for ISDN application equipment (for example, ISDN video codecs), but it retains provisions for non-ISDN application equipment by using PRI terminal adapters. In the same sense that a DEFINITY data module acts as a DCP or BRI terminal adapter between endpoint data (for example, V.35) and dialing (for example, RS-366) interfaces and a DCP interface, a PRI terminal adapter acts as a wideband terminal adapter between endpoint data and dialing interfaces and DEFINITY's line-side ISDN PRI interface.

The Wideband Switching Capability introduces PRI Endpoints on DEFINITY line-side interfaces. A PRI Endpoint consists of one or more contiguous B-channels on a line-side T1 or E1 ISDN PRI facility, and it has an extension number. Endpoints initiate and receive calls via ISDN SETUP messages that indicate the data rate and specific B-channels to be used, and they communicate all other call status information via standard ISDN messages. Any

DEFINITY ISDN signaling set (for example, AT&T, CCITT, ECMA) may be used for a line-side ISDNPRI facility.

Multiple PRI Endpoints on a one line-side facility are separate and distinct within the facility. Non-overlapping contiguous sets of B-channels are associated with each PRI Endpoint, and the endpoint equipment is expected to initiate calls within these boundaries.

The endpoint application equipment must be able to do the following: use standard ISDN-PRI signaling, adhere to the PRI Endpoint boundaries as administered on DEFINITY when initiating calls, and handle incoming calls appropriately based on the PRI Endpoint.

Signaling and B-channel States

These ports use a separate channel for signaling (for example, for call setup). This mode of operation is known as out-of-band signaling. The separate signaling channel is called a D-channel in ISDN terminology, and it carries all the call control signaling messages for the PRI Endpoint Port B-channels. The D-channel for these B-channels is an ISDN-PRI Signaling Link Port (ISDN-LNK). The signaling protocol used on the ISDN-PRI Signaling Link Port D-channel is defined by one of the four selectable ISDN-PRI Specifications: AT&T, CCITT, ECMA, and ANSI.

The ISDN-PRI Specification defines the possible SERVICE STATES for a B-channel. The service state is negotiated with the far-end terminal adapter, and it changes over time. Also, the service state may have a far-end or near-end component, and it is initialized to the Out-Of-Service/Far-End state. An attempt is made to negotiate the service state to In-Service.

NOTE:
The service state of a particular PRI Endpoint Port B-channel can be displayed by issuing the **status pri-endpoint <extension>** system technician command.

If a call is present, the ISDN-PRI Specification defines the permissible CALL STATES as well. There are tests in the short and long test sequences for PRI Endpoint Port that are designed to audit these states and to ensure agreement between both ends of the PRI wideband connection.

Alarming based on Service States:

A PRI Endpoint Port B-channel is alarmed with a WARNING if it is placed into a Maintenance/Far-End or Out-Of-Service/Far-End state. While in such a state, the port is unusable for calls to the terminal adapter. However, the user can still use the other remaining ports in the PRI Endpoint to make calls to and from the terminal adapter. When a WARNING alarm is raised, the **status pri-endpoint <extension>** command should be used to determine the exact state of the port.

Other alarms can be diagnosed by using the short and/or long test sequences. Note that a PRI Endpoint Port B-channel can be placed into a Far-End Service State either by direct action of the far-end terminal adapter or by inaction of the far-end terminal adapter. For example, if they do not respond to a Remote Layer 3 Query (see Test #260 for ISDN-PRI Signaling Link Port), the associated PRI Endpoint Port B-channels are placed into the Maintenance/Far-End service state.

A PRI Endpoint Port is a port on a UDS1 interface circuit pack. Therefore, this port depends on the health of the UDS1 interface circuit pack for proper operation (see Figure 11-83). As noted earlier, a PRI Endpoint Port B-channel also depends on an ISDN-PRI Signaling Link Port D-channel (ISDN-LNK) to carry the signaling traffic. If there is a problem with the ISDN-PRI Signaling Link Port, the PRI Endpoint Port is affected. The ISDN-PRI Signaling Link Port, in turn, depends on the PI-LINK (Processor Interface Link). Processor Interface Link problems affect the ISDN-PRI Signaling Link Port. Keep this hierarchy of dependencies in mind when diagnosing problems.

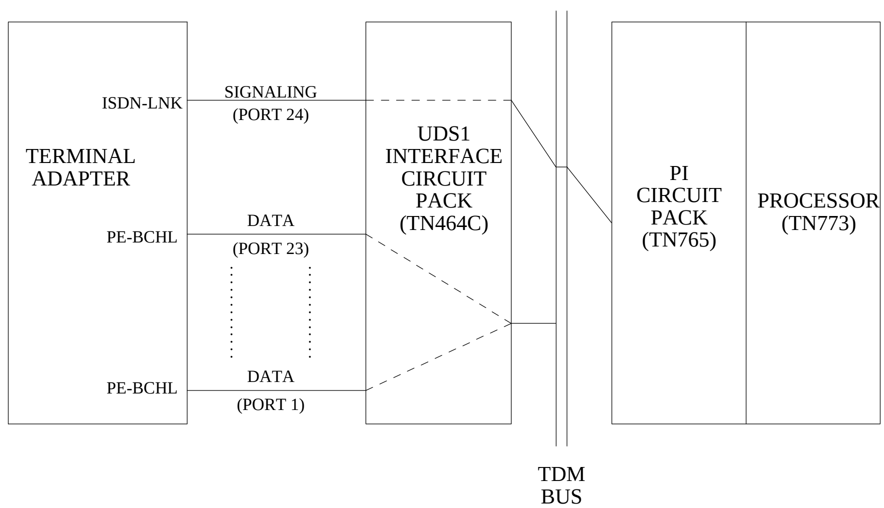

Figure 11-83. PRI Endpoint Port Interactions [INTEL]

PRI Endpoint Port Service States

This section defines the possible service states of a PRI Endpoint Port, and it explains the reason for each service state. This section also provides the recommended recovery procedures (when required).

Service States

- In-Service (INS)

  The B-channel is in its normal operating state.

- Out-of-Service/Far-end (OOS/FE)

  A B-channel is initialized to this state when administered. The switch sends messages to the far-end terminal adapter to negotiate the B-channel into service. If the far-end terminal adapter does not respond to the messages within a certain time period, the service state remains out-of-service, and maintenance periodically resends the messages. The port is unusable for calls incoming to the switch and outgoing to the terminal adapter (although other ports in the PRI Endpoint can still be used for incoming and outgoing calls).

- Out-of-Service/Near-end (OOS/NE)

  This is the state of the port whenever one of the following is true: a hardware failure exists on the signaling link, the NPE Crosstalk Test fails, or the port is busied out by system technician. In this state, the port is unusable for calls incoming to the switch or outgoing to the terminal adapter (although other ports in the PRI Endpoint can still be used for incoming and outgoing calls). No messages are sent to the far-end terminal adapter until the signaling link comes back into service or until the port is released by system technician.

- Maintenance/Far-end (MTC/FE)

  This state is reached when the far-end terminal adapter does not respond to messages sent over the signaling link for a particular port after a certain amount of time. This state is different from OOS/FE inasmuch as the signaling link must be up initially and the B-channels must be in-service. The switch periodically sends messages to the far-end terminal adapter in an attempt to negotiate the port (B-channel) into service. The port is unusable for calls outgoing to the terminal adapter. However, the port services incoming call requests from the far-end (although other ports of the PRI Endpoint can still be used to answer calls incoming to the switch or to place outgoing calls to the terminal adapter). Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in-service to MTC/FE, stable calls are unaffected.

- Maintenance/Near-end (MTC/NE)

  The port (B-channel) is in this state if the signaling link (PI-LINK) is busied out by system technician. The port (B-channel) is also temporarily in this state if the system technician has issued a **test port PCSSpp l** or a **test**

pri-endpoint <extension> l command. Note that transitions into MTC/NE do not drop stable calls. Therefore, a system technician-demanded **busyout link lnk-no** command does not drop stable wideband calls. In this state, the B-channel is not usable either for new calls incoming to the switch or for new calls outgoing to the terminal adapter.

- Pending States (PEND)

  If the near-end is expecting a timed response from the far-end for a request to change the service state of a port, the state of the port reflects a Pending state. For example, if the port is out-of-service/far-end and if an in-service message is sent to the far-end, the service state of the port is OOS/FE-PEND/INS (that is, out-of-service/far-end-Pending/in-service). The far-end has a certain amount of time to respond to the message. The service state reflects this pending state until the timer expires.

The following diagram of the PRI Endpoint Port service states shows the common progression from one service state to another and the event that caused the change of state.

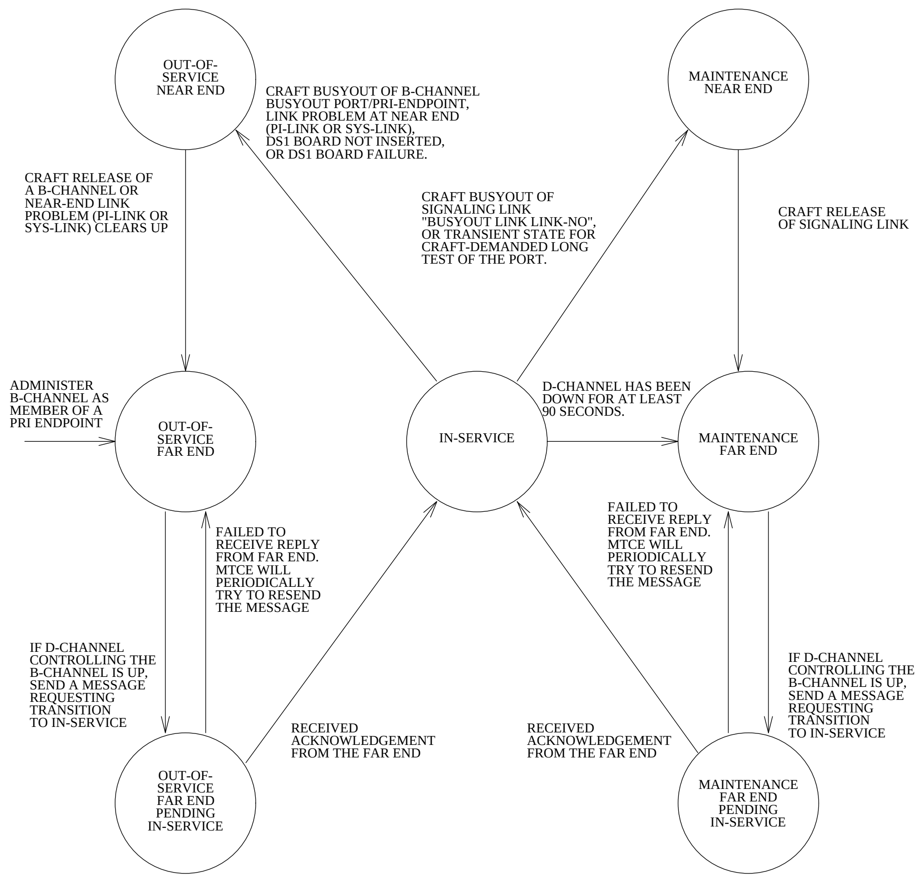

Figure 11-84. Common Progressions in Service States

PRI Endpoint Port Service States

The following chart summarizes each of the different PRI Endpoint Port service states that can result when the **status pri-endpoint <extension>** command is issued. From the results of the status command, match the service state to the corresponding column. Proceed down the column until an "X" is found. The left column indicates possible reasons why the port is in this state, and the right column suggests possible recovery mechanisms. If an alarm against PE-BCHL is present, it is indicated below the "X."

NOTE:
Refer to "Troubleshooting PRI Endpoint Problems" in Chapter 5, "Routine Maintenance Procedures" for a layered approach to the processing of PRI Endpoint problems.

Table 11-250. PRI Endpoint Port Service States

Possible Problem Source	O/S-NE	O/S-FE	O/S-FE Pend-ins	maint -NE	maint-FE	maint-FE Pend-ins	INS	Possible Recovery Route
ISDN wideband calls being completed.							X	Normal Operation.
Port busied out by system technician?	X Warning Alarm							Release port via **release pri-endpoint extension** or **release port PCSSpp**.
NPE Crosstalk Test failed?	X Minor Alarm							Replace UDS1 Interface CP.
DS1 circuit pack lost signal?	X							UDS1 Interface CP removed? DS1 cable disconnected? Terminal adapter problems? Far-end terminal adapter restarting? Faulty UDS1 Interface CP?
Check UDS1-BD.								Refer to UDS1-BD for repair procedures.
Far-end problems?		X Warning Alarm						Check administration and the status of the corresponding port on the far-end terminal adapter.
Service Message sent, waiting for reply from far-end terminal adapter (2 minutes).			X			X		Wait a couple minutes until Pending State not present, check service state.

Continued on next page

Table 11-250. PRI Endpoint Port Service States — *Continued*

Possible Problem Source	O/S-NE	O/S-FE	O/S-FE Pend-ins	maint -NE	maint-FE	maint-FE Pend-ins	INS	Possible Recovery Route
Processor Interface Link busied out by system technician? Check link status. [MIPS only].				X				Release link via **release link lnk-no.**
Signaling link has been down for over 90 seconds?					X Warning Alarm			See ISDN-SGRP, ISDN-LNK, PI-LINK and/or SYS-LINK and follow repair procedures. Is far-end terminal adapter currently restarting?
Repeated failure of far-end to respond to messaging?					X Warning Alarm			Periodically Maintenance will try to resend messages. To speed process, run system technician-demanded test **test port PCSSpp** (Test #256).
Far-end port busied out (OOS/FE). Far-end port being tested (MTCE/FE).		X Warning Alarm			X Warning Alarm			Check status of far-end terminal adapter.

Hardware Error Log Entries and Test to Clear Values

PRI Endpoint Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	Any	None			test port PCSSpp sh r 1
15 (b)	Any	Audit and Update Test (#36)			
18 (c)	0	busyout pri-endpoint <extension> busyout port <PCSSpp>	WARNING	OFF	release pri-endpoint <extension> release port <PCSSpp>
129 (d)		None	WARNING	OFF	test port PCSSpp sh r 1
130 (e)		None	WARNING	ON	test port PCSSpp sh
257 (f)	Any	None			test port PCSSpp sh r 1

1793 (j)	Any	None			test port PCSSpp sh r 1
3073 (k)	Any	Service State Audit (#256)			test port PCSSpp sh r 2
3585 (l)	Any	None			None

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error type indicates a disagreement between the switch and the terminal adapter at the other end of the connection with regard to the ISDN *call* state of the PRI Endpoint Port. This switch automatically tries to recover by clearing the call (that is, the call is torn down). The **status pri-endpoint <extension>** command can be used to determine the state of the port.

When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate the associated errors (if any).

c. The PRI Endpoint Port has been busied out by a **busyout pri-endpoint <extension>** command or by a **busyout port <PCSSpp>** command. No wideband calls can be made to this port (although wideband calls can still be made to other ports within this PRI Endpoint if others ports are in service).

d. The far-end terminal adapter changed its ISDN *service* state to either "out-of-service" or "maintenance." This may be a temporary condition due to the testing of this port by the far-end terminal adapter *or* by a hardware problem with the port. Outgoing calls to the terminal adapter are not allowed over the port (although calls can still be made to other ports that are in service within the same PRI Endpoint). To investigate the status of the port, issue the **status pri-endpoint <extension>** command.

e. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

f. This error type indicates a disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN service state of the PRI Endpoint Port. This switch tries to recover by performing a service state audit. The **status pri-endpoint <extension>** command can be used to determine the state of the port.

   When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

g. This port is not recognized by the far-end terminal adapter. Investigate the PRI Endpoint administration for both the switch and the terminal adapter and make changes as necessary.

h. The Conference Circuit Test (#7) failed on this port. See Test #7 for the repair procedures.

i. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for the repair procedures.

j. This error indicates a failure of the UDS1 Interface circuit pack. When running the Short Test Sequence, the results of the Signaling Link State Check Test (#255) are important.

k. Two Service State Audit attempts have failed (see Test #256). The port is not usable for any outgoing calls to the terminal adapter (although incoming calls from the terminal adapter are accepted over this port, other ports in the PRI Endpoint can still be used for both incoming and outgoing calls to and from the terminal adapter) until the test passes and the port state is changed to in-service (use the **status pri-endpoint <extension>** command to investigate the port status).

l. This error type appears when the switch receives an ISDN RESTART message for an ISDN port that is not idle. Usually, calls are not cleared via the RESTART message. Therefore, this error type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the port's ISDN call state at the time that the unexpected request to restart the channel is received from the remote terminal adapter. This information can be useful if dropped calls (cutoffs) are being reported by users of the PRI Endpoint.

The following list contains important Aux values. Any other such values can be ignored.

10	A call in a stable, talking state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message. This state is called the "active" state.
4, 7, 8, 260, 263	A call that did not reach the active state but at least reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
1, 3, 6, 9, 265	A call that has not yet reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
11, 12, 19, 531, 267, 268	A call that was in the process of clearing has been nonetheless cleared by the far-end terminal adapter with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end terminal adapter is attempting to clear ports that it thinks are in a "hung" state. The RESTART message brings the port to an idle condition.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit and Update Test (#36)	X	X	ND
Signaling Link State Check Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and it provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots that are reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's long test sequence, and it takes about 20 to 30 seconds to complete.

Table 11-251. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use **status pri-endpoint <extension>** commands to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and if the port is not in use, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-251. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM Bus errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. Refer to TDM Bus Maintenance to diagnose any active TDM Bus errors. 1. If system has no TDM Bus errors, and if it is not handling heavy traffic, repeat the test at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. The **list measurements tone-receiver** command displays information on the system's tone receiver. 1. Look for TTR-LEV errors in the Error Log. If errors are present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If errors are present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use **status pri-endpoint <extension>** commands to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1117	ABORT	A service state audit message is outstanding. 1. Wait two minutes and then try again.

Continued on next page

Table 11-251. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2020	ABORT	The test did not run due either to an already existing error on the specific port or to a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. The PE-BCHL is moved to the out-of-service/near-end state. 1. Replace the circuit pack.
	PASS	The port is able to communicate over the TDM Bus.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and it provides conferencing functions on a per port basis. The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and to conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 11-252. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status pri-endpoint <extension>** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status pri-endpoint <extension>** command to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and if the port is not in use, escalate the problem.
1020	ABORT	The test did not run due either to an already existing error on the specific port or to a more general circuit pack error. 1. Examine Error Log for existing errors against this port or against the circuit pack, and attempt to diagnose the already existing error.

Continued on next page

Table 11-252. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Replace the circuit pack. Even though wideband calls do not use the conferencing feature on the NPE, this failure indicates problems with the circuit pack hardware.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using the other port tests and by examining the terminal adapter or the external wiring.

Audit and Update Test (#36)

This test sends port level translation data from the switch processor to the UDS1 interface circuit pack to ensure that the port's translation is correct. The port audit operation verifies the consistency of the current state of the port that is kept in the UDS1 interface circuit pack and in the switch software.

Table 11-253. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	The test failed due to internal system error. 1. Retry the command at one minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	The port translation has been updated successfully. The current port states kept in the UDS1 interface circuit pack and in the switch software are consistent. If the port is busied out, the test does not run, but returns PASS. To verify that the port is in-service: 1. Enter **status pri-endpoint <extension>** to verify that the port is in-service. If the port is in-service, no further action is necessary. If the port is out-of-service, go to Step 2. 2. Enter the **release pri-endpoint <extension>** command or the **release port <PCSSpp>** command to put the port back into in-service. 3. Retry the test command.

Signaling Link State Check Test (#255)

As is noted in the general description for a PRI Endpoint Port, the operation of the PRI Endpoint Port depends on the health of the UDS1 interface circuit pack and of the TN765 Processor Interface Link. This test checks the status of those critical elements.

Table 11-254. TEST #255 Signaling Link State Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete the test on this port, do one of the following: 1. Re-attach the disconnected PRI terminal adapter, or 2. Disable the rollabout video feature on this circuit pack by entering the **change ds1 PCSS** command, and set the field "Alarm when PRI Endpoint Detached?" to "y."
4	FAIL	There is a problem with the Signaling Channel and/or with the Processor Interface Link. 1. Consult the procedure for the ISDN-PRI Signaling Group (ISDN-GRP) and/or the procedures for Processor Interface Link (PI-LINK). Further information may also be obtained by consulting the procedures for the ISDN-PRI Signaling Channel (ISDN-LNK).
8	FAIL	There is a problem with the UDS1 interface circuit pack. 1. Consult the procedures for UDS1 interface circuit pack (UDS1-BD).
	PASS	The signaling link hardware is okay.

Service State Audit (#256)

As is noted in the general description for PRI Endpoint Port, these ports may be in one of several service states as defined by the ISDN-PRI Specification. This test performs a service state audit with the far-end terminal adapter to ensure that both sides agree on the service state.

A PASS for this test simply means that an audit message was successfully composed and sent out to the far-end terminal adapter. The ISDN Specification allows up to two minutes for a reply. If no reply is received within that two minute window, this switch automatically tries once again. If that attempt fails, an error is logged (Error Type 3073), and the switch attempts a recovery by automatically retrying approximately every 15 minutes. If the port was initially in the INS (in-service) state, it is now placed into the MTC/FE (maintenance state, far-end problem) state. Until a Service State Audit attempt is successful, no outgoing calls are placed over this port, but incoming calls are be accepted. The service state of this port does not affect the service state of other ports in the PRI Endpoint. If an incoming call that uses this port is presented while in such a state, a Service State Audit attempt is immediately attempted (that is, the switch does not wait for the 15 minute cycle, but instead tries to recover immediately). To investigate the status of this PRI Endpoint Port, issue the **status pri-endpoint <extension>** command.

Table 11-255. TEST #256 Service State Audit Test

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link has failed. As a result, the system cannot send any messages on behalf of this port. 1. Check the results of Test #255 (Signaling Link State Check).
1117	ABORT	A service state audit message is outstanding. 1. Wait two minutes and try again.
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete the test on this port, do one of the following: 1. Re-attach the disconnected PRI terminal adapter, or 2. Disable the rollabout video feature on this circuit pack by entering the **change ds1 PCSS** command, and set the field "Alarm when PRI Endpoint Detached?" to "y."

Continued on next page

Table 11-255. TEST #256 Service State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	Wait four minutes and then check the Error Log for any new occurrences of Errors Type 3073. If there are no occurrences of this error type, both sides of the ISDN connection agree on the service state, and the negotiation succeeded. If there is a new occurrence of Error Type 3073, the negotiation failed (that is, the far-end terminal adapter twice failed to respond within the mandatory two minute window). This switch automatically retries approximately every 15 minutes. If the port was initially in the INS (in-service) state, it is now be placed into the MTC/FE (maintenance, far-end problem) state (refer to the "Service States" section, which precedes the PE-BCHL "Hardware Error Log Entries and Test to Clear Values" table). Incoming calls are accepted, but no outgoing calls are originated from this port. If an incoming call is presented, another Service State Audit is immediately performed in an attempt to bring the PRI Endpoint Port to the proper state.

Call State Audit Test (#257)

If a call is active on the port, the switches on both sides of the connection should agree on the ISDN state of the call as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end terminal adapter about the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end terminal adapter, **the call is torn down.**

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end terminal adapter. The ISDN Specification allows up to two minutes for a reply. If a reply is not received within the two minute window, a protocol time-out violation is recorded in the error log against the associated signaling channel (ISDN-PRI Signaling Link Port, which is listed in the Error Log as ISDN-LNK; the Error Type is 1).

Table 11-256. TEST #257 Call State Audit Test

Error Code	Test Result	Description/ Recommendation
1019	ABORT	An audit is already in progress. 1. Wait two minutes and try again.
1113	ABORT	The signaling link has failed. As a result, the system cannot send any messages on behalf of this port. 1. Check the results of Test #255 (Signaling Link State Check).
1116	ABORT	The port is in an out-of-service ISDN service state. 1. A call cannot be present if the port is in an ISDN out-of-service state. As a result, a call state audit would be inappropriate, and no action is necessary. (Use the **status pri-endpoint <extension>** command to investigate the ISDN state of the port).
1700	ABORT	Rollabout video abort. The PRI terminal adapter associated with this PRI endpoint extension is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete the test on this port, do one of the following: 1. Re-attach the disconnected PRI terminal adapter, or 2. Disable the rollabout video feature on this circuit pack by entering the **change ds1 PCSS** command, and set the field "Alarm when PRI Endpoint Detached?" to "y."

Continued on next page

Table 11-256. TEST #257 Call State Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	This switch sent a call state auditing message to the far-end terminal adapter to verify the state of the call active on this port. If a call state mismatch is found, the call is torn down within two minutes. If no call was active, no message was sent.

PI-BD (Processor Interface Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
PI-BD	MINOR	test interface PCS sh	Processor Interface Circuit Pack
PI-BD	WARNING	test interface PCS sh	Processor Interface Circuit Pack

1 Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for either the first or second Processor Interface circuit packs).

The TN765 Processor Interface (PI) circuit pack provides a front-end processor to the TN777 Processor circuit pack. The PI circuit pack implements the packet layer and link layer of the X.25 protocol (DCS, AUDIX, CMS, OCM links) as well as the link layer of the ISDN-PRI protocol (ISDN links). A G1, G3iV1.1-286, or G3iV2-386 system without High or Critical Reliability supports up to two circuit packs. A High or Critical Reliability system supports up to four Processor Interface circuit packs, two in each carrier. Only one pair of the circuit packs on a single carrier can be active at a given time. The other two are in Standby mode. The TN765 is a downloadable circuit pack. This means that at reboot, system power-up, or via system technician command, Processor Interface firmware is downloaded to the circuit pack. For other restarts, a Checksum Test is performed on the firmware. If the Checksum Test fails, then the firmware is downloaded again. The firmware can be automatically downloaded at any time via the **reset interface PCS** system technician command.

On the Active SPE complex or in an unduplicated system, Processor Interface maintenance is mainly used for alarming the circuit pack. If System Communication Interface (PI-SCI) finds an error or alarm condition that can be associated with an on-board problem with the Processor Interface (PI-BD) circuit pack, then it alarms both the System Communication Interface and the Processor Interface circuit pack. Processor Interface circuit pack maintenance is also used to test the common circuit pack functions on the circuit pack. If these tests fail, a circuit pack level alarm is raised on the Processor Interface circuit pack (PI-BD). Port level alarms are raised against PI-PT. See PI-PT (Processor Interface Port) Maintenance documentation for details.

On the Standby SPE complex, the testing of the Processor Interface circuit pack is different. The Standby Processor Interface circuit pack is tested daily via scheduled maintenance or on system technician demand. These tests are to check the Standby PIs hardware and firmware so that if an SPE interchange takes place, the Processor Interface communication links (DCS, ISDN, or AUDIX, for example) recover on the new Active Processor Interface circuit pack in a short time. Since the Processor Interface firmware is downloadable, if the firmware checksum fails during scheduled maintenance, then the circuit pack can be downloaded again at this time instead of during the SPE interchange. The Processor Interface firmware can be unconditionally downloaded to the Standby SPE circuit pack via the **reset interface PCS** command, where PCS is the carrier/slot of a Standby PI. The command executes the Standby Processor Interface Board Test (#423), but with a download option.

The Active Processor Interface circuit pack is tested in the PI-SCI (System Communication Interface) Maintenance documentation. Refer to that section for details. The test command is **test interface PCS** where PCS is the port network number, carrier, and slot of one of the Standby Processor Interface circuit packs. If the Standby Processor Interface circuit pack is tested, the test sequence for the Standby Processor Interface is followed. If the Active Processor Interface circuit pack's PCS is given, then tests in the Active Processor Interface test sequence are run. On the Active PI, if there are no enabled Processor Interface links on the Communication-Interface Links Form, only the XXX-BD (Common Port Circuit Pack) tests execute.

Hardware Error Log Entries and Test to Clear Values

The following indicates entries that may be found in the Error Log for Processor Interface circuit packs. Since the Processor Interface circuit pack has Common Port Circuit Pack functionalities, then cross reference XXX-BD (Common Port Circuit Pack) Maintenance documentation for more information. Test #423 is the only test that is described in this section. XXX-BD (Common Port Board) Maintenance describes the other tests mentioned in the following table.

PI-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test interface PCS sh r 1
1 (a)	0	Circuit pack removed or SAKI Test (#53)	MINOR	ON	
23 (b)	0	None	WARNING	OFF	
54 (c)	0	None	MAJOR	ON	test interface PCS l
124 (d)	Any	None	MAJOR	ON	test interface PCS l
125 (e)		None	MINOR	ON	
257	65535	Control Channel Test (#52)	MINOR	ON	test interface PCS
257 (f)	Any	None			
513 (g)	Any	None			
769 (h)	4358	None			
1025 (i)	4363	NPE Audit Test (#50)			test interface PCS sh
1538 (j)	Any	None	MINOR	ON	
3585 (d)	Any	None Test (#423)	MAJOR	ON	reset interface PCS l
3840 (i)	Any	None			
3841	Any	Standby PI Circuit Pack Test (#423)	MAJOR	ON	test interface PCS sh
3999(k)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

WARNING:

7The "test interface long" command resets the PI-BD and cause all ISDN-PRI and BX.25 links to come down.

Notes:

a. This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

   NOTE:
   The alarm is logged about 11 minutes after the circuit pack has been removed and/or SAKI Test (#53) fails.

   If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, then replace the circuit pack. See **CAUTION** statement below. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack.)

   CAUTION:
   Reseating the circuit pack may cause a system restart if the circuit pack is located on an Active SPE complex.

   If this is a Duplicated Option system, verify that there is an equal number of Processor Interface circuit packs in each SPE complex. If there is not an equal number of Processor Interface circuit packs, this condition could cause alarms on the STBY-SPE, DUPINT, SHDW-CIR, as well as the PI-BD.

b. The circuit pack has been logically administered but not physically installed. If this alarm remains active for more than 30 minutes, follow the normal escalation procedures. **DO NOT PHYSICALLY RESEAT THE CIRCUIT PACK!** The alarm is cleared when the circuit pack is installed and initialization maintenance runs on it. The Standby Processor Interfaces alarm is cleared when Standby maintenance runs on it.

c. Processor Interface-SCI detected an error while trying to reset the TN765 PI circuit pack. This error indicates a loss of communication with the circuit pack. If this error continues, then replace the TN765 circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack. See PI-SCI Maintenance documentation for additional errors.

d. PI-SCI logged errors that resulted in an error being logged and an alarm being raised against PI-BD. Refer to the PI-SCI Maintenance documentation and resolve all alarms against PI-SCI. If this alarm resulted in an SPE-interchange, issue the **test interface PCS sh** command to try to resolve the PI-BD alarm.

e. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to re-administer this slot to match the circuit pack inserted.

f. This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

g. This error, when reported with Aux Data in the range of 4352 to 4358, indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack.

h. This error can be ignored, but look for other errors on this circuit pack.

i. This error is not service-affecting and no action is required.

j. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with Error Code 2000.

   2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.

   3. A **list configuration** command shows that the circuit pack and ports are properly installed.

   The system tries to restore the circuit pack within 15 minutes. If the error recurs after 15 minutes, replace the circuit pack. (Refer to the "Handling Control Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures".)

k. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Standby Processor Interface Circuit Pack Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Standby Processor Interface Circuit Pack Test (#423)	X	X	ND
Standby Processor Interface Port Test (#404) (a)	X	X	ND
Control Channel Loop Test (#52)	X	X	ND
NPE Audit Test (#50)	X	ND	

1 D = Destructive; ND = Nondestructive

a. This test is repeated up to four times since there are four ports on the circuit pack. Cross-reference PI-PT (Processor Interface Port) Maintenance documentation for information about these tests.

Control Channel Loop Around Test (#52)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as Control Channel Loop Around Test (#52).

NPE Audit Test (#50)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as NPE Audit Test (#50).

Standby Processor Interface Circuit Pack Test (#423)

This test is run only in a High or Critical Reliability system. This test is run on Processor Interface circuit packs that are currently in Standby Mode and thus no active calls are up on these circuit packs. It is very important to periodically test the Standby Processor Interface circuit packs to ensure their health in case of an SPE-interchange. This test is run either by system technician demand (**test interface PCS** or **reset interface PCS**) or during scheduled maintenance. The test resets the circuit pack. The main purpose of this test is to perform a Checksum Test on the downloadable firmware or to download new Processor Interface firmware if the **reset interface PCS** command is used. If the checksum fails, then the firmware is downloaded again from the tape.

Table 11-257. TEST #423 Standby Processor Interface Board Test

Error Code	Test Result	Description/ Recommendation
9,10	ABORT	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-257. TEST #423 Standby Processor Interface Board Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1124	ABORT	There are currently no enabled Processor Interface links in the system. 1. Wait and run this test when links are enabled and the PI-SCI (System Communication Interface) has been started up. 2. If this error persists, follow normal escalation procedures.
1	FAIL	Could not reset the Processor Interface circuit pack. 1. Wait one minute, and retry the command. 2. If this test continues to fail, replace TN765 Processor Interface (PI) circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack. 3. If problem continues to persist, escalate the problem.
16 80 94 102	FAIL	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If problem still exists, redownload firmware via **reset interface** command. 3. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-257. TEST #423 Standby Processor Interface Board Test — *Continued*

Error Code	Test Result	Description/ Recommendation
23 199	FAIL	Download of Processor Interface firmware failed. 1. Wait one minute and retry. A tape access problem could be present. Check that tape is in tape drive. 2. If the problem persists and Standby TAPE is idle when command is entered, then a problem could exist in either the Standby TAPE or the Processor Interface circuit pack. Replace the tape with a new tape that contains Processor Interface firmware. Retry the command. 3. If the problem still exists, then refer to the TAPE Maintenance documentation for possible TAPE errors. If there are no TAPE errors, repeat the test command up to five times. If problem still exists, replace the TN765 circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack. 4. If problem still exists with new TN765 Processor Interface circuit pack, replace TAPE drive.
9000s	FAIL	Processor Interface Download failed. 1. Refer to TABLE A, Tape Unit Data Table, and follow the repair recommendations.
	PASS	TN765 Processor Interface circuit pack initialized correctly. Processor Interface links (X.25 and ISDN) should recover now. See PI-LINK Maintenance documentation for more information if links do not recover.

PI-LINK (Processor Interface Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PI-LINK	MINOR	test link lnk-no l	Processor Interface Link
PI-LINK	WARNING	test link lnk-no l	Processor Interface Link

NOTE:
Reference lnk-no via the **display communication-interface links** command.

The Processor Interface (PI) Communication Link is the physical link that connects DEFINITY G1, G3iV1.1-286, or G3iV2-386 to an adjunct such as AUDIX, another Node in a DCS network, or an ISDN-PRI connection. These links are either X.25 (DCS, AUDIX, or MIS) or ISDN (ISDN-PRI). The system supports up to four of these links per TN765 Processor Interface circuit pack. PI-LINK maintenance actually monitors several hardware devices: Processor Interface ports, TN754 or TN784 Digital Line ports, PDMs, TDMs, MTDMs, MPDMs, and DS1 facilities. Henceforth, "data module" refers to either PDM, TDM, MPDM, or MTDM. **In much of the following link documentation, the repair procedures described mention various hardware configurations. Choose the procedure appropriate to your configuration.**

The Processor Interface circuit pack provides an EIA connection. This connection can be administered only on Link 1 in a system without High or Critical Reliability. The EIA port is used when an adjunct (AUDIX, for example) is near (less than 25 feet) or further if a modem is used. The EIA port can also be used to connect two PBXs together via DCS. The EIA port cannot be used in a High or Critical Reliability system.

The Processor Interface Link can be in three different states. These states can be seen via the **status link lnk-no** system technician command. If the link is in a *maintenance busy* state, then the system technician had instructed the Processor Interface to be in maintenance busy by entering the **busyout link lnk-no** command or the Processor Interface Link is not established and maintenance is trying to bring it up. This probably means that an error condition is occurring somewhere on the link that keeps the link from being logically connected and carrying data. If the link is busied out, then it can be put back into service by issuing a **release link lnk-no** command. This restarts the link. If the link is for DCS, then it may speed the recovery of the link if **busyout link lnk-no** and **release link lnk-no** are executed on the switch that is establishing the connection (see the Communication-Interface Links form). The link can be in a *disconnected* state if the link cannot be started up. In this case, maintenance tries to establish the link periodically. If the link is up and data is being sent successfully, then the link is in the *in-service* state.

NOTE:
When an ISDN-PRI link is busied out via a system technician command, the associated B-channels (ISDN-TRK) are moved to the maintenance and/or far-end state. As a result, stable calls are NOT dropped, but the trunks are removed from the trunk hunt group to prevent them from being selected for outgoing calls. See ISDN-TRK Maintenance documentation.

Up to two Processor Interface circuit packs can be active on the same carrier in the system. Thus, there can be a maximum of eight Processor Interface links in service at any one time. If an error or alarm is detected by PI-LINK that can be associated with a physical port on the Processor Interface circuit pack, then the Processor Interface Port MO is alarmed, which indicates a defective port on the circuit pack. Refer to the PI-PT (Processor Interface Port) Maintenance documentation for details.

It is useful to use the **status processor-channel channel-no** command when troubleshooting the PI-LINK. A processor channel corresponds to a processor application (also called a session) and more than one may be using the same physical link (only for X.25 links). The relevant field of the status screen is the "channel status:" which can be in 1 of 7 different states (see the following table). State 6 is normal state for the processor channel for X.25 links and state 10 is normal state for ISDN links. States 9 and 10 are only applicable to ISDN links.

States	Description
1	Incorrect translations or channel not assigned.
3	Attempting to reset the channel but no response from the other end. Getting stuck in this state may be caused by hardware problems, a DS1 synchronization problem or a DCE/DTE conflict in the Communication-Interface Link Form (one end of the link must be DCE and the other must be DTE).
4	The other end acknowledged the channel reset (which means that the two ends are physically connected) but a processor channel connection has not occurred yet. Getting stuck in this state may indicate that translations are incorrect, such as remote processor channel mismatch. To recover from this situation, execute the **busyout link lnk-no** and **release link lnk-no** commands. If this is unsuccessful, then use the **reset interface** command (note that this is a **destructive** command that tears down all four links). This problem may also be caused by a noisy link or DS1 synchronization problems.
6	This is the normal state of the channel. The link is in the data transfer state which means that the application is able to send data over the link.

Continued on next page

States	Description
7	One or more unexpected messages have arrived; software is attempting to resynchronize the two ends. Usually it takes up to five minutes for the software to recover once it is in this state.
9	ISDN-PRI link is currently down. It is periodically restarted or can be forced to restart via **busyout/release link lnk-no**.
10	ISDN-PRI link is up. This is the normal state of the channel. The link is in data transfer state, which means that ISDN data can be sent over the link.

Figure 11-85 shows the Processor Interface Communications Link (PI-LINK) Interactions.

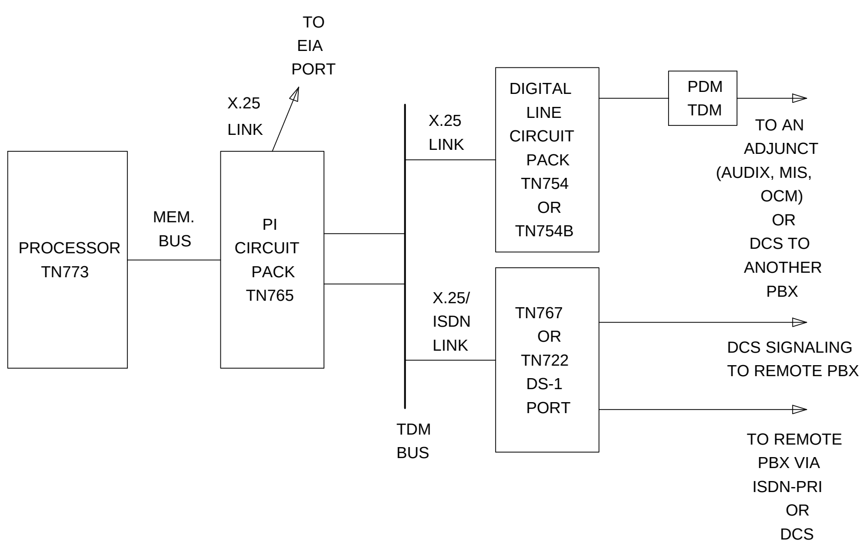

Figure 11-85. Processor Interface Link Interactions

Hardware Error Log Entries and Test to Clear Values

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test link <lnk-no> sh
1 (a)	Any	none	MAJOR/ WARNING[2]	OFF	busyout/release link lnk-no

Continued on next page

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

3 This error type initially raises a warning alarm. If this error type persists, and alarms are not downgraded on this MO due to the values of **set options**, then, after a period of time, a Major alarm

Notes:

a. A permanent switched call was dropped. Check the "Link Recovery" section.

b. The TN765 Processor Interface circuit pack detected an error on a specific link via background maintenance. If the link is down, busyout and then release the link. If this fails, check all connections. If the error reappears consistently, see "Link Recovery" section.

c. Processor Interface software or firmware detected an error condition on this link. Internal software should initiate the recovery for the link. If the link is still down, see the "Link Recovery" section.

   Aux values of concern; any others can be ignored.

   0 Processor Interface circuit pack indicates that the ISDN-PRI link is down.

   1 An internal software audit indicates that this link has been in overload for at least 20 seconds and is hung.

   2 No internal software buffers are available to process a link transition (that is, down to up, or up to down). The transition is lost.

   17 The allocation of a new software write buffer to the Processor Interface circuit pack failed.

d. Translation Error—check all administration for the link. Possibly the destination DS1-BD or DIG-BD is not inserted. Busyout and then release the link to restart it. This is not a Processor Interface hardware problem. If the problem persists, then follow normal escalation procedures.

Aux values of concern; any others can be ignored.

2	Link translation error. If the communication-processor link form indicates this link's destination is a tac+extension, then bring up the dialplan form. If an extension exists with the same first digit as the tac, then this PI link will not establish. To alleviate this problem, either remove the extension on the dialplan form, or change the destination field on the communication-processor link form to use a UDP extension to dial the far-end.
8	Port not administered in software.

e. This error occurs when the Processor Interface link fails to be established. Check all connections and administration. This could also occur as a result of another error, the failure of Test #182, for example. If the other error on the link can be cleared, then this error may also clear. See the "Link Recovery" section.

Aux values of concern; any others can be ignored.

1, 2	System error. If the error continues to appear, escalate the problem.
7	System error. If this error is occurring on all administered links with the same Aux Data and all links are alarmed, then execute the **reset interface** command to restore all the links. If the error continues or if the error is not on all links, then escalate the problem.
12	One of the two Loop Around Tests failed (#182 or #183). See the "Link Recovery" section.
13	Hardware problem with DS1 facility is affecting ISDN links. Refer to DS1-BD Maintenance documentation.
19	A transient state associated with the D-channel backup protocol. The link is being held in the busy state until call control can be moved to the new active link. No action needs to be taken.

Continued on next page

32771 32772	The remote endpoint indicates that the call is up and the local PBX cannot complete the call. Check trunk status (on the remote end and the local end) if a DS1 trunk is used, or check the status of the data module (PDM,TDM, etc.) if a data module is used in the link. The commands are **status trunk trk-grp/member** or **status data-module <ext>**. If the destination is in-service/active, then the commands are **busyout trunk trk-grp/member** and **release trunk trk-grp/member** (on both sides of the link if this is a DCS link). If a data module is used in the link, then use a **busyout data-module <ext>** command followed by a **release data-module <ext>** command. The Processor Interface Link must be busied prior to busying the trunk or data module. Release the Processor Interface Link via **release link lnk-no** command and the Processor Interface Link re-starts. If this fails, check the status of the TN765 port using **status data <ext>** where **<ext>** is the extension of the port from the interface extension in the Display Communication Link form; if the state is "in-service/idle" then manually call the TN765 port and transfer the call to appropriate destination, either a DS1 Trunk Access Code or the data module extension. See "Link Recovery" if error still occurs and link See "Link Recovery" if error still occurs and link does not establish.
32779 32782 32801	Administration problem; check that the Processor Interface data module extension exists via the **status data-module <ext-no>** command. Verify that the destination extension exists and that the correct routing pattern is used. In addition, check that the Processor Interface data module and the destination extension are correctly administered on the COS and/or COR forms.
32813	Administration problem; check all administration.
32815	The off-premise call timed-out. Check the "Off-Premises Tone Detect Timeout Interval" on the Feature-Related System Parameters Form. The time-out is administered between 6 and 25 seconds. No response was received from the remote destination. Check the status of the remote destination. This might also indicate possible synchronization problems. Network synchronization sources should be checked on all networked switches. Also see the SYNC Maintenance documentation.
32814	Call was answered but not by a remote data module. Check the remote destination extension and verify that this is a data module.
32841	Call went over the trunk and received ring back but did not receive modem answer tone. Check the remote destination for automatic answering.
65528	Administration problem; check all administration.

Continued on next page

65532	Call setup timed out; retry, and check destination. If the destination is an adjunct (CMS, AUDIX, etc.), then check if the terminal ready light is lighted on the PDM. If not, then the adjunct is down. If the destination is another PBX, then the PBX might be restarting. Retry and escalate the problem if this error persists.
65535	Link specified is out-of-range (1 through 8).

f. This error message indicates that the TN765 Processor Interface circuit pack could not transmit the message the software sent to it. See the "Link Recovery" section if the error continues. This is a normal error during "hot start" SPE-interchanges.

g. Excessive resets on the link. Usually indicates that the remote end is down or the physical connection is broken. A warning alarm is raised initially, followed by a Major alarm if the problem is not cleared. See the "Link Recovery" section.

h. Excessive I-frame retransmission. Could indicate a noisy link. Recover as in previous note. Aux values indicate the retransmission rate per minute. See the "Link Recovery" section.

i. If the Aux Data value is 9, then the destination circuit pack (DIG-BD or DS1-BD) is not inserted. Otherwise, DS1 maintenance detected a hardware failure. (DS1 cable disconnected, loss of signal, DS1-BD problems.) Not a Processor Interface Link problem. Check DS1-BD maintenance. Only applicable to ISDN links. Aux value useless. Once the DS1 signal is restored, maintenance automatically restarts the Processor Interface Link. To hasten this process, test the appropriate DS1 Interface circuit pack via **test board PCS** command. When Test #138 (loss of signal) passes, the Processor Interface Link recovers shortly.

   In addition to an indication that the link failed to establish the PI-LINK 2561 AUX_Data, the hardware error log is also updated. This error may indicate two possible conditions:

   1. A failure to detect the DTR from the peripheral.

      When the DTR is not detected by the data module the AUX_Data is set to 40. This indicates that the problem is most likely with the peripheral or the connection to the peripheral.

2. A time-out on the EIA interface query request to the data module.

   When the data module fails to respond to the EIA interface (query request) the AUX_Data is set to 41. This may indicate problems with the data module or connection to the data module. Other errors specific to the data module may also be logged if this is the case.

j. TN765 PI-BD determined that the ISDN link went down. Check connectivity with the other end. Busyout and then release the link to recover. Occurs if DS1 maintenance detected a problem or the remote end is busied out or is down. This also occurs if the ISDN link is unstable or if there is excessive noise on the line. See the "Link Recovery" section.

k. Excessive LAPD (link-access procedure on the D-channel) invalid frame errors. Could be a noisy line or problems with the TN765 Processor Interface circuit pack. Also check DS1-BD Maintenance documentation. See the "Link Recovery" section.

l. Occurs 90 seconds after a 2817 Error Code if link does not recover. At this time, all ISDN trunks associated with this link are put into a maintenance far-end state (see ISDN-TRK for details). See the "Link Recovery" section.

m. The application level process associated with the link has failed to establish a data connection with the far end. This problem prevents data from being processed. The condition may exist even if the link is in a data transfer state. Busyout, and release the link to restart it. This is not a Processor Interface hardware problem. If the problem persists, follow normal escalation procedures.

   Aux values of concern; any others can be ignored.

433	OCM application did not start correctly. Escalation for this problem may also include rebooting the OCM adjunct.
435	Application level process could not connect to session layer process.

n. Excessive (over threshold) HDLC transmit or receive error rates were reported. Aux Data is the HDLC error rate reported. See the Link Recovery section for troubleshooting this problem

Link Recovery

This section describes the general procedure to take to recover from link errors and alarms. Refer to the "Troubleshooting ISDN-PRI Problems" section in Chapter 5, "Routine Maintenance Procedures", before proceeding with this "Link Recovery" strategy.

1. Determine the link status using the **status link** command. If the link status is "in-service" and (for X.25 links) all the pairs of processor channels are complete under "LOCAL/REMOTE PROCESSOR CHANNELS" (that is,

every "/" is followed by a processor channel number, not a blank), then the link is operating correctly and no further action should be taken. If the link status is not "in-service," then go to Step 2. If the link status is "in-service" and (for X.25) some of the processor channel pairs are incomplete (remote channel not specified, meaning that the processor channels are not connected), then look at the status of "status processor-channel" for the local processor channels that are not connected.

2. Look for active PI-SCI alarms and follow the procedure for those alarms if there are any. If there are no PI-SCI problems, go on to the next step.

3. If the link is still down, restart the link via the **busyout link lnk-no** system technician command followed by the **release link lnk-no** command. This sequence tears down the call and then tries to bring it back up. If the link is for DCS, it may speed the recovery of the link if **busyout link lnk-no** and **release link lnk-no** commands are executed on the switch that is establishing the connection (see Communication Link form). If the link does not recover, go on to the next step.

4. Check the status of the remote endpoint.

   a. If the link is busied out, release it.

   b. Is the switch down or restarting?

5. If link was never brought up:

   a. Using *DEFINITY Communications System, Generic 1 and System 75 Administration and Measurement Reports,* 555-200-500 and *DEFINITY Communications System Generic 3 Implementation*, 555-230-653, for instructions as needed, verify that the administration is correct as follows:

   — Enter the **display ds1 PCSS** command. Check the compatibility of the DS1 parameters with the far-end and the CSU.

   — Enter the **display communication-interface links** command.

   — Enter the **display communication-interface processor-channels** command. Enter the **display communication-interface hop-channels** command (if hop-channels are being used).

   — Enter the **display trunk <grp>/<mbr>** command (if DS1 is being used for DCS).

   — Enter the **status sync** command (if DS1 is being used)—make sure the primary synchronization is administered.

6. If link is an EIA link:

   — Verify via the Communication-Interface Links form that the information for the EIA connection is correct on the local and remote PBXs.

7. Try to isolate the problem in the link if hardware is at fault. Test the link via the **test link lnk-no long** system technician command.
   a. If Test #182 fails three times, replace the TN765 circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid". If Test #182 still fails, escalate the problem.
   b. If Test #182 passes and Test #183 fails, replace the TN754 or TN784 Digital Line or the TN722 or TN767 DS1 Interface circuit pack, whichever is used in the link. If Test #183 still fails, replace the TN765 PI-BD. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid". If Test #183 still fails, escalate the problem.
8. If the preceding tests pass:

   Check the physical transmission link:
   a. Are all the circuit packs physically installed?
   b. Are the cables still connected throughout?
   c. Check DS1-BD error section for possible connectivity problems if DS1-BD is used in link connection.
   d. Check CSU options.
9. Finally, restart the Processor Interface circuit pack via **reset interface PCS**. This resets the circuit pack and restarts ALL the links on it.
10. If the preceding procedure was followed and links still do not recover, escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *PI Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence. REMINDER: The command line entry to test the PI-LINK MO is: **test link lnk-no (s or l)**.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Interface Loop Around Test (#182)		X	D
TDM Loop Around Test (#183)		X	D
ISDN Hardware Test (#234)		X	ND
Link Quality Test (#233)	X	X	ND
Data Module Internal Loop Around Test (#175)[2]		X	ND
Digital Line NPE Crosstalk Test (#9)[2]		X	ND
Port Circuit Information Channel and Control Channel Loop Around Test (#13)[2]		X	ND
Data Module Audits Test (#17)[2]	X	X	ND

1 D = Destructive; ND = Nondestructive

2 If the PI-LINK under test is BX.25 and if there is an MPDM or an MTDM as part of the link, then the PI-LINK test sequence is expanded to include the tests on the data module. These tests are run via the PDMODULE or TDMODULE maintenance object. Refer to the PDMODULE TDMODULE (Data Module) Maintenance documentation for descriptions and details of these tests.

Processor Interface Loop Around Test (#182)

This test is destructive.

The Processor Interface Loop Around Test is an on-board Loop Around Test. The test requires that the system technician issue a **busyout link lnk-no** command before this test is run. This means that the DCS, AUDIX, or ISDN link, for example, is torn down. It does not access the TDM Bus at all. When the circuit pack is put into local loop around mode, frames are looped internally on the circuit pack. If the test fails, the Processor Interface circuit pack reports the failure. It is a good check of most of the working hardware on the Processor Interface circuit pack.

Table 11-258. TEST #182 Processor Interface Loop Around Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Link was not busied out via system technician. 1. Busyout the link via the **busyout link lnk-no** command. 2. Retry the test command. If this continues to abort, escalate the problem.
2 4 9	ABORT	1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
16 80 84 85 93 94 102	ABORT	Internal System Error or possible TN765 PI-BD failure. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, then reset the PI-BD via the **test interface PCS long** system technician command. 3. If problem still exists, replace the TN765 PI-BD. 4. If problem reappears, follow normal escalation procedures.

Continued on next page

Table 11-258. TEST #182 Processor Interface Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
12	FAIL	PI-BD reported that Loop Around Test failed. 1. Retry the test. 2. If it continues to fail, try resetting the circuit pack by the **test interface PCS long** command. This TEARS down all other links on this circuit pack (DCS, AUDIX, ISDN, etc.). 3. If the problem still exists, replace the TN765 circuit pack. 4. If problem reappears, follow normal escalation procedures.
	PASS	The on-board Loop Around Test on the TN765 circuit pack passed. Most of the hardware on the circuit pack was tested except for the TDM Bus buffers. If problem is isolated to TN765 and this test passes, then replace TN765 circuit pack since TDM Bus buffers could be at fault.
13	ABORT	The TN765 circuit pack has not been reset yet or is currently being reset. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to abort with error code 13, then check status of all BX.25 and/or ISDN-PRI links on this TN765 via the **status link lnk-no** command. If all links are not in-service, then reset the TN765 using the **test interface PCS long** command. 3. If the TN765 fails to reset, refer to the PI-SCI section of this manual. 4. Else, retry the **test link lnk-no** command. 5. If the test still aborts with error code 13 or from step 2, and some links are in-service and a error code is still present, escalate the problem.

TDM Loop Around Test (#183)

This test is destructive.

This test requires that you enter the **busyout link lnk-no** command before running the test. This means that the DCS, AUDIX, or ISDN link, for example, are torn down. This test checks the health of the TN754 or TN784 DIG-LINE or the TN722 or TN767 DS1 Interface circuit pack. This depends on which circuit pack is used on the link. The TN754 or TN784 Digital Line or DS1 Interface circuit pack is put into loop around mode while the PI-BD is instructed to go into remote loop around. If this test fails, and the previous Test #182 passes, then the TN754 or TN784 Digital Line or the DS1 Interface circuit pack should be replaced. It is not run on ports administered as EIA.

Table 11-259. TEST #183 TDM Loop Around Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Link was not busied out via system technician. 1. Busyout the link via the **busyout link lnk-no** command. 2. Retry the test command. If the test continues to abort, escalate the problem.
2 4 8	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
6	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
9	ABORT	TN754 or TN784 Digital Line or TN722 or TN767 DS1 Interface circuit pack is not installed. 1. Install circuit pack and retry the test. 2. If test continues to abort with Error Code 9, then escalate the problem.

Continued on next page

Table 11-259. TEST #183 TDM Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
13	ABORT	The TN765 circuit pack has not been reset yet or is currently being reset. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to abort with error code 13, then check status of all BX.25 and/or ISDN-PRI links on this TN765 via the **status link lnk-no** command. If all links are not in-service, then reset the TN765 using the **test interface PCS long** command. 3. If the TN765 fails to reset, refer to the PI-SCI section of this manual. 4. Else, retry the **test link lnk-no** command. 5. If the test still aborts with error code 13 or from step 2, and some links are in-service and a error code is still present, escalate the problem.
16 80 84 85 93 94 102	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, then reset the PI-BD via the **test interface PCS long** command. 3. If problem still exists, replace the TN765 circuit pack. 4. If problem reappears, follow normal escalation procedures.
1005	ABORT	The test is not applicable if the EIA port is being used as part of the link.

Continued on next page

Table 11-259. TEST #183 TDM Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
12	FAIL	PI-BD reported that Loop Around Test failed. 1. Retry the test. 2. If Test #182 fails, see section for Test #182 first. 3. If Test #182 passes and Test #183 continues to fail, replace either the TN754 or TN784 Digital Line or the TN722 or TN767 DS1 Interface circuit pack. 4. If Test #183 still fails, replace the TN765 PI-BD. 5. Escalate on further failures.
	PASS	The loop around from the TN765 PI-BD to the Digital Line or DS1 Interface circuit pack and then back to the PI-BD passed.

Link Quality Test (#233)

This test queries the TN765 circuit pack for the latest error rates (number/minute) for certain counters that are kept by the TN765. The test passes if all the error rates are below a certain threshold. The counters that are queried are the Level 2 Reset SABM(E) [Set Asynchronous Balanced Mode (Extended)] counter, the Level 2 I-frame Retransmission counter, and the invalid LAPD frame counter.

Table 11-260. TEST #233 Link Quality Test

Error Code	Test Result	Description/ Recommendation
3 11 24	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. If the test continues to abort, escalate the problem.
13	ABORT	The TN765 circuit pack has not been reset yet or is currently being reset. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to abort with error code 13, then check status of all BX.25 and/or ISDN-PRI links on this TN765 via the **status link lnk-no** command. If all links are not in-service, then reset the TN765 using the **test interface PCS long** command. 3. If the TN765 fails to reset, refer to the PI-SCI section of this manual. 4. Else, retry the **test link lnk-no** command. 5. If the test still aborts with error code 13 or from step 2, and some links are in-service and a error code is still present, escalate the problem.
4 16385	FAIL	Excessive Level 2 resets (SABM) on link.
16386		Excessive Level 2 I-frame retransmission. Possible noisy link. 1. See PI-LINK (Processor Interface Link) Maintenance documentation for this maintenance object.

Continued on next page

Table 11-260. TEST #233 Link Quality Test — *Continued*

Error Code	Test Result	Description/ Recommendation
16388	FAIL	Excessive LAPD invalid frame errors. Could be a noisy link or problems with the near-end Processor Interface circuit pack or with the far-end. 1. See DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for DS1 Interface circuit pack problems. 2. See PI-LINK (Processor Interface Link) Maintenance documentation for this maintenance object.

Continued on next page

Table 11-260. TEST #233 Link Quality Test — *Continued*

Error Code	Test Result	Description/ Recommendation
16387	FAIL	Excessive Level 2 resets and excessive Level 2 I-frame retransmission.
16389	FAIL	Excessive Level 2 resets and excessive LAPD invalid frame errors.
16390	FAIL	Excessive Level 2 I-frame retransmissions and excessive LAPD invalid frame errors.
16391	FAIL	Excessive Level 2 I-frame retransmissions, excessive LAPD invalid frame errors, and excessive Level 2 resets. 1. See PI-LINK (Processor Interface Link) Maintenance documentation for this maintenance object.
16392	FAIL	HDLC receive rate exceeded the threshold.
16400	FAIL	HDLC transmit rate exceeded the threshold.
16393-16425	FAIL	Other combinations of above individual failures can be calculated as follows: 16384 = 0X4000 16385 = 0X4001 16386 = 0X4002 16388 = 0X4004 16316 = 0X4010
	PASS	PI-LINK currently does not have any of the above errors.

ISDN Hardware Check Test (#234)

This test checks the status of the ISDN hardware which is the DS1 Interface circuit pack and cabling. Status of the DS1 port is kept by the system. The state of the port can be in-service or out-of-service. This state is updated by DS1 Interface circuit pack maintenance. If DS1 maintenance detects a problem with the physical medium near-end or far-end, the Processor Interface Link maintenance is instructed to restart the link. Therefore, if this test fails, the port is considered out-of-service and the link cannot be brought up until DS1 maintenance changes the state to in-service. This is more of a status inquiry than a test. Thus, the only recovery procedure is to refer to DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation.

Table 11-261. TEST #234 ISDN Hardware Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	This test only runs for ISDN-PRI links. This link is a BX.25 link and, thus, aborts.
	FAIL	Indicates that there is a physical problem with the DS1 facility link. 1. Cross-reference DS1 Interface circuit pack errors for possible reason. Refer to DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation. 2. Retry the test. It continues to fail until the DS1 problem is cleared up.
	PASS	DS1 facility is functioning correctly.

PI-PT (Processor Interface Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
PI-PT	MAJOR	test interface PCS sh	Processor Interface Port
PI-PT	WARNING	release data-module <ext>	Processor Interface Port

1 Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for either the first or second Processor Interface circuit packs).

PI-PT is the physical port on the TN765 Processor Interface circuit pack. If the Processor Interface Link (PI LINK) MO raises an alarm that can be correlated to an on-board port problem, then PI-PT is alarmed. In a system without High or Critical Reliability, there are no tests that run directly on Processor Interface port. The PI-LINK MO is responsible for the testing of the TN765 ports along with DCS links, AUDIX links, ISDN links, etc. Refer to the PI-LINK (Processor Interface Link) Maintenance documentation for details. In a High or Critical Reliability system, Processor Interface port is used to test the ports on the Standby Processor Interface circuit packs. If the test fails, a Major alarm is raised. More importantly, if a software requested SPE-interchange takes place and an alarm is raised on the Processor Interface port, then the interchange may abort due to alarm severities.

Hardware Error Log Entries and Test to Clear Values

Processor Interface Port PI-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test interface PCS sh r 1
1		Standby PI Port Test (#404)	MAJOR	ON	test interface PCS sh
18	0	busyout data-module <ext>	WARNING	OFF	release data-module <ext>
123 (a)	Any	None	MAJOR	ON	test link lnk-no
130 (b)		None			
257 (a)	Any	None	MAJOR	ON	test link lnk-no l

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. PI-LINK raised this alarm against PI-PT. The Processor Interface Loop Around test failed on one of the ports. Refer to PI-LINK Maintenance documentation for details on resolving this alarm. If this error resulted in an SPE-interchange, then issue the **test interface PCS sh** command on the Standby Processor Interface to try to resolve the alarm.

b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests: Descriptions and Error Codes

PI-PT can be tested by issuing the **test interface PCS** command on the Standby Processor Interface circuit pack. If the Active TN765 Processor Interface circuit pack is tested, then the active test sequence is run (**which is DESTRUCTIVE**). [Refer to PI-SCI (System Communication Interface) Maintenance documentation for details on these tests]. Only the Standby Processor Interface test sequence runs tests directly on PI-PT.

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Standby Processor Interface Port Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Standby Processor Interface

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Audit Test (#50) (a)		X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Standby Processor Interface Circuit Pack Test (#423) (b)	X	X	ND
Standby Processor Interface Port Test (#404)	X	X	ND

1 D = Destructive; ND = Nondestructive

Active Processor Interface

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SCI Start (#176) (c)		X	D
SCI Self Test (#231) (c)	X	X	ND
NPE Audit Test (#50) (a)		X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for information about these tests.

b. Refer to the PI-BD (Processor Interface Circuit Pack) Maintenance documentation for information about this test.

c. Refer to the PI-SCI (System Communication Interface) Maintenance documentation for information about these tests.

Standby Processor Interface Port Test (#404)

This test is the same as Test #182 in the Processor Interface Link (PI-LINK) Maintenance documentation. However, this test only runs on the Standby Processor Interface circuit pack. It is an on-board loop around test. This test checks the health of physical port on the circuit pack. If the test fails, then a Major alarm is raised on the circuit pack. When the circuit pack is put into local loop around mode, frames are looped internally on the circuit pack. If the test fails, the Processor Interface circuit pack reports the failure. It is a good check of most of the working hardware on the Processor Interface circuit pack.

Table 11-262. TEST #404 Standby Processor Interface Port Test

Error Code	Test Result	Description/ Recommendation
2 9 16 80 84 85 93 94 102	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1124	ABORT	The PI link for this port is currently disabled. This test does not run on disabled PI links. 1. Retry this test if the PI link is re-enabled. Enter the **display communication-interface link** command to verify that this link has been disabled.
1125	ABORT	The Processor Interface Loop Around Test on this port could not be executed since the Processor Interface circuit pack is not in the correct state. 1. Check PI-BD for possible errors and resolve them first. 2. Rerun the **test interface PCS sh** command. 3. If the test continues to abort while the PI-BD Test (#423) passes, escalate the problem.

Continued on next page

Table 11-262. TEST #404 Standby Processor Interface Port Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051	ABORT	Refer to the STBY-SPE Maintenance documentation for a description of these error codes.
12	FAIL	Processor Interface circuit pack reported that Loop Around Test failed. 1. Retry the test. 2. If the test continues to fail, try resetting the circuit pack via the **reset interface PCS** command. 3. If test continues to fail, replace the TN765 circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack.
	PASS	TN765 Processor Interface Circuit Pack Loop Around Test passed. The hardware associated with this port is functioning properly.

PI-SCI (System Communication Interface)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
PI-SCI[2]	MAJOR	test interface PCS (See Warning)	System Communication Interface

1 Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for Processor Interface circuit packs 1 or 2).

2 For additional repair information, see also PI-BD (Processor Interface Circuit Pack) Maintenance documentation.

WARNING:

The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.

The PI-SCI (System Communication Interface) MO is used to put the TN765 Processor Interface circuit pack into a state such that BX.25 (DCS, AUDIX, etc.) and ISDN links can be established. The TN765 Processor Interface circuit pack has downloadable firmware. It is the responsibility of PI-SCI to download the firmware to the TN765 circuit pack during initialization. Failures while communicating with the TN765 circuit pack are logged against the PI-SCI MO. There can be up to two SCIs. There is a one-to-one correlation of PI-SCI to Processor Interface circuit packs. In a High or Critical Reliability system, there can be four Processor Interface circuit packs, but only two on the same carrier are active at any one time. If errors against the SCI can be related to the Processor Interface circuit pack, then the circuit pack MO is alarmed (PI-BD). See also PI-LINK (Processor Interface Link) and PI-BD (Processor Interface Circuit Pack) Maintenance documentation.

When investigating BX.25 (DCS, AUDIX, etc.) and ISDN link problems, resolve PI-SCI errors initially, since they might clear up the Processor Interface link problems.

Hardware Error Log Entries and Test to Clear Values

PI-SCI System Communication Interface Error Log Entries

2817 (i)	Any	none	MAJOR/ WARNING[3]	OFF	test interface PCS l[2]
2818 (j)	Any	none	MAJOR/ WARNING[3]	OFF	test interface PCS l[2]
3073 (f)	Any	none	MAJOR/ WARNING[3]	OFF	test interface PCS l[2]

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 See WARNING below.

WARNING:
The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.

3 Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. An error occurred during a hot start processor element interchange that caused the associated Processor Interface links (BX.25 and/or ISDN-PRI) to go down temporarily. If these errors reoccur and there are no other errors against PI-BD or PI-SCI escalate the problem; otherwise, resolve the other alarm first.

2055	The checksum of the PI memory was not able to be retrieved.
2056	The PI was not able to be put into a stable state such that the switch to the new active PI failed to keep the existing PI links up.
2057	The active PI was unable to copy the image of its memory to the standby PI.
2058	System software error.

b. This error indicates a possible hardware failure on the TN765 Processor Interface circuit pack. If the error persists, and the SCI is unstable (resets often), type in **test interface PCS long** command. The Processor Interface firmware is redownloaded if the checksum fails. If the problem still exists, automatically redownload the Processor Interface firmware by typing **reset interface PCS**. If this doesn't work, then replace the TN765 Processor Interface circuit pack. Further problems should be escalated. These errors also raise alarms against the PI-BD (Processor Interface Circuit Pack).

NOTE:
To replace an SPE complex circuit pack in a Duplication Option System follow the procedures in Chapter 8, "Reliability Systems: A Maintenance Aid". For a Non-Duplication Option System follow procedures in Chapter 5, "Routine Maintenance Procedures" for instructions on how to replace the Processor circuit pack (TN786 or TN790).

Use the following steps for G3i-386 and later systems where the Processor Interface firmware resides in the flash ROM memory in the Processor circuit pack (i.e. TN786 or TN790) instead of Tape as in G3i-286. If the firmware can't be successfully downloaded into the Processor Interface circuit pack after entering the "reset interface PCS" command, then use the following steps:

1. Replace the TN765 Processor Interface circuit pack:
2. After the new TN765 Processor Interface circuit pack has been inserted successfully, enter "test interface PCS long" command to verify the results of tests.

If the error still indicates the failure for downloading the firmware into Processor Interface circuit pack, then it's possible that the firmware stored in the Processor circuit pack (TN786 or TN790) is corrupted.

3. Follow the Chapter 5, "Routine Maintenance Procedures" Software Upgrade procedure to load the system software from the Memory Card with the correct software release number.

   After the system software is successfully loaded into Processor circuit pack, boot the system up with the customer translation memory card in slot.

   If the failure for downloading the firmware into Processor Interface circuit pack persists after the system reboot, it's possible that the flash ROM chips in Processor circuit pack (TN786 or TN790) may be defective.

4. Replace the Processor circuit pack and repeat the step (3) to load the system software into the Processor circuit pack. Boot the system up again.

   If the failure for downloading the firmware into Processor Interface circuit pack persists after the system reboot, it's possible that the M-BUS at the backplane of control carrier may be defective. Replace the control carrier.

c. Error while communicating with TN765 circuit pack. The software lost handshake with the Processor Interface circuit pack. See Note (b) for recovery.

d. Error while communicating with TN765 circuit pack. See Note (b) for recovery. This error can also be caused by line problems. Investigate possible transmission errors or noise on the associated line.

e. An Aux Data value of 23 indicates that the software failed to open the tape in order to download the Processor Interface firmware. Check if the tape is currently in use (that is, if it is spinning or if the yellow LED is on). When the tape is idle, reissue the **test interface PCS long** command. If the test still fails or if the Aux Data value was other than 23, then refer to Test #176 (Sci Start Test) for details on recovery. For all other Aux Data values, reissue the **test interface PCS long** command, and refer to Test #176 (SCI Start Test) for details on recovery.

   NOTE:
   For G3i-386 and later, see Note (b) for recovery.

f. Error while communicating with TN765 circuit pack. See Note (b) for recovery. These errors also raise alarms against the PI-BD (Processor Interface Circuit Pack).

g. Download of Processor Interface firmware failed. If this error persists, then replace the TN765 Processor Interface circuit pack. This error also raises an alarm against PI-BD if the threshold is reached.

h. An audit of the firmware failed. If BX.25 and ISDN links are still up, no action is needed. If Processor Interface circuit pack is reset continuously, recover as in Note (b).

i. Error while communicating with TN765 Processor Interface circuit pack. See Note (b) for recovery. System software problem internal to the process that monitors Processor Interface link activity. Escalate the problem if error causes the Processor Interface to be reset (loss of service is noticed).

j. This error indicates that the TN765 Processor Interface circuit pack did not clear up the overload condition within one minute of logging the initial 2817 error (overload detected). The circuit pack was reset and all Processor Interface links on that circuit pack were also reset. If this error continues to occur, escalate the problem.

Short and Long Test Sequences

The SCI and Processor Interface circuit pack are both tested via the same system technician command. The system technician command is **test interface PCS l** or **sh** where PCS is an active Processor Interface circuit pack.

WARNING:
The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.

For information about testing the Standby Processor Interface circuit pack, see PI-BD Maintenance documentation. If the Active Processor Interface has no enabled links (see Communication-Interface Links Form in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids"), only XXX-BD (Common Port Circuit Pack) tests execute.

System Technician Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SCI Start Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SCI Start Test (#176)		X	D
SCI Self Test (#231)	X	X	ND
Control Channel Loop Test (#52) (a)	X	X	ND
NPE Audit Test (#50) (a)		X	ND

1 D = Destructive; ND = Nondestructive

a. For information about these tests, refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation. These tests are run on the PI-BD (Processor Interface Circuit Pack) Maintenance object.

SCI Start Test (#176)

This test is destructive.

This test restarts the System Communication Interface. This implies all BX.25 (DCS, AUDIX, mis, etc.) and ISDN links are restarted. The checksum of the downloadable firmware is tested. If the checksum fails, the firmware is redownloaded from tape. If it passes, SCI Start completes and the associated BX.25 and ISDN Links are started up. If a circuit pack needs to be replaced, refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on replacing an SPE circuit pack.

In G3i-386 and later, the Processor Interface circuit pack firmware is downloaded from the flash ROM memory of Processor circuit pack. If the checksum test fails, then the firmware is re-downloaded again from Processor circuit pack. If it passes, SCI Start completes and the associated BX.25 and ISDN links are started up. If the checksum failure persists, refer the footnote (b) of Hardware Error Table for repair procedure.

Table 11-263. TEST #176 SCI Start Test

Error Code	Test Result	Description/ Recommendation
9 10	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	Could not reset the Processor Interface circuit pack. 1. Wait one minute, and retry the command. 2. If test continues to fail, replace TN765 Processor Interface circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack. 3. If problem continues to persist, escalate the problem.

Continued on next page

Table 11-263. TEST #176 SCI Start Test — *Continued*

Error Code	Test Result	Description/ Recommendation
16 80 94 102	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If problem still exists, redownload firmware via **reset interface** command. 3. For G3i-386 and later, see note (b) of Hardware Error Table for repair procedure
200	FAIL	Checksum of Processor Interface failed. 1. Wait one minute and retry. 2. If the test continues to fail with a checksum failure, there could be corruption on the tape. Replace the tape with a new tape that contains Processor Interface firmware. Retry the command. For G3i-386 and later, see note (b) of Hardware Error Table for repair procedure. 3. In G3i-286 if the problem continues to exist after replacing the tape, then replace the TN765 Processor Interface circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions about replacing an SPE complex circuit pack. Retry the command. If problem persists, escalate the problem.

Continued on next page

Table 11-263. TEST #176 SCI Start Test — *Continued*

Error Code	Test Result	Description/ Recommendation
23 199 9000s	FAIL	Processor Interface Download failed. Refer to TABLE A Tape Unit Aux Data Table and follow the repair recommendations. 1. Wait one minute and retry. Could be tape access problem. Check that a tape exists in the tape drive. For G3i-386 or later, see note (b) of Hardware Error Table for repair procedure 2. If problem persists and TAPE is idle when command is entered, then a problem may exist in either the TAPE or the Processor Interface circuit pack. Replace the tape with a new tape that contains Processor Interface firmware. Retry the command.
	PASS	TN765 Processor Interface circuit pack initialized correctly. Processor Interface links (BX.25 and ISDN) should recover now. See PI-LINK for more information if links do not recover.

SCI SELF TEST Test (#231)

This is an on-board test which checks the basic functionality of the TN765 circuit pack. This test runs in the background periodically, or it can be invoked via the **test interface PCS** command. If this test continuously fails, then replace the TN765 Processor Interface circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack.

Table 11-264. TEST #231 SCI Self Test

Error Code	Test Result	Description/ Recommendation
11	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
13	ABORT	The TN765 PI circuit pack has not been reset yet or is currently being reset. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort with error code 13, then reset the TN765 via "test interface PCS long". **CAUTION:** *Resetting the TN765 will cause all BX.25 (Audix, cms, etc.) and ISDN-PRI links to be briefly torn down.* 3. If TN765 fails to be reset, refer to test 176 section description. 4. If the test still aborts with error code 13, escalate the problem.

Continued on next page

Table 11-264. TEST #231 SCI Self Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4xxx	FAIL	Hardware on the TN765 Processor Interface failed. 1. 4000 - Assigned data link hardware failure. 2. 4001 - Unassigned data link hardware failure. 3. 4002 - CPU function test failed - hardware failure. 4. 4003 - Local Processor Interface RAM memory test failed - hardware failure. 5. 4004 - Local EPROM memory test failed - hardware failure. 6. For all of the above errors, retry the test. If it fails again, the Communication Interface should be restarted. Type in a **reset interface** command. If the reset is successful, retry the **test interface** command. If Test #231 still fails with error codes other than 4001, then replace TN765 Processor Interface circuit pack. Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace an SPE complex circuit pack. If test fails with Error Code 4001, then an on-board failure is associated with a non-used port on Processor Interface circuit pack. TN765 circuit pack should be replaced if this port will be used in the future.
	PASS	TN765 Processor Interface circuit pack passed self-test. On-board hardware is functioning correctly.

PKT-BUS (Packet Bus)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
PKT-BUS	MAJOR	test pkt P l r 2	Packet Bus
PKT-BUS	MINOR	test pkt P l	Packet Bus
PKT-BUS	WARNING	test pkt P l	Packet Bus

1 Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

The Packet Bus consists of a single bus, and one such bus appears in each port network. The Packet Bus in each port network is physically independent. Therefore, there is one instance of the Packet Bus maintenance object for each port network.

In DEFINITY G3iV1.1-286 or G3iV2-386, the Packet Bus is used to carry ISDN-BRI and ASAI signaling information. The SPE interface to the Packet Bus is in the TN778 Packet Control circuit pack (PKT-CTRL). Packet Bus maintenance is performed only when the Packet Bus is enabled on the Maintenance-Related System Parameters form. Packet Bus testing is dependent on the Packet Bus port (M/T-PKT) of the TN771 Maintenance/Test circuit pack (M/T-BD), the TN778 Packet Control Circuit Pack (PKT-CTRL), the TN570 Expansion Interface circuit pack (EXP-INTF), and on the ISDN-BRI circuit packs (BRI-BD). Packet Bus tests may abort if some of this hardware is not present in the system. Also, these tests may yield inconsistent results if some of this hardware is defective.

The interactions between the Packet Bus and the circuit packs that use the bus are complex. For this reason, the Packet Bus can be alarmed due to a circuit pack failure and, conversely, circuit packs can be alarmed due to a Packet Bus failure. Chapter 9, "Packet Bus Fault Isolation and Correction" describes Packet Bus maintenance and also the interactions of the bus with the Packet circuit packs. The chapter discusses fault isolation and correction procedures, and it should be referenced for all procedures and required decisions. The "Packet Bus Fault Isolation Flowchart" section of Chapter 9, "Packet Bus Fault Isolation and Correction" is the normal starting point in the chapter for experienced technicians. However, technicians who are unfamiliar with the Packet Bus and its use in DEFINITY G3iV1.1-286 or G3iV2-386 should refer to the introductory material. This section on PKT-BUS is limited to a description of the Error and Alarm Log entries for the Packet Bus maintenance object and to a description of the Packet Bus test sequence.

A failure of one or more circuit packs that use the Packet Bus can cause a Packet Bus alarm. In addition, a Packet Bus failure can cause loss of service to one or more such circuit packs, as well as to the ports and endpoints associated with the ISDN-BRI circuit pack (BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, and ASAI-ADJ). These interactions are discussed in the "Circuit Packs That Use the Packet Bus" section of Chapter 9, "Packet Bus Fault Isolation and Correction".

The following list summarizes some of the important points to consider when working with the Packet Bus. For a complete description of these points, refer to the introductory sections of Chapter 9, "Packet Bus Fault Isolation and Correction".

- The Maintenance/Test circuit pack (TN771) is a critical tool for isolating Packet Bus faults. This circuit pack is present in each port network of a High or Critical Reliability system that is using the Packet Bus. In a Standard system, the circuit pack may be included as a Customer option. If a TN771 is not present, **one must be taken to the customer site** to allow for proper fault isolation. (A determination as to whether a TN771 circuit pack is in the system is made by entering the **list configuration** command.) Use of the Maintenance/Test Packet Bus port facilities is described under "The Maintenance/Test Circuit Pack (TN771)" in Chapter 9, "Packet Bus Fault Isolation and Correction". Also, in the same chapter, the section entitled "Special Precaution Concerning the TN771" describes other circumstances when a TN771 must be taken to the customer site.
- Certain catastrophic Packet Bus failures have an effect on Packet circuit pack, port, and endpoint maintenance. The following list summarizes the impact of such failures in this regard. For further details, refer to the "Maintenance of the Packet Bus" section of Chapter 9, "Packet Bus Fault Isolation and Correction":
  - ISDN-BRI circuit pack (BRI-BD) in-line errors indicating possible Packet Bus failures are placed into the error log, but are not acted upon.
  - ISDN-BRI port (BRI-PORT, ABRI-PORT) in-line errors indicating possible Packet Bus failures **are neither placed into the error log nor acted upon**.
  - ISDN-BRI endpoint (BRI-SET, BRI-DAT, ASAI-ADJ) in-line errors **are neither placed into the error log nor acted upon**.
  - Circuit pack and port in-line errors that are not relevant to the Packet Bus or that indicated a circuit pack failure are acted upon in the normal fashion.
  - Normal background maintenance (periodic and scheduled) is not affected.
  - Foreground maintenance (for example, commands executed on the Manager I terminal) are not affected.

  The actions in the previous list serve to reduce the system load, which could become excessive if too many maintenance objects are affected by a Packet Bus failure. However, such an excessive load should in no way impede the isolation and the correction of the faults.

When the actions in the list are implemented, Error Type 3329 is logged against PKT-BUS, and a Warning alarm is raised (although other Packet Bus errors in many cases raise more severe alarms, thereby overriding the Warning alarm).

- A Packet Bus failure in the Processor Port Network (PPN) causes Packet traffic (ISDN-BRI, ASAI) in the Expansion Port Networks (EPNs) to fail, even though there is no Packet Bus failure in the EPN. This is true because all Packet traffic requires communication with the Packet Control (PKT-CTRL) circuit pack in the PPN. Due to this requirement, a PPN Packet Bus failure must be investigated first whenever Packet Bus failures occur in multiple port networks.

Hardware Error Log Entries and Test to Clear Values

PKT-BUS Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test pkt
1 (a)	1-2	Packet Circuit Pack Audit Test (#570)	MAJOR	ON	test pkt P l r 2
257 (b)	Any	Packet Control Bus Loop Around Test (#571)	MAJOR	ON	test pkt P l r 2
513 (c)	1-24	Maintenance/Test Circuit Pack Query Test (#572)	MAJOR	ON	test pkt P l r 2
1793 (d)	Any	none			
2049 (e)	1-3	Maintenance/Test Circuit Pack Query Test (#572)	MINOR	ON	test pkt P l r 2
2305 (f)	1-24	Maintenance/Test Circuit Pack Query Test (#572)			test pkt P l
3329 (g)	1-7 or 1000-1007	none	WARNING	ON	test pkt P l
3585 (h)	Any	none	MINOR	ON	test pkt P l
3841 (i)	Any	none	MINOR	OFF	

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

NOTE:
For PKT-BUS, an ON-BOARD alarm indicates a problem with the Packet Bus itself.

Notes:

a. Within the last minute, packet circuit packs have reported errors that indicate a possible Packet Bus failure. The Aux Data value is 1 or 2, indicating that only one or more than one Packet circuit pack (respectively) have reported a possible Packet Bus failure.

b. Packet Bus maintenance has been unable to perform loop around tests from the TN778 Packet Control circuit pack (PKT-CTRL) to itself. This could indicate faults on the Packet Control circuit pack rather than on the Packet Bus. Examine the Error and Alarm Logs for any such errors.

c. The Maintenance/Test Packet Bus port (M/T-PKT) for this port network has determined that there are more Packet Bus faults than the port can correct. The Aux Data value indicates the number of faulty leads.

d. Packet circuit packs have detected possible Packet Bus failures via in-line error or background test failure. Examine the Error and Alarm logs for more specific PKT-BUS errors.

e. The Maintenance/Test Packet Bus port (M/T-PKT) has caused Packet Bus leads to be swapped to spare leads. This error appears only in a High or Critical Reliability system. The Aux Data value indicates the number of faulty leads. If this is the only active error against the Packet Bus, **the Packet Bus is still in service**. Therefore, due to the disruptive nature of the Packet Bus Fault Isolation and Correction procedures, repairs should be deferred until a time when these procedures cause the least interruption in service. This matter is resolved via consultation with the customer. However, be sure not to delay repairs for too long, since the switch is not able to recover from another Packet Bus failure until the existing one is resolved. The procedure described in the section entitled "Special Precaution Concerning the TN771" in Chapter 9, "Packet Bus Fault Isolation and Correction" is used to ensure that the Maintenance/Test is giving correct information. This procedure may require that a new TN771 be taken to the customer site.

f. The Maintenance/Test Packet Bus port (M/T-PKT) has detected open leads on the Packet Bus. The Aux Data value indicates the number of open leads.

g. Packet circuit pack, port, and endpoint maintenance has been disabled due to a Packet Bus failure. The Aux Data value indicates which sources have reported errors that have caused maintenance to be disabled. These sources include the following:

- In-line errors from Packet circuit packs.
- Packet Bus Uncorrectable report from the Maintenance/Test Packet Bus port (M/T-PKT).
- Packet Bus Interface Failure report from the Packet Control

  (PKT-CTRL).
- In an EPN, packet circuit pack, port, and endpoint maintenance will be disabled if a Packet Bus failure occurs in the PPN.

The Aux Data values that indicate these sources are identified in the following table:

Aux Data	Packet Circuit Pack	Maint/Test Circuit Pack	Packet Control
1/1001	X		
2/1002		X	
3/1003	X	X	
4/1004			X
5/1005	X		X
6/1006		X	X
7/1007	X	X	X

If the Aux Data value is in the range 1000-1007, then Packet circuit pack, port, and endpoint maintenance has been disabled in the EPN due to a PPN Packet Bus failure. If the value is greater than 1000, then there is also a failure of the packet Bus in this EPN and the source of the other information can be determined from the table above.

NOTE:
It is important to remember that problems reported by Packet circuit packs may be caused by **any** circuit pack. However, only Packet circuit packs can detect such problems (inasmuch as TDM-only circuit packs are not affected by these problems).

h. Include Packet circuit pack, port, and endpoint maintenance has been disabled due to more than one circuit pack reporting in-line errors. If this occurs more than three times in 15 minutes (that is, if maintenance is disabled due to errors and then re-enabled because no more errors are reported), a Minor alarm is raised against the Packet Bus. Note that this error may still be present in the error log even if the "Circuit Pack Audit Test" reports that only one circuit pack has indicated a problem. This occurs if more than one circuit pack reported errors with in any one minute interval since the Packet Bus fault occurred.

NOTE:
Because alarms against a Maintenance Object are not resolved until all alarming has been cleared, an alarm due to a missing Maintenance/Test Packet Bus must be cleared by installing a Maintenance/Test circuit pack before it can be determined if other Packet Bus alarms have been resolved.

i. The Maintenance/Test Packet Bus port (M/T-PKT) for this port network is not in service. This error appears only in a High or Critical Reliability system, and it can occur in the following cases:

- The Packet Bus port has been busied out (indicated by an Error Type 18), and a Warning alarm is active against M/T-PKT in the same port network. Release the port by entering the **release port PCSS04** command.
- The Packet Bus port has failed. Look for alarms against M/T-PKT, and attempt to resolve these alarms.
- The Maintenance/Test circuit pack was not recognized by the system at the last system restart. Replace the Maintenance/Test circuit pack. There is no Maintenance/Test circuit pack installed in this port network. One must be installed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when you are inspecting errors in the system. By clearing error codes associated with the *Packet Circuit Pack Audit Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Circuit Pack Audit Test (#573)	X	X	ND
Maintenance/Test Circuit Pack Query Test (#572)	X	X	ND
Packet Control Bus Loop Around Test (#571)	X	X	ND

1 D = Destructive; ND = Nondestructive

Packet Control Bus Loop Around Test (#571)

This test uses circuitry on the Packet Control circuit pack (TN778) to look for faults on the Packet Bus. If the Packet Control circuit pack has detected parity errors on the Packet Bus, or if it is unable to loop back data to itself, the test fails. The test passes if no parity errors are detected and if data is successfully looped back.

This test provides information only for the PPN of a standard system. If the test is run in an EPN or in the PPN of a High or Critical Reliability system, the test aborts.

Table 11-265. Test #571 Packet Control Bus Loop Around Test

Error Code	Test Result	Description/ Recommendation
1022	ABORT	No Packet Control circuit pack exists in this port network. 1. This test gives information only for the PPN. Ignore results from this test whenever it is run in other port networks.
1024	ABORT	The Packet Control circuit pack is in use by Packet Control maintenance at this time. The test cannot be completed until the Packet Control circuit pack becomes available. 1. Wait for Packet Control maintenance to finish using the Packet Control circuit pack. (The green LED goes out.) 2. Re-enter the command.
1141	ABORT	The Packet Control circuit pack is out-of-service. 1. Determine if the Packet Control circuit pack is busied out (this is indicated by an Error Type 18 logged against PKT-CTRL). If the pack is busied out, release the pack by entering the **release packet-control** command. Then re-enter the command. 2. If the Packet Control circuit pack is NOT busied out, refer to PKT-CTRL Maintenance documentation for recommended repair procedures.

Continued on next page

Table 11-265. Test #571 Packet Control Bus Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1143	ABORT	This test is run only in High or Critical Reliability systems. 1. Ignore results from this test whenever it is run in a High or Critical Reliability system. 2. If this system does not have High or Critical Reliability, escalate the problem.
2000	ABORT	The test timed-out while waiting for the packet to be returned from the loop around. 1. Re-enter the command at one minute intervals a maximum of five times. 2. If the test continues to abort, check for problems with the Packet Control (look for PKT-CTRL errors in the Error and Alarm Logs). 3. If there is no problem with the Packet Control circuit pack, escalate the problem.
2076	ABORT	The parity error check circuitry on the Packet Control circuit pack is not functioning correctly. 1. Run the test again. 2. If the same abort occurs again, refer to PKT-CTRL Maintenance documentation to attempt to correct the fault.
2060	ABORT	The link on the Packet Bus that is being used to perform the test has failed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, check for problems with the Packet Control (look for PKT-CTRL error in the Error and Alarm Logs). 3. If there is no problem with the Packet Control circuit pack, escalate the problem.

Continued on next page

Table 11-265. Test #571 Packet Control Bus Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Maintenance could not allocate all of the necessary system resources to perform this test.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The Packet Control Bus Loop Around Test failed (parity errors were detected from the test packet).
2	FAIL	The Packet Control Bus Loop Around Test failed (the Packet Control circuit pack could not bring up a loop around link on the Packet Bus). 1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9, "Packet Bus Fault Isolation and Correction" to determine the cause of the test failures.
	PASS	No faults have been detected on the Packet Bus by the Packet Control circuit pack. This indicates that the Packet Bus is operating correctly.

Maintenance/Test Circuit Pack Query Test (#572)

This test queries the Maintenance/Test Packet Bus port about the state of health of the Packet Bus. If the Maintenance/Test circuit pack indicates that the Packet Bus has faults, the test fails. The corresponding failure code describes the severity, type, and number of faults. The test passes if the Packet Bus is fault-free.

NOTE:
A Maintenance/Test circuit pack is usually not present in a Standard system unless the customer has purchased this circuit pack to use for ISDN-PRI test calls, or to enhance the system's ability to quickly recognize a Packet Bus failure.

Table 11-266. TEST #572 Maintenance/Test Circuit Pack Query Test

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The Packet Bus port of the Maintenance/Test circuit pack is out of service. 1. Determine if the port is busied out. If so, release the port by entering the **release port PCSS04** command. Re-enter the test command. 2. If there are alarms active against the Packet Bus port (M/T-PKT), refer to M/T-PKT Maintenance documentation to resolve them. Then re-enter the test command.
1142	ABORT	No Maintenance/Test circuit pack Packet Bus port is in service in this port network. 1. If this system has High or Critical Reliability, either (a) the Maintenance/Test circuit pack for this port network has failed, and should be replaced, (b) the Maintenance/Test circuit pack has been busied out, and should be released, or (c) there is no Maintenance/Test circuit pack in this port network, and one must be installed. 2. In a system without High or Critical Reliability, the Maintenance/Test Packet Bus Port may not be present. If the port is present, and if it is busied out or has failed, release or replace the circuit pack. If there is no Maintenance/Test circuit pack, ignore the results of this test for this port network.

Continued on next page

Table 11-266. TEST #572 Maintenance/Test Circuit Pack Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	The test timed-out while waiting for an uplink CCMS response from the Maintenance/Test Packet Bus port. 1. Re-enter the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, check for problems with the Maintenance/Test Packet Bus port (look for M/T-PKT in the Error and Alarm Logs). 3. If there is no problem with the Maintenance/Test Packet Bus port, escalate the problem.
2059	ABORT	The Maintenance/Test Packet Bus port has reported a hardware failure. 1. Refer to M/T-PKT Maintenance documentation to correct the problem. 2. Re-enter the test command. 3. If the test continues to abort with this code, escalate the problem.
2077	ABORT	The Maintenance/Test Circuit Pack Query located more than one Maintenance/Test Packet Bus port in the port network. **NOTE:** The software should not allow this to occur. This is an internal system error. Escalate the problem, but also attempt the following work-around steps. 1. Remove all Maintenance/Test circuit packs from the port network. 2. Insert one Maintenance/Test circuit pack (there should not be more than one in a port network). 3. Re-enter the test command.

Continued on next page

Table 11-266. TEST #572 Maintenance/Test Circuit Pack Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Maintenance could not allocate all of the necessary system resources to perform this test.
2500	ABORT	An internal operation failed; the test could not be completed. 1. Re-enter the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
XYZZ	FAIL	The Maintenance/Test Packet Bus port has detected faults on the Packet Bus. The error code is encoded as follows:
1xxx		The Maintenance/Test Packet Bus port has reconfigured the Packet Bus around the faulty leads. This should occur only in High or Critical Reliability systems.
2xxx		The Maintenance/Test Packet Bus port is unable to correct all of the Packet Bus faults it has detected.
x0xx		None of the Packet Bus faults are open faults.
x1xx		At least some of the Packet Bus faults are open faults. Look for Error Type 2305 in the Error Log. The Aux Data value indicates the number of open leads.
xxZZ		The last two digits of the error code indicate the total number of faulty Packet Bus leads the Maintenance/Test Packet Bus port has detected. 1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9, "Packet Bus Fault Isolation and Correction" to determine the cause of the failures.
	PASS	No faults have been detected on the Packet Bus by the Maintenance/Test circuit pack. This indicates that the Packet Bus is operating correctly.

Packet Circuit Pack Audit Test (#573)

This test determines whether Packet circuit packs have reported Packet Bus-related in-line errors within the last minute. If so, the failure code indicates whether one or more circuit packs have reported failures within the last minute.

Due to the one minute time constraint included as part of this test, the test is designed to delay 15 seconds before returning a result in cases where the test has failed within the last five minutes. This procedure helps ensure that a repeated sequence of the test does not always yield the same result. If no failure has occurred in the last five minutes, a PASS is returned immediately.

Table 11-267. Test #573 Packet Circuit Pack Audit Test

Error Code	Test Result	Description/ Recommendation
2500	ABORT	An internal operation failed; the test could not be completed. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	One Packet circuit pack has reported Packet Bus-related in-line errors within the last minute.
2	FAIL	More than one Packet circuit pack has reported Packet Bus-related in-line errors within that last minute. 1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9, "Packet Bus Fault Isolation and Correction" to determine the cause of the error reports.
	PASS	No Packet circuit packs have reported Packet Bus-related in-line errors within the last minute. This indicates that the Packet Bus is healthy, or that a Packet Bus fault is transient or is being caused by a faulty Packet circuit pack. If this test passes while there are other signs of a Packet Bus failure (as indicated, for example, in the Error/Alarm Logs or by other test failures), refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9, "Packet Bus Fault Isolation and Correction" to isolate the problem.

PKT-CTRL (Packet Control Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PKT-CTRL	MAJOR	reset packet-control C l[1]	Packet Control Circuit Pack
PKT-CTRL	MINOR	test packet-control C l[2]	Packet Control Circuit Pack
PKT-CTRL	WARNING	release packet-control C	Packet Control Circuit Pack

1 If the specified Packet Control circuit pack is in the active SPE, it must first be busied-out via the **busyout packet-control C** command. After testing has completed, the Packet Control circuit pack should be released from the busyout state via the **release packet-control C** command.

2 Where C is the carrier designation (A or B) and should be specified only in a High or Critical Reliability system.

CAUTION:

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems that are not isolated to the Packet Control. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction" in addition to the MO documentation for Packet Bus.

The TN778 Packet Control circuit pack is the hardware component that serves as the interface between the SPE and the Packet Bus. It terminates the Link Access Procedure D (LAPD) protocol and provides support for thousands of signaling links. As shown in Figure 11-86, a Packet Control link generally terminates on the Packet Control circuit pack and a packet endpoint which is connected to a Packet circuit pack. An ASAI adjunct is an example of a packet endpoint, and a TN556 is an example of a Packet circuit pack. In G3iV1.1-286 or G3iV2-386, the following Packet circuit packs (packs that can connect to the Packet Bus) are available:

- TN556 ISDN-BRI Line Circuit Pack
- TN570 Expansion Interface Circuit Pack

- TN771 Maintenance/Test Circuit Pack
- TN778 Packet Control Circuit Pack

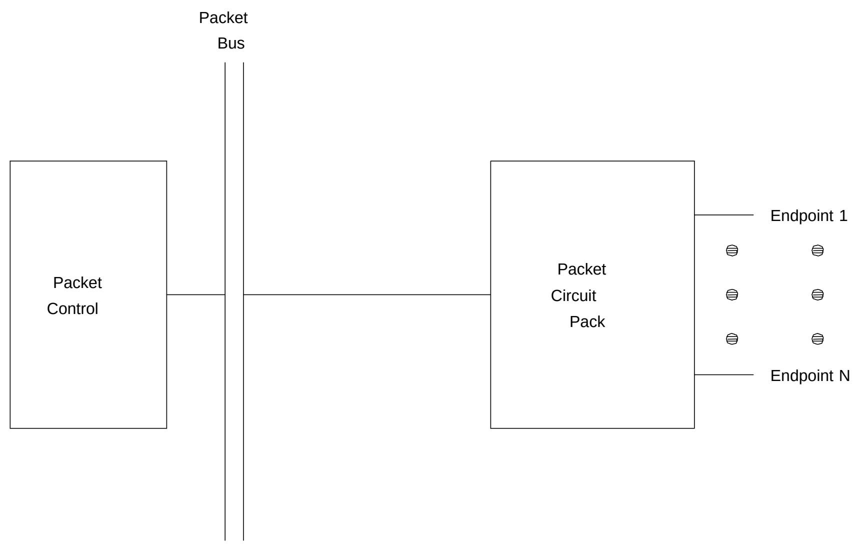

Figure 11-86. Hardware Configuration

The Packet Control circuit pack is not administered in the normal manner; there is no **add** or **remove** command associated with it. However the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form indicates if the Packet Control circuit pack is "administered." If the "Packet Bus Activated?" field is set to "yes," a Packet Control circuit pack should be installed in the system, since the Packet Control circuit pack is required in systems which use the Packet Bus. If a Packet Control circuit pack is not installed, and the "Packet Bus Activated?" field is set to "yes," a major on-board alarm is raised against the PKT-CTRL MO. This alarm indicates that the Packet Control circuit pack is "missing." Refer to the "Maintenance-Related System Parameters Form" section in Chapter 5, "Routine Maintenance Procedures" for more information on the "Packet Bus Activated?" field.

Note that the Packet Control circuit pack is listed by the **list configuration all** or **list configuration control** commands only if the Packet Control circuit pack is physically inserted into its slot and the Packet Bus is activated by setting the "Packet Bus Activated?" field to "yes" on the Maintenance-Related System Parameters Form. If the Packet Control circuit pack is physically inserted into its slot but the Packet Bus is not activated, then the Packet Control circuit pack will not appear in the output of the **list configuration all** or **list configuration control** commands.

The **status packet-control C** command provides useful information about the Packet Control circuit pack. This command displays the service state of the circuit pack and various link-related information. The service state "out" indicates that service is not being provided and users are being disrupted. Maintenance takes the Packet Control circuit pack out-of-service due to certain faults, or as a result of the **busyout packet-control C** command being run. Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for more information on the **status packet-control** command.

Hardware Error Log Entries and Test to Clear Values

Packet Control Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1(a)	Any	None	MAJOR	ON	reset packet-control C (k)
18	0	busyout packet-control C	WARNING	OFF	release packet-control C
257 (b)	Any	None	MAJOR	ON	reset packet-control C (k)
513 (c)	0	None			
769 (d)	Any	Loop Around Test (#585)			
1025 (e)	1	Parity Circuitry Test (#584)	MINOR	ON	test packet-control C l
1281 (f)	0	None			
1537 (g)	0	None			
1793 (h)	0	None			
2049 (i)	0	None			
2305 (j)	Any	Download Test (#581)	MAJOR	OFF	reset packet-control C

Notes:

a. This error occurs when maintenance software resets the Packet Control circuit pack due to an in-line error or certain test failures. Once a threshold number of these errors occur, maintenance places the Packet Control circuit pack into an out-of-service state, and a major on-board alarm is raised on the Packet Control circuit pack.

b. This error occurs due to certain in-line errors and test failures. This error is very serious, and when it occurs maintenance software immediately escalates testing to the destructive reset test (#586).

c. This error indicates that a loss of communication was detected between the SPE software and the Packet Control circuit pack. No alarm is raised. However, if this error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.

d. This error occurs when the Packet Control Loop Around Test (#585) fails because a link cannot be established or because the Packet Control circuit pack cannot send and receive data correctly. No alarm is raised.

However, if this error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.

e. This error occurs when the Packet Control Parity Circuitry Test (#584) fails, thus indicating a possible fault with the parity circuitry in detecting Packet Bus parity errors. If this error occurs a number of times exceeding a defined threshold, a minor on-board alarm is raised.

f. This error occurs when a certain circuit pack-level diagnostic test fails, thus indicating a transient fault (which has been recovered) existed on the Packet Control/Packet Bus interface. No alarm is raised because the error does not isolate the fault to the Packet Control circuit pack. However, if the error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.

g. This error occurs when a certain circuit pack-level diagnostic test fails, indicating there is a fault on the Packet Control/Packet Bus interface. No alarm is raised because the Packet Bus may be the source of problem. When this error occurs, Packet Bus maintenance is notified, thereby causing appropriate tests to run.

h. This error occurs when a parity error is detected by the Packet Control circuit pack, indicating some data sent over the Packet Bus is corrupted. No alarm is raised against the Packet Control circuit pack because the problem may be associated with the Packet Bus. When this error occurs, Packet Bus maintenance is notified, thereby causing appropriate tests to run.

i. This error occurs when the Packet Control circuit pack receives a threshold number of frames with invalid address. No alarm is raised because there is no direct indication of a Packet Control fault. The frames may be corrupted by the sending side or by the Packet Bus. No maintenance activity is triggered by this error. No action is required.

j. This error occurs when the Packet Control Download Test (#581) fails. Once a threshold number of these errors occur, a major off-board alarm is raised. Maintenance software retries the download test repeatedly until it passes. Since the **reset packet-control C** command causes the firmware to be downloaded and provides additional diagnostics on this error type, this command should be used when a download failure has occurred.

k. If the specified Packet Control circuit pack is in the active SPE, it must first be busied-out via the **busyout packet-control C** command. After testing has been completed, the Packet Control circuit pack should be released from the busyout state via the **release packet-control C** command.

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the tables below. By clearing error codes associated with the *Packet Control Parity Circuitry Test,* for example, you may also clear errors generated from other tests in the testing sequence..

Active PKT-CTRL

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Control Reset Test (#586)			D
Packet Control Parity Circuitry Test (#584)		X	ND
Packet Control Loop Around Test (#585)	X	X	ND
Packet Control Error Counter Read and Clear Test (#583)		X	ND

1 D = Destructive; ND = Nondestructive

Standby PKT-CTRL

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Packet Control Reset Test (#586)	X	X	ND
Packet Control Loop Around Test (#585)	X	X	ND
Packet Control Error Counter Read and Clear Test (#583)	X	X	ND

1 D = Destructive; ND = Nondestructive

Packet Control Error Counter Read and Clear Test (#583)

This test involves reading and clearing the error counters on the Packet Control circuit pack. The test is performed by sending multiple maintenance requests to the Packet Control circuit pack and waiting for the response to each of the "read and clear" commands from the circuit pack.

Table 11-268. TEST #583 Packet Control Error Counter Read and Clear Test

Error Code	Test Result	Description/ Recommendation
1029 2011 2012 2013 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-268. TEST #583 Packet Control Error Counter Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	FAIL	The Packet Control circuit pack is not operational. A busied-out Packet Control circuit pack can still be operational. 1. Determine if the Packet Control circuit pack has an active major alarm (via the **display alarm** command). If it does, follow the recommended repair procedures to retire the alarm. Once the alarm is retired, the original command can be retried. 2. If the Packet Control circuit pack does not have an active major alarm, wait one minute and retry the original command. If the Error Code 1141 is again observed, go to the next step. 3. If the Packet Control circuit pack is on the active SPE and is not currently busied-out, issue the **busyout packet-control C** command. Issue the **reset packet-control C** command. If the reset command fails, follow the recommended repair procedures for Test #586. If the reset command passes, issue the **release packet-control C** command (if the Packet Control circuit pack is on the active SPE), and reissue the original command. If the original command again aborts with Error Code 1141, escalate the problem.

Continued on next page

Table 11-268. TEST #583 Packet Control Error Counter Read and Clear Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Software was unable to read and clear the Packet Control circuit pack error counters. 1. Retry the command. 2. If the same error code is observed, and the Packet Control circuit pack is on the active SPE and is not currently busied-out, issue the **busyout packet-control C** command. Issue the **reset packet-control C** command. If the reset command fails, follow the recommended repair procedures for Test #586. If the reset command passes, issue the **release packet-control C** command (if the Packet Control circuit pack is on the active SPE), and then reissue the original command.
	PASS	The Packet Control circuit pack succeeded in servicing the read and clear error counter requests.

Packet Control Parity Circuitry Test (#584)

This test checks the error detection capability of the Packet Control circuit pack's circuitry by verifying that it correctly identifies frames on the Packet Bus with parity errors.

NOTE:
This test aborts in a High or Critical Reliability system, or in a system with an alarmed PPN Packet Bus.

Table 11-269. TEST #584 Packet Control Parity Circuitry Test

Error Code	Test Result	Description/ Recommendation
1024	ABORT	The Packet Control circuit pack's parity circuitry is currently being used by another maintenance test. 1. Retry the command at one-minute intervals a maximum of five times.
1139	ABORT	The PPN Packet Bus is alarmed. 1. Try to retire the alarm associated with the PKT-BUS (Packet Bus). Refer to the Alarm log via the **display alarm** command. 2. Retry the command when the alarm associated with the Packet Bus circuit pack is retired.

Continued on next page

Table 11-269. TEST #584 Packet Control Parity Circuitry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The Packet Control circuit pack is not operational. **NOTE:** A busied-out Packet Control circuit pack can still be operational. 1. Determine if the Packet Control circuit pack has an active major alarm (via the **display alarm** command). If it does, then follow the recommended repair procedures to retire the alarm. Once the alarm is retired, the original command can be retried. 2. If the Packet Control circuit pack does not have an active major alarm, then wait one minute and retry the original command. If the Error Code 1141 is observed again, go to the next step. 3. If the Packet Control is not currently busied-out and is on the active SPE, issue the **busyout packet-control C** command. Issue the **reset packet-control C** command. If the reset command fails, follow the recommended repair procedures for Test #586. If the reset command passes, issue the **release packet-control C** command (if the Packet Control circuit pack is on the active SPE), and then reissue the original command. If the original command again aborts with Error Code 1141, escalate the problem.
1143	ABORT	The test should not be run in a High or Critical Reliability system. 1. No action is required since the parity circuitry is not used to monitor the Packet Bus in a High or Critical Reliability system.
2100	ABORT	Was unable to allocate necessary resources. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 11-269. TEST #584 Packet Control Parity Circuitry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The Packet Control parity circuitry is malfunctioning. 1. Issue **test packet-control C long** command to retry the test. 2. This could be caused by a Packet Bus fault. Refer to Chapter 9, "Packet Bus Fault Isolation and Correction" for the procedures to be followed. 3. The Packet Control circuit pack needs to be replaced. However, it is likely that the Packet Control is providing service, and only its ability to maintain the Packet Bus is affected by the fault. If the Packet Control appears to be providing service (packet endpoints are functioning and/or the **status packet-control C** command indicates that links are established), it is not critical to replace the circuit pack immediately, and a time may be chosen to minimize customer down-time.
	PASS	The Packet Control parity circuitry is functioning properly.

Packet Control Loop Around Test (#585)

This test checks whether the Packet Control circuit pack can send and receive data correctly. The test performs the following major functions:

1. Establishes an LAPD link from the Packet Control circuit pack to itself. (See Figure 11-87.)
2. Transmits and receives test data over the testing link.

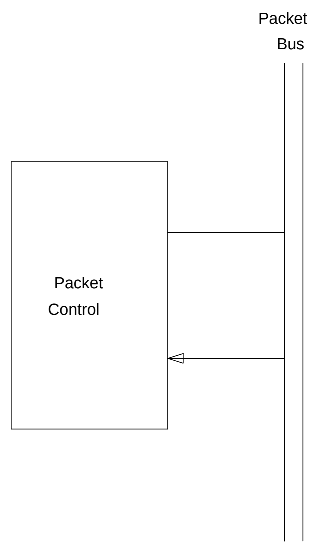

Figure 11-87. Test Configuration

Table 11-270. TEST #585 Packet Control Loop Around Test

Error Code	Test Result	Description/ Recommendation
1029 2011 2012 2013 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1139	ABORT	The Packet Bus is alarmed. 1. Try to retire the alarm associated with the Packet Bus. Refer to the Alarm Log via the **display alarm** command. 2. Retry the command when the alarm associated with the Packet Bus circuit pack is retired.

Continued on next page

Table 11-270. TEST #585 Packet Control Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The Packet Control circuit pack is not operational. **NOTE:** A busied-out Packet Control circuit pack can still be operational. 1. Determine if the Packet Control circuit pack has an active major alarm (via the **display alarm** command). If it does, follow the recommended repair procedures to retire the alarm. Once the alarm is retired, the original command can be retried. 2. If the Packet Control circuit pack does not have an active major alarm, wait one minute and retry the original command. If the Error Code 1141 is again observed, go to the next step. 3. If the Packet Control circuit pack is not currently busied-out and is on the active SPE, issue the **busyout packet-control C** command. Issue the **reset packet-control C** command. If the reset command fails, follow the recommended repair procedures for Test #586. If the reset command passes, issue the **release packet-control C** command (if the Packet Control circuit pack is on the active SPE), and then reissue the original command. If the original command again aborts with Error Code 1141, escalate the problem.
2500	ABORT	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-270. TEST #585 Packet Control Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1-3	FAIL	Maintenance was unable to establish a loop around link from the Packet Control circuit pack back to itself, or was unable to receive the data that was sent out over one side of the loop around link. 1. Issue **test packet-control C short** command to retry the test. 2. If the same error code is observed, maintenance software automatically escalates the testing. No specific action is required.
	PASS	The Packet Control circuit pack can send and receive data correctly.

Packet Control Reset Test (#586)

This test resets the Packet Control circuit pack, downloads Packet Control circuit pack firmware form tape, and then causes the Packet Control circuit pack to begin operation.

WARNING:

This test is destructive and disrupts service when run on the Packet Control circuit pack in the Active SPE. This test is not destructive when run on the Packet Control circuit pack in the Standby SPE of a High or Critical Reliability system. When this test is run on the Packet Control circuit pack on the Active SPE, the "busyout packet-control C" command must be executed first. Once testing has been completed, a busied-out Packet Control should be released via the release packet-control C command.

Table 11-271. TEST #586 Packet Control Reset Test

Error Code	Test Result	Description/ Recommendation
1029 2011 2012 2013 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1015	ABORT	The Packet Control circuit pack is not busied out. 1. Retry the command after running the **busyout packet-control C** command.

Continued on next page

Table 11-271. TEST #586 Packet Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1152	ABORT	The Packet Control circuit pack hardware was successfully reset and the circuit pack was successfully put back into service. However, a new image of Packet Control circuit pack firmware was not able to be downloaded from the tape, because the tape was unavailable. Nonetheless, the existing firmware on the circuit pack is valid, and there is no need to repeat this test.
2500	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1-3	FAIL	The reset test failed. 1. Retry the command. 2. If it fails again with the same error code, replace the Packet Control circuit pack.

Continued on next page

Table 11-271. TEST #586 Packet Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
5	FAIL	The SPE could not communicate with the Packet Control circuit pack. This indicates that either the Packet Control circuit pack is not installed or that it has failed. 1. Examine the appropriate carrier to determine if there is a Packet Control circuit pack in the correct slot. If there is, go to the next step. If there isn't, the problem is that the Packet Control circuit pack is administered (that is, the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form is set to "y") but the circuit pack isn't installed. If the system is supposed to have a Packet Control circuit pack, the system must be upgraded appropriately (see upgrade documentation). If the system is not supposed to have a Packet Control circuit pack, then the Packet Control circuit pack should be unadministered by setting the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form to "n." Refer to the "Maintenance-Related System Parameters Form" section in Chapter 5, "Routine Maintenance Procedures" for more information on the "Packet Bus Activated?" field. 2. Retry the command. 3. If it fails again with the same error code, replace the Packet Control circuit pack.

Continued on next page

Table 11-271. TEST #586 Packet Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1150 1188 1189 1190	FAIL	The Packet Control circuit pack was not successfully downloaded, and the Packet Control circuit pack currently does not contain valid downloadable firmware. The error codes have the following meanings: 1150- Generic tape error (not any of the following three errors) 1188- Internal system error 1189- Tape currently in use 1190- No tape cartridge in tape drive 1. Verify that there is a tape cartridge in the tape unit. 2. If the tape unit is in use (the yellow LED on the tape drive is on and there is tape cartridge motion), wait until the first request is complete. **If there does not appear to be tape motion and/or the yellow LED on the tape drive is not on, then go to the next step.** 3. Retry the command at one-minute intervals a maximum of three times. 4. Verify that the tape unit is not alarmed. Use the **display alarm** command and refer to the TAPE Maintenance documentation for recommended repair procedures to retire the alarm, if one exists; otherwise go to the next step. 5. If the test has failed consistently with the 1150 error code, then escalate the problem. If the test has failed consistently with the 1188 error code, replace the tape cartridge and then retry the reset command. If this does not correct the problem, then escalate the problem. If the test failed consistently with the 1189 error code, then escalate the problem. If the test failed consistently with the 1190 error code, then replace both the tape cartridge and the tape drive (refer to "Tape Maintenance and Repair Procedures" in the TAPE section for directions on replacing the tape drive).

Continued on next page

Table 11-271. TEST #586 Packet Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2064	FAIL	The downloaded firmware cannot be executed with this hardware vintage of the Packet Control circuit pack. 1. Retry the command. 2. If it fails again with the same error code, replace the tape cartridge and retry the reset command. If the test fails with this same error code, then escalate the problem.
2065	FAIL	The tape does not contain valid Packet Control circuit pack firmware. 1. Retry the command. If the same error code is returned, replace the tape and then retry the command. If the test continues to fail with this error code, then escalate the problem.
2073	FAIL	After being downloaded from the tape, the Packet Control circuit pack does not contain valid downloadable firmware in its memory. 1. Retry the command. 2. If the tests fails again with the same error code, then the tape may contain corrupted Packet Control circuit pack firmware. Replace the tape and retry the command. If the test still fails with this error code, then replace the Packet Control circuit pack. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-271. TEST #586 Packet Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2102	FAIL	As the Packet Control circuit pack firmware was being downloaded from system tape, a block of data could not be read from the tape. This indicates a problem with the tape unit, and not with the Packet Control circuit pack. 1. Test the TAPE with the long option and with a repeat option of 3. If any of the tests fail, or if there are any tape alarms, refer to the TAPE Maintenance documentation and follow the recommended repair procedures. If a tape problem is detected and then fixed, then retry the reset command. 2. If no tape problem was detected in the previous step, then there may be a problem with the area on the tape where the Packet Control circuit pack firmware resides. Replace the tape cartridge and then retry the reset command. 3. Escalate the problem.
2500	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The reset command passed and the Packet Control circuit pack is operational. If the Packet Control circuit pack was busied-out, it needs to be released (via the **release packet-control C** command) before it can be considered in service.

PMS-LINK (Property Management System Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PMS-LINK	MINOR	test pms l	PMS Link
PMS-LINK	WARNING	test pms	PMS Link

Property Management System (PMS) is a stand-alone computer system that a hotel/motel-type and a hospital-type environment use for services such as reservations, registration, messaging, housekeeping, night audit, billing, and inventory. The PMS Link provides a communications channel between DEFINITY Generic 1 or Generic 3iV2 and a customer-owned PMSs so that the PMS can interrogate the system about the information related to the following features:

- Message Waiting Notification
- Controlled Restriction
- Housekeeping Status
- Check-in/Check-out
- Room Change/Room Swap

Refer to *DEFINITY Communications System Generic 3 Feature Description*, 555-230-204 for details on the PMS feature. The PMS Link is administered to a data extension that provides a standard EIA 232C interface to the PMS. A PMS can be connected through a data module (PDM, MPDM, DTDM) and a port on the TN754 or TN754B Digital Line circuit pack, or through an ADU and a port on the TN726 Digital Line circuit pack.

PMS Link Maintenance provides a strategy for maintaining the link between DEFINITY Generic 1 and Generic 3iV2 and a PMS device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Link Maintenance uses a "try-and-wait" mechanism for maintaining the PMS Link. If a PMS Link is torn down due to an error, PMS Link Maintenance attempts to bring up the link immediately. If the trial of "Link Setup" fails, PMS Link Maintenance waits for five minutes before the next retry. If the number of retries reaches the value of a threshold (12), a Minor alarm is raised for service attention.

PMS Link Maintenance does not cover the maintenance of the elements composing the PMS physical link [the external PMS device, Data Module (PDM/MPDM/DTDM), and Digital Line Port of TN754 or TN754B Digital Line circuit pack, ADU and Data Line Port of TN726 Data Link circuit pack, and Data Channels on TN777 Network Control circuit pack]. If PMS Link Maintenance cannot restore the PMS Link, then the maintenance tests of these individual components of the PMS Link must be executed to diagnose faults. If system technician-demanded **test pms-link** command fails, no alarm is generated.

Procedures for Restoring the PMS Link

1. Determine the status of the PMS Link.

   Enter **status pms** command and make sure that the PMS Link is not busied out for maintenance. If the link is "down," then continue with the next step.

2. Where does the PMS Link connect?

   Enter **display system hospitality** and find out the destinations of the PMS Link.

3. Determine the status of the data extension.

   Enter **status data <extension>** command and verify whether the data extension is in in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

4. Is a data channel on Network Control circuit pack in in-service/idle state?

   Enter **list data** command and find out the extension numbers of data channels on Network Control circuit pack. Enter **status data <extension>** command and make sure that at least one data channel is in in-service/idle state. If no data channel is available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If present, refer to the DATA-BD (Network Control Circuit Pack) Maintenance documentation; if not present, escalate the error.

5. Is the external PMS device available?

   Make sure that the PMS device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the PMS device.

It is recommended that you busy out the PMS Link before executing maintenance tests over objects composing the PMS Link. If the PMS Link is busied out, then all PMS Link maintenance actions are deactivated. The interference to tests of other MO is off.

Hardware Error Log Entries and Test to Clear Values

PMS Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test pms sh r 1
18 (a)	0	busyout pms-link	WARNING	OFF	release pms-link
257 (b)	0-6, 99, 255	Link Retry Test (#215)	MINOR/ WARNING[2]	OFF	test pms-link l
513 (c)	0-6,255	None			test pms-link
769 (d)	0-6,255	None			
1025 (e)	4x[3]	None			
1281 (f)	1x[3]	None			
1537 (g)	Nx[3]	None			
1793 (h)	0-6,255	None			test pms-link
2049 (i)	0-6,255	None			
2305 (j)	5x[3]	None			release pms-link or test pms-link
2561 (k)	0-6,255	None			test pms-link
2817 (l)	10x[3] 20x[3] 30x[3]	None			
3073 (m)	7x[3]	None			
3841 (n)	2x[3]	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

3 Is any integer.

Notes:

a. The PMS Link has been busied out for system technician-demanded maintenance via the **busyout pms-link** command. The link is torn down. Enter the **release pms-link** command to restore the link.

b. The Link Retry Test (#215) fails. The Aux Data field contains either the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04) or an Error Type of 99 indicating no data channels are available for setting up the link, or an Error Type of 255 for the internal system error generated upon initialization or power-up. Refer to the "Procedures for Restoring the PMS Link" section for resolution.

c. The PMS physical link is down due to the following causes: cable to the PMS device is disconnected; the PMS device is powered off; or the data extension to which the PMS device connects has been busied out. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04) or an Error Type of 255 for the internal system error generated upon initialization or power-up. Check the connectivity of wire and cable among wall jacket, data module, and the PMS device. Enter **status data <extension>** and verify that the data extension of the PMS device is in in-service/idle state. If the data extension is not available, then refer to the "Procedures for Restoring the PMS Link" section for recommended repair strategy.

d. No communication between DEFINITY Generic 1 or Generic 3iV2 and PMS for a period of time (the time is specified in "system hospitality" administration). The PMS Link is torn down. To clear this error, refer to the "Procedures for Restoring the PMS Link" section.

e. The link was taken down because the switch could not receive an incoming message from the PMS. The message from the PMS repeatedly had corrupted data or the switch received requests for acknowledgment but never received a message to be processed. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

f. The link was taken down because the switch could not send an outgoing message. The message, which was sent but not acknowledged, was flushed. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

g. The PMS has been busied out for maintenance at the request of the PMS. The PMS Link is torn down. The reason code (N), if present, is that supplied by the PMS in the request message. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.

h. PBX buffer overflows due to either heavy call traffic or PMS protocol message rate being faster than the PMS/PBX protocol specifications allow. The PMS Link is torn down. PMS Link maintenance software waits for five minutes before attempting to set up the link again. If this error type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log (see Note).

NOTE:
The PMS should be checked for adherence to message rate defined in the PMS/PBX protocol specifications. No alarm is raised against this error.

i. The attempt to swap the database between PBX and PMS failed three times consecutively due to excessive PMS/PBX protocol violations, buffer overflows, or PMS Link outages. The PMS Link is NOT torn down. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.

j. The PMS Link has been busied out for system technician-demanded maintenance via the **busyout pms-link** command or has been brought down via the **test pms-link long** command. The PMS Link is torn down, and PMS Link maintenance stops attempting to reestablish the link in the case where the **busyout pms-link** command has been used. When the **test pms-link long** command has been used, PMS Link maintenance continues to try to reset the link. To restore the PMS Link after use of the **busyout pms-link** command, issue the **release pms-link** command. To restore the PMS Link after use of the **test pms-link long** command, issue the **test pms-link** command.

k. The PMS Link is physically established, but the protocol has not been started by the PMS before the protocol timer expires. The PMS Link is NOT torn down. If this error type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

NOTE:
The PMS should be checked to make sure that it attempts to start the protocol according to the PMS/PBX protocol specifications. No alarm is raised against this error.

l. Error Type 2817:

Aux values of concern:

10x The PMS violated the application protocol. The first message after a request to initiate a database exchange was not the start of a database exchange. The message is processed. If this error type with this aux data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. See Note.

20x The PMS violated the application protocol. The start of a database exchange was received in a state in which it was not expected. The message is ignored. If this error type with this Aux data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. See the next Note.

30x The PMS violated the application protocol. The end of a database exchange was received when no exchange was in progress. The message is ignored. If this error type with this Aux Data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

NOTE:
The PMS should be assessed for adherence to the PMS/PBX protocol specifications. No alarm is raised against this error.

m. The link was taken down by the switch because the threshold for application protocol violations has been exceeded by the PMS. The protocol never started and messages were received and/or messages were received in a state in which they were not expected. (Refer to Error Type 2817 for recommended strategy.)

n. Link was taken down by the switch because the threshold for link protocol violations has been exceeded by the PMS. PMS is sending "garbage" to the switch.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1 D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external PMS device. If the link has been disconnected already, then this test just returns "PASS." All resources allocated for a PMS Link are released after this test.

Table 11-272. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40 50	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1010	ABORT	The PMS Link has been busied out and placed in the out-of-service state. 1. Enter **release pms-link** command to release the PMS Link from busyout state. 2. Retry **test pms long** command to execute the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The PMS Link is torn down.

Link Retry Test (#215)

This test sends a message to the PMS software process to make a data call to the extension where the PMS device connects. If the PMS Link is already up, then this test passes without making any data call.

Table 11-273. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10 20	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
30	ABORT	Internal System Error. 1. Refer back to the "Procedures for Restoring the PMS Link" section for resolution.
1010	ABORT	The PMS Link has been busied out and placed in the out-of-service state. 1. Enter **release pms-link** command to release the PMS Link from busyout state. 2. Retry **test pms** command to execute the test.
	FAIL	The PMS Link CANNOT be established. 1. Refer back to the "Procedures for Restoring the PMS Link" section for restoring the PMS Link.
	PASS	The PMS Link is up.

PMS-PRNT/JNL-PRNT (PMS Printer Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PMS-PRNT/JNL-PRNT	MINOR	test journal pms-log/wakeup-log l	PMS Printer/ Journal Printer
PMS-PRNT/JNL-PRNT	WARNING	test journal pms-log/wakeup-log	PMS Printer/ Journal Printer

NOTE:
PMS-PRNT stands for the pms-log printer. JNL-PRNT stands for the wakeup-log printer. Since the maintenance strategy for the both the JNL-PRNT and PMS-PRNT MOs is the same, both of these MOs are described in this section.

In DEFINITY Generic 1 and Generic 3iV2, there are up to two journal printers. They are identified as the wakeup-log printer which is shared between the Automatic Wakeup feature and the Emergency Access to Attendant feature to print scheduled reports and log of events, and the pms-log printer which is used as a backup of the PMS output device to print the audit trail data of all PMS transactions executed by the system and the PMS Housekeeping Status Change events while the PMS Printer Link is not available. The journal printer link is administered to a data extension that provides a standard EIA 232C interface to the printer. The printer can be connected through a data module (PDM, MPDM, DTDM) and a port on the TN754 or TN754B Digital Line circuit pack, or through an ADU and a port on the TN726 Data Line circuit pack.

PMS Printer Link Maintenance provides a strategy in the system for maintaining the link between the system and a PMS device (an external Journal Printer device). The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Printer Link Maintenance uses a try-and-wait mechanism for maintaining the PMS Printer Link. If a PMS Printer Link is torn down due to an error, PMS Printer Link Maintenance intends to bring the link up immediately. If the trial of Link Setup fails, PMS Link Maintenance waits for five minutes before the next retry. If the number of retries reaches the value of a threshold (15), a Minor alarm is raised for service attention.

PMS Printer Link Maintenance does not cover the maintenance of the elements composing the journal printer physical link, for instance, the external printer device, Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 or TN754B Digital Line circuit pack, ADU and Data Line Port of TN726 Data Line circuit pack, and Data Channels on TN777 Network Control circuit pack. If PMS Printer Link Maintenance cannot restore the PMS Printer Link, then the maintenance tests of these individual components of the PMS Link must be executed to diagnose faults.

Procedures for Restoring the PMS Printer Link

1. Determine the status of the PMS Printer Link.

   Enter **status journal-printer wakeup-log|pms-log** command and make sure that the journal printer link is not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the journal printer link connect?

   Enter **display system hospitality** and find out the destinations of the PMS Printer Link.

3. Determine the status of the data extension.

   Enter **status data extension** command and verify whether the data extension is in the in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

4. Is a data channel on Network Control circuit pack in the in-service/idle state?

   Enter **list data** command and find out the extension numbers of data channels on Network Control circuit pack. Enter **status data extension** command and make sure that at least one data channel is in the in-service/idle state. If no data channel is available, look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation; if not present, escalate the error.

5. Is the external printer device available?

   Make sure that the printer device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the printer device.

It is recommended that you busyout the PMS Printer Link before executing maintenance tests over objects composing the PMS Printer Link. If the PMS Printer Link is busied out, then all PMS Printer Link maintenance actions are deactivated. The interference to tests of other MOs is off.

Hardware Error Log Entries and Test to Clear Values

PMS-PRNT/JNL-PRNT Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test journal wakeup-log|pms-log sh
18 (a)	0	busyout journal wakeup-log/ pms-log	WARNING	OFF	release journal wakeup-log|pms-log
257 (b)	0, 3 to 6 255	Link Retry Test (#215)	MINOR/ WARNING[2]	OFF	test journal wakeup-log|pms-log 1
513 (c)	0, 3 to 6 255				test journal wakeup-log|pms-log
769 (d)					

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Both PMS Printer and Journal Printer are administered to the same extension, and the printer is not connected. Refer to the "Procedures for Restoring the PMS Printer Link" section for resolution.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. System Technician busied out the Journal Printer Link. The link is torn down. Enter **release** command to restore the link.

b. Link Retry Test (#215) fails. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04), an Error Code 255 for the internal system error, or 0 which indicates that the data module connected to the PMS Printer Link is out-of-service. Refer to "Procedures for Restoring the PMS Printer Link" section for resolution.

c. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The PMS Printer Link physical link is down due to the following causes: cable to the printer device is disconnected, the printer device is powered off, or the data extension where the printer device connects to has been busied out. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04). Check the connectivity of wire and cable among wall jacket, data module, and the printer device. Enter **status data <extension>** and verify that the data extension of the printer device is in the in-service/idle state. If the data extension is not available, then refer to the "Procedures for Restoring the PMS Printer Link" section for resolution.

d. Link idle timer; link comes down. This error indicates that the printer device is in an off-line state, for example, paper jam or paper out for a printer device. Check the printer device and act promptly to put it back to on-line state. Enter **test journal wakeup-log|pms-log** command to set up the printer link.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1 D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external printer device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a PMS Printer Link are released after this test.

Table 11-274. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40	ABORT	Internal System Error.
50	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1010	ABORT	The link has been busied out to out-of-service. 1. Enter **release journal wakeup-log|pms-log** command to release the link from busyout state. 2. Retry **test journal wakeup-log|pms-log l** command to execute the test.
	FAIL	Internal System error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The link is torn down.

Link Retry Test (#215)

This test sends a message to the journal printer management software process to make a data call to the extension where the printer device connects to. If the journal printer link is already up, this test passes without making any data call.

Table 11-275. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10	ABORT	Internal System Error.
20	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
30	ABORT	Internal System Error. 1. Refer to the "Procedures for Restoring the PMS Printer Link" section for instructions.
1010	ABORT	The PMS Printer Link has been busied out to out-of-service. 1. Enter **release journal wakeup-log|pms-log** command to release the link from busyout state. 2. Retry **test journal wakeup-log|pms-log l** command to execute the test.
	FAIL	The link CANNOT be established. 1. Refer to the "Procedures for Restoring the PMS Printer Link" section for instructions.
	PASS	The link is up.

POWER (Battery & Battery Charger) for AC-Powered Systems

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
POWER	MINOR	test environment P	Battery & Battery Charger

1 Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

Generic 1 and Generic 3iV2 offer two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configuration may be powered by either an external AC or DC power source.

NOTE:
For environment maintenance, PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate section(s).

- For a single-carrier cabinet system, refer to the DC-POWER (Single-Carrier Cabinet Power) Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for AC-Powered Systems, CARR-POW (Carrier Port Power Unit) for AC-Powered Systems, or POWER (Battery & Battery Charger) for AC-Powered Systems.
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for DC-Powered Systems, CARR-POW (Carrier Port Power Unit) for DC-Powered Systems, or POWER (Battery & Battery Charger) for DC-Powered Systems.

The G3iV1.1-286 or G3iV2-386 multicarrier cabinet is equipped with rechargeable batteries that can span short AC power outages. In a multicarrier PPN system with High or Critical Reliability, the cabinet can be powered for 10 seconds from the batteries. After this time, all port carrier power is shed and the control carrier is powered for another 10 minutes. In a High or Critical Reliability PPN system, these times are cut to five seconds and five minutes, respectively. In an EPN multicarrier cabinet, the entire cabinet can be powered for 15 seconds from the batteries, after which time the entire cabinet is powered down.

In a multicarrier cabinet system, the POWER (Battery & Battery Charger) MO represents the battery charger and the battery which are located in the lower left corner of the cabinet. Should anything go wrong with the battery or charger, they must be replaced using the procedure described in "Replacing the Battery and Battery Charger" below. The system detects one of the following three problems with the batteries or charger:

1. Reserve Fault—The charger has detected a problem within itself or the batteries and has notified the system.
2. High Charge Rate—The batteries are charging at a high charge rate. This means that batteries with a low charge are being recharged or that a problem may exist with the batteries or the charger.
3. Prepare to Disconnect (Low Battery)—The batteries are in danger of being drained to a point where the batteries would be damaged. This warning often occurs after multiple power failures.

   The batteries take 30 hours to fully charge after being drained. A fully charged battery pack should bridge two power failures without causing a low battery warning to occur.

Replacing the Battery and Battery Charger

Use the procedure below to replace the Battery and Battery Charger:

1. Move the power switch on the battery charger to OFF.

   WARNING:
   Always turn off the battery charger before replacing the batteries. Failure to do so results in damage to the 397B battery charger.

2. Disconnect the cord from the outlet on the front of the battery charger.
3. Remove the screw at the top left of the cover and open the cover to access the charger.
4. Check the battery voltages at the test points. The test points on the CE Distribution Unit check all 3 batteries wired in series (the voltages should read 144 volts, 3X48 volts = 144 volts) .

   NOTE:
   An ordinary voltmeter can be used to check battery voltages at the test points, but it may not produce valid results. If the battery voltage readings are below 48 volts (the voltages at test points should read 144 volts, 3X48 volts = 144 volts), the battery is probably defective. However, a normal voltage reading does not necessarily mean the battery is good; under load, a defective battery with a normal reading on the voltmeter may discharge rapidly.

5. Check the battery dates and replace the batteries if they are more than four years old or if a POWER alarm is present.

   NOTE:
   If any defective batteries are found, replace all of them. Batteries are ordered in sets of three and should be replaced as such.

6. If no defective batteries are found, replace the entire charger.
7. Close the cover and secure it with the screw.
8. Reconnect the cord and move the power switch to ON.

Hardware Error Log Entries and Test to Clear Values

Battery & Battery Charger Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test environment P sh r 1
1	Any	Battery & Battery Charger Query Test (#5) (Error Code 8)	MINOR	ON	test environment P sh r 1
257	Any	Battery & Battery Charger Query Test (#5) (Error Code 4)	MINOR	ON	test environment P sh r 1
769	Any	Battery & Battery Charger Query Test (#5) (Error Code 2)	MINOR	ON	test environment P sh r 1
3840	1005 or 1028	Battery & Battery Charger Query Test (#5)		ON	test environment P sh r 1

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query Test (#5)	X	X	ND
AC Power Query Test (#78) (a)	X	X	ND
Power Unit Query Test (carrier E) (#127) (b)	X	X	ND
Power Unit Query Test (carrier D) (#127) (b)	X	X	ND
Power Unit Query Test (carrier A) (#127) (b)	X	X	ND
Power Unit Query Test (carrier B) (#127) (b)	X	X	ND
Power Unit Query Test (carrier C) (#127) (b)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.

b. Refer to CARR-POW (Carrier Port Power Unit) Maintenance documentation for a description of this test

c. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.

e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:
This test only shows up in the test sequence if there is a Tone-Clock circuit pack in the port network being tested.

Battery & Battery Charger Query Test (#5)

This test queries the Maintenance/Tape Processor in a multicarrier cabinet PPN system without High or Critical Reliability, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. During this test, the status LED battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

Table 11-276. TEST #5 Battery & Battery Charger Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Battery Charger is not connected. 1. If the system has a UPS supplying the power, ignore this error since the UPS supplies the power, not the battery and battery charger. 2. The batteries probably need charging and may be drained if there were power outages. Reconnect the battery charger to allow the batteries to recharge. If Test #5 is run before the batteries are completely charged, the test fails. 3. Wait 24 hours and rerun the test.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all DUPINT (Duplication Interface) errors in a Duplicated Option PPN, PR-MAINT (Maintenance/Tape Processor) errors in a standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Repeat the test. 4. If the test continues to ABORT with a 2000 error code, escalate the problem.
2028	ABORT	Internal System Error prevented the extinguishing of the Battery Charger status LED. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The system is in nominal power holdover, and the battery is currently so low that the system disconnects power very shortly. 1. If power returns, the port carriers in the PPN should power up again. All the circuit packs should be reinserted, and the system should continue to operate normally. There will probably be a Minor alarm against Battery & Battery Charger because the batteries are recharging. 2. If power does not return, the system shuts down to prevent damage to the batteries. If power is restored, the system reboots. **No manual intervention is required.** 3. Rerun the test. If the test still fails, the PR-MAINT (Maintenance/Tape Processor) in a multicarrier cabinet PPN system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a PPN for a system with High or Critical Reliability, or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that ARE NOT be detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	The battery is currently being charged at the high charge rate. 1. After 30 hours, the battery should be fully charged, and this error should disappear. 2. If after 30 hours the battery is still in the high charge rate, an alarm is raised. Display the Error Log with the **display errors** command and select the category "environ" to display only environment-related errors. Look for POWER errors of type 257. The FIRST OCCURRENCE of this error indicates the time when the battery started charging. Use this time as the starting point to determine if the battery has been charging for 30 hours. If the battery has been charging for 30 hours, then replace the battery. **CAUTION:** *Read the section, "Replacing the Battery and Battery Charger" before proceeding.*

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL *(cont'd.)*	3. If the batteries were replaced, it can take up to 24 hours for the new batteries to be charged (new batteries are shipped uncharged). If Test #5 is run again before the batteries are completely charged, the test fails. If the charger was replaced, some time must be allowed for the new charger to recharge the batteries. Therefore, in either case, wait at least 24 hours and rerun the test. If the test still fails, the PR-MAINT (Maintenance/Tape Processor) in a multicarrier cabinet PPN system without High or Critical Reliability, the DUPINT (Duplication) Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that ARE NOT be detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. Resolve all alarms on these MOs, and rerun the test. If the test still fails, escalate the problem.
6	FAIL	This indicates that Error Codes 2 and 4 have occurred. Refer to these descriptions. Also, refer to the description for Error Code 14 for this test.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
8	FAIL	**NOTE:** For a Global AC MCC (J58890CH) use the procedures outlined in step 3. There is a reserve power fault. A problem exists with the battery charger (more probable) or the battery (less probable). 1. Replace the battery charger or the battery. The fault should disappear. However, the test fails with Error Code 4 if the battery is charging. **WARNING:** *Always turn off the battery charger before replacing the batteries.* 2. Rerun the test. If the test still fails with an error code other than 4 (that is, there is something wrong besides the battery needing charging), the PR-MAINT (Maintenance/Tape Processor) in a multicarrier cabinet PPN system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a PPN for a High or Critical Reliability, or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that ARE NOT be detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, then follow normal escalation procedures.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
8 *(cont'd.)*	FAIL *(cont'd.)*	3. Procedures for a Global MCC (J58890CH): a. Look to see if any "red" LEDs are "on" on any of the rectifier modules or the BIU (Battery Interface Unit) located in the Power Distribution Unit (J58890CH). b. If the BTW (Battery Temp Warning) LED on the BIU is "on" check the batteries for a over temp condition[(a)] if temp is normal[(a)] replace the BIU, If the test still fails replace the battery in a small battery system. For a large battery system escalate the problem. c. If the BIF (Battery Interface Unit) LED is "on" replace the battery interface unit. d. If the BNA (Battery Not Available) LED is "on" check the battery connections including connector J20. e. If you have an alarm and all LEDs are ok (PWR OK and BOK) on the rectifier modules, and the BIU (Battery Interface Unit), make sure the BIU and the RM0850 rectifiers are seated properly (plugged in). If the BOK LED on the BIU is ok use the following information to check the number of rectifiers serving this cabinet: Number of carriers per cabinet | Number of rectifiers per cabinet 1 — 2 2 — 3 3 — 3 4 — 4 5 — 4 If the number of rectifiers is correct replace the maintenance circuit pack in the EPN or PPN. 4. If the test still fails, then follow normal escalation procedures.

Continued on next page

Table 11-276. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10	FAIL	This indicates that Error Codes 2 and 8 have occurred. Refer to these descriptions. Also, refer to the description for Error Code 14 for this test.
12	FAIL	This indicates that Error Codes 4 and 8 have occurred. Refer to these descriptions. Also, refer to the description for Error Code 14 for this test.
14	FAIL	This indicates that Error Codes 2, 4, and 8 have occurred. Refer to these descriptions. **NOTE:** This could also indicate that the detection logic on the DUPINT (Duplication Interface), PR-MAINT (Maintenance/Tape Processor), or EPN MAINT (Maintenance) circuit pack is defective. Such an error will not be detected by the respective maintenance. If many environment tests are failing, replace the suspect circuit pack (depending on system configuration).
	PASS	The Maintenance/Tape Processor in a multicarrier cabinet PPN system without High or Critical Reliability, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN have reported that the status of Battery & Battery Charger is good.

POWER (Battery & Battery Charger) for DC-Powered Systems

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
POWER	MINOR	test environment P	Battery & Battery Charger

1 Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

DEFINITY Generic 1 and Generic 3iV2 offer two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configurations may be powered by either an external AC or DC power source.

NOTE:
For environment maintenance, the PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate section(s).

- For a single-carrier cabinet system, refer to the DC-POWER (DC Power) Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for AC-Powered Systems, CARR-POW (Carrier Port Power Unit) for AC-Powered Systems, or POWER (Battery & Battery Charger) for AC-Powered Systems.
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for DC-Powered Systems, CARR-POW (Carrier Port Power Unit) for DC-Powered Systems, or POWER (Battery & Battery Charger) for DC-Powered Systems.

In a DC-powered multicarrier cabinet system, the POWER MO still exists, but serves no functional purpose. Because the system cannot determine the type of powering provided, all POWER tests should always pass or abort. Since the tests should never fail, POWER alarms should not be raised.

Hardware Error Log Entries and Test to Clear Values

Battery & Battery Charger Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]*	0	Any	Any	Any	test environment P sh r 1
1	Any	Battery & Battery Charger Query Test (#5) (Error Code 8)	MINOR	ON	test environment P sh r 1
257	Any	Battery & Battery Charger Query Test (#5) (Error Code 4)	MINOR	ON	test environment P sh r 1
769	Any	Battery & Battery Charger Query Test (#5) (Error Code 2)	MINOR	ON	test environment P sh r 1
3840 (a)	1005 or 1028	Assoc. Test Battery & Battery Charger Query Test (#5)		ON	

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. This error occurs only in a multicarrier cabinet and can be ignored but not cleared for DC-powered systems.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Battery & Battery Charger Query			
Test (#5)	X	X	ND
AC Power Query Test (#78) (a)	X	X	ND
Power Unit Query Test (carrier E) (#127) (b)	X	X	ND
Power Unit Query Test (carrier D) (#127) (b)	X	X	ND
Power Unit Query Test (carrier A) (#127) (b)	X	X	ND
Power Unit Query Test (carrier B) (#127) (b)	X	X	ND
Power Unit Query Test (carrier C) (#127) (b)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Sensors Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to AC-POWER (AC Power) documentation for a description of this test.

b. Refer to CARR-POW (Carrier Port Power Unit) for AC- and DC-Powered Systems Maintenance documentation for a description of this test.

c. Refer to EMG-XFER (Emergency Transfer) documentation for a description of this test.

d. Refer to CABINET (Cabinet Sensors) documentation for a description of this test.

e. Refer to EXT-DEV (External Alarm) documentation for a description of this test.

f. Refer to RING-GEN (Analog Ring Generator) documentation for a description of this test.

NOTE:
This test shows up in the test sequence only if there is a TN768 or TN780 Tone-Clock circuit pack in the port network being tested.

Battery & Battery Charger Query Test (#5)

This test queries the Maintenance/Tape Processor in a standard PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. In a DC-powered system, this test should never fail. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

Table 11-277. TEST #5 Battery & Battery Charger Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
1005	ABORT	Battery charger is not connected since the system uses DC power and the battery charger and battery are for AC-powered systems. 1. Ignore this error in DC-powered systems.
2000	ABORT	Response to the test request was not received within the allowable time period.
2028	ABORT	Internal System Error prevented the extinguishing of the Battery Charger status LED. 1. Although this test is not relevant for DC-powered systems, this error should trigger close monitoring of the system as this error means that internal system problems exist.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-277. TEST #5 Battery & Battery Charger Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
any	FAIL	The Maintenance/Tape Processor in a multicarrier cabinet Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in a multicarrier cabinet system EPN is incorrectly reporting a problem with power. If this test fails, the problem is with the circuit pack and not with POWER. 1. The suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. 2. If the test still fails, follow normal escalation procedures.
	PASS	All that can be inferred is that the PR-MAINT (Maintenance/Tape Processor) in a Standard system PPN, the DUPINT (Duplication Interface) circuit pack in a PPN for a High or Critical Reliability system, or the EPN MAINT (Maintenance) circuit pack in an EPN multicarrier cabinet system is working properly.

PR-MAINT (MainTenance Processor [TN790 RISC Systems])

MO Name As It Appears In Alarm Log	Alarm Level	Initial System Technician Command To Run	Full Name of MO
PR-MAINT	MIN[1]	test processor a/b sh/l	Maintenance/Tape Processor[2]

1 Alarms on the PROCR, and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

2 The full Name of the MO in the TN790 RISC system is MainTenance Processor.

NOTE:
Prior to DEFINITY ECS Release 5, the full maintenance object (MO) name for a system with a TN773 processor circuit pack is PR-MAINT (Maintenance/Tape Processor). For a system with a TN786 processor circuit pack, the full Name of the MO is MainTenance Processor.

The TN790 Processor circuit pack is comprised of the RISC Processor (PROCR), the MainTenance Processor (PR-MAINT), and the Memory (PR-MEM). On the TN790 circuit pack, PR-MAINT is responsible for monitoring the sanity of the RISC Processor.

PR-MAINT contains the hardware required for controlling the environmental conditions. The Maintenance/Tape Processor provides the serial interfaces for the administration terminal and DCE port. The Maintenance Processor also provides the communications interface to INADS for alarm reporting and remote maintenance capability. INADS connectivity is through the internal or external modem. The external modem is connected to the DCE port. When the external modem is the administered modem option the internal modem is disabled.

The TN790 has a higher speed 9600 baud internal modem or can support an external modem connected to the DCE port.

Hardware Error Log Entries and Test to Clear Values

Maintenance/Tape Processor Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value[1]
0[2]	0	Any	Any	Any	test processor a/b sh r 1
1(a)	Any	MTP Reset Test (#101)	MIN	ON	test processor a/b l r 3
257(b)	Any	MTP Sanity Handshake Test (#106)			test processor a/b r 2
513(c)	Any	MTP Analog Loop Around Test (#103)	MIN	ON	test processor a/b r 8
769(d)	Any	MTP Dual Port Ram Test (#104)	MIN	ON	test processor a/b l r 3
1025(e)	Any	MTP Outpulse Relay Test (#102)	MIN	OFF	test processor a/b r 5
1537(f)	Any	MTP SAT Loop Around Test (#228)	MIN	ON	test processor a/b r 3
1793(g)	Any	MTP Aux Loop Around Test (#229)	MIN	ON	test processor a/b r 3
2049(h)	Any	External Modem Present Test (#230)	MIN	OFF	test processor a/b r 2

1 The MTP Reset Test (#101) logs you off. The MTP Dual Port Ram Test (#104) can also log you off. You must manually repeat the command with the ‘‘long’’ option the designated number of times when testing from the PPN SAT.

2 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The MTP Reset Test (#101) has failed.

b. The MTP Sanity Handshake Test (#106) has failed.

c. The MTP Analog Loop Around Test (#103) has failed.

d. The MTP Dual Port Ram Test (#104) has failed. An error of 769 with an aux data of 5 indicates a hardware problem and testing will not clear it. The circuit pack should be replaced.

e. The MTP Outpulse Relay Test (#102) has failed.

f. The MTP SAT Loop Around Test (#228) has failed.

g. The MTP Aux Loop Around Test (#229) has failed.

h. The External Modem Present Test (#230) has failed.

NOTE:
Refer to the FAIL section of each test that fails for further instructions.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *MTP Reset Test,* for example, you may also clear errors generated from other tests in the testing sequence.

The following table is for the TN790 [RISC] System:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Cache Test (#895)(a)		X	ND
Processor Cache Audit (#896)(a)	X	X	ND
Processor Bus Timeout Exception Test (#82)(a)	X	X	ND
Processor BOOTPROM Checksum Test (#80)(a)	X	X	ND
Processor Write Buffer Test (#900)(a)	X	X	ND
Memory Burst Read Test (#908)(a)	X	X	ND
Read All Memory Test (#85)(a)		X	ND
Memory Parity Error Detection Test (#87)(a)	X	X	ND
Flash Memory Checksum Test (#86)(a)		X	ND
Memory Functional Test (#332) (b)(c)		X	D
MTP Outpulse Relay Test (#102)(d)	X	X	ND
External Modem Present Test (#230)(d)(e)	X	X	ND
MTP Analog Loop Around Test (#103)(d)	X	X	ND
MTP Sanity Handshake Test (#106)	X	X	ND
MTP SAT Loop Around Test (#228)	X	X	ND
MTP Aux Loop Around Test (#229)	X	X	ND
MTP Reset Test (#101)		X	D
MTP Dual Port Ram Test (#104)(d)		X	D

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to PROCR (TN790 RISC Processor) Maintenance documentation for a description of these tests.

b. Refer to PR-MEM (TN790 RISC Memory) Maintenance documentation for a description of these tests.

c. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

d. This test only runs on the Active SPE.

e. This test aborts if an external modem is not administered.

MTP Reset Test (#101)

This test is destructive. The test resets the MainTenance Processor. The destructive nature of this test causes the following:

- System Access Terminal to log off
- DCE port to terminate data transmission
- Any current memory card access to terminate and also to tear down any remote access INADS connection

Table 11-278. TEST #101 MTP Reset Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-278. TEST #101 MTP Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1196	FAIL	The MTP did not respond to being reset. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
1197	FAIL	The Maintenance Processor was reset, but it responded with a NOT PASS status, indicating that it did not pass initialization correctly. The MTP is not functioning correctly. The system should continue to function, but it will not have the ability to save translation to tape, or to read tape if the system needs to be rebooted. Environmental monitoring is lost, as is communication with the Standby Processor. 1. Repeat the command at one minute intervals a maximum of five times. 2. If test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
	PASS	The Maintenance Processor was reset, and it passed initialization correctly. The other MTP tests should be examined to verify that the MTP is functioning correctly. 1. Enter **test processor a/b** and verify that the MTP is functioning correctly.

MTP Outpulse Relay Test (#102)

This test is a nondestructive test.When the internal modem is administered, the test validates the correct operation of the remote access CO trunk used by INADS. The MTP first goes off-hook, then on-hook on this trunk. If the loop current is detected, the test passes. If the external modem is administered the MTP sends an AT command sequence that will cause the external modem to go OFF-HOOK and wait for dial-tone. If the modem detects dial-tone, the test passes. This test is not allowed if the remote access line is in use.

Table 11-279. TEST #102 MTP Outpulse Relay Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1018	ABORT	The test has been disabled via administration. 1. To enable the test, issue the **change system-parameters maintenance** command, and set the test remote access port field to ‘‘y.’’ (If you have an INADS line, set the field to ‘‘y.’’ 2. Rerun the test.
1030	ABORT	This test is not run on the Standby SPE.
1131	ABORT	INADS port is busy because the system is reporting alarms to INADS, or because INADS is dialed into the system. 1. If INADS is communicating with the switch the INADS trunk is working. There is no need to run this test. 2. Or if required. Wait about ten minutes(untill the INADS session is terminated) and then re-enter the command.
1000 2500	ABORT	System software resources required to run this test are not available. Internal system error.

Continued on next page

Table 11-279. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033		Couldn’t send MTP message. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	MTP did not respond to the test request. 1. Repeat the test at one minute intervals a maximum of five times. 2. If all MTP tests are aborting, execute the **test processor a/b long** command in order to reset MTP and to examine the results of the MTP Reset Test (#101). 3. Replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) 4. If only the MTP outpulse relay test is aborting, escalate the problem.
1050	ABORT	System could not determine if the testing of the INADS port is administered. 1. Enter the **change system-parameters maintenance** command. Verify that the “Test Remote Access Port?” field is set to “y.” 2. Repeat the command at one minute intervals a maximum of five times. 3. If the data on the Maintenance-Related System Parameters Form is correct, escalate the problem.

Continued on next page

Table 11-279. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	MTP reported test failure. No loop current detected. The following steps apply to either an internal or external modem (Some additional steps apply to an external modem only.). 1. Repeat the command at one minute intervals a maximum of five times. 2. For an external modem, if the test continues to fail: a. If Test #230 failed, use the external modem recommendations listed in Test #230. b. If Test #230 passes, the MTP most likely received a NO DIAL TONE response to the ATD command sent from the MTP. This problem is between the modem and the INADS trunk. 3. If the test continues to fail, examine the INADS trunk for connectivity, and manually check for loop current. 4. If there is no INADS trunk, this test should be disabled. To disable the test, issue the **change system-parameters maintenance** command, and change the Test Remote Access Port field to "n." 5. If the INADS trunk checks out okay, but the test still fails, check the backplane connector wiring. 6. If the backplane wiring checks out okay, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, 'Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)

Continued on next page

Table 11-279. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	MTP detected a loop current on the remote access port. 1. If the system cannot call INADS, or INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct. Approved external modems with factory default settings are expected to work if administered correctly using the **change system-parameters** command.

MTP Analog Loop Around Test (#103)

This test is a nondestructive test. The test does a loop around by using the MTP INADS channel. Test data is sent through the modem out toward the INADS trunk. The data is looped around before the actual trunk, and it comes back into the on-board modem. The data is then verified for integrity. The internal modem is tested when the internal modem is selected. The external modem is tested when the external modem is selected.

When an external modem is administered in place of the internal modem, the test loops data in the MTP DUART ahead of the connection to the external modem. This test also causes the MTP DUART to verify that **Clear-To-Send (CTS)** is being supplied by the modem.

NOTE:
The test does not send any data onto the INADS trunk. However, in order to pass, the test does require the trunk to be present

Table 11-280. TEST #103 MTP Analog Loop Around Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1018	ABORT	The test has been disabled via administration. 1. To enable the test, issue the **change system-parameters maintenance** command, and set the Test Remote Access Port field to ‘‘y.’’ 2. Rerun the test.
1030	ABORT	This test is not run on the Standby SPE.

Continued on next page

Table 11-280. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1131	ABORT	INADS port is busy because the system is reporting alarms to INADS, or because INADS is dialed into the system. 1. If INADS is communicating with the switch the INADS trunk is working. There is no need to run this test. 2. Or if required. Wait about ten minutes (until the INADS session is terminated) and then re-enter the command.
1000 2033	ABORT	System software resources required to run this test are not available. Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	MTP did not respond to the test request. 1. Repeat test at one minute intervals a maximum of five times. 2. If only the MTP Analog Loop Around Test is aborting, escalate the problem. 3. If all MTP tests are aborting, execute the **test processor a/b long** command in order to reset MTP, and examine the results of the MTP Reset Test (#101).
2500	ABORT	Internal System software Error 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-280. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1050	ABORT	System could not determine if the testing of the INADS port is administered. 1. Enter the **change system-parameters maintenance** command, and verify the entry for the Test Remote Access Port field. 2. Repeat the command at one minute intervals a maximum of five times. 3. If the data on the Maintenance-Related System Parameters Form is correct, escalate the problem.

Continued on next page

Table 11-280. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	MTP reported test failure. The system is not able to reliably contact INADS with alarm data. However, the system continues to provide good service. 1. For an internal modem: a. If MTP Outpulse Relay Test (#102) is also failing, check for the presence of the INADS trunk, and resolve any INADS trunk problems. b. If Test #102 passes, the fault is on the Processor circuit pack. The circuit pack should be replaced at your convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) 2. For an external modem: a. Check the power to the modem. b. Check the RS232 cable connections from the DCE terminal on the switch to the DTE connector on the modem. Transmit, Receive, RTS, and CTS signals must be communicating between the MTP DUART hardware and the modem hardware c. The MTP DUART or related circuitry on the processor circuit pack may have failed. The circuit pack should be changed at your convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)

Continued on next page

Table 11-280. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	For an internal modem—MTP detected correct data through the loop back connection. For an external modem—The test detected correct data through the loop back in the MTP DUART hardware ahead of the RS232 connection to the modem, and received a CTS signal from the external modem. 1. If the system cannot call INADS, or if INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct.

MTP Dual Port Ram Test (#104)

This test is destructive.

The test terminates any PPN SAT session, and it is a coordinated test of the MTP dual port ram (DPR). The DPR is a section of memory that is shared by the MTP and by the RISC Processor circuit pack. Control messages and data are passed through the DPR. The test forces both sides to read and write the DPR simultaneously in alternate locations.

The DPR test causes the PPN SAT to log off before the test result is displayed. The test result is determined according to the terminal from which the test is run. If the test is run from the PPN SAT, system technician should log back in and examine the Error Log for an error against PR-MAINT, with Error Type 769, no Aux Data. This error entry indicates that the MTP DPR Test failed and that the Processor circuit pack should be replaced. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)

NOTE:
If the test is being run from a terminal other than the PPN SAT (for example, EPN SAT, remote access, etc.), the test results are displayed on the screen.

NOTE:
A dial-up (through the INADS port) does not display the results discussed in the previous paragraph. However, a dial-up through data channels does display these results.

Table 11-281. TEST #104 MTP Dual Port Ram Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1000	ABORT	System software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1030	ABORT	This test in not run on the Standby SPE.
2000	ABORT	The response to the test request was not received within the allowable time period.
2028	ABORT	System software resources required to run this test are not available.

Continued on next page

Table 11-281. TEST #104 MTP Dual Port Ram Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2029	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The dual port RAM is not functioning correctly. Communication between the processor and MTP is lost. The system is not able to report environmental alarms, communicate with the Standby SPE, or reboot from tape, if necessary. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
	PASS	Dual port RAM is functioning. Communication exists between the 80286/386/RISC Processor circuit pack and the MTP.

MTP Sanity Handshake Test (#106)

This test is a nondestructive test. The MTP Sanity Handshake Test is simply a query from a maintenance process to the MTP. The MTP must reply for the test to pass.

Table 11-282. TEST #106 MTP Sanity Handshake Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1000	ABORT	System software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2000	ABORT	The response to the test request was not received within the allowable time period.

Continued on next page

Table 11-282. TEST #106 MTP Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033	ABORT	1. Internal system error.Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The MTP did not respond to the Sanity Handshake Query. 1. Re-enter command with the ‘‘long’’ option. 2. If the test continues to fail, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
	PASS	The MTP responded to the Sanity Handshake Query.

Continued on next page

MTP SAT Loop Around Test (#228)

This test is a nondestructive test. The test places the SAT channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. Although the test is nondestructive, it causes loss of keyboard input from the PPN SAT.

Table 11-283. TEST #228 MTP SAT Loop Around Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1000	ABORT	System software resources required to run this test are not available.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2000	ABORT	The response to the test request was not received within the allowable time period.

Continued on next page

Table 11-283. TEST #228 MTP SAT Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2033 2034	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The SAT channel failed the Loop Back Test. The SAT is probably unusable for administration or maintenance. The EPN SAT, if available, or remote access can still be used. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
	PASS	The SAT channel passed the Loop Back Test. 1. If the PPN SAT is not usable, check the SAT itself, along with the cabling.

MTP Auxiliary Loop Around Test (#229)

This test is a nondestructive test. The test places the Auxiliary channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. The Auxiliary channel is used as the CDR output port

Table 11-284. TEST #229 MTP Auxiliary Loop Around Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1000	ABORT	The system software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test has been disabled via administration. The **change system-parameters cdr** command needs to administer CDR. (Refer to the Implementation Manual for more information on administering this port.)

Continued on next page

Table 11-284. TEST #229 MTP Auxiliary Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period
2033		Internal system error.
2034		Port Busy. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2500	ABORT	The system software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1048	ABORT	An External Modem is administered to this port.
	FAIL	The Auxiliary channel failed the Loop Back Test. The AUX port is probably not sending any auxiliary data to the auxiliary collection device. 1. Repeat the command at one minute intervals for a maximum of five times. 2. If test continues to fail, replace the Processor circuit pack replaced at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)
	PASS	The Auxiliary channel passed the Loop Back Test. The auxiliary port is functioning correctly. 1. If no auxiliary data is being recorded, check the auxiliary collection device, and verify that it has been set up and connected correctly.

MTP External Modem Present Test (#230)

This test is a nondestructive test on the remote access line, and will run only if the channel is idle. The test validates the presence of an external modem with a firmware invoked AT command. The test will pass if the modem responds with "OK" to the AT command.

Table 11-285. TEST #230 External Modem Present Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1018	ABORT	The test has been disabled via administration. 1. To enable the test, issue the **change system-parameters maintenance** command, and set the Test Remote Access Port field to ‘‘y.’’ 2. Rerun the test.
1030	ABORT	This test is not run on the Standby SPE.
1131	ABORT	INADS port is busy because the system is reporting alarms to INADS, or because INADS is dialed into the system. 1. If INADS is communicating with the switch the INADS trunk is working. There is no need to run this test. 2. Or if required. Wait about ten minutes(untill the INADS session is terminated)and then re-enter the command.
1000 2033	ABORT	System software resources required to run this test are not available. Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-285. TEST #230 External Modem Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1049	ABORT	External Modem is not administered.
1050	ABORT	System could not determine if the testing of the INADS port is administered. 1. Enter the **change system-parameters maintenance** command, and verify the entry for the Test Remote Access Port field. 2. Repeat the command at one minute intervals a maximum of five times. 3. If the data on the Maintenance-Related System Parameters Form is correct, escalate the problem.
2000	ABORT	MTP did not respond to the test request. 1. Repeat test at one minute intervals a maximum of five times. 2. If only the MTP External Modem test is aborting, escalate the problem. 3. If all MTP tests are aborting, execute the **test processor a/b long** command in order to reset MTP, and examine the results of the MTP Reset Test (#101).

Continued on next page

Table 11-285. TEST #230 External Modem Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal System software Error 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	MTP reported test failure. The system is not able to reliably contact INADS with alarm data. However, the system continues to provide good service. The MTP did not receive an **OK** response after sending the **AT** command to the modem. 1. If test #103 failed, follow the external modem recommendations for that test failure. 2. If Test #103 passes: a. Check the RS232 cable connections from the DCE terminal on the switch to the DTE terminal on the modem. RTS and CTS signals are being communicated between the MTP DUART hardware and the modem hardware. Transmit and receive signals may not be communicated correctly. b. Check the modem administration using the **change system-parameters maintenance** command, especially changes from default parameters. c. Check the modem settings, especially changes from factory defaults. **DANGER:** *The fault may be on the Processor circuit pack. The circuit pack should be replaced at your convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)*

Continued on next page

Table 11-285. TEST #230 External Modem Present Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	MTP detected correct data from the external modem. The MTP received an **OK** response after sending the **AT** command to the modem. 1. If the system cannot call INADS, or if INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct. If an external modem is being used instead of the internal MTP modem, modem settings may be wrong. Approved external modems with factory default settings are expected to work if administered correctly using the **change system-parameters maintenance** command.

PR-MAINT (MainTenance/Tape Processor [286 systems] or Maintenance Processor [386 Systems])

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PR-MAINT	MIN[1]	test processor a/b sh/l	Maintenance/Tape Processor[2]

1 Alarms on the TAPE [G3iV1.1-286 system only], PROCR, and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

2 The full Name of the MO in a G3iV1.1-286 system is Maintenance/Tape Processor. In a 386 system [G3iV2-386, G3sV2, or G3vsV2], the full Name of the MO is Maintenance Processor.

NOTE:
For systems with a TN790 Processor Circuit Pack use maintenance object PR-MAINT (MainTenance Processor TN790 RISC Systems).

The 80286 Processor and Maintenance/Tape Processor comprise the TN773 Processor circuit pack [G3iV1.1-286]. The 80386 Processor, Memory, and MainTenance Processor comprise the TN786B Processor circuit pack [386 systems]. This section applies to both the TN773 [G3iV1.1-286] and TN786B [386 systems] circuit packs.

The TN773 Processor circuit pack is comprised of the 80286 Processor (PROCR) and the Maintenance/Tape Processor (PR-MAINT). On the TN773 circuit pack, PR-MAINT is responsible for monitoring the sanity of the 80286 Processor, and it contains the hardware required for controlling the tape drive (see Figure 11-88).

The TN786B Processor circuit pack is comprised of the 80386 Processor (PROCR), the MainTenance Processor (PR-MAINT), and the Memory (MEMORY). On the TN786B circuit pack, PR-MAINT is responsible for monitoring the sanity of the 80386 Processor.

The major difference between the two circuit packs is that on the TN786B circuit pack, there is no tape for PR-MAINT to control and Memory is on the circuit pack. The rest of the functionality is the same. On both circuit packs, PR-MAINT contains the hardware required for controlling the environmental conditions. The Maintenance/Tape Processor provides the serial interfaces for the administration terminal and CDR ports. The Maintenance/Tape Processor also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

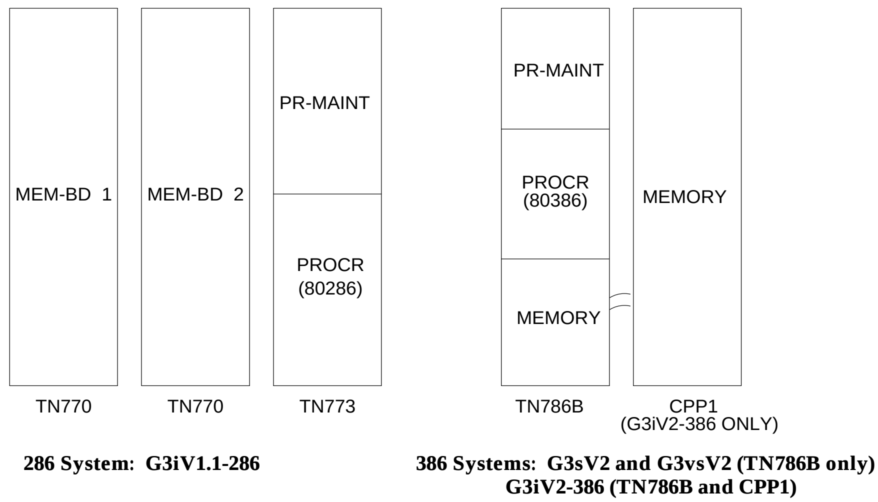

Figure 11-88. Configurations for 286 and 386 Systems

Hardware Error Log Entries and Test to Clear Values

Maintenance/Tape Processor Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value[1]
0[2]	0	Any	Any	Any	test processor a/b sh r 1
1 (a)	Any	MTP Reset Test (#101)	MIN	ON	test processor a/b l r 3
257 (b)	Any	MTP Sanity Handshake Test (#106)			test processor a/b r 2
513 (c)	Any	MTP Analog Loop Around Test (#103)	MIN	ON	test processor a/b r 8
769 (d)	Any	MTP Dual Port Ram Test (#104)	MIN	ON	test processor a/b l r 3
1025 (e)	Any	MTP Outpulse Relay Test (#102)	MIN	OFF	test processor a/b r 5
1537 (f)	Any	MTP Manager I Loop Around Test (#228)	MIN	ON	test processor a/b r 3
1793 (g)	Any	MTP Aux Loop Around Test (#229)	MIN	ON	test processor a/b r 3

1 **[G3iV1.1-286 only]:** Software does not accept the repeat option. You must manually repeat the command with the "long" option the designated number of times. **[For all systems]:** You must manually repeat the command with the "long" option the designated number of times from the administration terminal or from a remote administration terminal because the Sanity Timer Test (#83) logs you off.

2 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The MTP Reset Test (#101) has failed.

b. The MTP Sanity Handshake Test (#106) has failed.

c. The MTP Analog Loop Around Test (#103) has failed.

d. The MTP Dual Port Ram Test (#104) has failed. An error of 769 with an aux data of 5 indicates a hardware problem and testing will not clear it. The circuit pack should be replaced.

e. The MTP Outpulse Relay Test (#102) has failed.

f. The MTP Manager I Loop Around Test (#228) has failed.

g. The MTP Aux Loop Around Test (#229) has failed.

NOTE:
Refer to the FAIL section of each test that fails for further instructions.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *MTP Reset Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Software Initiated Interrupt Test (#77) (a)	X	X	ND
Processor ROM Checksum Test (#80) (a)	X	X	ND
Processor Non-maskable Interrupt Test (#82) (a)	X	X	ND
Processor Sanity Timer Test (#83) (a)		X	D
MTP Reset Test (#101)		X	D
MTP Dual Port Ram Test (#104)		X	D
MTP Sanity Handshake Test (#106)	X	X	ND
MAP Manager I Loop Around Test (#228)	X	X	ND
MTP Analog Loop Around Test (#103)	X	X	ND
MTP Outpulse Relay Test (#102)	X	X	ND
MTP Aux Loop Around Test (#229)	X	X	ND
Read All Memory Test (#85)(b)		X	ND
Memory Error Detection Test (#87)(b)	X	X	ND
Text Checksum Test (#86)(b)		X	ND
Memory Functional Test (#332) (b)(c)		X	D
Memory Board Check Test (#631) (b)	X	X	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to PROCR (8028/803866 Processor Circuit Pack) Maintenance documentation for a description of these tests.

b. Refer to MEMORY [386 systems only] Maintenance documentation for a description of these tests.

MTP Reset Test (#101)

This test is destructive. The test resets the Maintenance/Tape Processor. The destructive nature of this test causes the following:

- Administration terminal to log off
- CDR port to terminate data transmission
- Any current tape access to terminate and also to tear down any remote access INADS connection

Table 11-286. TEST #101 MTP Reset Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
10102	ABORT	System software resources required to run this test are not available.
10104	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-286. TEST #101 MTP Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10105	FAIL	The MTP did not respond to being reset. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*

Continued on next page

Table 11-286. TEST #101 MTP Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10106	FAIL	The Maintenance/Tape Processor was reset, but it responded with a NOT PASS status, indicating that it did not pass initialization correctly. The MTP is not functioning correctly. The system should continue to function, but it will not have the ability to save translation to tape, or to read tape if the system needs to be rebooted. Environmental monitoring is lost, as is communication with the Standby Processor. 1. Repeat the command at one minute intervals a maximum of five times. 2. If test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The Maintenance/Tape Processor was reset, and it passed initialization correctly. The other MTP tests should be examined to verify that the MTP is functioning correctly. 1. Enter **test processor a/b** and verify that the MTP is functioning correctly.

MTP Outpulse Relay Test (#102)

This test is a nondestructive test. The test validates the correct operation of the remote access CO trunk used by INADS. The MTP first goes off-hook, then on-hook on this trunk. If the loop current is detected, the test passes. This test is not allowed if the remote access line is in use.

Table 11-287. TEST #102 MTP Outpulse Relay Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1018	ABORT	The test has been disabled via administration. 1. To enable the test, issue the **change system-parameters maintenance** command, and set the test remote access port field to "y." (If you have an INADS line, set the field to "y." If you are testing the Standby PR-MAINT, a **refresh spe-standby** command must be successfully executed before you proceed to Step 2. 2. Rerun the test.
1131	ABORT	INADS port is busy because the system is reporting alarms to INADS, or because INADS is dialed into the system. 1. Wait about ten minutes and then re-enter the command.
10201	ABORT	System software resources required to run this test are not available.
10202	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-287. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10203	ABORT	MTP did not respond to the test request. 1. Repeat the test at one minute intervals a maximum of five times. 2. If all MTP tests are aborting, execute the **test processor a/b long** command in order to reset MTP and to examine the results of the MTP Reset Test (#101). 3. Replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) ⚠ **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.* 4. If only the MTP outpulse relay test is aborting, escalate the problem.

Continued on next page

Table 11-287. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10204	FAIL	MTP reported test failure. No loop current detected. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, examine the INADS trunk for connectivity, and manually check for loop current. 3. If there is no INADS trunk, this test should be disabled. To disable the test, issue the **change system-parameters maintenance** command, and change the Test Remote Access Port field to "n." If this test is failing on the Standby SPE, issue the **refresh spe-standby** command, and rerun the test. 4. If the INADS trunk checks out okay, but the test still fails, check the backplane connector wiring. 5. If the backplane wiring checks out okay, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, 'Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	MTP detected a loop current on the remote access port. 1. If the system cannot call INADS, or INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct.

Continued on next page

Table 11-287. TEST #102 MTP Outpulse Relay Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10205	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
10206	ABORT	System could not determine if the testing of the INADS port is administered. 1. Enter the **change system-parameters maintenance** command. Verify that the "Test Remote Access Port?" field is set to "y." 2. Repeat the command at one minute intervals a maximum of five times. 3. If the data on the Maintenance-Related System Parameters Form is correct, escalate the problem.
10208	ABORT	The remote access port is busy. INADS is probably dialed into the switch. 1. If INADS is dialed in, the INADS trunk is working. There is no need to run the test.

MTP Analog Loop Around Test (#103)

This test is a nondestructive test. The test does an on-board loop around by using the MTPINADS channel. Test data is sent through the on-board modem out toward the INADS trunk. The data is looped around before the actual trunk, and it comes back into the on-board modem. The data is then verified for integrity.

NOTE:
The test does not send any data onto the INADS trunk. However, in order to pass, the test does require the trunk to be present.

Table 11-288. TEST #103 MTP Analog Loop Around Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	(Refer to STBY-SPE Maintenance documentation for a description of these error codes.)
1018	ABORT	The test has been disabled via administration. 1. To enable the test, issue the **change system-parameters maintenance** command, and set the Test Remote Access Port field to 'y'. If you are testing the Standby PR-MAINT, a **refresh spe-standby** command must be successfully executed before you can proceed to Step 2. 2. Rerun the test.
1131	ABORT	The INADS port is busy because the system is reporting alarms to INADS, or because INADS is dialed into the system. 1. Wait about 10 minutes and then re-enter the command.

Continued on next page

Table 11-288. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10301	ABORT	System software resources required to run this test are not available.
10302 10309	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
10303 10310	ABORT	MTP did not respond to the test request. 1. Repeat test at one minute intervals a maximum of five times. 2. If only the MTP Analog Loop Around Test is aborting, escalate the problem. 3. If all MTP tests are aborting, execute the **test processor a/b long** command in order to reset MTP, and examine the results of the MTP Reset Test (#101).
10305	ABORT	Internal System software Error 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
10306	ABORT	System could not determine if the testing of the INADS port is administered. 1. Enter the **change system-parameters maintenance** command, and verify the entry for the Test Remote Access Port field. 2. Repeat the command at one minute intervals a maximum of five times. 3. If the data on the Maintenance-Related System Parameters Form is correct, escalate the problem.
10308	ABORT	The remote access port is busy. INADS is probably dialed into the switch. 1. Wait until INADS session is terminated and then re-enter the command.

Continued on next page

Table 11-288. TEST #103 MTP Analog Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
10311	ABORT	Test #102 MTP Outpulse Relay Test failed. 1. Refer to Error Code 10204 of the MTP Outpulse Relay Test (#102) for directions.
10304	FAIL	MTP reported test failure. The system is not able to reliably contact INADS with alarm data. However, the system continues to provide good service. 1. If MTP Outpulse Relay Test (#102) is also failing, check for the presence of the INADS trunk, and resolve any INADS trunk problems. 2. If Test #102 passes, the fault is on the Processor circuit pack. The circuit pack should be replaced at your convenience. (Refer to Chapter 8, 'Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	MTP detected correct data through the loop back connection. 1. If the system cannot call INADS, or if INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct.

MTP Dual Port Ram Test (#104)

This test is destructive.

The test terminates any PPN Manager I session, and it is a coordinated test of the MTP dual port ram (DPR). The DPR is a section of memory that is shared by the MTP and by the 80286/386 Processor circuit pack. Control messages and data are passed through the DPR. The test forces both sides to read and write the DPR simultaneously in alternate locations.

The DPR test causes the PPN Manager I to log off before the test result is displayed. The test result is determined according to the terminal from which the test is run. If the test is run from the PPN Manager I terminal, system technician should log back in and examine the Error Log for an error against PR-MAINT, with Error Type 769, no Aux Data. This error entry indicates that the MTPDPR Test failed and that the Processor circuit pack should be replaced. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.)

WARNING:

If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.

If the test is being run from a terminal other than the PPN Manager I (for example, EPN Manager I, remote access, etc.), the test results are displayed on the screen.

NOTE:

A dial-up (through the INADS port) does not display the results discussed in the previous paragraph. However, a dial-up through data channels does display these results.

Table 11-289. TEST #104 MTP Dual Port Ram Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	(Refer to STBY-SPE Maintenance documentation for a description of these error codes.)
1000	ABORT	System software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1030	ABORT	The component on which the test was to be run is on the Standby SPE. This test may be run on this component only when it resides on the Active SPE. 1. For a recommended maintenance procedure, refer to ABORT Error Code 1030 in STBY-SPE Maintenance documentation.
2000	ABORT	Response to the test request was not received within the allowable time period.
2028	ABORT	System software resources required to run this test are not available.
2029	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-289. TEST #104 MTP Dual Port Ram Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The dual port RAM is not functioning correctly. Communication between the processor and MTP is lost. The system is not able to report environmental alarms, communicate with the Standby SPE, or reboot from tape, if necessary. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	Dual port RAM is functioning. Communication exists between the 80286/386 Processor circuit pack and the MTP.

MTP Sanity Handshake Test (#106)

This test is a nondestructive test. The MTP Sanity Handshake Test is simply a query from a maintenance process to the MTP. The MTP must reply for the test to pass.

Table 11-290. TEST #106 MTP Sanity Handshake Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1000	ABORT	System software resources required to run this test are not available.
2033	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-290. TEST #106 MTP Sanity Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The MTP did not respond to the Sanity Handshake Query. 1. Re-enter command with the "long" option. 2. If the test continues to fail, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack [386 systems] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The MTP responded to the Sanity Handshake Query.

MTP Manager I Loop Around Test (#228)

This test is a nondestructive test. The test places the Manager I channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. Although the test is nondestructive, it causes loss of keyboard input from the PPN Manager I.

Table 11-291. TEST #228 MTP Manager I Loop Around Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1000	ABORT	System software resources required to run this test are not available.
2000	ABORT	The response to the test request was not received within the allowable time period.
2033 2034	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-291. TEST #228 MTP Manager I Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Manager I channel failed the Loop Back Test. The Manager I is probably unusable for administration or maintenance. The EPN Manager I, if available, or remote access can still be used. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to fail, replace the Processor circuit pack at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The Manager I channel passed the Loop Back Test. 1. If the PPN Manager I is not usable, check the Manager I itself, along with the cabling.

MTP Auxiliary Loop Around Test (#229)

This test is a nondestructive test. The test places the Auxiliary channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. The Auxiliary channel is used as the CDR output port.

Table 11-292. TEST #229 MTP Auxiliary Loop Around Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1000	ABORT	The system software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test has been disabled via administration. The **change system-parameters cdr** command needs to administer CDR. (Refer to the Implementation Manual for more information on administering this port.)
2000	ABORT	Response to the test request was not received within the allowable time period.
2033 2034	ABORT	Internal system error. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
22902 22903	ABORT	The system software resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-292. TEST #229 MTP Auxiliary Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Auxiliary channel failed the Loop Back Test. The AUX port is probably not sending any auxiliary data to the auxiliary collection device. 1. Repeat the command at one minute intervals for a maximum of five times. 2. If test continues to fail, replace the Processor circuit pack replaced at your earliest convenience. (Refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for information on how to replace a circuit pack in the control carrier.) **WARNING:** *If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The Auxiliary channel passed the Loop Back Test. The auxiliary port is functioning correctly. 1. If no auxiliary data is being recorded, check the auxiliary collection device, and verify that it has been set up and connected correctly.

PR-MEM (TN790 RISC Memory)

MO Name As It Appears In Alarm Log	Alarm Level	Initial System Technician Command To Run	Full Name of MO
PR-MEM[1]	MAJOR	test memory a/b lo c	TN790 RISC Memory
PR-MEM[1]	MINOR	test memory a/b sh c	TN790 RISC Memory

1 The maintenance object is "PR-MEM" because all of the Memory used by the RISC Processor is on the TN790 Processor circuit pack.

NOTE:
For G3iV1.1-286, G3iV2-386, G3sV2, G3vsV2 systems refer maintenance objects MEM-BD (Memory) and MEMORY for 386 systems.

The TN790 RISC Memory contains the DEFINITY software and firmware. The Processor circuit pack is the most critical component in the system.

For testing purposes, the circuit pack is logically separated into PR-MAINT, PROCR, and PR-MEM. This means that a memory problem requires that the Processor be replaced. These systems contain two types of memory: Flash ROM and DRAM. Flash ROM is memory that contains the boot image, part of the low-level maintenance firmware, PI firmware, and PACCON firmware. This type of memory is not erased during circuit pack resets. It can be reprogrammed via the **upgrade software** command or a Reset System 4/5 using a software memory card.

One section of the Flash ROM (BOOTPROM) containing the system initialization functions and the low-level diagnostic programs is programmed at the factory and is not reprogrammed by the **upgrade software** command. DRAM is used for software data storage, and it changes constantly. Both types of memory are present on the Processor circuit pack. The diagnostics run appropriate tests on both memories.

DRAM is replaceable and installed in 3 Single In-line Memory Module (SIMM) sockets on this circuit pack. Replacement of these SIMMs is described in "Install the SIMM on the TN790 Processor Circuit Pack" in Chapter 5, "Routine Maintenance Procedures".

For all system activity, the Processor must be able to access the Memory. If the Processor cannot do this, the system goes into SPE-down mode. In SPE-down mode, fatal Memory errors may show up as Processor errors. This merely indicates that the Processor and the Memory are very closely linked as a matter of course.

If the initialization diagnostics fail, refer to the "Procedure for SPE-Down Mode" section in Chapter 4, "Initialization and Recovery".

Hardware Error Log Entries and Test to Clear Values

Memory Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test memory a/b l r 1
1	Any	Flash Memory ChecksumTest (#86)	MAJOR	ON	test memory a/b l r 5
3(a)	Any	Flash Memory ChecksumTest (#86)	MAJOR	ON	test memory a/b l r 5
1025	Any	Memory Parity Error DetectionTest (#87)	MINOR	ON	test memory a/b r 3
1281	Any	Memory Burst Read Test (#908)	MAJOR	ON	test memory a/b l r 2
1793	Any(b)(c)	Read All Memory (#85)	MAJOR	ON	test memory a/b l r 1
2049(d)	Any(b)(c)	Memory Functional Test (#332)	MAJOR	ON	test memory a/b l r 1

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error (3) indicates that a software patch has been applied and either the software patch is bad or was installed incorrectly.

1.Back out the software patch and run the **test memory UUCS long** command to verify that the problem has been cleared.

2.If the PBX system is equipped with High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and this error occurs, a SPE interchange will occur if the health of the standby SPE permits the interchange.

b. The following Aux Data indicate SIMM Failures

1.SIMM A

2.SIMM B

3.SIMM A & SIMM B

4.SIMM C

5.SIMM A & SIMM C

6.SIMM B & SIMM C

7.SIMM A, SIMM B, & SIMM C

c. Aux Data of 100 is an LMM Flash Checksum initialization failure.

d. There are Functional Memory Test errors against the Processor circuit pack. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate errors in the order in which they are presented in the table that follows when you are inspecting errors in the system. By clearing error codes associated with the *Read All Memory Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor CacheTest (#895)(a)		X	ND
Processor Cache Audit (#896)(a)	X	X	ND
Processor Bus Timeout Exception Test (#82)(a)	X	X	ND
Processor BOOTPROM Checksum Test (#897)(a)	X	X	ND
Processor Write Buffer Test (#900)(a)	X	X	ND
Memory Burst Read Test (#908)	X	X	ND
Read All Memory Test (#85)		X	ND
Memory Parity Error Detection Test (#87)	X	X	ND
Flash Memory Checksum Test (#86)		X	ND
Memory Functional Test (#332) (b)		X	D
MTP Outpulse Relay Test (#102) (c)	X	X	ND
MTP External Modem Present Test (#230) (c)	X	X	ND
MTP Analog Loop Around Test (#103) (c)	X	X	ND
MTP Sanity Handshake Test (#106	X	X	ND
MTP SAT Loop Around Test (#228) (c)	X	X	ND
MTP Aux Loop Around Test (#229) (c)	X	X	ND
MTP Reset Test (#101) (c)		X	D
MTP Dual Port Ram Test (#104) (c)		X	D

1 D = Destructive; ND = Nondestructive

For example, you may also clear errors generated from other tests in the testing sequence.

a. Refer to PROCR (TN790 RISC Processor) Maintenance documentation for a description of these tests .

b. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

c. Refer to PR-MAINT (MainTenance Processor) Maintenance documentation for a description of these tests.

Read All Memory Test (#85)

This test is a nondestructive test. The test reads every memory location in memory. A failure of this test indicates a DRAM failure in the Processor circuit pack. DRAM is replaceable and installed in 3 Single Inline Memory Module (SIMM) sockets on this circuit pack. Replacement of these SIMMs is described in the "Circuit Pack Replacement Procedure" section.

Table 11-293. TEST #85 Read All Memory Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-293. TEST #85 Read All Memory Test ***— Continued — Continued***

Error Code	Test Result	Description/ Recommendation
1 - 7	FAIL	If the system can still provide service, this indicates that the Processor circuit pack has a problem with memory or the RISC processor, but can still function. At the customers convenience run the destructive "**reset system 4**" command to boot the system and write to all of the memory locations. This will clear transient parity errors and test for permanent parity errors. This complete memory testing during initialization will cause "SPE DOWN" if a parity error is detected and the PROCR circuit pack should be replaced. If parity errors reoccur within several weeks, record the error code information indicating which memory modules failed, together with the extended interval between failures. After recording the information and at the customers convenience replace the PROCR circuit pack and escalate the problem.
	PASS	The Memory is healthy.

Flash Memory Checksum Test (#86)

This test is a nondestructive test. The test computes the checksum of the DEFINITY Generic 3 software and firmware loaded from the Software Memory Card (SOFTWARE MEM-CARD). A failure of this test indicates corruption of the Flash Memory. However, this failure does NOT always indicate a hardware problem. **DO NOT REPLACE** the Processor circuit pack when this is the only error. A system restart via the **reset system 4** command starting with inserting the Software Memory Card for this system followed by re-inserting the Translation Memory Card memory card should be implemented at the customer's earliest convenience.

In a High or Critical Reliability system, an **upgrade software** command can be used with the Software Memory Card for the system followed by re-inserting the Translation Memory Cards as directed by this upgrade procedure. This command performs the same operation as the **reset system 4** command but is much less service-disruptive.

Table 11-294. TEST #86 Text Checksum Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowabletime period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-294. TEST #86 Text Checksum Test **— *Continued***

Error Code	Test Result	Description/ Recommendation
2500	ABORT	Internal System Error. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1 - 7	FAIL	The system may or may not continue to operate correctly. The system may fail later when some action requires access to the corrupted area of the Text. 1. The Flash ROM should be reprogrammed via the **upgrade software** command. The memory card should contain the same vintage software that is currently in the system. Refer to the "Software Upgrade" section in this manual. 2. If the test continues to fail, replace the TN790 Processor circuit pack and repeat step 1. 3. If the test continues to fail, escalate the problem.
	PASS	The checksum is correct.

Memory Parity Error Detection Test (#87)

This test is a nondestructive test. The test is run on a few reserved locations in memory. A failure of this test indicates a failure on the Processor circuit pack.

This test determines if the parity circuitry is working. Accordingly, the test determines if parity errors can be detected. The parity circuitry is used to detect DRAM memory failures.

Table 11-295. TEST #87 Memory Parity Error Detection Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1 - 7	FAIL	The parity detection circuitry is not working correctly. If the system can still provide service, this indicates that the Processor circuit pack has a problem but can still function. 1. The TN790 Processor circuit pack should be replaced. The failure is identifying the PROCR as being bad and only the PROCR circuit pack needs to be replaced. 2. If the test still fails, escalate the problem.
	PASS	The parity detection circuitry is working.

Memory Functional Test (#332)

This test is destructive.

This test ensures that every DRAM memory location can be accessed and changed independently. Running this test wipes out all data in DRAM memory. This test is performed during a **reset system 4** or **reset system 5**. If the test fails during a **reset system** command, refer to the "Procedure for SPE-Down Mode" in the Chapter 4, "Initialization and Recovery" for the recommended maintenance strategy. This test can be run as a long demand test on the standby SPE.

Table 11-296. TEST #332 Memory Functional Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1000	ABORT	System resources required to run this test are not available. 1. Repeat the command at one minute intervals a maximum of three times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-296. TEST #332 Memory Functional Test **— *Continued***

Error Code	Test Result	Description/ Recommendation
1 - 7	FAIL	The Standby SPE Processor circuit pack is defective. 1. Repeat the command at one minute intervals a maximum of five times. 2. If the test still shows a failure, the Processor circuit pack should be replaced. 3. If the test continues to fail, escalate the problem.
	PASS	The Standby SPE Processor circuit pack is healthy.

Memory Burst Read Test (#908)

This test verifies that the Memory Burst Read function works properly on the Processor circuit pack.

Table 11-297. TEST #908 Memory Burst Read Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1022 1335 2500	ABORT	Internal System Error. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
1 - 7	FAIL	The Burst Read circuit is not functioning properly. 1. If the test fails, replace the Processor and retry the test. 2. If the test continues to fail after replacing the Processor circuit pack, follow normal escalation procedures.
	PASS	The Burst Read portion of the Processor circuit pack is operating correctly.

PRI-CDR/SEC-CDR (PRI-CDR Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PRI-CDR/SEC-CDR	MINOR	test cdr-link primary/secondary l	CDR Link
PRI-CDR/SEC-CDR	WARNING	test cdr-link primary/secondary	CDR Link

The CDR feature records detailed call information on all incoming and outgoing calls on specified trunk groups and sends this information to an CDR output device. The two physical links can be administered for connecting external CDR output devices to the system. They are identified as the primary CDR (PRI-CDR) link and the secondary CDR (SEC-CDR) link. The CDR link can be administered to a data extension or the EIA port on the system TN773 Processor circuit pack which provides a standard EIA 232C interface. The external CDR output devices are:

- 94A Local Storage Unit (LSU)
- TELESEER CDR Unit
- AT&T Call Accounting System (CAS)
- AT&T Call Detail Recording Unit (CDRU)
- Printer
- Host computer
- Personal computer (PC)
- Customer-provided equipment

Refer to *DEFINITY Communications System Generic 3 Feature Description*, 555-230-204 or *DEFINITY Communications System Generic 1 and Generic 3 Feature Description,* 555-230-201, for details of the CDR feature.

CDR Link Maintenance provides a strategy for maintaining the link between the system and an external CDR output device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. CDR Link Maintenance uses a try-and-wait mechanism for maintaining the CDR link. If the CDR link is torn down due to an error, CDR Link Maintenance intends to bring the CDR link up. If the Link Setup trial fails, CDR Link Maintenance waits 30 seconds before the next retry. If the number of retries reaches the value of a threshold (two), a Minor alarm is raised for service attention.

The following physical configurations are supported for the CDR link:

- From the EIA port of Processor circuit pack to an CDR output device through the standard EIA 232C interface.
- From a data channel on TN777 Network Control circuit pack to a data extension where the CDR output device connects via the standard EIA 232C interface.

  The data extension can be a PDM, MPDM, DTDM, or ADU. The PDM, MPDM, and DTDM connect to a Digital Line Port of TN754 or TN754B Digital Line circuit pack; ADU connects to a Data Line Port of TN726 Data Link circuit pack.

NOTE:
In duplicated systems it is possible for a failure on one of the processor circuit packs to bring down the CDR link even if it is the standby processor. This problem can not be resolved by interchanging processors because the CDR ports on each of the processor circuit packs are connected via WIRE-OR.

CDR Link Maintenance does not cover the maintenance of the elements composing the CDR physical link, which are as follows:

- External CDR output device
- EIA port on Processor circuit pack
- Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 or TN754B Digital Line circuit pack
- ADU and Data Line Port of TN726 Data Link circuit pack
- Data Channels on TN777 Network Control circuit pack

If CDR Link Maintenance cannot restore the CDR link, then the maintenance tests of these individual components of the CDR link must be executed to diagnose faults.

Procedures for Restoring the CDR Link

1. Get the status of CDR links.

   Enter **status cdr-link** command and make sure that the CDR links are not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the CDR link connect to?

   Enter **display system feature** and find out the destinations of CDR links. Continue to the next step.

3. Is the destination an extension or the EIA port?

If the destination is an extension number, then enter the **status data extension** command and verify whether the data extension is in the in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log and refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

If the destination is "eia," then look for PR-MAINT errors in the Hardware Error Log. If present, refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation.

4. Is a data channel on TN777 Network Control circuit pack in the in-service/idle state?

   Enter **list data** command and find out the extension numbers of data channels on TN777 Network Control circuit pack. Enter **status data extension** command and make sure that at least one data channel is in the in-service/idle state. If no data channel is available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation; if the problem persists, escalate the error.

5. Is the external CDR output device available?

   Make sure that the CDR output device is on-line and ready for service. Check the physical connectivity between Data Module and the CDR output device or between the EIA port on backplane of the switch and the CDR output device.

It is recommended to busy out the CDR link before executing maintenance tests over the CDR link. If the CDR link is busied out, then all CDR link maintenance actions are deactivated. The interference to tests of other MO is off.

Hardware Error Log Entries and Test to Clear Values

CDR Link Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test cdr-link primary|secondary sh
18 (a)	0	busy out cdr	WARNING	OFF	release cdr-link primary|secondary
		primary|secondary			
25 (b)	0 3 to 6 9 99 255	Link Retry Test (#215)	MINOR/ WARNING[2]	OFF	test cdr-link primary|secondary l
513 (c)	0 3 to 6 9				test cdr-link primary|secondary
1025 (d)					
1281 (e)					

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. System Technician has busied out the CDR link to out-of-service state. The CDR link is torn down.

b. Link Retry Test (#215) fails. The Aux Data field contains either the Channel ID of Data Channels on the TN777 circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04, and 9 for EIA port) or an Error Code of 99 indicating that no data channels are available for setting up the link, or an Error Type of 255 indicating an internal system error. Refer to the preceding "Procedures for Restoring the CDR Link" for resolution.

c. The CDR physical link is down due to the following causes: cable to the CDR output device is disconnected; CDR output device is powered off, the data extension where the CDR output device connects to has been busied out or there is a scheduled daily interchange. The Aux Data field contains the Channel ID of Data Channels on the TN777 circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04, and 9 for EIA port). Check the connectivity of wire and cable among wall jacket, data module, and the CDR output device. Enter **status data extension** and verify that the data extension of the CDR output device is in the in-service/idle state. If the data extension is not available, then refer to the preceding "Procedures for Restoring the CDR Link" for resolution. Issue the **display system-parameters-maintenance** command to see the start time of daily maintenance. If the error occurs and is resolved during the interval of daily maintenance, then the error can be ignored.

d. This error indicates that the CDR output device is in an off-line state, for example, paper jam or paper out for a printer device. The CDR link is torn down. Check the CDR output device and act promptly to put it back to on-line state. Enter **test cdr-link primary|secondary** command to set up the CDR link.

e. Software detects an overflow of CDR records generated in the switch due to the heavy trunk traffic and low speed CDR output device. If both primary and secondary links are ON, the secondary link is torn down temporarily for two minutes to speed up the output process to the primary link. No action is necessary for this error type.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND

1 D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external CDR output device. If the link has been disconnected already, this test just returns PASS. All resources allocated for an CDR link are released after this test.

Table 11-298. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40	ABORT	Internal System Error.
50	ABORT	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1010	ABORT	The CDR link has been busied out to out-of-service. 1. Enter the **release cdr-link primary|secondary** command to release the CDR link from busyout state. 2. Retry the **test cdr-link primary|secondary long** command to execute the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The CDR link is torn down.

Link Retry Test (#215)

This test sends a message to the CDR software process to make a data call to the extension where the CDR output device connects to or opens the EIA port to the CDR output device. If the CDR link is already up, this test is passed without making any data call or opening the EIA port.

Table 11-299. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10	ABORT	Internal System Error.
20	ABORT	Internal System Error. Internal error in Maintenance Action Process (MAP). MAP returns an error back to maintenance script (HMM). Timer expires while waiting for the reply from MAP. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
30	ABORT	Internal System Error. 1. Refer to "Procedures for Restoring the CDR Link" for instructions.
1010	ABORT	The CDR link has been busied out to out-of-service. 1. Enter **release cdr-link primary|secondary** command to release the CDR link from busyout state. 2. Retry **test cdr-link primary|secondary long** command to execute the test.
	FAIL	The CDR link CANNOT be established. 1. Refer to the "Procedures for Restoring the CDR Link" for instructions.
	PASS	The CDR link is up.

PROC-SAN (Process Sanity Audits)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PROC-SAN	none	none	Process Sanity Audits

The Process Sanity Audits MO is responsible for monitoring the sanity of software processes in the system. If the Process Sanity Audits MO detects that a process has gone insane (does not respond to a sanity message within an allotted time period), the process is restarted. If the Process Sanity Audits MO detects that multiple processes (or a single key process) do not respond to sanity messages within an allotted time period, a system recovery action is initiated.

The Process Sanity Audits MO has no alarms and no tests. Certain errors are logged to the Hardware Error Log for information purposes only.

Hardware Error Log Entries and Test to Clear Values

Process Sanity Audits Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	none
10 (a)	0	none	none	none	none
204 (a)	any	none	none	none	none

1 Look for other errors of the same type and deal with them accordingly.

a. These errors indicate that a system recovery action has been taken because one or more software processes failed to respond to a sanity audit in a timely fashion. As a result of the recovery action, the system may have temporarily suspended service for a period of time surrounding the error. If these errors persist, escalate the problem immediately.

PROCR (TN790 RISC Processor Circuit Pack)

MO Name As It Appears In Alarm Log	Alarm Level	Initial System Technician Command To Run	Full Name of MO
PROCR	MAJOR	test processor a/b lo r/c	TN790 RISC Processor Circuit Pack
PROCR	MINOR	test processor a/b sh r/c	TN790 RISC Processor Circuit Pack

NOTE:
For systems with a TN773 [G3iV1.1-286] or a TN786B Processor circuit pack, see maintenance object PROCR (Processor Circuit Pack) in this section.

NOTE:
Alarms on the PR-MEM, PROCR and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

This section applies to the TN790 [G3iV5, G3sV5, or G3vsV5]. The TN790 has a RISC processor (PROCR) that uses on-board Flash ROM and DRAM memory (PR-MEM). This circuit pack also contains the MainTenance Processor (PR-MAINT).

The RISC Processor circuit pack portion is responsible for the execution of the DEFINITY Generic 3 software package. This includes all of the call processing, maintenance, and administration functions. The RISC Processor circuit pack is the most critical component to the correct operation of the system.

The PR-MAINT (MainTenance Processor for RISC systems) is responsible for monitoring the sanity of the RISC Processor circuit pack as well as the environmental conditions. The PR-MAINT provides the serial interfaces for the SAT and for the Digital Communications Equipment (DCE) ports. The PR-MAINT also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

In High and Critical Reliability systems, the PR-MAINT is part of the communications path between the Active Processor Element and the Standby Processor Element.

Hardware Error Log Entries and Test to Clear Values

RISC Processor Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value[1]
0[2]	0	Any	Any	Any	test processor a/b r 1
1(a)	Any	BOOTPROM Checksum Test (#80)	MAJOR	ON	test processor a/b r 5
513		Processor Write Buffer Test (#900)	MAJOR	ON	test processor a/b r 1
1025(b)	Any	Processor Cache Audit (#896)	MINOR	ON	test processor a/b r 2
1281	Any	Processor Cache Test(#895)	MAJOR	ON	test processor a/b r 1
1793(c)		Processor Bus Timeout Exception Test (#82)	MAJOR	ON	test processor a/b r 2
2049(d)(e)	Any	Processor Sanity Timer Test	MINOR	ON	test processor a/b l c
2305(d)(f)	Any	Address Matcher Test	none	ON	test processor a/b l c

1 The MTP Reset Test (#101) logs you off. The MTP Dual Port Ram Test (#104) can also log you off.

2 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The BOOTPROM Checksum Test (#80) failed. Refer to the FAIL condition of this test for further action.

b. A parity error was detected in the processor’s data cache or instruction cache. Aux Data indicates the difference in the number of parity errors since the last report.

c. The Processor Bus Timeout Test (#82) failed. Refer to the FAIL condition of this test for further action.

d. Aux Data of 100 is an LMM initialization failure.

e. The Processor Sanity Timer Test failed during a reset level 4 or 5 initialization. reset system 4 at the customers convenience and if the alarm occurs again, replace the processor circuit pack. The system will run with this failure, but it is not protected if the system software has a sanity problem. The test processor a/b long clear command will clear this alarm, but the sanity timer is only tested during initialization so the alarm will occur again and the system is not protected against insane software.

f. The Address Matcher Test failed during a reset level 4 or 5 initialization. This failure is not alarmed because the address matcher is only used for high level debugging. The processor circuit pack should be replaced if the Address Matcher is needed for troubleshooting.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *Processor Bus Timeout Exception Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Cache Test (#895)		X	ND
Processor Cache Audit (#896)	X	X	ND
Processor Bus Timeout Exception Test (#82)	X	X	ND
Processor BOOTPROM Checksum Test (#80)	X	X	ND
Processor Write Buffer Test (#900)	X	X	ND
Memory Burst Read Test (#908)(a)	X	X	ND
Read All Memory Test (#85)(a)		X	ND
Memory Parity Error Detection Test (#87)(a)	X	X	ND
Flash Memory Checksum Test (#86)(a)		X	ND
Memory Functional Test (#332) (a) (b)		X	D
MTP Outpulse Relay Test (#102) (c)	X	X	ND
MTP External Modem Present Test (#230) (c)	X	X	ND
MTP Analog Loop Around Test (#103) (c)	X	X	ND
MTP Sanity Handshake Test (#106) (c)	X	X	ND
MTP SAT Loop Around Test (#228) (c)	X	X	ND

Continued on next page

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
MTP Aux Loop Around Test (#229) (c)	X	X	ND
MTP Reset Test (#101) (c)		X	D
MTP Dual Port Ram Test (#104) (c)		X	D

1 D = Destructive; ND = Nondestructive

a. Refer to PR-MEM Maintenance documentation for a description of these tests.

b. There are Functional Memory Test errors against the Processor circuit pack. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a reset system 4 command or a reset system 5 command.

c. Refer to PR-MAINT (MainTenance Processor) Maintenance documentation for a description of these tests.

Processor BOOTPROM Checksum Test (#80)

This test is a nondestructive test. This test computes the checksum of the Processor's bootstrap BOOTPROM and compares it to a predetermined value stored within the BOOTPROM. A failure of this test indicates the BOOTPROM is corrupt.

Table 11-300. TEST #80 Processor BOOTPROM Checksum Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-300. TEST #80 Processor BOOTPROM Checksum Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The computed checksum did not match the BOOTPROM checksum. The system may not continue to operate correctly. The system may fail at some future date when the corrupted area the bootstrap BOOTPROM is accessed. 1. Replace the Processor circuit pack. 2. If the test continues to fail after replacing the Processor circuit pack, follow normal escalation procedures. To replace the Processor circuit pack, refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures".
	PASS	The computed checksum matched the BOOTPROM checksum. This part of the Processor will continue to operate normally.

Processor Bus Timeout Exception Test (#82)

This test is a nondestructive test. The test is used to verify that the RISC Processor can intentionally cause a BUS TIMEOUT EXCEPTION (BTE) and then verifies if it vectors to the correct interrupt routine. This is basically a test of the internal operation of the RISC Processor chip and the bus timeout circuitry.

Table 11-301. TEST #82 Processor Bus Timeout Exception Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-301. TEST #82 Processor Bus Timeout Exception Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The interrupt was not detected or acted upon. 1. Repeat the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, the Processor circuit pack should be replaced. The replacement must have enough memory for this system. Refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures". 3. If replacement of the Processor circuit pack still results in test failure, the following circuit packs should be replaced, one at a time in the order provided: TN765 Processor Interface, TN777B Network Control, TN778 Packet Control, and TN772 Duplication Interface circuit packs. The test should then be repeated. 4. If the test still fails after you replace all the circuit packs discussed in the previous step, follow normal escalation procedures.
	PASS	The interrupt was correctly detected. The RISC Processor is functioning correctly.

Processor Cache Test (#895)

This test is a nondestructive test. This test overwrites the contents in the Instruction and Data Caches, requiring them to be refilled during normal execution.

This test verifies that the Processor Instruction and Data Caches are functional. Some errors in the caches will simply reduce performance by forcing instructions or data to be read from memory more often than would normally be necessary. In any case, cache problems are serious and the Processor circuit pack must be replaced as soon as possible if they are detected.

Table 11-302. TEST #895 Processor Cache Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-302. TEST #895 Processor Cache Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Processor cache is not functioning correctly. 1. Replace the Processor circuit pack immediately. 2. If the test continues to fail after replacing the Processor circuit pack, follow normal escalation procedures. To replace the Processor circuit pack, refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures".
	PASS	The cache portion of the Processor circuit pack is operating correctly.

Processor Cache Audit (#896)

This nondestructive audit checks the state of the Cache Parity bit maintained by the RISC CPU. If this bit is set, there may be problems with either the CPU, the Instruction, or Data Cache. An indication of bad cache parity won't itself mean that the system won't operate, but minor to severe performance degradation may be present. For example, a single bad bit in either cache could cause this bit to be set. If the faulty word is seldom accessed, the impact will be small. If the bit is accessed frequently, there could be serious problems with much, or all, of the cache (stuck data bit) with the only direct indication again being the cache parity error or cache test error.

Table 11-303. TEST #896 Processor Cache Audit

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-303. TEST #896 Processor Cache Audit — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Cache Parity Error bit is set, there may be problems with either the CPU or the Instruction or Data Cache. 1. Retry the command. 2. If the test continues to fail, run test processor a|b long. 3. If the Processor Cache test (#895) or the Processor Cache Audit (#896) fails, replace the Processor circuit pack. 4. If the test continues to fail after replacing the Processor pack, follow normal escalation procedures. To replace the Processor circuit pack, refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures".
	PASS	The Processor has not detected any parity errors in the Instruction and Data Caches since the last time this audit was run.

Processor Write Buffer Test (#900)

This test is a nondestructive test. This test verifies that the Write Buffer operates properly on the Processor circuit pack. Failure of this test is serious. The Processor circuit pack must be replaced as soon as possible.

Table 11-304. TEST #900 Processor Write Buffer Test

Error Code	Test Result	Description/ Recommendation
100	ABORT	The requested test did not complete within the allowable time period. 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
	FAIL	The Processor Write Buffer is not operating correctly. 1. Replace the Processor circuit pack immediately. 2. If the test continues to fail after replacing the Processor circuit pack, follow normal escalation procedures. To replace the Processor circuit pack, refer to "Replacing Port Circuit Packs" in Chapter 5, "Routine Maintenance Procedures".
	PASS	The Write Buffer portion of the Processor circuit pack is operating correctly.

PROCR (Processor Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PROCR	MAJOR	test processor a/b sh r/c	80286/386 Processor Circuit Pack

NOTE:
For systems with a TN790 RISC Processor circuit pack see maintenance object PROCR (TN790 Circuit Pack) in this section.

NOTE:
Alarms on the TAPE [286 systems only], MEM-BD [386 systems only], PROCR and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

This section applies to both the TN773 [G3iV1.1-286] and the TN786B Processor circuit packs (PROCR). The TN786B has a 80386 processor that uses on-board flash ROM and DRAM memory, while the TN773 has a 80286 processor that uses DRAM memory only.

The TN773 Processor circuit pack is comprised of the 80286 Processor (PROCR) and the Maintenance/Tape Processor (PR-MAINT). Memory is on two TN770 Memory circuit packs: MEM-BD 1 and MEM-BD (see Figure 11-89).

The TN786B Processor circuit pack is comprised of the 80386 Processor (PROCR), the MainTenance Processor (PR-MAINT) and Memory (MEM-BD). Except for G3iV2-386, which also contains the CPP1 circuit pack, 386 systems contain just the TN786B circuit pack. (see Figure 11-89).

The 80286/386 Processor circuit pack portion is responsible for the execution of the DEFINITY Generic 1 software package. This includes all of the call processing, maintenance, and administration functions. The 80286/386 Processor circuit pack is the most critical component to the correct operation of the system.

The PR-MAINT (Maintenance/Tape Processor for G3iV1.1-286 and MainTenance Processor for 386 systems) is responsible for monitoring the sanity of the 80286/386 Processor circuit pack as well as the environmental conditions. The PR-MAINT provides the serial interfaces for the administration terminal and for the Call Detail Recording (CDR) ports. For G3iV1.1-286 only, the PR-MAINT contains the hardware required for controlling the tape drive. The PR-MAINT also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

In High and Critical Reliability systems, the PR-MAINT is part of the communications path between the Active Processor Element and the Standby Processor Element.

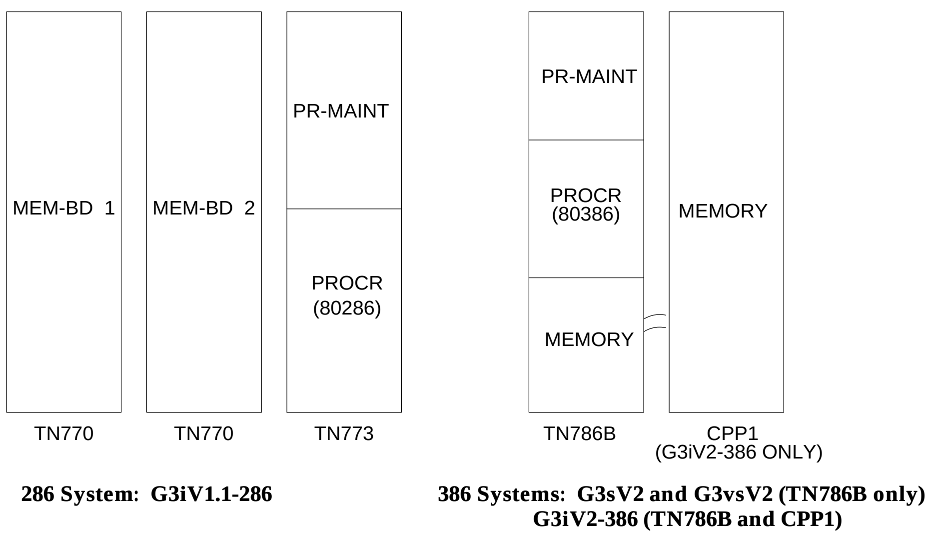

Figure 11-89. Configurations for 286 and 386 Systems

Hardware Error Log Entries and Test to Clear Values

80286/386 Processor Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value[1]
0[2]	0	Any	Any	Any	test processor a/b r 1
1 (a)	0	Software Initiated Interrupt Test (#77)	MAJOR	ON	test processor a/b r 3
769 (b)	0	ROM Checksum Test (#80)	MAJOR	ON	test processor a/b r 5
1025 (c)	0	Processor Non-maskable Interrupt Test (#82)	MAJOR	ON	test processor a/b r 2
1281 (d)	0	Processor Sanity Timer Test (#83)	MAJOR	ON	test processor a/b l r 2

1 Software does not accept the repeat option on the TN773 circuit pack [G3iV1.1-286]. The repeat option is valid only on the TN786B circuit pack. You must manually repeat the command with the long option the designated number of times from the administration terminal and from a remote SAT because the Sanity Timer Test (#83) logs you off. In G3iV1.1-286, if the **test processor long** System Technician command is executed six times back-to-back, the system goes into SPE-DOWN mode.

2 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The Software Initiated Interrupt Test (#77) failed. Refer to the FAIL condition of this test for further action.

b. The ROM Checksum Test (#80) failed. Refer to the FAIL condition of this test for further action.

c. The Processor Non-maskable Interrupt Test (#82) failed. Refer to the FAIL condition of this test for further action.

d. The Processor Sanity Timer Test (#83) failed. Refer to the FAIL condition of this test for further action.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *Processor Non-maskable Interrupt Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Processor Non-maskable Interrupt Test (#82)	X	X	ND
Processor ROM Checksum Test (#80)	X	X	ND
Processor Software Initiated Interrupt Test (#77)	X	X	ND
Processor Sanity Timer Test (#83)		X	D
MTP Outpulse Relay Test (#102) (a)	X	X	ND
MTP Analog Loop Around Test (#103) (a)	X	X	ND
MTP Sanity Handshake Test (#106) (a)	X	X	ND
MTPSAT Loop Around Test (#228) (a)	X	X	ND
MTP Aux Loop Around Test (#229) (a)	X	X	ND
MTP Reset Test (#101) (a)		X	D
MTP Dual Port Ram Test (#104) (a)		X	D
Read All Memory Test (#85)(b)		X	ND
Memory Error Detection Test (#87)(b)	X	X	ND
Text Checksum Test (#86)(b)		X	ND
Memory Functional Test (#332) (c)(b)		X	D
Memory Board Check Test (#631) (b)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation for a description of these tests.

b. Refer to MEMORY [386 systems only] Maintenance documentation for a description of these tests.

Processor Software Initiated Interrupt Test (#77)

This test is a nondestructive test. The test verifies if the 80286/386 Processor can exercise the three types of software-initiated interrupts:

- Divide by zero
- Single step
- One byte interrupt instruction.

Table 11-305. TEST #77 Processor Software Initiated Interrupt Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-305. TEST #77 Processor Software Initiated Interrupt Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The processor did not detect the software interrupt condition. As a result, the processor executed the incorrect interrupt vector. The system may or may not continue to operate correctly. 1. Repeat the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, the Processor circuit pack should be replaced. Refer to "Circuit Pack Replacement Procedure" in Chapter 8, "Reliability Systems: A Maintenance Aid". **WARNING:** *If the TN786B circuit pack [386 systems only] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The processor detected the software interrupt condition, and it executed the correct interrupt vector. The system continues to operate correctly.

Processor ROM Checksum Test (#80)

This test is a nondestructive test. The test computes the checksum of the processor's bootstrap ROM, and it compares this checksum to a predetermined value stored within the ROM. A failure of this test indicates corruption of the ROM.

Table 11-306. TEST #80 Processor ROM Checksum Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
	FAIL	The computed checksum did not match the ROM checksum. The system may or may not continue to operate correctly. The system may fail later when some action requires access to the corrupted area of the bootstrap ROM. 1. The Processor circuit pack should be replaced. Refer to "Circuit Pack Replacement Procedure" in Chapter 8, "Reliability Systems: A Maintenance Aid". **WARNING:** *If the TN786B circuit pack [386 systems only] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*
	PASS	The computed checksum matched the ROM checksum. The system continues to operate normally.

Processor Non-maskable Interrupt Test (#82)

This test is a nondestructive test. The test is used to verify that the 80286/386 Processor can detect and respond to non-maskable interrupts. For example, the processor intentionally causes a BUS TIMEOUT EXCEPTION (BTE) and then verifies if it vectors to the correct interrupt routine. This is basically a test of the internal operation of the 80286/386 CPU chip.

Table 11-307. TEST #82 Processor Non-maskable Interrupt Test

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-307. TEST #82 Processor Non-maskable Interrupt Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The interrupt was not detected or acted upon. 1. Repeat the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, the Processor circuit pack should be replaced. Refer to "Circuit Pack Replacement Procedure" in Chapter 8, "Reliability Systems: A Maintenance Aid". **WARNING:** *If the TN786B circuit pack [386 systems only] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.* 3. If replacement of the Processor circuit pack still results in test failure, the following circuit packs should be replaced, one at a time in the order provided: TN770 Memory [G3iV1.1-286 only] Expansion Memory [G3iV2-386 only] TN765 Processor Interface, TN777B Network Control, TN778 Packet Control, and TN772 Duplication Interface circuit packs. The test should then be repeated. 4. If the test still fails after you replace all the circuit packs discussed in the previous step, the problem must be in the control carrier, and the carrier should be replaced.
	PASS	The interrupt was correctly detected. The 80286/386 CPU chip is functioning correctly.

Processor Sanity Timer Test (#83)

This test is destructive.

This test causes service to be disrupted for about seven seconds on the TN773 and for about one second on the TN786B. During this time, the system does not respond to any user action.

This test checks to see if the 80286/386 processor watch-dog sanity timer is functioning correctly. The processor intentionally allows the sanity timer to time out. If the processor detects itself being reset, the test passes, and the processor continues to execute normally. If the processor does not detect a reset, the test has failed. If this test continues to fail, the processor pack should be replaced as soon as possible. The sanity timer is not critical to system operation, but it is needed for processor recovery if the processor stops functioning.

Table 11-308. TEST #83 Processor Sanity Timer Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System software resources required to run this test are not available. 1. Repeat the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-308. TEST #83 Processor Sanity Timer Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The sanity timer did not time out as expected. The system continues to function normally. If the processor gets into an infinite loop, the reset CANNOT be detected, and the system DOES NOT reboot itself to clear the problem. 1. Repeat the command at one-minute intervals a maximum of five times. 2. If test continues to fail, the Processor circuit pack should be replaced as soon as possible.
	PASS	The sanity timer went off as expected. The system continues to function normally. If the processor gets into an infinite loop, the reset IS detected, and the system reboots itself to clear the problem.

RING-GEN (Analog Ring Generator)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
RING-GEN	MAJOR	test environment P	Analog Ring Generator

1 Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

All analog phones in DEFINITY Generic 1 cabinets must be provided with a voltage that allows them to ring. The Analog Ring Generator MO represents the device that provides the ringing voltage for analog phones in a multicarrier or single carrier cabinet system. In a multicarrier cabinet system, the Analog Ring Generator resides in the PDU. Figure 11-90 shows the position of the PDU and illustrates that fuse F9 is used for the Analog Ring Generator. Figure 11-91 shows the position of the fuses on the PDU and describes how to replace a fuse. In a single carrier cabinet system, the Analog Ring Generator is part of the WP-91153 power unit, and each carrier in the single carrier cabinet contains its own Analog Ring Generator. A ringing voltage generator failure means that no ringing will occur on analog phones; however, ringing on digital and hybrid phones will still occur.

The ringing voltage is monitored by the Tone-Clock circuit pack. In a port network with duplicated Tone-Clocks, it is the active Tone-Clock that performs this function. In an EPN made up of single-carrier cabinets, the Tone-Clock monitors only the ringing voltage in the carrier that contains the tone clock.

Also, if the TN2182 Tone-Clock is installed in the Processor Interface slot, the ringing voltage is not monitored.

The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. For more information, refer to the "Troubleshooting Backplane Voltage Problems" section in Chapter 5, "Routine Maintenance Procedures".

Emergency Transfer Query Test (#124) (d)	X	X	ND
Cabinet Sensors Query Test (#122) (e)	X	X	ND
External Alarm Lead Query Test (#120) (f)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.

b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.

c. Refer to CARR-POW (Carrier Port Power Unit) for AC- and DC-Powered Systems Maintenance documentation for a description of this test.

d. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

e. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.

f. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

Single-Carrier Cabinet

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Analog Ring Generator Initialization Test (#117)	X	X	ND
Analog Ring Generator Query Test (#118)	X	X	ND
Single-Carrier Power Query Test (#79) (a)	X	X	ND
Emergency Transfer Query Test (#124) (b)	X	X	ND
External Alarm Lead Query Test (#120) (c)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to DC-POWER (Power) Maintenance documentation for a description of this test.

b. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.

c. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

Analog Ring Generator Initialization Test (#117)

The TN768, or TN780 will report an error to the system software if the ringing voltage falls to low (only if system software has made a request to the TN768, or TN780 to monitor the voltage). The Analog Ring Generator Initialization Test sends a request to the TN768, or TN780. If there are redundant tone/clock circuit packs in the port network, then the request is sent only to the active tone/clock.

Table 11-309. TEST #117 Analog Ring Generator Initialization Test

Error Code	Test Result	Description/ Recommendation
1 1000 1001 1003 1115 2012 2100	ABORT	The system software is unable to determine the active tone/clock circuit pack, unable to allocated the resources necessary to run the test, or unable to send a down link message. 1. Wait for the green LED on the active tone/clock to go out; use the **status port-network** command to determine the active Tone/Clock circuit pack. 2. Rerun the test. If the test aborts again, refer to TDM-CLK Maintenance documentation.
2000	ABORT	Response to the request was not received within the allowable time period. 1. Look for TDM-CLK errors and alarms. Resolve all other Tone/Clock problems first. 2. Rerun the test.
1005	ABORT	The tone/clock is unable to read the analog ringing voltage level when the tone/clock is in the Processor Interface slot. This test is not available for the Processor Port Network in this configuration.
	PASS	The active Tone/Clock has successfully been enabled to monitor the ringing voltage level.

Analog Ring Generator Query Test (#118)

This test requests the Active Tone-Clock circuit pack to check the ringing voltage. The tone/clock circuit pack replies with PASS if the ringing voltage is adequate to ring the analog phones. If not, the active tone/clock circuit pack replies with a FAIL. The Analog Ring Generator Query Test then reports the result.

Table 11-310. TEST #118 Analog Ring Generator Query Test

Error Code	Test Result	Description/ Recommendation
1 1000 1001 1003 1115 2012 2100	ABORT	Could not seize the resources to run the test. Other maintenance is running on the active tone/clock circuit pack. 1. Wait for the green LED on the active tone/clock circuit pack to go out; (use the **status port-network** command to determine the Active tone/clock circuit pack). 2. Rerun the test. If the test aborts again, refer to TDM-CLK (TDM Bus Clock) Maintenance documentation.
2000	ABORT	Response to the request was not received within the allowable time period. 1. Look for TDM-CLK errors and alarms. Resolve all other tone/clock problems first. 2. Rerun the test.
1005	ABORT	The tone/clock is unable to read the analog ringing voltage level when the tone/clock is in the Processor Interface slot. This test is not available for the Processor Port Network in this configuration.

Continued on next page

Table 11-310. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	Ringing voltage is below acceptable levels. PROCEDURE FOR A MULTI-CARRIER CABINET SYSTEM. 1. If this is a High or Critical Reliability system, determine the active Tone-Clock circuit pack by issuing a **status port network** command. Make the Standby Tone-Clock circuit pack active via the **set tone-clock PC** command and rerun the test. a. If the test passes, the trouble is with the new Standby Tone-Clock circuit pack. Refer to the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details on replacing the Standby Tone-Clock circuit pack. After the circuit pack is replaced, make this Tone-Clock active again by issuing the **set tone-clock PC** command and rerun the test. b. If the test fails, then proceed with Step 2. 2. Look for and resolve CARR-POW (Carrier Port Power Supply Unit) alarms first, and then rerun the test. 3. Check fuse F9 on the Power Distribution Unit. Replace F9 if it is blown, and rerun the test. If the test still fails, then an Analog Line circuit pack could be defective and causing the Analog Ring Generator and/or fuse F9 to fail. 4. Unseat all Analog circuit packs in the affected cabinet, and replace fuse F9 again if needed. Rerun the test.

Continued on next page

Table 11-310. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	5. If the test passes, then the Analog Ring Generator is healthy, and one of the Analog circuit packs is defective. Replace the Analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. When the defective Analog circuit pack is found, replace it. Rerun the test. If the test still fails, proceed with Step 6. 6. Since the test still fails, the Analog Ring Generator is defective. Replace the Analog Ring Generator as follows: a. Open the PDU compartment door. The door is hinged on the right and has a magnetic latch on the left. b. If the reset button on the Analog Ring Generator is out, press it in. c. Originate calls to several analog stations on different port circuit packs in different carriers in the affected port network. d. If called stations ring, the fault is cleared. Proceed to Step f. If no stations ring, replace the Analog Ring Generator. To replace the Analog Ring Generator, first disconnect the output (P6) and input (P7) connectors from the Analog Ring Generator and then remove the two screws at the base of the Analog Ring Generator. e. Replace the Analog Ring Generator, secure it with the two screws at the base, and replace the P6 and P7 connectors (P6 goes on top). f. Rerun the test. If the test still fails, proceed to Step 7. 7. The active tone/clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the Active tone/clock and rerun the test. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details on replacing the tone/clock. Rerun the test. If the test still fails, escalate the problem.

Continued on next page

Table 11-310. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	PROCEDURE FOR A SINGLE-CARRIER CABINET SYSTEM. This failure indicates that there is no ringing voltage in the carrier where the active tone/clock circuit pack resides. Other carriers may or may not have ringing voltage. 1. If this is a Duplicated Option system, then determine the active Tone-Clock circuit pack by issuing a **status port-network** command. Make the Standby Tone-Clock circuit pack active via the **set tone-clock PC** command and rerun the test. a. If the test passes, then the trouble is with the "new" Standby Tone-Clock circuit pack. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details on replacing the Standby Tone-Clock circuit pack. After the circuit pack is replaced, make this Tone-Clock active again by issuing the **set tone-clock PC** command and rerun the test. b. If the test fails, then proceed with Step 2. 2. Unseat all analog circuit packs in the cabinet that contains the Active Tone/Clock circuit pack and rerun the test. 3. If the test passes, then the Analog Ring Generator is healthy and one of the analog circuit packs is defective. Replace the analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. When the defective analog circuit pack is found, replace it. Rerun the test. If the test still fails, go to Step 4. 4. Replace the WP-91153 power unit for the affected carrier, and rerun the test. If the test still fails, go to Step 5. 5. The active tone/clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the active tone/clock and rerun the test. Refer to TONE-BD Maintenance documentation for details on replacing the active tone/clock circuit pack. Rerun the test. If the test still fails, escalate the problem.

Table 11-310. TEST #118 Analog Ring Generator Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	FOR A MULTI-CARRIER CABINET SYSTEM. The analog ringing voltage level is acceptable. FOR A SINGLE-CARRIER CABINET SYSTEM. For a single-carrier cabinet stack, ringing voltage is acceptable in the cabinet containing the active tone/clock circuit pack.

S-SYN-BD (Speech Synthesis Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
S-SYN-BD	MIN	test board PCSS sh	Speech Synthesis Circuit Pack
S-SYN-BD	WRN	test board PCSS sh	Speech Synthesis Circuit Pack

1 Where P is the port network number (1 for PPN and 2 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also S-SYN-PT (Speech Synthesis Port) Maintenance documentation for related port information.

S-SYN-PT (Speech Synthesis Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
S-SYN-PT	MAJOR	test port PCSSpp sh	Speech Synthesis Port
S-SYN-PT	MINOR	test port PCSSpp l	Speech Synthesis Port
S-SYN-PT	WARNING	test port PCSSpp sh	Speech Synthesis Port

1 Where P is the port network number (1 for PPN and 2 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN725 Speech Synthesis circuit pack provides four independent Speech Synthesis Ports which may be connected to any of the voice time slots on the TDM Bus. Each Speech Synthesis Port consists of a speech synthesizer device (SSD) and is managed by a custom-coded programmable speech synthesizer (PSS) controller. The PSS controller is, in turn, controlled by the on-board microprocessor via a command interface specifically designed for this application. The PSS controller's main function is the orderly transfer of encoded speech from the speech vocabulary read-only memory (ROM) to the SSDs. The SSDs decode it and produce 64 kb/s 5-255 PCM (Pulse Code Modulation) speech. The encoded speech is stored in up to 512K bytes of on-board read-only memory (ROM). In addition, each Speech Synthesis Port has an associated dual-tone multifrequency (DTMF) receiver to receive touch-tone digits from a station set connected to the port via a voice time slot. The station set may be connected to the Speech Synthesis Port through either a line or trunk circuit.

When there is an incoming call to a port, the "listen" network time slot is connected to the DTMF receiver input and the "talk" network time slot is connected to the SSD output. This enables the Speech Synthesis Port to support speech synthesis features or touch-tone input with voice response features. Some of the features that use the Speech Synthesis Port's capabilities include Leave Word Calling, Automatic Circuit Assurance, Automatic Wakeup (hotel-motel), and do Not Disturb (hotel-motel).

The Speech Synthesis circuit pack should not be confused with the Announcement circuit pack as different voice features are supported by each circuit pack.

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. An in-line failure of the on-board microprocessor/PSS handshake has occurred. Refer to Test #168 for repair procedures.

b. This error type indicates that the circuit pack been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. A transient error that does not cause an alarm can occasionally occur during a SPE, TDM BUS, or Tone Clock interchange. Test the port and follow the instructions for conference Test (#7).

d. This error is not service-affecting and no action is required.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test,* for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Speech Synthesis PSS Handshake Test (#168)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND

Speech Synthesis Memory Test (#166)	X	X	ND
Speech Synthesis DSP Tone Test (#165)	X	X	ND
Speech Synthesis SSD Inquiry Test (#167)	X	X	ND
Speech Synthesis DTMF Receiver Inquiry Test (#164)	X	X	ND
Speech Synthesis Parameter Update Test (#169)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may occur. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 11-311. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any Active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-311. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test and the test has been aborted. You must wait until the port is idle (yellow LED if off) before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-311. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining the Error Log.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 11-312. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test and the test has been aborted. You must wait until the port is idle (yellow LED if off) before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1020	ABORT	The test did not run due to an already existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.

Table 11-312. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Retry the test. 2. If the Test continues to fail then replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining the Error Log.

Speech Synthesis DTMF Receiver Test (#163)

A series of DTMF tones are conferenced from the TDM Bus into the port's DTMF receiver and checked to see if the correct tones have been detected during the correct intervals. If all the DTMF tones were detected correctly, the test passes. If any of the tones were not detected correctly, the test fails.

Table 11-313. TEST #163 Speech Synthesis DTMF Receiver

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-313. TEST #163 Speech Synthesis DTMF Receiver — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	DTMF tones were not detected. This type of failure may cause features using touch-tone input to the Speech Synthesis Port to malfunction. 1. Verify that the Tone-Clock circuit pack is functioning correctly by checking the Error Log and using the **test tone-clock long** command. 2. If the test fails again, replace the Speech Synthesis circuit pack.
	PASS	The port has detected all DTMF tones correctly. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis DTMF Receiver Inquiry Test (#164)

This test determines the sanity of the port's DTMF receiver. The on-board microprocessor tests the port's DTMF receiver and determines if it is in a sane (test passes) or insane (test fails) condition.

Table 11-314. TEST #164 Speech Synthesis DTMF Receiver Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The DTMF receiver for this port is insane. 1. If the test fails again, replace the circuit pack.
	PASS	The DTMF receiver for this port is sane. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis DSP Tone Test (#165)

The digital signal processor (DSP) associated with each port can generate a 440-Hz tone whose presence can be detected by TN748 General Purpose Tone Detector circuit packs. A 440-Hz tone is generated for 500 msec on a specified time slot which is being listened to by the detector circuit. If the detector determines the tone is present on the time slot, the test passes; otherwise, it fails.

Table 11-315. TEST #165 Speech Synthesis DSP Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001 1002 1003	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 11-315. TEST #165 Speech Synthesis DSP Tone Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1021	ABORT	The 440-Hz tone was not detected by the Tone Detector circuit and inter-digit time-out has occurred on the Tone Detector circuit. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, verify all Tone Detector circuit packs in the system are functioning correctly by checking the Error Log and using the **test board PCSS long** command. Replace any faulty Tone Detector circuit packs and repeat the test. 3. If the test continues to abort, replace the Speech Synthesis circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The 440-Hz tone was not detected by the Tone Detector circuits. 1. If the test fails again, verify all Tone Detector circuit packs in the system are functioning correctly by checking the Error Log and using the **test board PCSS long** command. Replace any faulty Tone Detector circuit packs and repeat the test. 2. If the test fails again, replace the Speech Synthesis circuit pack.
	PASS	The 440-Hz tone has been detected correctly. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis Memory Test (#166)

The encoded speech for the Speech Synthesis circuit pack is stored in on-board read-only memory. A checksum is computed for each 32K speech memory block and compared against a known checksum value. If all computed checksum values are successfully compared against the stored checksum values, the test passes. If, while testing the speech complex memory, the on-board microprocessor finds a memory error, the test is terminated and a failure is reported. This type of failure may affect other ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

Table 11-316. TEST #166 Speech Synthesis Memory Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1019	ABORT	Test is already running on a different port, possibly due to background maintenance activity. Only one of these tests may be active on a circuit pack at a time. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-316. TEST #166 Speech Synthesis Memory Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The computed checksum from the speech vocabulary read-only memory did not compare correctly with the stored checksum. This type of failure may cause features using the Speech Synthesis Port's speech services to malfunction and result in degradation of synthesized speech quality ranging from insignificant to major. 1. Replace the circuit pack.
	PASS	The computed checksum values were successfully compared against the stored checksum values. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis SSD Inquiry Test (#167)

This test determines the sanity of the specified port's Speech Synthesis Device (SSD). The on-board microprocessor tests the port's SSD and determines if it is in a sane (test passes) or insane (test fails) condition. Other ports on the Speech Synthesis circuit pack continue to function correctly during this type of failure.

Table 11-317. TEST #167 Speech Synthesis SSD Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The SSD is insane. 1. Replace the circuit pack.
	PASS	The SSD is sane. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis PSS Handshake Test (#168)

This test verifies control functionality between the on-board microprocessor and PSS controller. A failure occurs if either of the following events occur:

- The on-board microprocessor times out while waiting for the PSS controller to respond.
- An invalid command is received by the on-board microprocessor from the PSS controller.

This type of failure affects all four ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

Table 11-318. TEST #168 Speech Synthesis PSS Handshake Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-318. TEST #168 Speech Synthesis PSS Handshake Test — *Continued*

Error Code	Test Result	Description/ Recommendation
Any	FAIL	The on-board microprocessor has timed out while waiting for the PSS controller to respond or an invalid command has been received by the on-board microprocessor from the PSS controller. This type of failure may cause features using the Speech Synthesis Port's speech services to malfunction. 1. Replace the circuit pack.
	PASS	The on-board microprocessor/PSS handshake is working correctly. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.

Speech Synthesis Parameter Update Test (#169)

This test updates the DTMF interdigit time-out parameter used by the Speech Synthesis circuit pack to be consistent with that specified by the switch processing element (SPE).

Table 11-319. TEST #169 Speech Synthesis Parameter Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call and therefore unavailable for certain tests. You must wait until the port is idle (yellow LED if off) before retesting. 1. If the port is idle, retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	An internal system error has occurred. 1. If the test continues to fail, escalate the problem.
	PASS	The DTMF interdigit time-out parameter has been updated. 1. User-reported troubles should be investigated using other tests and by verifying that other ports on this circuit pack are working correctly.

SEC-CDR (SEC-CDR Link Maintenance)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
PRI-CDR/SEC-CDR	MINOR	test cdr-link primary/secondary l	CDR Link
PRI-CDR/SEC-CDR	WARNING	test cdr-link primary/secondary	CDR Link

The SEC-CDR (SEC-CDR Link) maintenance strategy is covered in the PRI-CDR/SEC-CDR (PRI-CDR Link) Maintenance documentation.

SHDW-CIR (Common Shadow Circuit)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SHDW-CIR[1]	MAJOR	test duplication 1C sh	Common Shadow Circuit

1 Determine the carrier to test via the Port field from the Alarm or Error Log.

The Common Shadow Circuit is that portion of the Duplication Interface circuit pack that is responsible for memory shadowing in a High or Critical Reliability system. All memory writes on the active SPE are detected by the Common Shadow Circuit on the active Duplication Interface circuit pack via the Memory Bus (M-BUS—bus used by control complex circuit packs to write/read memory and to communicate with one another). The write information is then passed to the Common Shadow Circuit on the Standby Duplication Interface circuit pack via the ICC which then executes the write into the Standby Memory circuit pack via the Standby M-BUS. In this way, the Standby SPE is kept up-to-date with the Active SPE and, as a result, is always ready to take over for the Active SPE.

Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for a detailed description of SPE-to-SPE connectivity and STBY-SPE (Standby SPE) Maintenance documentation for a description of how the Standby SPE is maintained.

Hardware Error Log Entries and Test to Clear Values

Common Shadow Circuit Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test duplication 1C sh r 1
1		Common Shadow Circuit Loop Back Test (#283)	MAJOR	ON	test duplication 1C r 3
257	Any	Common Shadow Circuit Time-Out Query Test (#285)	MAJOR	OFF	test duplication 1C l r 3
513	1,2	Common Shadow Circuit Address Decoder Test (#284)	MAJOR	ON	test duplication 1C r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Duplication Interface Circuit Pack Status Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Duplication Interface Circuit Pack Status Query Test (#315) (a)	X	X	ND
Duplication Interface Circuit Pack Sanity Circuit Test (#273) (a)		X	D
Duplication Interface Circuit Pack Sanity Maze Test (#277) (a)	X	X	ND
Duplication Interface Circuit Pack SPE A Loop Back Test (#275) (a)	X	X	ND
Duplication Interface Circuit Pack SPE B Loop Back Test (#276) (a)	X	X	ND
Duplication Interface Circuit Pack Manager I Loop Back Test (#274) (a)	X	X	ND
Inter-Duplication Interface Circuit Pack Loop Back Test (#280) (a)	X	X	ND
Duplication Interface Circuit Pack Background Test Query Test (#271)	X	X	ND
Duplication Interface Circuit Pack Invalid Message Query Test (#272) (a)	X	X	ND
Common Shadow Circuit M-BUS Time-Out Query Test (#285)		X	ND
Common Shadow Circuit Loop Back Test (#283)	X	X	ND
Common Shadow Circuit Address Decoder Test (#284)	X	X	ND
SPE Select Switch Query Test (#278) (b)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for description of this test.

b. Refer to SPE-SELEC (SPE Select Switch) Maintenance documentation for description of this test.

Common Shadow Circuit Loop Back Test (#283)

This test allows maintenance to loop data through the common shadow circuit and examine the results. The test is designed to test the shadow data and shadow address portions of the common shadow circuit. The test is done entirely on the Duplication Interface circuit pack.

The Common Shadow Circuit is put into Maintenance Mode before the test is run. Maintenance software writes data into an address in the maintenance address space. This data is routed through the common shadow circuit and put into the FIFO bank of the common shadow circuit. Maintenance reads the contents of the FIFO bank and compares them with the value written to the maintenance address space. The test is repeated with another address in the maintenance address space.

This test does not disable the common shadow circuit and can be run with no disruption in service. The test must be executed from control carrier B to test the Duplication Interface B Common Shadow Circuit and from control carrier A to test the Duplication Interface A Common Shadow Circuit.

Table 11-320. TEST #283 Common Shadow Circuit Loop Back Test

Error Code	Test Result	Description/ Recommendation
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051	ABORT	Refer to the STBY-SPE Maintenance documentation for a description of these error codes.
1022	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The Common Shadow Circuit portion of the Duplication Interface circuit pack is defective and the Duplication Interface circuit pack must be replaced. 1. Follow the "Repair Procedures for High and Critical Reliability" section in Chapter 8, "Reliability Systems: A Maintenance Aid" and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, escalate the problem.

Continued on next page

Table 11-320. TEST #283 Common Shadow Circuit Loop Back Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or from Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315) in DUPINT Maintenance documentation.
	PASS	Part of the Common Shadow Circuit is operating properly; however, Tests #284 and #285 must pass before the Common Shadow Circuit on this Duplication Interface circuit pack is considered sane.

Common Shadow Circuit Address Decoder Test (#284)

This test verifies the operation of the shadow address decoder portion of the common shadow circuit. Software writes data into memory locations that should not be shadowed. The maintenance register of the common shadow circuit is examined to determine if the shadow address decoder permitted the write to be shadowed. The test fails if the writes were shadowed. This test is run only when demanded by maintenance software and can be run on both Duplication Interface circuit pack A and Duplication Interface circuit pack B. The same addresses used in the Common Shadow Circuit Circuit Loop Back Test (#283) are used.

Table 11-321. TEST #284 Common Shadow Circuit Address Decoder Test

Error Code	Test Result	Description/ Recommendation
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051	ABORT	Refer to the STBY-SPE Maintenance documentation for a description of these error codes.
	ABORT	Internal System Error.
1022	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-321. TEST #284 Common Shadow Circuit Address Decoder Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Common Shadow Circuit portion of the Duplication Interface circuit pack is defective and the Duplication Interface circuit pack must be replaced. 1. Follow the "Repair Procedures for High and Critical Reliability" in Chapter 8, "Reliability Systems: A Maintenance Aid" and replace the Duplication Interface circuit pack. 2. Rerun the test. If the test still fails, escalate the problem.
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315) in DUPINT Maintenance documentation.
	PASS	Part of the Common Shadow Circuit is operating properly; however, Tests #283 and #285 must pass before the Common Shadow Circuit on this Duplication Interface circuit pack is considered sane.

Common Shadow Circuit M-BUS Time-Out Query Test (#285)

An M-BUS time-out occurs when the Common Shadow Circuit on the Standby SPE attempts a memory write to the Memory circuit pack via the M-BUS and the write fails. The Common Shadow Circuit M-BUS Time-Out Query first tries to refresh the Standby SPE memory and then queries the Common Shadow Circuit on the Standby Duplication Interface circuit pack for the number of M-BUS time-outs. If there were any M-BUS time-outs, the test fails.

Table 11-322. TEST #285 Common Shadow Circuit M-BUS Time-Out Query Test

Error Code	Test Result	Description/ Recommendation
1029 1030 2011 2012 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051 2054	ABORT	Refer to the STBY-SPE Maintenance documentation for a description of these error codes.
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2013	ABORT	System resources required to run this test are not available.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-322. TEST #285 Common Shadow Circuit M-BUS Time-Out Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The tested Common Shadow Circuit is experiencing time-outs while trying to write to the Memory circuit pack over the M-BUS. 1. Verify that there are the same number of PI (Processor Interface) circuit packs in each carrier. 2. Verify that there are the same number of PKT-CTRL (Packet Control) circuit packs in each carrier. 3. Resolve all other DUPINT (Duplication Interface Circuit Pack), SHDW-CIR (Common Shadow Circuit), and PR-MAINT (Maintenance/Tape Processor) alarms before addressing this problem. 4. Rerun the test. If the test still fails, then the Memory circuit pack on the tested carrier is defective or the M-BUS is defective on the Standby carrier. Refer to the "Repair Procedures for High and Critical Reliability" section in Chapter 8, "Reliability Systems: A Maintenance Aid", and replace the Memory circuit pack. 5. Rerun the test. If the test still fails, escalate the problem. 6. Test the Standby SPE with the **test standby-pe short** command, and address all Duplication Interface circuit pack, Common Shadow Circuit, and Maintenance/Tape Processor tests that do not pass.
	NO BOARD	The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B). 1. Refer to NO BOARD for a description of the Duplication Interface Circuit Pack Status Query Test (#315) in DUPINT Maintenance documentation.
	PASS	Part of the Common Shadow Circuit is operating properly. However, Tests #283 and #284 must pass before the Common Shadow Circuit on this Duplication Interface circuit pack is considered sane.

SHDW-LNK (Memory Shadowing Link)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SHDW-LNK	MAJOR	test shadow-link	Memory Shadowing Link

A High or Critical Reliability system contains two SPEs. One is known as the Active SPE and is the SPE that is currently responsible for all call processing, administration, and maintenance activities being performed by the system. The other SPE is known as the Standby SPE. The role of the Standby SPE is to be ready to take over as the Active SPE in the event that the current Active SPE fails.

The Standby SPE is usually in a mode known as Standby Mode in which it is ready to assume the role of the Active SPE. To do this, Standby SPE Memory (MEM-BD) must be an up-to-date reflection of Active SPE Memory. This is accomplished via the memory shadowing mechanism described below.

The SHDW-CIR (Common Shadow Circuit) on the Active SPE Duplication Interface circuit pack (DUPINT, TN772) detects all memory writes that the Active SPE Processor (PROCR) makes to Active SPE Memory. The Active SPE Common Shadow Circuit sends this information to the Common Shadow Circuit on the Standby SPE Duplication Interface circuit pack via the Inter-Carrier Cable (ICC). The Common Shadow Circuit on the Standby SPE Duplication Interface circuit pack then writes the data to Standby SPE Memory. This logical connection between Active SPE Memory and Standby SPE Memory is known as the SHDW-LNK (Memory Shadowing Link).

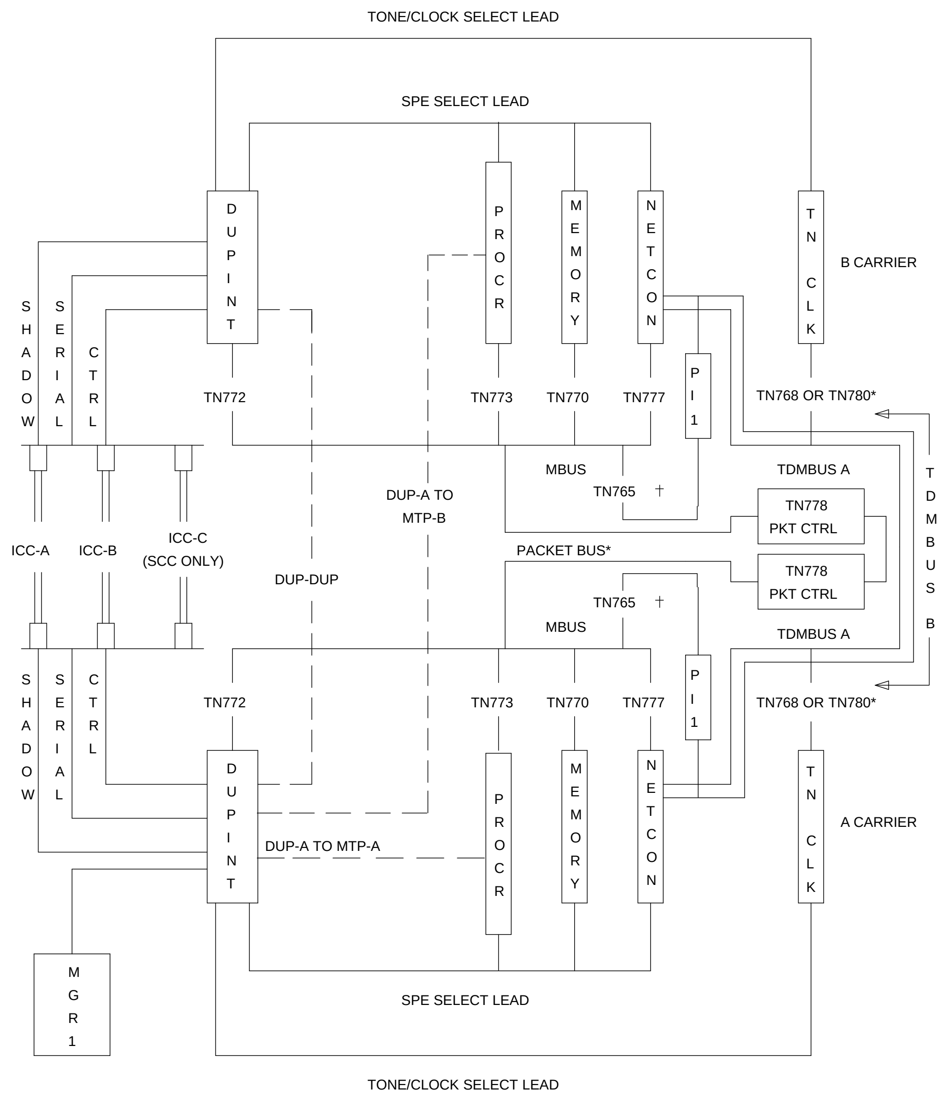
Although most of the components comprising the Memory Shadowing Link (that is, Active SPE Memory, both sets of Common Shadow Circuit, and Standby SPE Memory) may be tested individually, it is useful to test the integrity of the entire logical connection to verify that the shadowing mechanism is functional and that Standby SPE Memory is the same as Active SPE Memory. Therefore, this testing is done under the guise of the Memory Shadowing Link.

The logical connection between the Memory circuit packs of the two SPEs of a High or Critical Reliability system is shown in Figure 11-92. This connection includes the A carrier memory bus, the A carrier TN772 Duplication Interface circuit pack, the shadow extension in the ICC, the B carrier TN772 Duplication Interface circuit pack, and the B carrier memory bus. The dotted lines in Figure 11-92 represent important logical connections between components. The following abbreviations are used in Figure 11-92:

- DUPINT for Duplication Interface Circuit Pack
- PR MAINT for Maintenance/Tape Processor

- PROCR for 80286 or 80386 Processor Circuit Pack
- MEMORY for Memory [286 System only]
- CPP1 for Memory Expansion [G3iV2-386 only]
- MEM-CARD for Flash Memory Card [386 System only]
- NETCON for Network Control Circuit Pack
- PACKET BUS for Packet Control Pack
- TN CLK for Tone-Clock Circuit Pack
- MGR I for Manager I (G1) or G3MT Terminal
- TDM-BUS for Time Division Multiplex Bus
- M-BUS for Memory Bus
- ICC for Inter-Carrier Cable

Please refer to the DUPINT, SHDW-CIR, MEM-BD, PROCR, PR-MAINT, and STBY-SPE Maintenance documentation for more detailed descriptions of these components.



* G1.2 ONLY.
† MCC ONLY.
(IN A SINGLE-CARRIER CABINET CONFIGURATION, THERE CAN BE EITHER 0 or 1 PROCESSOR INTERFACE CIRCUIT PACK. IN A MULTI-CARRIER CABINET CONFIGURATION, THERE CAN BE 0, 1, OR 2 PROCESSOR INTERFACE CIRCUIT PACKS.)

Figure 11-92. SHDW-LNK Interactions for a High or Critical Reliability System

Hardware Error Log Entries and Test to Clear Values

Standby SPE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test shadow-link
2047		Shadow Link Test (#318)	MAJOR	OFF	test shadow-link
2048		Shadow Link Test (#318)	MAJOR	OFF	test shadow-link
2049		Shadow Link Test (#318)	MAJOR	OFF	test shadow-link
2050		Shadow Link Test (#318)	MAJOR	OFF	test shadow-link

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Shadow Link Test,* for example, you may also clear errors generated from other tests in the testing sequence.

The Short and Long Test Sequences for Memory Shadowing Link are identical. Only one test (Test #318) tests the Memory Shadowing Link.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Shadow Link Test (#318)	X	X	ND

1 D = Destructive; ND = Nondestructive

Shadow Link Test (#318)

Interactions

One interaction with the Standby SPE that results when testing the Memory Shadowing Link is as follows:

If the Standby SPE is in Maintenance Mode because a previous test command on a Standby SPE component was issued within the last three minutes, the Active SPE takes the Standby SPE out of Maintenance Mode and puts it in Standby Mode when the Shadow Link Test is run. Therefore, issuing another test command on a Standby SPE component requires that the Standby SPE be put into Maintenance Mode again before the test is run. Thus, the user notices a 1- to 20-minute delay when running another Standby SPE test after executing the Shadow Link Test (see the next Note).

NOTE:
In most cases, the delay lasts only one to two minutes. However, a 20-minute delay is possible.

Another interaction that the Memory Shadowing Link has with the Standby SPE is that if the Shadow Link Test fails, an error of type 67 is logged, and an alarm is raised against the STBY-SPE (Standby SPE). This is because the failure of the Shadow Link Test implies that Standby SPE Memory may not be an up-to-date reflection of Active SPE Memory and, therefore, that the Standby SPE may not be ready to take over as the Active SPE. Refer to "Hardware Error Log Entries and Test to Clear Values" section of STBY-SPE (Standby SPE) Maintenance documentation for more details.

Test Description

Because of the number and nature of steps that it performs, the Shadow Link Test takes from 1 to 5 minutes to run, depending on the load that the system is experiencing at the time. The Shadow Link Test performs the following activities to verify the integrity of the Memory Shadowing Link:

For a 286 based system:

- Disables shadowing from Active SPE Memory (MEM-BD) to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor (PR-MAINT) to release the Standby SPE processor (PROCR) for the Standby SPE Processor to clear Standby SPE Memory (zero all memory locations).
- Waits for Standby SPE Processor to report that Standby SPE Memory was successfully cleared.
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE processor reset.

- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).
- Disables shadowing from Active SPE Memory to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to release the Standby SPE Processor for the Standby SPE Processor to perform a RAM checksum test on Standby SPE Memory (just updated by the refresh operation).
- Waits for Standby SPE Processor to report the results of the RAM checksum test.
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE Processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).

For a 386/flash based system:

- Disables shadowing from Active SPE Memory (MEM-BD) to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor (PR-MAINT) to release the Standby SPE processor (PROCR) for the Standby SPE Processor to clear a magic area in Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).
- Disables shadowing from Active SPE Memory to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to release the Standby SPE Processor for the Standby SPE Processor to perform a verification on the magic area in Standby SPE Memory (just updated by the refresh operation).
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE Processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).

NOTE:
The shadowing verification method used for 80386 systems does not do a complete RAM checksum. It only clears a special magic area in the Standby SPE's memory and then updates that area by shadowing. It then verifies the value in that magic area based on the Active SPE's value. Thus,

the test is not as comprehensive in terms of testing the memory aspect of shadowing as is the 80286 method. The reason for this is the inability to shadow flash memory.

Manager I (G1) or G3MT Message Line Errors

In addition to Shadow Link Test (#318) Error Codes, the following Manager I (G1) or G3MT message line errors may be displayed when attempting to run this test. They are:

- "Standby SPE not available; for information use status system"

  This message line error corresponds to Error Code 2020. It is displayed if the Shadow Link Test is attempted within the first five minutes of a restart of the Active SPE (that is, prior to the Active SPE holding the Standby SPE reset and refreshing it).

- "Standby SPE busy with another task; for information use status system"

  This message line error corresponds to Error Code 2018. It is displayed if the Shadow Link Test is attempted while the Active SPE is performing some Maintenance Mode activity on the Standby SPE other than system technician-demanded maintenance.

- "Cannot interrupt Standby SPE while entering maintenance mode; please try later"

  This message line error is displayed when **test shadow-link** has been issued and subsequently canceled and then **refresh spe-standby** is issued while maintenance software is in the process of performing the Shadow Link Test. Allow up to three minutes for the Shadow Link Test to complete before issuing the **refresh spe-standby** command again.

In either case, the following actions should be taken:

1. Issue the **refresh spe-standby** command to put the Standby SPE in Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use ‘display errors’ to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, escalate the problem.
2. Repeat the command.
3. Issue the **test spe-standby long** command.

Table 11-323. TEST #318 Shadow Link Test

Error Code	Test Result	Description/ Recommendation
1029 2011 2012 2013 2014 2018 2020 2024 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2047	FAIL	The Standby SPE Maintenance/Tape Processor released the Standby SPE processor with a request to clear Standby SPE Memory; Standby SPE Memory was not successfully cleared. 1. Check for Standby SPE Processor errors and alarms. Refer to PROCR (80286 Processor Circuit Pack) Maintenance documentation and follow the prescribed procedures. 2. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory) Maintenance documentation and follow the prescribed procedures. 3. If all problems found in Steps 1 and 2 have now been repaired, proceed with Step 5. If no problems were found in Steps 1 and 2, proceed with Step 4.

Table 11-323. TEST #318 Shadow Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2048	FAIL	The Standby SPE Maintenance/Tape Processor released the Standby SPE Processor with a request to perform the RAM Checksum Test on Standby SPE Memory and the RAM checksum was determined to be incorrect. This indicates that a problem exists with one or more components that make up the Memory Shadowing Link such that Active SPE Memory was not accurately shadowed to Standby SPE Memory. 1. Check for both Active SPE and Standby SPE Common Shadow Circuit errors and alarms. Refer to SHDW-CIR (Common Shadow Circuit) Maintenance documentation and follow the prescribed procedures. 2. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory) Maintenance documentation and follow the prescribed procedures. 3. Check the Inter-Carrier Cable to see if it is loose or disconnected. If so, follow the repair procedures for reconnecting the Inter-Carrier Cable described in Chapter 8, "Reliability Systems: A Maintenance Aid". 4. If all problems found in Steps 1, 2, or 3 have now been repaired, proceed with Step 9. If no problems were found in Steps 1, 2, or 3, proceed with Step 5. 5. Issue the **display errors** command and check to see if an Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 9, 10, and 11.

Table 11-323. TEST #318 Shadow Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2049	FAIL	The Standby SPE Maintenance/Tape Processor released the Standby SPE processor with a request to perform the RAM Checksum Test on Standby SPE Memory. The RAM checksum was correct; however, a significant discrepancy was detected between two special Standby SPE Memory locations that should contain the same time stamp value as the one shadowed over from the Active SPE. This indicates that a problem exists with one or more components that make up the Memory Shadowing Link such that Active SPE Memory was not accurately shadowed to Standby SPE Memory. 1. Check for both Active SPE and Standby SPE Common Shadow Circuit errors and alarms. Refer to SHDW-CIR (Common Shadow Circuit) Maintenance documentation and follow the prescribed procedures. 2. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory) Maintenance documentation and follow the prescribed procedures. 3. Check the Inter-Carrier Cable to see if it is loose or disconnected. Also if intermittent problems are occurring inspect the Inter-Carrier Cable for cuts or broken leads. If so, follow the repair procedures for reconnecting the Inter-Carrier Cable described in Chapter 8, "Reliability Systems: A Maintenance Aid". 4. If all problems found in Steps 1, 2, or 3 have now been repaired, proceed with Step 9. If no problems were found in Steps 1, 2, or 3, proceed with Step 5. 5. Issue the **display errors** command and check to see if an Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 9, 10, and 11.

Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, escalate the problem. 10. Repeat the test. 11. Issue the **test spe-standby long** command to thoroughly test all Standby SPE components.

Continued on next page

Table 11-323. TEST #318 Shadow Link Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2050	FAIL	The Standby SPE Maintenance/Tape Processor released the Standby SPE Processor with a request to perform the RAM Checksum Test on Standby SPE Memory. The RAM checksum was correct and the two special Standby SPE Memory locations contain the same time stamp value as the one shadowed over from the Active SPE; however, that time stamp value is significantly different from the value of the Standby SPE's Time-of-Day clock. This indicates that either the Active SPE Time-of-Day clock has never been set (for example, at system installation time) or that the Active SPE Time-of-Day clock was set (with a significant change) while shadowing to the Standby SPE was disabled. 1. Issue the **refresh spe-standby** command to put the Standby SPE in Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, escalate the problem. 2. Issue the **set time** command and set the Time-of-Day clock. 3. Repeat the test.
	PASS	When the Shadow Link Test passes, the integrity of the Memory Shadowing Link has been verified and as long as memory shadowing is enabled, Standby SPE Memory is an up-to-date reflection of Active SPE Memory. This test also provides a positive indication of the functionality of Active SPE Memory, both sets of Common Shadow Circuit, and Standby SPE Memory.

SPE-SELEC (SPE Select Switch)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
SPE-SELEC	MAJOR	test duplication-interface 1C sh	SPE Select Switch
SPE-SELEC	WARNING	test duplication-interface 1C sh	SPE Select Switch

1 Where C is the carrier determined by the Port field in the error or alarm log.

The SPE Select Switch MO tracks the state of the SPE Select Switches in a High or Critical Reliability system. The switches are located on the Duplication Interface circuit pack and can be used to hard-select the active processor in a High or Critical Reliability system. Each switch has three positions: SPE-A (the left position), AUTO (the middle position), and SPE-B (the right position). To hard-select SPE-A, both switches must be in the SPE-A position. To hard-select SPE-B, both switches must be in the SPE-B position. Any other combination of SPE Select Switches leaves control of the active SPE to the software. Whenever a switch is out of the AUTO position, a Warning alarm is raised. If both switches are out of the AUTO position for six hours, a Major alarm is raised. Duplication Interface circuit pack B reports the state of the SPE-SELEC Switch B to Duplication Interface circuit pack A which, in turn, reports the state of SPE-SELEC Switch A directly to the system software.

NOTE:
Each switch is a separate MO. If both switches are out of the AUTO position, then both switches are alarmed.

It is also possible to get an "init cause" of the SPE-SELEC Switch if SPE B is active and power to carrier B is lost. In this case, an SPE switch to SPE A occurs, and the "init cause" shows either "SPE-Select Switch" or "SPE-Down."

Hardware Error Log Entries and Test to Clear Values

SPE Select Switch Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test duplication-interface 1C sh r 1
1	Any	SPE Select Query Test (#278)	WARNING/ MAJOR[2]	OFF	test duplication-interface 1C sh r
257	any	SPE Select Query Test (#278)	WARNING/ MAJOR[2]	OFF	test duplication-interface 1C sh r 2

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This error type initially raises a Warning alarm. If this error type persists and alarms are not downgraded on this MO due to the values of **set options**, then, after a period of time, a Major alarm is raised.

Notes:

a. The Warning alarm is upgraded to Major if the error is not resolved in six hours.

b. Determine the carrier (a or b) by the Port field in the Error or Alarm Log. For SPE-SELEC, the Port field is 1A (**test duplication interface a**) or 1B (**test duplication interface b**).

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Duplication Interface Circuit Pack Status Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Duplication Interface Circuit Pack Status Query Test (#315) (a)	X	X	ND
Duplication Interface Circuit Pack Sanity Circuit Test (#273) (a)		X	D
Duplication Interface Circuit Pack Sanity Maze Test (#277) (a)	X	X	ND
Duplication Interface Circuit Pack SPE A Loop Back Test (#275) (a)	X	X	ND
Duplication Interface Circuit Pack SPE B Loop Back Test (#276) (a)	X	X	ND
Duplication Interface Circuit Pack Manager I Loop Back Test (#274) (a)	X	X	ND
Inter-Duplication Interface Circuit Pack Loop Back Test (#280)	X	X	ND
Duplication Interface Circuit Pack Background Test Query Test (#271) (a)	X	X	ND
Duplication Interface Circuit Pack Invalid Message Query Test (#272) (a)	X	X	ND
Common Shadow Circuit M-BUS Time-out Query Test (#285) (b)		X	ND
Common Shadow Circuit Loop Back Test (#283) (b)	X	X	ND
Common Shadow Circuit Address Decoder Test (#284) (b)	X	X	ND
SPE Select Switch Query Test (#278)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to the DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for description of this test.

b. Refer to the SHDW-CIR (Common Shadow Circuit) Maintenance documentation for description of this test.

SPE Select Query Test (#278)

This test queries the Duplication Interface circuit pack for the state of SPE Select Switch. The test passes if the switch is in the AUTO position. The test fails if the switch is not in the AUTO position or if the Duplication Interface circuit pack is not present.

Table 11-324. TEST #278 SPE Select Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2033	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The switch currently selects SPE-A active.
2	FAIL	The switch currently selects SPE-B active. 1. Move the switch to the AUTO position. 2. Rerun the test. If the test still fails, follow normal escalation procedures.

Continued on next page

Table 11-324. TEST #278 SPE Select Query Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The Duplication Interface circuit pack is not present or not functioning. 1. Resolve all alarms logged against the Duplication Interface circuit pack (DUPINT). 2. Rerun the test. If the test still fails, follow normal escalation procedures.
	PASS	The Duplication Interface circuit pack has reported that the SPE Select Switch is in the AUTO position. 1. If a visual inspection shows the SPE Select Switch is not in the AUTO position, then resolve all alarms logged against Duplication Interface circuit pack (DUPINT). 2. Repeat the test. 3. If Duplication Interface circuit pack B is being tested and a visual inspection shows that the switch is not in the normal position, Duplication Interface circuit pack A may be incorrectly reporting the state of SPE-Select Switch B. Replace Duplication Interface circuit pack A, and rerun the test.

STBY-SPE (Standby SPE)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
STBY-SPE	WARNING	status system 1	Standby SPE
STBY-SPE	MAJOR	test spe-standby	Standby SPE

A High or Critical Reliability system contains two switch processing elements (SPEs). The first such element is known as the Active SPE. The Active SPE is currently responsible for all call processing, administration, and maintenance activities that are being performed by the system. The other SPE is known as the Standby SPE. The Standby SPE becomes the Active SPE whenever the current Active SPE fails. The Standby SPE does not perform call processing or administration activities. However, it does perform maintenance activities, but these activities are carried out completely under the direction of the Active SPE in order to monitor and maintain the health of the Standby SPE.

NOTE:
Verify that the Standby SPE is functional (no duplication alarms exist and the SPE has returned to the Standby Mode) by running the **status system 1** command. If the standby SPE is in the maint/idle mode with no standby alarms, use the **standby refresh** command to put the standby SPE into the standby mode. Verify the results by using the **status system 1** command. For more information about the **status system** command see Chapter 10 .

NOTE:
Only G3V1 (TN773), G3V2-386 (TN786B), G3iV5 (TN790), and later configurations supports High or Critical Reliability.

The Standby SPE is always in one of three modes: Standby, Maintenance, or Down. Usually, the Standby SPE is in Standby Mode. In this mode,

1. The Switch Control (SW-CTL) on the Standby SPE Network Control circuit pack is isolated from the TDM Bus so that it does not interfere with attempts by the Switch Control on the Active SPE Network Control circuit pack to control the TDM Bus
2. The Standby SPE (PKT-CTRL) Packet Control circuit pack is isolated from the Packet Bus to prevent interference with the activity on the Active SPE Packet Control circuit pack
3. The Standby SPE (PROCR) Processor is held in a reset state so that it does not run software
4. For G3iV2-386, the 12 volt power supply on the Standby SPE Network Control circuit pack (TN777B) can not be turned on when the Standby SPE Processor is held in the reset state

5. Standby SPE Memory (MEM-BD in G3iV1.1-286 or MEMORY in a G3iV2-386) is shadowed from Active SPE Memory. This means that Standby SPE Memory is updated to reflect every change in Active SPE Memory (for example, calls and administration changes). In G3iV2-386, the system memory consists of two types of memory: flash ROM for system boot image and initialized data, and DRAM for system read/write data. Only the DRAM portion in the Active SPE can be shadowed to the Standby SPE DRAM memory. In Standby Mode, the Standby SPE is available to assume the role of the Active SPE.

In certain circumstances, the Standby SPE is put into Maintenance Mode by the Active SPE. In this mode, the SW-CTL and PKT-CTRL on the Standby SPE are still isolated from the TDM Bus and Packet Bus, memory shadowing is disabled, and its processor is no longer held in a reset state. Data Channels on the standby SPE Network Control circuit pack can access the TDM bus, and the maintenance testing can be executed in this maintenance mode. The 12 volt power supply on the standby SPE Network Control circuit pack can also be turned on for Memory Card maintenance testing. In Maintenance Mode, the Standby SPE accepts maintenance activity requests from the Active SPE to perform testing on Standby SPE components. For many of the requested activities, maintenance software on the Standby SPE is restarted in order to conduct the activity. Translation saves and announcement saves may be performed on the Standby SPE when it is in Maintenance Mode. While in Maintenance Mode, the Standby SPE is not as readily available to assume the role of the Active SPE, but it may do so depending upon the severity of the Active SPE fault(s).

Whenever the Standby SPE is returned to Standby Mode from Maintenance Mode, its DRAM Memory is refreshed. This means that the Active SPE DRAM Memory is shadowed over to Standby SPE DRAM Memory. In G3iV2-386, the flash ROM memory in the Standby SPE is not refreshed, and the shadowing circuit cannot write data into the flash ROM memory. The refresh is necessary because, while in Maintenance Mode, memory shadowing to the Standby SPE is disabled and Standby SPE Memory is not updated to reflect changes in Active SPE Memory. After the refresh, Standby SPE Memory once again is an up-to-date reflection of Active SPE Memory.

The Standby SPE goes into Down Mode whenever certain error conditions are detected. These error conditions are described in detail in the "Hardware Error Log Entries and Test to Clear Values" section. Once the error condition(s) that cause(s) the Standby SPE to go into Down Mode are corrected, the Standby SPE is first put into Maintenance Mode to conduct testing on Standby SPE components. It is then returned to Standby Mode.

The current mode of the Standby SPE can be determined by issuing the **status system** command.

Components in Standby SPE Complex

The Standby SPE Maintenance Object is actually a composite of all the circuit packs in the Standby SPE. For G3iV1.1-286, these include the TN773 Processor circuit pack, the TN770 Memory circuit pack, the TN777 Network Control circuit pack, the TN774 Tape Unit, the TN778 Packet Control circuit pack, the TN765 Processor Interface circuit pack(s), and the TN772 Duplication Interface circuit pack. When located in the Standby SPE, all of these components are tested under the guide of the STBY-SPE maintenance object.

However, for G3iV2-386, the SPE complex requires a different set of circuit packs, including The TN786B Processor and the CPP1 Memory circuit pack, or the TN790 circuit pack, and the TN777B Network Control circuit pack with memory card. No Tape Unit is required for 386 configurations. The other circuit packs mentioned for G3iV1.1-286, including the TN778 Packet Control circuit pack, the TN765 Processor Interface circuit pack(s), and the TN772 Duplication Interface circuit pack are still used in G3iV2-386.

WARNING:

Verify that there is an identical set of SPE complex circuit packs in each SPE. For example, there should be the same number of Memory circuit pack(s) in each SPE. If there are Processor Interface circuit pack(s) (one or two) in the Active SPE, the same number of PI circuit packs must be present in the Standby SPE. If one SPE has a Packet Control Circuit Pack, the other SPE must also have one. If the set of circuit packs in each SPE is not identical, alarms could result against the STBY-SPE, DUPINT, SHDW-CIR, PI-BD, PKT-CTRL, PROCR, MEM-BD and MEMORY maintenance objects.

The accessing and testing of the Standby SPE may be affected by the health of the circuit packs through which the Active SPE communicates with the Standby SPE. These circuit packs include the Active SPE Processor circuit pack, the Duplication Interface circuit pack in the A carrier, and the Standby SPE Processor circuit pack. Additionally, the Inter-Carrier Cable (ICC) and the backplane affect the ability of the Active SPE to communicate with the Standby SPE. The ability to shadow Active SPE memory into Standby SPE memory is affected by the Duplication Interface circuit pack in the A carrier, the Duplication Interface circuit pack in the B carrier, and the Memory circuit pack(s) in the Standby SPE. Additionally, the Active SPE Memory Bus, the ICC, backplane, and the Standby SPE Memory Bus affect the ability to correctly shadow Active SPE memory into Standby SPE memory.

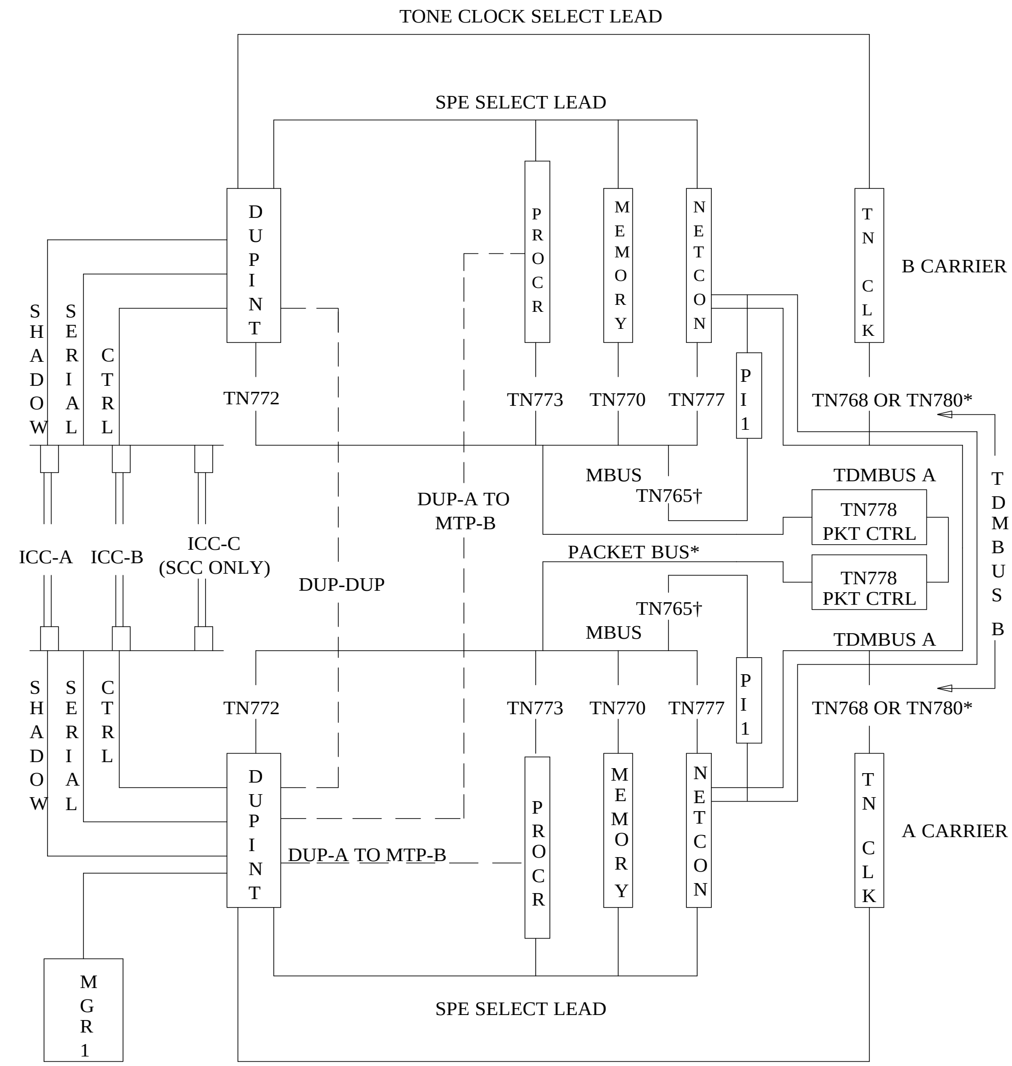
These dependencies can be seen in Figure 11-93 for G3iV1.1-286 and in Figure 11-94 for the G3iV2-386 or the TN790. These figures depict the interconnection between the two SPEs of a High or Critical Reliability system. The following abbreviations are used in the figures:

- DUPINT for Duplication Interface circuit pack
- PROCR/MEM for TN786B or TN790 Processor Circuit Packs with Memory

- PROCR for Processor Circuit Pack
- MEMORY for Memory Circuit Pack(s)
- MTP for Maintenance Processor in Processor Circuit Pack
- NETCON for Network Control Circuit Pack
- MEM CARD for Memory Card Plugged in the Network Control Circuit Pack
- PI for Processor Interface Circuit Pack(s)
- PKT CTRL for Packet Control Circuit Pack
- TN CLK for Tone-Clock Circuit Pack
- MGR *I for Manager I Terminal
- TDM BUS for Time Division Multiplex Bus
- PACKET BUS for Packet Bus
- M-BUS for Memory Bus
- ICC for Inter-Carrier Cable
- SCC for Single-Carrier Cabinet

The dashed lines in the figure represent important logical connections between components.

Refer to the DUPINT, SHDW-CIR, MEM-BD, MEMORY, PROCR, PR-MAINT, TDM-BUS, PKT-BUS, TDM-CLK, PI-BD, PI-SCI, PKT-CTRL, SW-CTL, DATA-CHL, 12V-PWR, CARD-MEM and STBY-SPE Maintenance documentation for more detailed descriptions of the individual components.



* G1.2 ONLY.
† MCC ONLY.
(IN A SINGLE-CARRIER CABINET CONFIGURATION, THERE CAN BE EITHER 0 OR 1 PROCESSOR INTERFACE CIRCUIT PACK. IN A MULTICARRIER CABINET CONFIGURATION, THERE CAN BE 0, 1, OR 2 PROCESSOR INTERFACE CIRCUIT PACKS.)

822(z)	any	A non-hot interchange to the standby SPE occurred.			See note (z).
826 (aa)	any	Standby software mismatch	MAJOR	ON	upgrade software

1 Run the short test sequence first. If all the tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

It is important to note that when more than one of the above error types exists at the same time, the alarm against the Standby SPE is cleared only when (1) any problems described by the Aux Data values for Error Types 1 and 257 are resolved **and** (2) all problems described in (b) through (o) are resolved.

Notes:

a. Aux Data value 0 is equivalent to Aux Data value 2017. All Aux Data values listed for Error Type 1 are described in "System Technician-Demanded Tests: Test Result Error Codes". These values are shared between Standby SPE maintenance activity results and the test results for the System Technician commands on Standby SPE components because the values represent the common set of problems that can be encountered when attempting to conduct any form of maintenance activity on the Standby SPE.

b. Error Type 58 is logged when the Duplication Interface circuit pack in the A carrier reports that the Standby SPE has gone into Down Mode. This implies an inability to communicate with the Standby SPE.

   The ability to communicate with the Standby SPE should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Standby SPE. If all of the tests execute such that no test returns an Aux Data value of 2014, 2015, 2016, 2017, 2022, 2024, or 2025, the Standby SPE was successfully put into Maintenance Mode. This indicates that the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the functionality of the communication path, look for the presence of Error Types 80, 81, and 106 and use the recommended commands to clear these errors.

c. Error Type 67 is logged when the Shadow Link Test (#318) fails. This implies that the shadowing mechanism is not functioning.

   The functionality of the Memory Shadowing Link should be checked by issuing the **test shadow-link** command. If the test passes, the memory shadowing mechanism may be functional. However, to restore the memory shadowing, look for the presence of Error Types 82, 85, and 106 and use the recommended commands to clear these errors.

d. Error Type 80 is logged when the Active SPE Maintenance/Tape Processor reports that the handshake that is maintained between the processor and the Duplication Interface circuit pack in the A carrier has been lost. This implies an inability to communicate with the Standby SPE.

   The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Active-MTP is operational.

   If the handshake between Dupint-A and Active-MTP is operational, the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the communication path, look for the presence of Error Types 58, 81, 82, 98, 99, and 106 and use the recommended commands to clear these errors.

e. Error Type 81 is logged when the Duplication Interface circuit pack in the A carrier reports that the handshake that is maintained between the circuit pack and the Maintenance/Tape Processor on the Standby SPE has been lost. This implies an inability to communicate with the Standby SPE.

   The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Standby-MTP is operational.

If the handshake between Dupint-A and Standby-MTP is operational, the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the communication path, look for the presence of Error Types 58, 80, 82, 98, 99, and 106 and use the recommended commands to clear these errors.

f. Error Type 82 is logged when the Duplication Interface circuit pack in the A carrier reports that the handshake that is maintained between the circuit pack and the Duplication Interface circuit pack in carrier B has been lost. This implies that the shadowing mechanism is not functioning.

   The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Dupint-B is operational. If the handshake between Dupint-A and Dupint-B is operational, the memory shadowing mechanism may be functional. However, to restore the memory shadowing, look for the presence of Error Types 67, 85, and 106 and use the recommended commands to clear these errors.

   NOTE:
   Because the handshake between Dupint-A and Dupint-B is tested in the background, the test results from executing the **test duplication-interface a** command do not indicate their current status. However, if the background testing determines that all three handshakes (that is, Dupint-A to Dupint-B, Dupint-A to Active-MTP, and Dupint-A to Standby-MTP) have become operational, and if there are no other current STBY-SPE errors, Error Types 80, 81, and 82 and the associated STBY-SPE alarm will be cleared in about 30 minutes.

g. Error Type 85 is logged when the Duplication Interface circuit pack detects that writes made to the Standby SPE Memory are not being acknowledged. This implies that the shadowing mechanism is not functioning.

   The presence of time-outs when shadowing to the Standby SPE Memory should be checked by issuing the **test duplication-interface a long** command. This command runs a test that forces memory writes to the Standby SPE Memory and detects time-outs waiting for acknowledgments. If time-outs are not detected, memory shadowing may be functional. However, to restore the functionality of memory shadowing, look for the presence of Error Types 67, 82, and 106 and use the recommended commands to clear these errors.

h. Error Type 98 is logged when the Active SPEMTP Dual Port RAM Test (#104) fails. This implies an inability to communicate with the Active MTP.

   The ability to communicate with the Active MTP should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Active SPE.

i. Error Type 99 is logged when the Active SPE detects that the handshake that is maintained between the Active SPE Processor and the Active SPE Maintenance/Tape Processor has been lost. This implies an inability to communicate with the Active MTP.

   The ability to communicate with the Active MTP should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Active SPE.

j. Error Type 106 is logged when the Standby SPE Memory Functional Test (#332) fails. This implies an inability to communicate with the Standby SPE and also that the shadowing mechanism is not functioning.

   The functionality of the Standby SPE Memory should be checked by issuing the **test memory a | b long** command, where "a | b" indicates the carrier that contains the Standby SPE. This command runs the Memory Functional Test. If the test passes, the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the functionality of the communication path, look for the presence of Error Types 58, 80, 81, 98, and 99 and use the recommended commands to resolve these errors.

   Additionally, if the Memory Functional Test passes, the memory shadowing mechanism may be functional. However, to restore the functionality of memory shadowing, look for the presence of Error Types 67, 82, and 85 and use the recommended commands to resolve these errors.

k. If Error Type 139 is present, this error type takes precedence over all other error types until it is resolved. This error type indicates an incompatibility between the two Processor circuit packs in a High or Critical Reliability system. For a High or Critical Reliability system to work, the two Processor circuit packs must function together so that the circuit packs can perform interchanges between themselves.

   Use the following procedure to resolve this error:

   1. Set the SPE-Select switches one at a time to select the Active SPE. This also forces the Tone-Clock in this SPE to become active.
   2. If the active SPE is the B carrier, issue the **test duplication-interface a long** command.
   3. Execute the **test spe-standby long** command.
   4. Use the **display error** command with the "dup-spe" category to see if the Error Code 139 recurred. If the error did not recur, and if all STBY-SPE tests have passed, the system is functioning normally.
   5. Restore the SPE-Select switches to normal.
   6. If Error Code 139 still exists (and if the STBY-SPE tests have failed), one of the Processor circuit packs must be replaced. The system will function normally, but it will not be able to interchange properly to the Standby SPE without service disruption. Replacing the Standby processor is the best solution to this problem. However, the processor must be replaced with one of a vintage that is

compatible with the current Active Processor. (Refer to the "Circuit Pack Replacement Procedure" section in Chapter 8, "Reliability Systems: A Maintenance Aid".)

However, if it is found that the Active processor must be replaced (for example, the Standby processor is of a newer vintage), the repair strategy is more complex. Use the following procedure to replace the Active Processor circuit pack:

NOTE:
Replacing the Active Processor circuit pack will disrupt service. Schedule this procedure at the customer's convenience.

1. Set the SPE-Select switches one at a time to select the Standby SPE. An SPE-interchange with a reset level of 3 or 4 results.
2. Replace the new Standby (and former Active) SPE Processor circuit pack with a circuit pack of the appropriate vintage. (Refer to the "Circuit Pack Replacement Procedure" section in Chapter 8, "Reliability Systems: A Maintenance Aid".)
3. Issue the **test spe-standby long** command. Use the **display error** command with the "dup-spe" category to verify that all tests pass and that Error Type 139 does not recur.
4. Restore the SPE-Select switches to their normal position.

l. Error Type 149 occurs when the Standby SPE goes into down mode during system technician demanded testing. Wait three minutes, then look for other STBY-SPE errors and follow the procedures described for these errors.

m. Aux Data value 0 is equivalent to Aux Data value 2017. Aux Data values 2014, 2015, 2017, 2021, 2024, and 2051 for Error Type 257 are described in the "System Technician-Demanded Tests: Test Result Error Codes". The Aux Data values 2048, 2049, and 2050 for Error Type 257 are described in SHDW-LNK (Memory Shadowing Link) Maintenance documentation. These values are shared between Standby SPE maintenance activity results and the test results for System Technician commands on Standby SPE components because the values represent the common set of problems that can be encountered when attempting to conduct any form of maintenance activity on the Standby SPE.

Error Type 257 with an Aux Data value of 2051 and a Major alarm results when, in attempting to refresh the Standby SPE, it is determined that software cannot communicate with the Duplication Interface circuit pack in the A carrier. This implies that the shadowing mechanism is not functioning. This error type is accompanied by Error Type 80.

Error Type 257 with an Aux Data value of 2051 and no alarm results when, in attempting to refresh the Standby SPE, it is determined that software cannot communicate with the Duplication Interface circuit pack in the B carrier. This does not necessarily imply that the shadowing mechanism is not functioning, but it **is** possible that it is not functioning. This error type is accompanied by Error Type 82. However, Error Type 82 may not be logged until sometime later.

n. After issuing the specified command(s) to clear this alarm, perform the following procedure to clear the STBY-SPE alarm:

   1. If all the tests pass or abort, issue a **refresh spe-standby** command. If the refresh is successful, wait one minute and then check for alarms against STBY-SPE. If the refresh was not successful, or if there are still alarms against STBY-SPE, continue attempts to resolve other STBY-SPE error types. The **busyout spe-standby** and **release spe-standby** commands may also be used to clear out STBY-SPE alarms. After entering the **busyout spe-standby** command followed by the **release spe-standby** command, all STBY-SPE alarms are retired and, one minute later, the equivalent of scheduled maintenance is run on the standby SPE. Note that the **busyout spe-standby** and **release spe-standby** commands do not affect alarms on other Maintenance Objects in the standby processor complex.
   2. If some of the tests fail, refer to the appropriate MO section and follow the procedures described there.

The following table summarizes the error types that may affect the functionalities of the Communication Path to the Standby SPE and of Memory Shadowing. To restore the function, all error types that may affect the function must be investigated and resolved by following the recommended commands or procedures.

Function Affected	Error Types
Communication Path To Standby SPE	58, 80, 81, 98, 99, 106, 1 with Aux Data values 2016, 2017, 2022, 2024, or 2025; 139 with Aux Data value 2015.
Memory Shadowing	67, 82, 85, 106, 257 with Aux Data values 2014, 2015, 2021, 2024, 2048, 2049, 2050, or 2051.

o. Error Type 801 (80386 only) is logged when the **upgrade software** command failed due to the loss of communication with the Standby SPE during the upgrade. This implies that the software reprogramming of the Standby SPE never completed.

   The **upgrade software** command should be re-executed. If it fails again, the Standby SPE Processor circuit pack should be replaced.

p. Error Type 802 (80386 only) is logged when the **upgrade software** command failed due to the bad flash checksum on the Standby SPE after the completion of the upgrade. This implies that the on-board flash memory may not be functional. The Standby SPE is running the new software while the Active SPE is still running the old software. However, due to the bad flash checksum, the behavior of the Standby SPE may be unpredictable.

The **upgrade software** command should be re-executed. If the command fails again, the Standby SPE Processor circuit pack should be replaced.

q. Error Type 803 (80386 only) is logged when the **upgrade software** command failed due to the failure to insert the translation card-mem into the Standby SPE in time during the reboot immediately following a successful upgrade. This implies that the Standby SPE is running the new software while the Active SPE is still running the old software.

   The translation card-mem should be inserted into the Standby SPE at the appropriate time so as to allow the **upgrade software** command to be re-executed.

r. Error Type 804 (80386 only) is logged when the **upgrade software** command failed due to a loss of communication with the Standby SPE during the reboot immediately following a successful software upgrade. This implies that the communication path between the Active SPE and the Standby SPE may not be functional.

   Issue the **test duplication-interface a** and the **test duplication-interface b** commands. If the tests pass, re-execute the **upgrade software** command.

s. Error Type 805 (80386 only) is logged when the **upgrade software** command failed due to the failure to insert the software card-mem in the Active SPE in time.

   The software card-mem should be inserted into the Active SPE at the appropriate time so as to allow the **upgrade software** command to be re-executed.

t. Error Type 806 (80386 only) is logged when the **upgrade software** command failed due to a bad flash checksum on the new Standby SPE after an upgrade of the old Standby SPE and SPE-Interchange. This implies that the on-board flash memory may not be functional. The behavior of the Standby SPE may unpredictable.

   The **upgrade software** command should be re-executed. If the command fails again, the Standby SPE Processor circuit pack should be replaced.

u. Error Type 807 (80386 only) is logged when the **upgrade software** command failed due to the failure to insert the translation card-mem into the new Standby SPE after an upgrade of the old standby SPE and SPE-Interchange.

   The translation card-mem should be inserted into the Standby SPE.

v. Error Type 808 (80386 only) is logged when the **upgrade software** command failed due to the loss of communication with the new Standby SPE during an upgrade following the upgrade of the old standby SPE and SPE-Interchange. This implies that the programming of the Standby SPE never completed.

Use the "Special Upgrade Procedure" to re-execute an upgrade on the Standby SPE only. If the upgrade fails again, the Standby SPE Processor circuit pack should be replaced.

w. Error Type 809 (80386 only) is logged when the **upgrade software** command failed due to the failure to perform an SPE-Interchange immediately after the successful upgrade of the Standby SPE. This implies possible problems with the Dupint circuit packs.

   Issue the **test duplication-interface a** and **test duplication-interface b** commands. If the tests pass, re-execute the **upgrade software** command.

x. Error Type 810 (80386 only) is logged when the **upgrade software** command failed due to a bad checksum on the software card-mem during the upgrade of the new Standby SPE following the successful upgrade of the old Standby SPE and of SPE-Interchange.

   The software card-mem should be replaced by one that has a good checksum. The **upgrade software** command should be re-executed.

y. Whenever an SPE interchange is forced by using the **health-override** option as part of the **reset system interchange** command, a WARNING OFF circuit pack STBY-SPE alarm is raised, and the Fault Severity Level (FSL) of the new standby SPE is raised to its highest possible value to prevent an SPE interchange back to the original active SPE. This artificial FSL lasts one hour or until a **busyout spe-standby** command is executed, followed by a **release spe-standby** command. After this time, the FSL of the two SPEs are recomputed, and the healthiest SPE becomes or remains active.

z. The system interchanged from the active SPE to the standby SPE with a restart that is more disruptive to service than the normal system hot start. The switches were not used to force this interchange. The level of restart can be observed by using the **display initcauses** command. Look for other alarms on the standby SPE that possibly caused this interchange. Also see "Reset System Interchange (High or Critical Reliability Systems Only)" in Chapter 4, "Initialization and Recovery".

aa. The software vintage in the Standby SPE does not match the software vintage in the active SPE.

   The **upgrade software** command should be executed for the standby SPE as described in Chapter 5, "Routine Maintenance Procedures".

System Technician-Demanded Tests

The following commands can be used to test and manipulate part or all of the standby SPE:

- **busyout spe-standby**

The **busyout spe-standby** command is used to stop all standby maintenance activity, disable shadowing, and hold the standby processor reset. A warning off circuit pack alarm is also raised against STBY-SPE MO. This command is more powerful than the **refresh spe-standby** command because it preempts the standby and enters maintenance mode, where as the **refresh spe-standby** does not do this.

- **release spe-standby**

  The **release spe-standby** command is used to remove the busyout condition, restore memory shadowing, and force a refresh. One minute after the command is executed, the equivalent of standby scheduled maintenance is run.

- **refresh spe-standby**

  The **refresh spe-standby** command is used to put the Standby SPE immediately into Standby Mode. The command conducts the same activities regardless of whether the Standby SPE is already in Standby Mode or whether it is in Maintenance Mode. Whenever this command is issued, any Standby SPE maintenance activity currently in progress (except for entering maintenance mode) is preempted, the Standby SPE Processor is held reset, and the Standby SPE's memory is refreshed. Recall that the refresh is necessary because, while the Standby SPE is in Maintenance Mode, memory shadowing is disabled. When the Standby SPE is returned to Standby Mode, its memory must be brought up-to-date with Active SPE memory.

  Because they can preempt Standby SPE maintenance activities, the **refresh spe-standby** and **busyout spe-standby** commands should be used judiciously. If the Standby SPE is in Maintenance Mode when one of these commands is issued, the current maintenance activity being conducted by the Standby SPE is immediately terminated with the following potential side-effects:

  - Testing of the Standby SPE components that are the target of the maintenance activity may not have completed. Depending on the maintenance activity and the point at which such activity is terminated, tests that detect faults and/or lack of faults on those Standby SPE components may not have had the opportunity to run. Accordingly, alarms will not be raised or retired on the components.
  - If the maintenance activity is Scheduled Maintenance, and if the **refresh spe-standby** or **busyout spe-standby** command is issued before a scheduled translation save is performed, the translation save is not completed, and the translation data on both the Active SPE and Standby SPE and on the tapes [G3iV1.1-286] or on the memory cards [G3iV2-386] do not reflect the changes made since the last translation save.

  In general, after a **refresh spe-standby** has been used, and after the user has finished working with the system, the **test spe-standby long** command should be issued in the event that the **refresh spe-standby** command preempted a Standby SPE maintenance activity. Testing the standby SPE allows standby maintenance to re-determine the health of the standby SPE and to compare this health to that of the active SPE. This testing could result in an SPE interchange to a healthier SPE.

If the **busyout spe-standby** command has been used, the **release spe-standby** command should also be used. The latter command fully tests the standby SPE one minute later.

Also, if the **refresh spe-standby** or **busyout spe-standby** command was used within the time frame that scheduled maintenance with a translation save was to have been conducted, the **save translation** command should be issued to ensure that the current translation data has been written to the Active SPE and Standby SPE tapes.

When using the **refresh spe-standby** to preempt Standby SPE maintenance activities, it may be necessary to issue the **refresh spe-standby** command multiple times in order to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the **status system** form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use ‘display errors’ to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later". Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** command.

- **reset spe-standby <level>**

  Normally, when the standby is brought into maintenance mode, it is done so with a Warm Restart. The **reset spe-standby** command can be used to bring the standby SPE from standby mode into maintenance mode with the requested restart level.

- **reset system-interchange <health-override>**

  If the health-override option is NOT specified, and if the standby Fault Severity Level (FSL) is less than or equal to that of the active SPE, and if the standby SPE is in standby mode, the interchange is allowed. Actually, if the standby FSL is less than that of the active FSL, the system does its own interchange in due time. If the FSL of the standby SPE is higher than that of the active SPE, but the alarmed standby maintenance objects do not affect the ability of the standby SPE to be put into standby mode, the command is rejected. This indicates that the health-override option can be used. If there are problems that would prevent the standby SPE from running system software, the command is rejected outright.

  If the health-override option is specified, and if the standby SPE is in standby mode, a Hot interchange is performed, regardless of the FSL level of the two SPEs. Once the interchange is performed, if the new active FSL is higher than the standby FSL, a STBY-SPE warning alarm is raised against the new standby SPE. This indicates that the system was forced to switch SPEs and is currently being held on the active SPE artificially. This prevents a SPE interchange back to the original active SPE. This STBY-SPE warning alarm lasts for one hour. After this time passes, system switches to the SPE with the lowest FSL.

The STBY-SPE alarm is also retired if there is some indication of system technician testing of the standby SPE before the one hour expires. The assumption here is that a system technician person is present because the health-override option was used. Therefore, if there is some indication that repair work is going on, the alarm generated by the health-override should be retired. The following are indications of system technician testing being done: the standby SPE is busied out and then released, the active SPE is hard selected via the switches, or a **test spe-standby long** command is performed.

On a G3iV2-386 system only, if the two SPEs are running different versions of software, and if this is the only standby SPE problem, the health-override option can be used to force a Cold 2 interchange to the standby SPE.

- **test processor [[0]1] a|b [short | long]**

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the PROCR-BD and PR-MAINT sections for a complete list of the tests that are run.

- **test memory [[0]1] a|b [short | long]**

  For this command, there is one additional test for the Standby SPE Memory circuit pack: the Memory Functional Test #332. Refer to the MEM-BD section for a complete list of the tests that are run.

- **test data-module <extension>**

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the DATA-CHL section for a complete list of the tests that are run.

- **test tape [[0]1] a|b [short | long]** (for 286 configuration only).

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the TAPE section for a complete list of the tests that are run.

- **test network-control [[0]1] a|b [short | long]**

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the SW-CTL, DATA-BD, DATA-CHL, and CARD-MEM sections for a complete list of the tests that are run.

- [G3iV2-386] **test card-mem [[0]1] a|b [short | long]**

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the CARD-MEM section for a complete list of the tests that are run.

- **test packet-control [[0]1] a|b [short | long]**

For **test packet-control**, the most significant difference between testing the Active Packet Control versus the Standby Packet Control is that the Reset Test (#586) runs on the Standby SPE Packet Control circuit pack. Also, the short and long options cause the identical set of tests to run. Refer to the PKT-CTRL section for a complete list of the tests that are run.

- **test interface [[0]1] a1 | a2 | b1 | b2 [short | long]**

  For this command, there is a single test for the Standby SPE Processor Interface circuit pack(s) and a single test for each Processor Interface Port on a Processor Interface circuit pack. These tests are different from the tests that are run for the corresponding Active SPE Processor Interface circuit pack(s) and Processor Interface Port(s). Refer to the PI-PT section for a complete list of the tests that are run.

- **test duplication-interface [0[1] a|b [short | long]**

  Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the DUPINT section for a complete list of the tests that are run.

- **test spe-standby [short | long]**

  The **test spe-standby [short | long]** command results in the execution of all tests that would be run if each of the previous commands in this list was executed individually. Because of the number of tests that it runs, **test spe-standby [short | long]** takes from 10 to 30 minutes to complete.

  The Short and Long Test Sequences for **test spe-standby** are listed on the following pages. Refer to the appropriate maintenance section for a complete description of each of the tests.

Test Sequence of Test SPE-Standby Command

Test Number	Name of Test and Associated Maintenance Object	Short Test Sequence	Long Test Sequence
332	Memory Functional Test (MEM-BD for 286 or MEMORY for 386)		X
318	Shadow Link Test (SHDW-LNK)		X
285	Common Shadow Circuit MBUS Time-out Query (SHDW-CIR)		X
283	Common Shadow Circuit Loop Back Test (SHDW-CIR)	X	X
284	Common Shadow Circuit Address Decoder Test (SHDW-CIR)	X	X
278	SPE Select Switch Query (SPE-SELEC)	X	X
315	Duplication Interface Status Query (DUPINT)	X	X

Test Sequence of Test SPE-Standby Command

Test Number	Name of Test and Associated Maintenance Object	Short Test Sequence	Long Test Sequence
275	Duplication Interface SPE A Loop Back Test (DUPINT)	X	X
276	Duplication Interface SPE B Loop Back Test (DUPINT)	X	X
280	Inter-Duplication Interface Loop Back Test (DUPINT)	X	X
271	Duplication Interface Background Test Query (DUPINT)	X	X
277	Duplication Interface Sanity Maze Test (DUPINT)	X	X
272	Duplication Interface Invalid Message Query (DUPINT)	X	X
274	Duplication Interface Manager I Loop Back Test (DUPINT)	X	X
273	Duplication Interface Sanity Circuit Test (DUPINT)		X
85	Read All Memory Test (MEM-BD for 286 or MEMORY for 386)		X
86	RAM Checksum Test (MEM-BD for 286 or MEMORY for 386)		X
87	**For a 286 Configuration:** Memory Error Detection/Correction/Exception Test (MEM-BD or MEMORY) **For a 386 Configuration:** Memory Parity Test (MEM-BD or MEMORY)	X	
631	**For 286 Configuration Only:** Memory Board Vintage Check Test (MEM-BD or MEMORY)	X	X
52	Control Channel Test (DATA-BD)	X	X
50	NPE Audit (DATA-BD)		X
For each administered Network Control Data Channel in the Standby SPE, the following DATA-CHL tests are run:			
107	Data Channel Reset (DATA-CHL)		X
108	Data Channel DPR Test (DATA-CHL)		X

Test Sequence of Test SPE-Standby Command

Test Number	Name of Test and Associated Maintenance Object	Short Test Sequence	Long Test Sequence
109	Data Channel Maintenance Loop Around Test (DATA-CHL)	X	X
110	Data Channel Crosstalk Test (DATA-CHL)	X	X
111	Data Channel Loop Back Test (DATA-CHL)	X	X
93	Switch Control Reset Test (SW-CTL)		X
325	Destructive EPN Maintenance Board Interface Test (SW-CTL)		X
95	Time-of-Day Clock Test (SW-CTL)	X	X
92	Control Channel Interface Test (SW-CTL)	X	X
94	Control Channel Transmission Test (SW-CTL)	X	X
324	EPN Maintenance Board Interface Test (SW-CTL)	X	X
77	Processor Software Initiated Interrupt Test (PROCR)	X	X
80	Processor ROM Checksum Test (PROCR)	X	X
82	Processor Non-Maskable Interrupt Test (PROCR)	X	X
83	Processor Sanity Timer Test (PROCR)		X
102	MTP Outpulse Relay Test (PR-MAINT)	X	X
103	MTP Analog Loop Around Test (PR-MAINT)	X	X
106	MTP Sanity Handshake Test (PR-MAINT)	X	X
228	MTP Manager I Channel Loop Around Test (PR-MAINT)	X	X
229	MTP Auxiliary Channel Loop Around Test (PR-MAINT)	X	X
101	MTP Reset Test (PR-MAINT)		X
104	MTP Dual Port RAM Test (PR-MAINT)		X

Test Sequence of Test SPE-Standby Command

Test Number	Name of Test and Associated Maintenance Object	Short Test Sequence	Long Test Sequence
For 286 Configuration, the following Tape tests are run:			
67	Tape Reset Test (TAPE)		X
692	Tape Block Error Test (TAPE)		X
65	Tape Read/Write Test (TAPE)		X
230	Tape DMA Address Latch Test (TAPE)	X	X
66	Tape Diagnostic Test (TAPE)	X	X
69	Tape Status Test (TAPE)	X	X
421	Tape Consistency Test (TAPE-DAT)		X
For a 386 configuration, the following Memory Card and 12 Volt Power Supply tests are executed:			
701	12 Volt Power Supply Test (12V-PWR)	X	X
695	Cartridge Insertion Test (CARD-MEM)	X	X
696	Cartridge Format and Read Test (CARD-MEM)	X	X
697	Cartridge Match Test (CARD-MEM)	X	X
698	Cartridge Write-Protected Test (CARD-MEM)	X	X
699	Cartridge Directory Sanity Check and Recovery Test (CARD-MEM)	X	X
694	Cartridge Translation Data Integrity Test (CARD-MEM)		X
693	Cartridge Erase/Write/Read Test (CARD-MEM)		X
703	Flash Data Consistency Test (FL-DATA)		X
For each Processor Interface circuit pack in the Standby SPE, the following PI-BD tests are run:			
52	Control Channel Test (PI-BD)	X	X
50	NPE Audit (PI-BD)		X
423	Standby PI Board Test (PI-BD)	X	X
For each administered Processor Interface Port, the following test is run:			
404	Standby PI Port Test (PI-PT)	X	X

Test Sequence of Test SPE-Standby Command

Test Number	Name of Test and Associated Maintenance Object	Short Test Sequence	Long Test Sequence
For a Packet Control circuit packet in the Standby SPE, the following three tests are run:			
586	Packet Control System Technician Reset Test (PKT-CTRL)	X	X
583	Packet Control Read and Clear Error Counter Test (PKT-CTRL)	X	X
585	Packet Control Loop Around Test (PKT-CTRL)	X	X

Useful Facts About Running Tests on the Standby SPE

Although this subsection is not about the individual test commands listed previously, several useful facts about executing these commands for Standby SPE components are mentioned here. These facts also apply to the **test spe-standby [short | long]** command.

1. If the Standby SPE is in Standby Mode, execution of the listed test commands results in the Active SPE putting the Standby SPE into Maintenance Mode. Up to a two minute delay may be observed before the first test in the sequence is run and its test results are displayed on the terminal. Each subsequent test in the sequence takes from 10 to 60 seconds to run, except for the CARD-MEM Erase/Write/Read test #693, which takes one to five minutes to run.
2. The **test memory [[0]1] a | b long** command is an exception to the first item. The first test in the sequence is the Memory Functional Test (#332) which takes from 30 seconds to two minutes. After the Memory Functional Test (#332) is run, the same delays described in Item 1 of this list are relevant.
3. The **test duplication-interface [[0]1] a | b long** command is also an exception to the first item. The first test in the sequence is the MBUS Time-out Query (#285) which takes from 30 seconds to 2 minutes to run. After the MBUS Time-out Query (#285) is run, the same delays described in Item 1 of this list are relevant.
4. The **test spe-standby long** command is also an exception to the first item. The first test in the sequence is, the Memory Functional Test (#332), takes from 30 seconds to two minutes to run. After the Memory Functional Test (#332) is run, the next test in the sequence, the Shadow Link Test (#318), takes from one to five minutes to run. After the Shadow Link Test (#318) is run, the next test in the sequence, the MBUS Time-out Query (#285), takes from 30 seconds to two minutes to run. After the MBUS Time-out Query (#285) is run, the same delays described in Item 1 of this list are relevant.
5. If one of listed test commands is executed so that the Active SPE puts the Standby SPE into Maintenance Mode, the Active SPE leaves the Standby SPE in Maintenance Mode for three minutes after the completion of the command. If an additional test command (with the exception of those described in Items 6, 7, and 8) is executed within three minutes, the one to 20-minute delay prior to the first test will **not** be observed. Each test in the sequence, including the first test, takes from 10 to 60 seconds to run.

   Furthermore, the Active SPE leaves the Standby SPE in Maintenance Mode for three minutes after the completion of the additional command. This is true for each additional test command issued on a Standby SPE component.
6. The **test memory [[0]1] a | b long** command is an exception to Item 5. Because of the nature of the Memory Functional Test (#332) the same delays as described in Item 2 are always observed for **test memory [[0]1] a | b long**.

7. The **test duplication-interface [[0]1] a | b long** command is also an exception to Item 5. Because of the nature of the MBUS Time-out Query (#285) the same delays as described in Item 3 are always observed for **test duplication-interface [[0]1] a | b long**.
8. The **test spe-standby long** command is also an exception to Item 5. Because of the nature of the Memory Functional Test (#285), the Shadow Link Test (#318), and the MBUS Time-out Query (#285) the same delays as described in Item 4 are always observed for **test spe-standby long**.
9. For test commands whose sequence spans multiple terminal screens (for example, **test spe-standby [short | long]**) the same 3-minute window that was described in Item 4 applies to pressing the "page" key to proceed to the next screen of test results. If the "page" key is not pressed within three minutes of the completion of the last test on the current screen, the one to 20 minute delay is observed before the first test on the next screen is run and its test results are displayed on the terminal. Each subsequent test on that screen takes from 10 to 60 seconds to run. If the "page" key is pressed within three minutes of the completion of the last test on the current screen, the one to 20 minute delay will **not** be observed.

Test Result Error Codes and Text Strings

The text string messages and error codes documented in the Error Codes tables at the end of this section may result from any of the system technician commands described earlier in this section.

In general, these error codes result from an inability of the Active SPE to successfully conduct a maintenance activity request on the Standby SPE and not from a problem detected by the test itself. In fact, all error codes except for 2015, 2021, 2047, 2048, 2049, and 2050 indicate that the test was not actually run.

If an error code returned from a test does not appear in the Error Code table, the Active SPE successfully conducted the maintenance activity request on the Standby SPE, and the test was actually run (in most cases). For details on this error code, refer to the documentation describing the specific object you now suspect as possibly being defective. In the Short and Long Test Sequences listed earlier in this section, the name of the object tested appears directly after each test number and name.

Several of the conditions corresponding to the error codes documented here may be detected as soon as the **test <component> [[0]1] a | b [short | long]** command is issued. The net result is that none of the tests in the sequence for the component will be attempted and a message will appear on the terminal message line describing why the command was rejected.

The following is a list of these text strings.

- **Cannot interrupt Standby SPE while entering maintenance mode; please try later**

  This message line error is displayed when a **refresh spe-standby** command is issued while maintenance software is in the process of putting the Standby SPE into Maintenance mode when any of the Error Types listed in "Hardware Error Log Entries and Test to Clear Value" have occurred and have not been resolved. It is also displayed when a system technician-demanded test has been issued and subsequently canceled because maintenance software is performing the Memory Functional Test, Shadow Link Test, or M-BUS Time-out Query. Another cause may be that maintenance software is in the process of putting the Standby SPE into Maintenance Mode to run any other system technician-demanded test that must be conducted on the Standby SPE in Maintenance Mode. Allow up to 10 minutes for the maintenance software to complete its attempt to put the Standby SPE into Maintenance Mode before issuing the **refresh spe-standby** command.

- **Cannot perform SPE interchange; for information use status system**

  This message is displayed in response to the **reset system interchange** command and because there are outstanding STBY-SPE errors. Display the error log using the "dup-spe" category, and following the procedures for all STBY-SPE errors.

- **Cannot reset standby SPE at this time; use the 'status system' command**

  This message is displayed when the standby SPE memory is not refreshed. Issue the **refresh spe-standby** command and try the reset again.

- **Could only hold Standby SPE reset because Active SPE is locked via SPE select switches**

  This message is displayed when the **refresh spe-standby** command is issued when the active SPE is selected via the SPE select switches. Because the select switches disable shadowing, the refresh command can not refresh the memory on the standby SPE. The only effect the refresh command has is to hold the standby SPE reset.

- **Refresh not successful; use the 'display errors' and the 'dup-spe' category to check for standby SPE errors**

  This message line error, which corresponds to Error Codes 2012, 2013, 2014, 2015, 2021, 2024, 2048, 2049, 2050, or 2051, is displayed when a **refresh spe-standby** command fails.

- **Standby SPE busy with another task; for information use status system**

  This message line error, which corresponds to Error Code 2018, is displayed if a test command on a Standby SPE component is attempted while the Active SPE is performing some Maintenance Mode activity on the Standby SPE other than system technician-demanded maintenance.

  1. Issue the **refresh spe-standby** command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** and **release spe-standby** command to put the standby into standby mode.
  2. Repeat the command.
  3. Issue the **test spe-standby long** command.

- **Standby** SPE **failed to reset with requested restart level; check for STBY-SPE errors**

- **Standby SPE memory not refreshed; use the 'refresh spe-standby' command**

When a command that requires the standby SPE to be brought into maintenance mode is entered, but the standby SPE memory is not refreshed, this message is displayed. Issue the **refresh spe-standby** command and retry the command.

- **Standby SPE not available; for information use status system**

  This message line error, which corresponds to Error Code 2020, is displayed if a test command on a Standby SPE component is attempted within the first five minutes of a restart of the Active SPE (that is, prior to the Active SPE holding the Standby SPE reset and refreshing it).

  1. Issue the **refresh spe-standby** command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use ‘display errors’ to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** and **release spe-standby** command to put the standby into standby mode.
  2. Repeat the command.
  3. Issue the **test spe-standby long** command.

- **Unable to interchange because the active SPE is locked active**

  An SPE interchange cannot be performed when the active SPE is locked via the SPE select switches. Move the select switches back to the auto position and retry the **reset system interchange** command.

- **Unable to interchange because the standby SPE is busied out**

  An SPE interchange can not be performed when the standby SPE is busied out. Release the standby SPE by entering the **release spe-standby** command and retry the command.

- **Unable to interchange due to alarms on the standby SPE; Use the ‘health-override’ option**

  When components in the standby SPE complex are alarmed, and if these Standby alarms are more severe than the alarms in the active SPE complex, the **reset system-interchange** command returns this message. Using the **reset system-interchange health-override** command forces the interchange. See the **Reset System** command page for more details.

Table 11-326. Test Result Error Codes Associated with the Standby SPE

Error Code	Test Result	Description/ Recommendation
4	ABORT	The Active SPE was unable to disable or enable shadowing from Active SPE memory to Standby SPE memory. The communication path between the Active SPE and the carrier A Duplication Interface circuit pack may have failed, or the carrier A Duplication Interface circuit pack may have failed. 1. Check for Active SPE Maintenance/Tape Processor errors and alarms. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation and follow the prescribed procedures. 2. Check for carrier A Duplication Interface circuit pack errors and alarms. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation and follow the prescribed procedures. 3. If the B carrier contains the Active SPE, check the Inter-Carrier Cable to see if it is loose or disconnected. If so, follow the repair procedures for connecting the Inter-Carrier Cable described in Chapter 8, "Reliability Systems: A Maintenance Aid". 4. If all problems found in Steps 1, 2, and 3 have now been repaired, proceed with Step 7. If no problems were found in Steps 1, 2, and 3, proceed with Step 5. 5. Issue the **display errors** command and check to see if an Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 7, 8, and 9.

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
4 *(cont'd.)*	ABORT	6. If no error type is logged, the problem may be the carrier A Duplication Interface circuit pack. ■ If the red LED on the carrier A Duplication Interface circuit pack is on, replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 7, 8, and 9. ■ If the red LED on the carrier A Duplication Interface circuit pack is not on **AND** if this is the first attempt to clear the problem, replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 7, 8, and 9. ■ If the LED is not on **AND** if this is the second attempt to clear the problem (that is, the carrier A Duplication Interface circuit pack has already been replaced), stop here and escalate the problem. 7. Issue the **refresh spe-standby** command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** and **release spe-standby** command to put the standby into standby mode. 8. Repeat the command. 9. Issue the **test spe-standby long** command.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
1029	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1030	ABORT	The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. If it is absolutely necessary to conduct this test on the Standby SPE component, implement the following steps to make it become an Active SPE component. 1. Issue the **refresh spe-standby** command to return the Standby SPE to Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, escalate the problem. 2. Issue the **reset system interchange** command in order to cause an SPE switch. At this point, the component resides on the Active SPE.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
1030 *(cont'd.)*	ABORT	3. Move the SPE Select switches to make the SPE with the problem the current Active SPE. This action prevents software from switching to the other SPE since the current SPE has the error against it. 4. Repeat the test. 5. If the test passes and the alarm is resolved, return the SPE Select switches to the AUTO position. 6. If the test fails and the defective circuit pack is identified, the circuit pack needs to be replaced. However, the circuit pack now resides on the current Active SPE. Return the SPE Select switches to the AUTO position. Issue the **refresh spe-standby** command and then execute a **reset system interchange** command to cause an SPE switch. 7. The system is now on the healthy SPE. Replace the defective circuit pack on the Standby SPE as previously identified in Step 4. Refer to the "Replacing Defective SPE Circuit Packs" section in Chapter 8, "Reliability Systems: A Maintenance Aid". 8. Repeat the procedure, beginning with Step 1.
2011 2012 2013	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2015	ABORT	The Standby SPE Maintenance/Tape Processor did not reply to an Active SPE request to hold the Standby SPE Processor reset. The communication path between the Active SPE and the Standby SPE Maintenance/Tape Processor may have failed, or the Standby SPE Maintenance/Tape Processor may have failed. Follow the procedures described for Error Code 2024 in the STBY-SPE section.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2016 2017	ABORT	The Active SPE attempted to put the Standby SPE into Maintenance Mode, but did not receive notification from the Standby SPE Maintenance software that it successfully entered Maintenance Mode **OR**, once in Maintenance Mode, the Standby SPE sent a request to the Active SPE to have the Active SPE conduct a portion of a test in the Standby SPE's behalf, but the Standby SPE did not receive a response to its request. In either case, the communication path between the Active SPE and the Standby SPE may have failed. Follow the procedures described for Error Code 2024 in the STBY-SPE section.
2018	ABORT	The test requires that a maintenance activity request be made to the Standby SPE; however, the request cannot be made because the Standby SPE is busy processing a previous maintenance activity request. 1. Issue the **refresh spe-standby** command to force the Standby SPE to Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 30 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the **status system** form after this attempt, escalate the problem. 2. Repeat the test. 3. Issue the **test spe-standby long** command to thoroughly test all Standby SPE components.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2019	ABORT	A translation save on the Standby SPE was not carried out because the Shadow Link Test failed. (The Shadow Link Test was done to verify the integrity of the translation data on the Standby SPE.) 1. Check for Memory Shadowing Link errors and alarms. Refer to SHDW-LNK (Memory Shadowing Link) Maintenance documentation and follow the prescribed procedures.
2020	ABORT	The test requires that a maintenance activity request be made to the Standby SPE; however, the request cannot be made because the Active SPE was restarted within the last five minutes and has not yet initialized the Standby SPE. Therefore, the Standby SPE is not available to handle maintenance activity requests. 1. Issue the **refresh spe-standby** command to force the Standby SPE to Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use ‘display errors’ to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the **status system** form after this attempt, escalate the problem. 2. Repeat the test. 3. If the Active SPE was restarted with a Cold 1 or a reboot, issue the **test spe-standby long** command to thoroughly test all Standby SPE components.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2021	ABORT	An attempt to refresh Standby SPE memory from Active SPE memory encountered a problem. In this case, the refresh from Active SPE Memory to Standby SPE Memory probably succeeded. However, the following steps should be followed just to verify that there are no problems. 1. Check for Active SPE Memory errors and alarms. Refer to MEM-BD (Memory circuit pack) Maintenance and follow the prescribed maintenance procedures. 2. Issue the **refresh spe-standby** command. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the **status system** form after this attempt, escalate the problem.
2022	ABORT	The Active SPE successfully put the Standby SPE into Maintenance Mode but received an incorrect response to a maintenance activity request that it made to the Standby SPE **OR,** once in Maintenance Mode, the Standby SPE sent a request to the Active SPE to have the Active SPE conduct a portion of a test in the Standby SPE's behalf, but the Standby SPE received an incorrect response to its request. The communication path between the Active SPE and the Standby SPE may have failed. Follow the procedures described for Error Code 2024 in the STBY-SPE section.
2023	ABORT	Internal System Error 1. Follow normal escalation procedures.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2024	ABORT	The Standby SPE Maintenance/Tape Processor did not respond to an Active SPE request to release the Standby SPE Processor to perform a function; **OR** the Standby SPE Processor was released but did not carry out the requested function and/or did not reply to the request; **OR** the Standby SPE Processor was released but cannot run because the Standby SPE Memory is defective. The communication path between the Active SPE and the Standby SPE Maintenance/Tape Processor may have failed, or the Standby SPE Maintenance/Tape Processor may have failed, or the Standby SPE Processor may have failed. 1. Check for Active SPE Maintenance/Tape Processor errors and alarms. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation and follow the prescribed procedures. 2. Check for carrier A Duplication Interface circuit pack errors and alarms. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation and follow the prescribed procedures. 3. Check for Standby SPE Maintenance/Tape Processor errors and alarms. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation and follow the prescribed procedures. 4. Check for Standby SPE Processor errors and alarms. Refer to PROCR (80286 Processor Circuit Pack) Maintenance documentation and follow the prescribed procedures. 5. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory circuit pack) Maintenance documentation and follow the prescribed procedures.

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2051	ABORT	When attempting to refresh Standby SPE memory from Active SPE memory, the Active SPE could not determine the status of one of the Duplication Interface circuit packs, or it determined that one of the Duplication Interface circuit packs was defective. 1. Check for carrier A Duplication Interface circuit pack errors and alarms. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation and follow the prescribed procedures. 2. Check for carrier B Duplication Interface circuit pack errors and alarms. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance and follow the prescribed procedures. 3. Check the Inter-Carrier Cable to see if the cable is loose or disconnected. If so, follow the repair procedures for reconnecting the Inter-Carrier Cable described in Chapter 8, "Reliability Systems: A Maintenance Aid". 4. If all problems found in Steps 1, 2, and 3 have now been repaired, proceed with Step 8. If no problems were found in Steps 1, 2, and 3, proceed with Step 5. 5. Issue the **display errors** command and check to see if Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 8, 9, and 10. 6. Issue the **display errors** command and check to see if Error Type 82 is logged against STBY-SPE. If so, the problem is the carrier B Duplication Interface circuit pack. Replace the carrier B Duplication Interface circuit pack as described in Chapter 8, "Reliability Systems: A Maintenance Aid" and proceed with Steps 8, 9, and 10. 7. If Error Type 80 or 82 is not logged, stop here and escalate the problem.

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
2051 *(cont'd.)*	ABORT	8. Issue the **refresh spe-standby** command to put the Standby SPE in Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, escalate the problem. 9. Repeat the test. 10. Issue the **test spe-standby long** command to thoroughly test all Standby SPE components.
2054	ABORT	This indicates an incompatibility between the two Processor circuit packs in a Duplication Option system. Follow the repair steps for STBY-SPE error 139 note (k).
2068	ABORT	When attempting to refresh Standby SPE memory from Active SPE memory, a problem was encountered when refreshing Packet Control circuit pack memory. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
other	ABORT	Any ABORT with an error code other than the ones listed previously indicates a problem that prevented the test from running. See Test Result of each maintenance object under test for details.

Continued on next page

Table 11-326. Test Result Error Codes Associated with the Standby SPE — *Continued*

Error Code	Test Result	Description/ Recommendation
other	FAIL	Any FAIL indicates that the test was actually run on the associated Standby SPE component. However, the test did not succeed and returned FAIL with the reason for the failure. See Test Result of each maintenance object under test for details.
	PASS	The test was actually successfully run on the associated Standby SPE component and returned PASS. See Test Result of each maintenance object under test for details.

STRAT-3 (Stratum 3 Clock)]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
STRAT-3	MAJOR	test synchronization	Stratum 3 Clock
STRAT-3	MINOR	test synchronization	Stratum 3 Clock
STRAT-3	WARNING	test synchronization	Stratum 3 Clock

The *Digital Synchronization Network Plan (PUB 60110)* specifies a hierarchy of synchronization nodes consisting of strata 1 to 4, where the sole Stratum 1 clock in the network is the most accurate. DEFINITY supports both Stratum 3 and Stratum 4 operations. Refer to SYNC (Synchronization) Maintenance documentation for details on Stratum 4 operation.

A Stratum 3 clock derives its timing from two DS1 references that are connected to a Stratum 3 or better (that is, lower stratum) source. The Stratum 3 clock provides a holdover of at least 24 hours should both DS1 references fail. (After 24 hours, the Stratum 3 clock still provides service but its accuracy may be degraded). The *Digital Synchronization Network Plan (PUB 60110)* requires that the Stratum 3 clock have duplicated components.

The recognition of the Stratum 3 clock itself as well as its alarm signals, is supported only by the TN780 Tone-Clock circuit pack. The TN780 Tone-Clock circuit pack is also backwards-compatible with the TN768 Tone-Clock circuit pack.

The Stratum 3 clock may be connected to either the PPN or an EPN if the TN780 Tone-Clock circuit pack(s) is present in that port network. However, for reliability, it is recommended that the clock be connected to the PPN. Refer to *DEFINITY Communications System Generic 3 Implementation*, 555-230-653 for details on how to move the Stratum 3 clock between port networks.

The only operation that software can perform is a query of the alarm leads. The only recovery action that can be performed on a catastrophic failure of the Stratum 3 clock is the utilization of the local oscillator on the Active TN780 Tone-Clock circuit pack. Neither software nor the TN780 Tone-Clock circuit pack can request additional information about the health of the Stratum 3 clock other than the information provided by the alarm leads. Furthermore, neither the software nor the TN780 Tone-Clock circuit pack can request that the external clock switch references, change configuration, disable/enable, initialize, etc.

In G3iV1.1-286 and G3iV2-386, the Stratum 3 clock has been implemented as an external that follows the specification in PUB 60110 for Stratum 3. Figure 11-95 shows how the Stratum 3 hardware configuration provides clock and alarm signals to the TN780 Tone-Clock circuit pack(s). The reference DS1 facilities are connected directly to the Stratum 3 clock for timing purposes, but the DS1 data may be routed into the switch by using a Y connector.

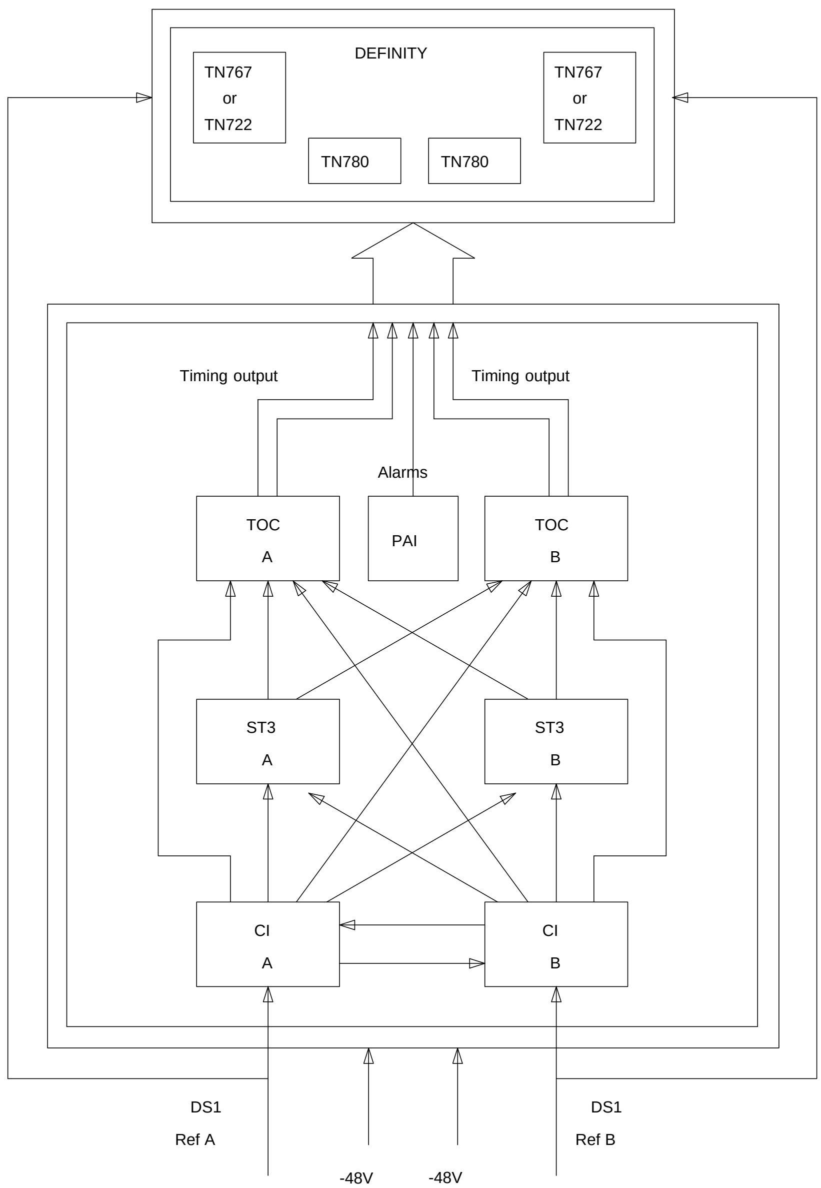

Figure 11-95. Stratum 3 Clock Hardware Configuration

NOTE:
When looking in the Stratum 3 cabinet, "A" card is on the left and "B" card is on the right.

Stratum 3 Clock LED Strategy

Red and green LEDs are provided on the components of the Stratum 3 clock for status and alarm indications.

WARNING:
The normal LED scheme is not followed for this device. Green LEDs do not indicate maintenance activity. There are no yellow LEDs, and there are more than three LEDs per circuit pack.

The Stratum 3 clock has the following components:

- 2 Clock Input cards (CI)

  Provides the logic to select the better DS1 reference or Clock Input card. The red FAIL LED on this card indicates a failure with the card or the DS1 reference connected to it.

- 2 Stratum 3 Cards (ST3)

  Provides 24-hour holdover. The red FAIL LED on this card indicates a failure with the card. Replace the card.

- 2 Timing Output Cards (TOC)

  Provides cable length compensation, multiple output ports, selection of the ST3, and CI outputs. This type of card has two red failure LEDs: one indicates a failure of the card; the other indicates a failure in one or more output ports. In either case, replace the card.

- 1 PBX Alarm Interface (PAI)

  Filters power supplied to the clock, provides fuse protection, and provides alarm indications based on inputs supplied by other cards. The six LEDs on this card provide indications for the six alarm or status conditions as follows:

  1. Loss of DS1 reference A.
  2. Loss of DS1 reference B.
  3. Loss of one clock unit.
  4. Loss of both clock units.
  5. Loss of one power supply.
  6. Loss of both power supplies.

NOTE:
Removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.

The output of the CI and PAI cards go directly to the TN780 Tone-Clock circuit pack via two 25-pair amp-terminated cables. All of the cards have red and/or green LEDs for providing status or alarm indications. The following table shows the Stratum 3 Clock LED indications.

NOTE:
The abbreviations used in the table were defined previously with the exception of SRC (source) and PLL (Phase Locked Loop).

Table 11-327. Stratum 3 Clock LED Indications

Card	Name	Color	Indication
PAI	REF A	Red	Loss of input reference A or CI A failed
	REF B	Red	Loss of input reference B or CI A failed
	ST A	Red	Failed Stratum 3 clock A
	ST B	Red	Failed Stratum 3 clock B
	PWR A	Green	-48VDC A present
	PWR B	Green	-48VDC B present
CI	FAIL	Red	Card failure
	DS1	Green	DS1 source present
	CC	Green	Composite clock source[1] present
	SRC ACTIVE	Green	Card is currently on-line
ST3	FAIL	Red	Card failure
	LOCK	Red	PLL lost sync with reference or holdover mode
	REF A	Red	Timing Reference from CI A
	REF B	Red	Timing Reference from CI B
TOC	FAIL	Red	Card failure
	PORT ALM	Red	Output port alarm (one or more)
	ST	Green	Reference present from ST clock
	INPUT	Green	Reference present from CI
	500’	Green	500 feet phase advance
	1000’	Green	1000 feet phase advance

1 Composite Clock source refers to the protocol used to electrically transfer timing from the Stratum 3 clock to the PBX switch. The Composite Clock source is not relevant to Definity Generic 1.1.

NOTE:
When looking in the Stratum 3 cabinet, "A" card is on the left and "B" card is on the right.

Hardware Error Log Entries and Test to Clear Values

Stratum 3 Clock Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test synchronization r 4
1 (d)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	OFF	test synchronization r 4
257 (e)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	OFF	test synchronization r 4
257 (c)		None	WARNING	ON	
513 (f)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	ON	test synchronization r 4
769 (g)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR	ON	test synchronization r 4
1025 (h)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR/ MAJOR(a)	ON	test synchronization r 4
1281 (i)	Any	Stratum 3 Clock Alarm Query (#649)	MINOR/ MAJOR(a)	ON	test synchronization r 4
1537 (b)		none	MINOR/ MAJOR(a)	ON	

1 Run the Short Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. In the context of the Stratum 3 clock, an OFF-BOARD alarm occurs when there is a DS1 facility problem; otherwise, the alarm is ON-BOARD indicating that there is a fault in the Stratum 3 clock or in the connection between the Stratum 3 clock and the PBX (Private Branch Exchange) switch. If the Stratum 3 clock cannot be referenced, and therefore the local oscillator on the TN780 Tone-Clock circuit pack must serve as the reference instead, a Major alarm is raised. Otherwise, a Minor alarm is raised.

b. This error can be caused by one of the following conditions:

   1. One or both TOCs (Timing Output Cards) may have failed,
   2. the connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack may be faulty, or
   3. the TN780 Tone-Clock circuit pack may be defective.

A Minor alarm results if the Stratum 3 clock can still provide timing to the PBX; otherwise, a Major alarm is raised because the Stratum 3 clock is not providing timing and the PBX is referencing the local oscillator on the TN780 Tone-Clock circuit pack. If only the Active TN780 Tone-Clock circuit pack were faulty, the Standby TN780 Tone-Clock circuit pack would become active and still synchronize to the Stratum 3 clock. When the system switches to the Standby Tone-Clock circuit pack, the alarm is resolved, and it raises a TDM-CLK (TDM Bus Clock) alarm to indicate that the TN780 Tone-Clock circuit pack may be defective.

If the alarm is minor:

Look for a red LED on either or both TOC cards. If there is a red LED, then replace the card. If there is no red LED, then, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After replacing the card or correctly rewiring the installation, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. Wait two minutes and then execute the **status synchronization** command. If Maintenance Name on the status screen shows "STRAT-3," then the problem is resolved. If not, then escalate the problem.

If the alarm is major:

Check connections between the Stratum 3 clock and the PBX. If there are no loose connections, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After reconnecting the loose connection or correctly rewiring it, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. Wait one minute, and then execute the **status synchronization** command. If Maintenance Name on the status screen shows "STRAT-3," then the problem is resolved. If not, then escalate the problem.

If the Standby Tone-Clock circuit pack become active:

Check connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack from which the system has just switched. If there are no loose connections, then, replace the TN780 Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section in the TDM-CLK (TDM Bus Clock) Maintenance documentation. Before switching back to the new TN780 Tone-Clock circuit pack, use the **test tone-clock PC long** command to check that the Tone-Clock is receiving a signal from the Stratum 3 clock. The notation "PC" denotes a port network number and carrier. If all tests pass, switch to the new Tone-Clock circuit pack via the **set tone-clock PC override** command. If Test #651 fails, then the original TN780 Tone-Clock should be reinserted, and the cable between the Stratum 3 clock and the TN780 Tone-Clock circuit pack should be replaced. If Test #651 continues to fail, then escalate the problem.

c. This error indicates that the Tone/Clock circuit pack in the master port network is not a TN780 Tone/Clock circuit pack when a Stratum 3 clock is administered. Verify that the Tone/Clock in the master port network is TN780.

d. This error indicates that the Stratum 3 clock has either reference A or CI card A failed. Please refer to the error code 1 in the test description of the Test #649 for the repair procedure.

e. This error indicates that the Stratum 3 clock has one power supply failed. Please refer to the error code 2 in the test description of the Test #649 for the repair procedure.

f. This error indicates that the Stratum 3 clock has one clock unit failed. Please refer to the error code 4 in the test description of the Test #649 for the repair procedure.

g. This error indicates that the Stratum 3 clock has either reference B or CI card B failed. Please refer to the error code 8 in the test description of the Test #649 for the repair procedure.

h. This error indicates that the Stratum 3 clock has all power supplies failed. Please refer to the error code 16 in the test description of the Test #649 for the repair procedure.

i. This error indicates that the Stratum 3 clock has all clock units failed. Please refer to the error code 32 in the test description of the Test #649 for the repair procedure.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Stratum 3 Clock Alarm Query Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Stratum 3 Clock Alarm Query (#649)	X	X	ND

1 D = Destructive; ND = Nondestructive

Stratum 3 Clock Alarm Query (#649)

The Stratum 3 clock provides the system with the following six alarm indications via the TN780 Tone-Clock circuit pack:

1. Reference A failed or CI card A failed.
2. Reference B failed or CI card B failed.
3. One power supply failed.
4. All power supplies failed.
5. One clock unit failed.
6. All clock unit(s) failed.

This test queries the Stratum 3 clock for its alarm status (through the TN780 Tone-Clock circuit pack) and reports the results of the query.

WARNING:
The removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query

Error Code	Test Result	Description/ Recommendation
1001	ABORT	The system could not allocate the necessary resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	This test aborts when it is run on a Stratum 4 system. Do not change synchronization to Stratum 3 without consulting the synchronization plan administrator for this switch.

Continued on next page

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	Either Reference A failed or CI card A failed. This condition usually indicates a failure of the DS1 reference; however, there may also be a failure of the CI card to which the reference is connected. System Technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure. If you are NOT ON-SITE, use the following procedure: 1. Look for DS1-BD (DS1 Interface Circuit Pack) errors using the **display error** command. Refer to the DS1-BD Maintenance documentation for recommended strategy to resolve any DS1-BD errors found. 2. If there are no DS1-BD errors OR after resolving all DS1-BD errors, issue the **test synchronization r 4** command to determine if the alarm is still present. If all repetitions of the tests pass, then the alarm no longer exists. Otherwise, system technician should be dispatched with a spare CI card to use the following instructions on-site. If you are ON-SITE, use the following procedure: 1. Look for a red LED on CI card A (that is, the left CI card). If there is a red LED, then replace the CI card, if a spare is available. If no spare CI is available on-site, proceed to Step 3. If after replacing the CI card, the red LED on the new CI card lights also, then proceed to Step 3. 2. If a spare CI card is available, replace the suspect CI card. Otherwise, issue the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures.

Continued on next page

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query — *Continued*

Error Code	Test Result	Description/ Recommendation
1 *(cont'd.)*	FAIL	3. Look for DS1-BD (DS1 Interface Circuit Pack) errors using the **display error** command. Refer to the DS1-BD Maintenance documentation for recommended strategy to resolve any DS1-BD errors found. If there are no DS1-BD errors, proceed to Step 5. 4. After all DS1-BD errors have been resolved, determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. 5. Check the DS1 reference A connections to the Stratum 3 clock. 6. Determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.
2	FAIL	One power supply failed. This error only occurs when the Stratum 3 clock has two power supplies, and one of them has failed. However, the clock can function with one power supply. 1. Locate the failed power supply by looking for a power supply with a red LED and replace it. 2. Determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, then follow the procedures for those test failures. If the problem persists after you have performed this procedure three times, then follow normal escalation procedures.

Continued on next page

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query — *Continued*

Error Code	Test Result	Description/ Recommendation
4	FAIL	One clock unit failed. 1. Look at the Stratum 3 cabinet for a red LED on a circuit card marked "ST3." Replace the card. 2. Determine if the alarm still exists by issuing the **test synchronization r 4** to clear the alarm. If any test repetitions fail, follow the procedures for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.
8	FAIL	Reference B failed or CI card B failed. This condition usually indicates a failure of the DS1 reference; however, there may also be a failure of the CI card to which the reference is connected. System Technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure. If you are NOT ON-SITE, use the following procedure: 1. If there are no DS1-BD errors OR after resolving all DS1-BD errors, issue the **test synchronization r 4** command to determine if the alarm is still present. If all repetitions of the tests pass, the alarm no longer exists. Otherwise, system technician should be dispatched with a spare CI card to use the following instructions on-site. If you are ON-SITE, use the following procedure: 1. Look for a red LED on a CI card B (the right CI card). If there is a red LED, replace the CI card, if a spare is available. If no spare CI is available on-site, proceed to Step 3. If after replacing the CI card, the red LED on the new CI card lights also, proceed to Step 3. 2. Otherwise, issue the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures.

Continued on next page

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query — *Continued*

Error Code	Test Result	Description/ Recommendation
8 *(cont'd.)*	FAIL	3. Look for DS1-BD (DS1 Interface Circuit Pack) errors using the **display error** command. Refer to the DS1-BD Maintenance documentation for recommended strategy to resolve any DS1-BD errors found. If there are no DS1-BD errors, proceed to Step 5. 4. After all DS1-BD errors have been resolved, determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. 5. Check the DS1 reference A connections to the Stratum 3 clock. 6. Determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.
16	FAIL	All power supplies failed. 1. Replace the failed power supplies. 2. If battery backup for the Stratum 3 clock is not supplied or if the battery backup holdover time has been exceeded, the system references the local oscillator on the Active TN780 Tone-Clock circuit pack until software detects one or both power supplies has(have) been restored (approximately 40 minutes). To speed up this restoration, issue the **test synchronization r 4** command. All tests should pass. If any repetitions should fail, follow the procedures for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.

Continued on next page

Table 11-328. TEST #649 Stratum 3 Clock Alarm Query — *Continued*

Error Code	Test Result	Description/ Recommendation
32	FAIL	All clock unit(s) failed. 1. Look at the Stratum 3 cabinet for red LEDs on circuit cards marked "ST3." Replace the card(s). 2. Determine if the alarm still exists by issuing the **test synchronization r 4** command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.
2101	FAIL	The TN780 Tone-Clock circuit pack detects loss of signal. Refer to Note (b) of the STRAT-3 Hardware Error Log Entries table in the STRAT-3 (Stratum 3 Clock) Maintenance documentation for replacement procedures.
	PASS	The Stratum 3 clock has reported that it has no alarm conditions. If synchronization problems have been reported, look for SYNC errors and refer to SYNC (Synchronization) Maintenance documentation for recommended strategy for those errors.

SVC-SLOT (Service Slot)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SVC-SLOT	MINOR	none	Service Slot

The Service Slot maintenance object is used to detect when an invalid circuit pack is inserted into a SERVICE slot. The SERVICE slot is the leftmost slot in the J58890BB Port Carrier. It is identified as circuit pack slot location "00" in all commands, field entries, and displays used by the system administrator and the service technician.

This slot does not provide tip and ring connectivity to the wall field. Therefore, only the following circuit pack types are allowed in the slot:

- Call Classifier (TN744)
- Integrated Announcement (TN750)
- Maintenance/Test (TN771C)
- Speech Synthesizer (TN725B)
- Tone Detector (TN748C)

A MINOR alarm is generated against the Service Slot maintenance object when a circuit pack of a type other than that included in the previous list is inserted into a SERVICE slot.

The Service Slot maintenance object name is used instead of the maintenance object name for the illegal circuit pack to prevent any attempt to assign a port to an illegal circuit pack that is physically inserted into the SERVICE slot.

Hardware Error Log Entries and Test to Clear Values

Service Slot Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
600 (a)		None	MINOR	ON	

Notes:

a. This error type indicates that a circuit pack type other than one of the following types was inserted into slot 00 (SERVICE slot) of the J58890BB port carrier.

- Call Classifier (TN744)
- Integrated Announcement (TN750)
- Maintenance/Test (TN771C)
- Speech Synthesizer (TN725B)
- Tone Detector (TN748C)

The code of the invalid circuit pack can be displayed by using the **list configuration board UUCSS** command, where "UU" is the universal cabinet number, "C" is the carrier number, and "SS" is the slot number (always 00) of the alarmed circuit pack.

Remove the invalid circuit pack to retire the alarm.

SW-CTL (Switch Control)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SW-CTL	MINOR	test network-control a/b sh	Switch Control
SW-CTL	MAJOR	test network-control a/b sh	Switch Control

The Switch Control resides on the TN777 Network Control (Netcon) circuit pack. The data channels (DATA-BD and DATA-CHL) also reside on the Netcon circuit pack. Standard systems have a single Netcon circuit pack and High and Critical Reliability systems have a Netcon circuit pack in each SPE complex. The Netcon in a standard system cannot be replaced without bringing the system down. The Netcon in the standby SPE of a High or Critical Reliability system can be changed without affecting normal system operation.

The Switch Control is used to send control information between port circuit packs and the processor (see Figure 11-96). This control information is sent via the PPN cabinet's Time Division Multiplex (TDM) Bus. The portion of the TDM Bus used to transmit control messages is called the control channel. The control channel can be on either TDM Bus A or TDM Bus B, but only one bus is used for the control channel at any given time.

The Switch Control is critical in the setup and takedown of all calls but is not involved in the voice or data transmission that takes place during established calls. It is the Switch Control that detects when port circuit packs are plugged into or removed from the PPN cabinet. This information is then sent to the processor. The Switch Control monitors the health of the control channel on the PPN cabinet TDM Bus and informs the processor when errors occur.

The Switch Control contains the hardware Time of Day (TIME-DAY) clock that the system uses for all its date and time information. In addition, the Switch Control also contains hardware to monitor critical system timing signals and informs the processor when these signals fail. For example, if the timing signals from a Tone-Clock circuit pack in the PPN cabinet fail, the Switch Control informs the processor, and the processor can switch in a spare Tone-Clock circuit pack, if one is available (High or Critical Reliability system).

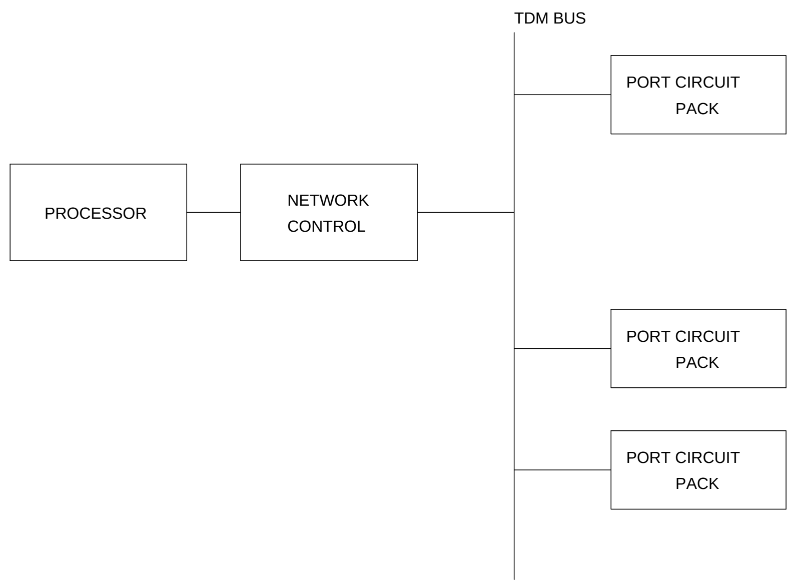

Figure 11-96. Switch Control Connectivity

Hardware Error Log Entries and Test to Clear Values

Switch Control Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test network-control a/b sh r 1
1	Any	Control Channel Test (#94)	MAJOR	ON	test network-control a/b r 3
2 (a)		Control Channel Test (#94)	MAJOR	ON	test network control a/b r 3
257 (b)	0 or 1	None			
513	(c)	Time of Day Clock Test (#95)	MINOR	ON	test network-control a/b l r 3
769 (d)	Any	None			
1025		Switch Control Loop Around Test (#92)	MAJOR	ON	test network-control a/b r 3
1281 (e)	Any	None			
1537		Switch Control Reset Test #93	MAJOR	ON	test network-control a/b l r 2
1793 (f)	Any	None			
2817		MCD Loop Around Test (#324)	MAJOR	ON	test network-control a/b r 2
3073		MCD Memory Test (#325)	MAJOR	ON	test network-control a/b r 3
3329 (g)		None	MAJOR	ON	(g)

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. This error may not cause a Switch Control alarm if Error Type 769 is also present since this error may actually be caused by the loss of clock signals and not by a Switch Control failure.

b. The 257 errors are reported to the processor by the Switch Control and indicate possible hardware problems on the Network Control circuit pack. The receipt of these errors causes Switch Control maintenance to run specific Switch Control tests. If there really is a problem, the Switch Control tests usually causes other errors to be logged. In the rare case where no other errors are logged but 257 errors are occurring at a high rate (more than 10 in the last hour), the Network Control circuit pack should be replaced at the customer's convenience.

c. If the Aux Data is less than 100, the test may have been interrupted by LMM operations. Wait one minute, then test again. Retry the test a maximum of three times. If the Aux Data is more than 100 or fails two out of three times with Aux Data less than 100, the Netcon circuit pack needs to be replaced.

d. A 769 error occurs when the Switch Control reports a loss of timing signals to the processor. When this error is present, the Switch Control is usually not alarmed since any Switch Control test failures are really the result of faulty signals from the PPN cabinet Tone-Clock circuit pack. See TDM-CLK (TDM Bus Clock) Maintenance documentation for the procedures needed to diagnose Tone-Clock circuit pack troubles.

e. This error indicates a loss of handshake between SW-CTL and the system software. Look for and resolve all other SW-CTL errors. In the rare case where no other errors are logged, but Error Type 1281 is occurring at a high rate (more than 10 in the previous hour), escalate the problem.

   For G3s, a loss of handshake between Switch Control in Network Control circuit pack (TN777B) and Processor circuit pack (TN786B or TN790) can be caused by the following components: Network Control circuit pack (TN777B), Processor circuit pack (TN786), Processor Interface circuit pack (TN765), Packet Control circuit pack (TN778), and M-BUS.

   Follow these repair steps:

   1. Look for and resolve all other SW-CTL errors.
   2. Look for and resolve all other PI-SCI, PI-BD, and PKT-CTRL errors.
   3. If the error indicates a failure in the Network Control circuit pack, Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions to replace the Network Control circuit pack. Boot the system up after the Network Control circuit pack has been inserted successfully into the control carrier.
   4. If the error of loss of handshake persists after the replacement of the Network Control circuit pack, then refer to Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions to replace the Processor circuit pack.

      Refer to the "Software Upgrade" section in Chapter 5, "Routine Maintenance Procedures", to load the system software from the Memory Card (J58890TG-1 List 3) with the correct software release into the Processor circuit pack. Boot the system up after the system software is successfully loaded into the Processor circuit pack.
   5. If the error of loss of handshake persists after the replacement of the Processor circuit pack, then escalate the problem and consider the replacement of the control carrier. It's possible that the M-bus on the backplane of the control carrier may be defective.

Recommended Repair Kits: Network Control circuit pack (TN777B), Processor circuit pack (TN786B or TN790), and Memory Card (J58890TG-1 List 3) with correct software release.

f. The Aux Data for this error is not meaningful. The 1793 errors are in-line errors that indicate a possible problem with the interface between the Switch Control and the processor. The receipt of these errors causes Switch Control maintenance to run specific Switch Control tests. If there really is a problem, the Switch Control tests usually causes other errors to be logged. In the rare case where no other errors are logged but 1793 errors are occurring at a high rate (more than 10 in the last hour), the Network Control circuit pack should be replaced at the customer's convenience.

g. This error indicates bad clock detection circuitry on the Netcon circuit pack. Replace the Netcon circuit pack according to the control carrier circuit pack replacement procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Switch Control Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Switch Control Reset Test (#93)		X	D
Control Channel Interface Test (#92)	X	X	ND
Control Channel Transmission Test (#94)	X	X	ND
Destructive EPN Maintenance Board Interface Test (#325)		X	D
EPN Maintenance Board Interface Test (#324)	X	X	ND
Time of Day Clock Test (#95)	X	X	ND
Control Channel Loop Around Test (DATA-BD) (#52) (a)	X	X	ND
NPE Audit Test (DATA-BD) (#50) (a)		X	ND
Data Channel Reset Test (DATA-CHL) (#107) (b)		X	D
Data Channel Interface Test (DATA-CHL) (#108) (b)		X	D
Maintenance Loop Around Test (DATA-CHL) (#109) (b)	X	X	ND
Data Channel Crosstalk Test (DATA-CHL) (#110) (b)	X	X	ND
Data Channel Local Loop Back Test (DATA-CHL) (#111) (b)	X	X	ND

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation for a description of these tests.

b. Refer to DATA-CHL (Network Control Channel) Maintenance documentation for a description of these tests.

Control Channel Interface Test (#92)

Loop back messages are sent to the Switch Control via the interface used for control channel messages. The messages are returned to the SPE for verification via the same interface.

Table 11-329. TEST #92 Control Channel Interface Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-329. TEST #92 Control Channel Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
other	FAIL	Messages could not be looped back through the control channel interface. If this is a standard system, the customer probably cannot make or receive calls. 1. This failure could be due to either a Netcon circuit pack hardware failure or the loss of system timing signals. If the Switch Control is alarmed, then a Netcon circuit pack failure should be suspected. If the Switch Control is not alarmed, investigate the possibility of the loss of system timing signals before attempting to replace the Netcon circuit pack. Test #94 also fails if the system timing signals are lost. If Test #94 passes, do not suspect the loss of timing signals. 2. Run the Short Test Sequence several times to make sure that this failure is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes running the Long Test Sequence may clear the problem. If the test is still failing, proceed to Step 3 or 4. 3. If the system is still able to process calls, replace the Netcon circuit pack at the customer's convenience (Standard system) or right away (High or Critical Reliability system). 4. If calls cannot be made, replace the Netcon circuit pack immediately. 5. The procedure for replacing the Network Control circuit pack (DATA-BD) in a High or Critical Reliability system is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The control channel interface between the processor and the Switch Control is working correctly.

Switch Control Reset Test (#93)

This test is destructive.

This test resets the Switch Control and determines if it can successfully go through its initialization sequence. The test is destructive since there is the possibility of losing some control messages to or from port circuit packs.

Table 11-330. TEST #93 Switch Control Reset Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to Standby SPE Maintenance documentation for a description of these error codes.

Table 11-330. TEST #93 Switch Control Reset Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000 or None	FAIL	The Switch Control could not be successfully reset. If this is a standard system, the customer probably cannot make or receive calls. 1. This failure could be due to either a Network Control circuit pack hardware failure or the loss of system timing signals. If the Switch Control is alarmed, then a Network Control circuit pack failure should be suspected. If the Switch Control is not alarmed, then investigate the possibility of the loss of system timing signals. See TDM-CLK (TDM Bus Clock) Maintenance documentation. If many port circuit pack LEDs are lit, suspect a TDM Bus Clock problem. If only the Network Control circuit pack LED is lit, suspect the Network Control circuit pack. If the Network Control circuit pack is determined to be at fault, proceed to Step 2. 2. If the system is still able to process calls, replace the Netcon circuit pack at the customer's convenience (Standard system) or right away (High or Critical Reliability system). 3. If calls cannot be made, replace the Netcon circuit pack immediately. 4. The procedure for replacing the Netcon circuit pack in a High or Critical Reliability system is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The Switch Control has initialized correctly. Look at results of the other tests to see if it is operating correctly.

Control Channel Transmission Test (#94)

Control channel messages are sent from the SPE to selected port circuit packs and the response from the port circuit packs is checked. This tests the ability of the Switch Control to send and receive messages on the control channel of the TDM Bus.

This test cannot run on the Standby SPE Switch Control. Therefore, it is possible to have defective hardware on the Standby Network Control circuit pack that is not detectable.

Table 11-331. TEST #94 Control Channel Transmission Test

Error Code	Test Result	Description/ Recommendation
0	ABORT	The port circuit packs necessary for this test are not available. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test keeps aborting for this reason, then the Network Control circuit pack should be replaced.
1030	ABORT	The Switch Control on the Standby SPE is being tested. 1. For recommended maintenance procedure, refer to ABORT Error Code 1030 in STBY-SPE Maintenance documentation.
2012	ABORT	Internal System Error.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.

Continued on next page

Table 11-331. TEST #94 Control Channel Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	FAIL	The Switch Control cannot communicate on the TDM Bus control channel. The customer probably cannot make or receive calls. 1. Run the Short Test Sequence several times to make sure this failure is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes, running the Long Test Sequence may clear the problem. Remember that the Long Test Sequence is **destructive**. Placing and receiving calls is affected for several seconds. 2. If there are no TDM Bus alarms against the Standby TDM Bus, switch the control channel from its current bus to the Standby bus. If this test passes on the new bus, investigate the possibility of TDM Bus failures. If the test fails even after the control channel is switched to the standby TDM Bus, proceed to Step 3 or 4. 3. If the system is still able to process calls, replace the Netcon circuit pack at the customer’s convenience (Standard system) or right away (High or Critical Reliability system). 4. If calls cannot be made, replace the Netcon circuit pack immediately. 5. The procedure for replacing the Netcon circuit pack in a High or Critical Reliability system is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The Switch Control can communicate with the port circuit packs over the TDM Bus.

Time of Day Clock Test (#95)

The short term accuracy of the Time of Day (TIME-DAY) clock is tested. The test reads the clock once, waits a short time, and reads the clock again. The second reading of the clock must be within certain limits relative to the first reading for the test to pass. The **display time** command can be used to display the current setting of the TIME-DAY clock.

Table 11-332. TEST #95 Time of Day Clock Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The test was interrupted by a higher priority task. 1. Rerun the test at one-minute intervals a maximum of five times. 2. If the test aborts five times, wait until the system is less heavily used and rerun the test at that time. 3. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
2012	ABORT	Internal System Error.
2013	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-332. TEST #95 Time of Day Clock Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2001	FAIL	The Time of Day clock could not be read. 1. Run the **set time** command and set the time to the current time. 2. Run the Short Test Sequence several times to determine if setting the time corrected the error. Proceed to Step 3 if the error is still occurring. 3. Replace the Netcon circuit pack at the customer's convenience (Standard system) or right away (High or Critical Reliability system).
other	FAIL	The accuracy of Time of Day clock is not within limits. 1. Run the Short Test Sequence several times to make sure the error is occurring consistently. 2. Replace the Network Control (DATA-BD) circuit pack at the customer's convenience (unduplicated system) or right away (High or Critical Reliability system). 3. The procedure for replacing the Network Control (DATA-BD) circuit pack is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The Time of Day clock on the Switch Control circuit pack is operating correctly.

Switch Control EPN Maintenance Board Interface Test (#324)

Loop back messages are sent to the Switch Control via the interface used for EPN maintenance circuit pack messages. The messages are returned to the SPE for verification via the same interface.

Table 11-333. TEST #324 Switch Control EPN Maintenance Board Interface Test

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The system does not contain an EPN so this test is not executed.
1030	ABORT	The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. 1. For recommended maintenance procedure, refer to ABORT Error Code 1030 in STBY-SPE Maintenance documentation.
32400	ABORT	Test disabled via software patch. 1. Escalate to the next tier level for instructions on enabling test.
2012 32413 32416 32423 32425	ABORT	Internal System Error.
2013 32411 32421	ABORT	Could not allocate the necessary system resources to run test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
32414 32417 32424 32427	ABORT	The messages failed to return (timed out) and were not verified. 1. Retry the command at one-minute intervals for a maximum of five retries. 2. If the test continues to abort and SW-CTL Test #325 passes, there is not a problem, but if SW-CTL Test #325 fails, follow the recommendations for SW-CTL Test #325.

Continued on next page

Table 11-333. TEST #324 Switch Control EPN Maintenance Board Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to Standby SPE Maintenance documentation for a description of these error codes.
	ABORT	Refer to STBY-SPE Maintenance documentation for a description of these error codes.
any	FAIL	This failure indicates that communications with the Maintenance circuit pack in the EPN is probably not possible. The EPN Manager I may not be usable. 1. Run the Short Test Sequence several times to make sure the error is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes running the Long Test Sequence may clear the problem. Remember the Long Test Sequence is **destructive**. Placing and receiving calls is affected for several seconds. 2. Replace the Netcon circuit pack whenever it is convenient for the customer (unduplicated system) or right away (High or Critical Reliability system). 3. The procedure for replacing the Netcon circuit pack is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The EPN Maintenance circuit pack interface between the processor and the Switch Control is working correctly. Test #325 is a more thorough test of this interface but it is **destructive**.

Switch Control Destructive EPN Maintenance Board Interface Test (#325)

This test is destructive.

This test writes test patterns into the EPN Maintenance circuit pack interface and verifies that it can read back these test patterns successfully. Messages to or from the EPN Maintenance circuit pack can be lost when this test is run.

Table 11-334. TEST #325 Switch Control Destructive EPN Maintenance Board Interface Test

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The system does not contain an EPN so this test is not executed.
32500	ABORT	Test disabled via software patch. 1. Escalate to the next tier level for instructions on enabling test.
2013 32511	ABORT	Could not allocate the system resources to run for this test.
2012 32513 32514	ABORT	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1029 2014 2015 2016 2017 2018 2020 2022 2024 2025 2051	ABORT	Refer to Standby SPE Maintenance documentation for a description of these error codes.

Table 11-334. TEST #325 Switch Control Destructive EPN Maintenance Board Interface Test — *Continued*

Error Code	Test Result	Description/ Recommendation
32515	FAIL	This failure indicates that communications with the Maintenance circuit pack in the EPN is probably not possible. The EPN Manager I may not be usable. 1. Run the Long Test Sequence several times to make sure the error is occurring consistently. Remember the Long Test Sequence is **destructive**. Placing and receiving calls is affected for several seconds. 2. Replace the Netcon circuit pack whenever it is convenient for the customer (unduplicated system) or right away (High or Critical Reliability system). 3. The procedure for replacing the Netcon circuit pack is described in Chapter 8, "Reliability Systems: A Maintenance Aid". The procedure for doing the same in systems without High or Critical Reliability is described in Chapter 5, "Routine Maintenance Procedures".
	PASS	The EPN Maintenance circuit pack interface between the processor and the Switch Control is working correctly.

(Synchronization)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SYNC	MAJOR	display errors	Synchronization Maintenance
SYNC	MINOR	display errors	Synchronization Maintenance
SYNC	WARNING	test synchronization	Synchronization Maintenance

The Synchronization Maintenance is composed of both hardware and software components and its purpose is to provide a common reference frequency for reliable digital communication between Generic 1 systems and other PBXs, COs or CPE. Synchronization is achieved via the use of several system components which include the Tone-Clock (TN768 or TN780), the DS1 Interface (TN722, TN767 or TN464 [G3iV2-386]), and the Expansion Interface (TN776 or TN570) circuit packs. Synchronization is achieved between the Processor Port Network (PPN) and the Expansion Port Networks (EPNs) via the Expansion Interface Link (EXP-LINK) between the networks. The TN570 and TN780 circuit packs are supported by G3iV1.1-286 and G3iV2-386. Depending on the network synchronization plan and the status of synchronization sources, the system timing reference may be a Tone-Clock circuit pack, DS1 interface circuit packs or an external Stratum 3 clock. Stratum 4 synchronization extracts timing information directly from a DS1 reference or from a Tone-Clock. Stratum 3 synchronization requires the use of a Stratum 3 clock which provides a timing signal, derived from DS1 references, to the TN780 Tone-Clock circuit pack. The external Stratum 3 clock is a more stable timing source than the Stratum 4 clock and provides 24-hour holdover in case of reference failures. The Stratum 3 clock has redundant components. Stratum 3 synchronization is available as an option for G3iV1.1-286 and G3iV2-386. Synchronization maintenance in DEFINITY Generic 1 is the same as that for G3iV1.1-286 and G3iV2-386 except for the use of Error Types 1793 and 2305, the support of the second EPN, and the Stratum 3 clock.

Stratum 4 Synchronization

The system can be configured with primary and secondary synchronization references (DS1 interface circuit packs) when using Stratum 4 synchronization. Both references are optional (since the local oscillator can be used), and the secondary reference is optional if a primary is provided. If this system is the master for the network, then its local oscillator would be used and no DS1s would be used as references.

If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference. If the secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, a Tone-Clock circuit pack provides the system timing source. The system does not revert to the primary if the current reference is the secondary and is failing; however the system switches from the local oscillator to another reference when the new reference becomes available. The following diagram should assist in understanding Stratum 4 Synchronization Maintenance components within the system. This diagram depicts a possible Generic 1.2 configuration; DEFINITY Generic 1 does not support two EPNs, but the operation and maintenance described below is the same except for the references to multiple EPNs.

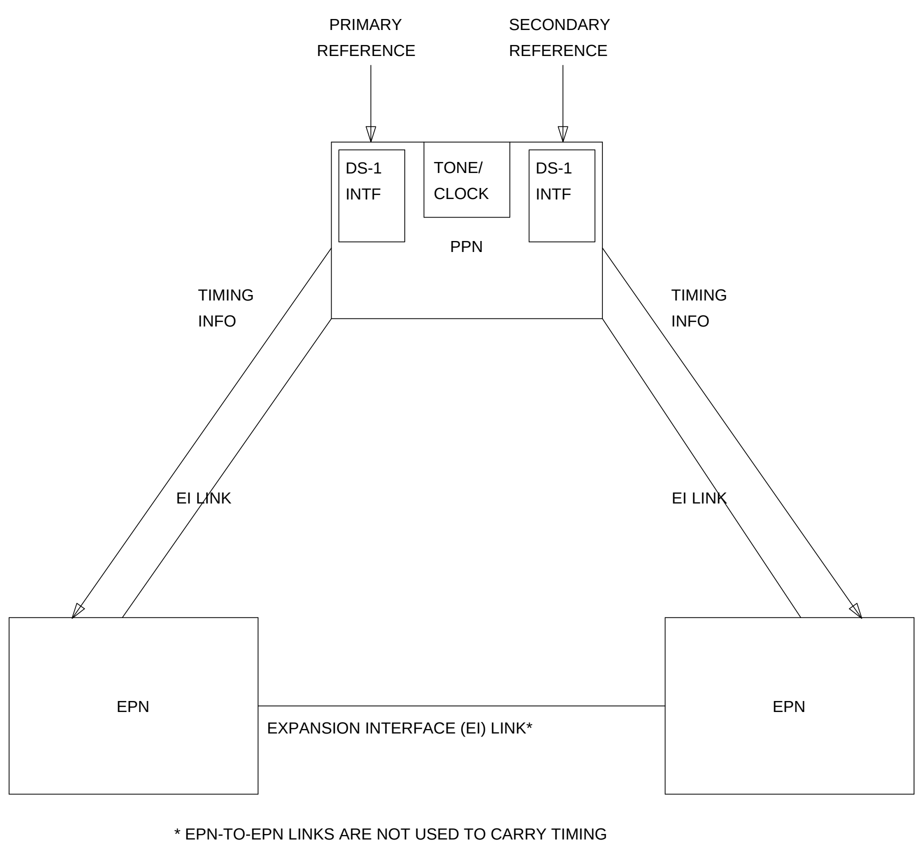

Figure 11-97. Typical Stratum 4 Synchronization Configuration

If the primary synchronization reference in the previous diagram is providing a valid timing signal, then the flow of system synchronization would travel from the

DS1 interface circuit pack in the PPN across the active Expansion Interface fiber link to the two EPNs. The PPNDS1 interface circuit pack provides a timing signal for the PPN Tone-Clock circuit pack and the PPN Tone-Clock circuit pack provides timing for all circuit packs in the PPN. The PPN Expansion Interface circuit pack uses the timing generated by the Tone-Clock circuit pack to generate a data stream which is sent across the Expansion Interface link to the Expansion Interface circuit packs in the two EPNs. The EPN Expansion Interface circuit pack uses the received data stream to generate a timing signal. The Tone-Clock circuit pack in the EPNs uses this signal to generate timing for all the circuit packs in their respective EPNs. The PPN, in the above mentioned scenario, is designated the *master* port network and the EPNs are called *slave* port networks. The *master* port network is defined as the port network that contains the system synchronization source. If the primary synchronization reference does not provide a valid timing signal, Synchronization Maintenance switches to the secondary reference. **Both the primary and secondary references must reside in the same port network, but there is no restriction as to in which port network both must reside (that is, both references may be in an EPN). The recommended placement of the references is in the PPN.**

There are two kinds of Stratum 4 synchronization that are supported: Type I and Type II. Stratum 4 type I is more stable than Type II and provides some switching capability at the hardware level. Stratum 4 Type II operation is the only synchronization strata provided by Generic 1. It is important to note that Stratum 4 Type I operation is not possible when one or both of the DS1 interface circuit packs providing the reference sources is a TN722. Both must be the TN767 or TN464 (suffix C or higher) [G3iV2-386].

Stratum 3 Types I and II are available with Generic 1, G3iV1.1-286, and G3iV2-386 systems. Stratum 4 Type I is not available for pre-Generic 1 releases. Both Type I and Type II operation are possible with the TN768 and TN780 Tone-Clock circuit packs.

Stratum 3 Synchronization

The following diagram may help you to understand the synchronization components needed for Stratum 3 synchronization.

NOTE:
This is only one possible configuration.

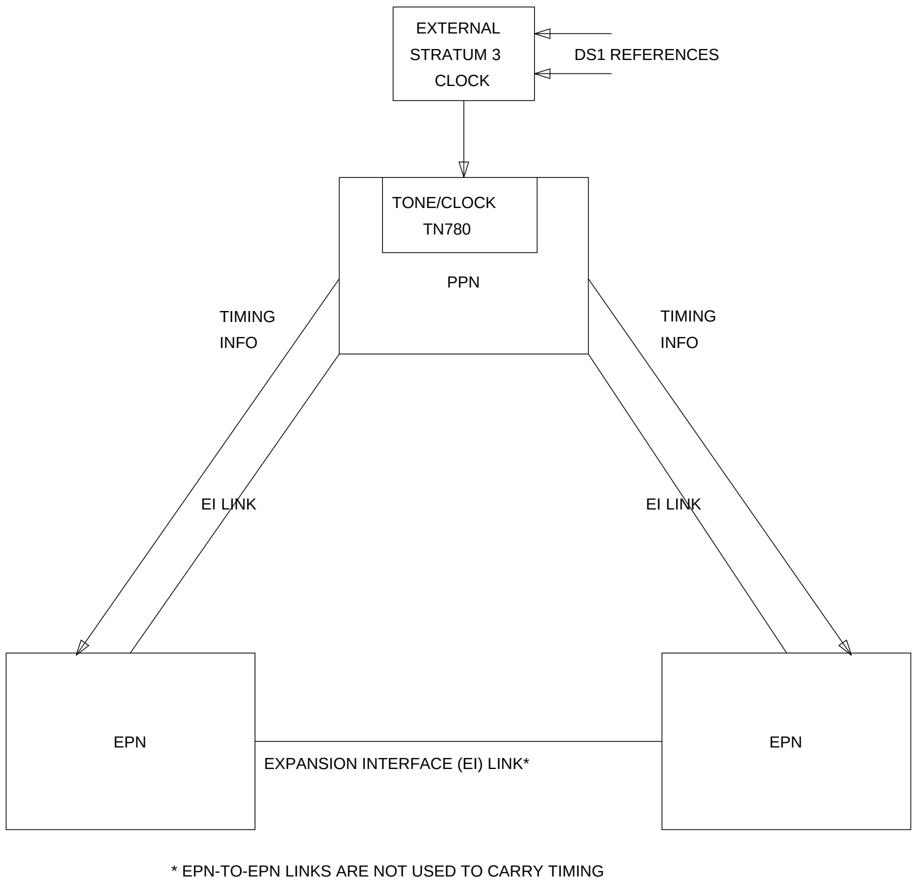

Figure 11-98. Example Stratum 3 Synchronization Configuration

For Stratum 3 synchronization, an external clock provides a timing signal to a TN780 Tone-Clock circuit pack, and the TN780 provides timing to all circuit packs in the port network in which the TN780 resides (that is, the PPN in the previous diagram). The PPN Expansion Interface circuit pack uses the timing generated by the TN780 to generate a data stream which is sent across the two Expansion Interface Links to the two EPNs to the EPN Expansion Interface circuit packs. The EPN Expansion Interface circuit packs use the received data stream to generate a timing signal which is used by the Tone-Clock circuit packs in the EPNs to provide timing for all circuit packs in both EPNs. (The Tone-Clock circuit pack is not necessarily a TN780; only the Tone-Clock circuit pack connected to the external Stratum 3 clock must be a TN780.) The PPN, in the above mentioned scenario, is designated the *master* port network and the EPNs are called *slave* port networks. The *master* port network is defined as the port network whose Tone-Clock is connected to the Stratum 3 clock.

NOTE:
The Stratum 4 equipment (usually a PBX) should never provide timing to a Stratum 3 PBX.

NOTE:
The external Stratum 3 clock may be connected to the TN780 Tone-Clock in any port network. However, it is recommended that it be connected to the PPN.

Synchronization Troubleshooting

For both Stratum 3 and 4 operation, major and minor alarms indicate that there is a problem with the system synchronization references. These alarms are resolved when the alarmed synchronization reference is restored.

The **status synchronization** and **display synchronization** commands are used to determine the current system synchronization reference and the primary and secondary references that are administered respectively.

Other commands associated with Synchronization Maintenance are **disable synchronization-switch** and **enable synchronization-switch.** These commands are used to disable the ability of Synchronization Maintenance to switch between synchronization references and to enable this switching ability, respectively. The **set synchronization** command is executed only after synchronization has been disabled and is used to manually switch to a specific synchronization reference. This command is useful to diagnose synchronization problems by forcing a specific reference (DS1 or Tone-Clock) to be the system synchronization reference to determine if a specific reference is providing a valid timing signal. For Stratum 3 operation, only a TN780 Tone-Clock circuit pack may be specified. To switch synchronization to the Stratum 3 clock, use the **enable synchronization-switch** command after verifying that the Stratum 3 clock is wired correctly.

The system synchronization planner must avoid creating a *timing loop* when administering the primary and secondary synchronization references in a system. A timing loop exists whenever a system receives timing from another system whose timing reference is directly or indirectly derived from itself. Timing loops can lead to loss of digital data between systems that are exchanging data with any system within the loop. An invalid timing signal is also generated by any system within the loop, thus propagating the invalid timing signal to any system(s) using a system within the loop as a synchronization reference. Figure 11-99 shows a timing loop and a correct distribution of timing between the systems.

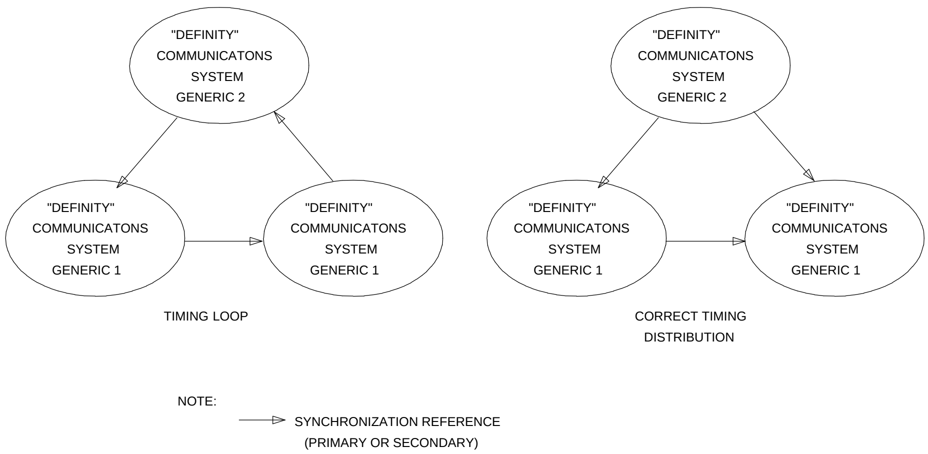

Figure 11-99. Synchronization Timing Loop

A correctly designed network has no loops and each piece of equipment in the network is supplied by a clock of equal or lower stratum (that is, the inputs to a Stratum 3 clock should NEVER be from a Stratum 4 device). **It is strongly recommended that the network administrator be consulted before administering any synchronization changes.**

The yellow LEDs of the TN768 and 780 Tone-Clock circuit packs flash in a specific pattern to indicate the status of the circuit pack. These flashing LED patterns are used to indicate if a Tone-Clock circuit pack is deriving timing from an external source or whether the Tone-Clock circuit pack is providing the timing signal for the port network. The yellow LED patterns for the TN768 and 780 Tone-Clock circuit packs are as follows:

1. Yellow LED is on 2.7 seconds and off .3 seconds—This light pattern indicates that an external timing source is being used as a synchronization reference and the circuit pack is in Active mode.
2. Yellow LED is on .3 seconds and off 2.7 seconds—This light pattern indicates that the local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference and the circuit pack is in Active mode.
3. Yellow LED stays on—This light pattern indicates that the circuit pack has been reset but no translation has been downloaded. This pattern indicates the circuit pack is providing clocks and is in Active mode.
4. Yellow LED off is an indication that the Tone-Clock circuit pack is in Standby mode (neither generating tones nor supplying clocks).

5. The following two patterns may occur when the circuit pack is either in Active or Standby mode. The best approach to determine the mode of the circuit pack is to use the **status system** system technician command.

   - Maintenance running on the Standby circuit pack is indicated by the following pattern (yellow and green LEDs flashing): LED on .1 seconds, off for .2 seconds, on for .1 seconds, off for .4 seconds, on for .4 seconds, off for .4 seconds.

   - Green flashing and yellow flashing in a pattern different than the previously mentioned pattern indicates that maintenance is running on the Active circuit pack.

Hardware Error Log Entries and Test to Clear Values

Synchronization Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test synchronization
1 (a)[1]	Any	None	WARNING/ MINOR(j)[2]	OFF	None
18 (b)	0	disable sync	WARNING	OFF	enable sync
257 (c)[1]	Any	None	WARNING/ MINOR(j)[2]	OFF	None
513 (d)[1]	Any	None	WARNING/ MAJOR(j)[2]	OFF	None
769 (e)		None	MAJOR/ WARNING[3]	OFF	None
1793 (f)[4]	0-50	None	MAJOR/ WARNING	OFF	enable sync
2049 (g)(i)[4]	0	None	WARNING	OFF	None
2305 (h)(i)[4]	0	None	WARNING	OFF	None

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This error type initially raises a Warning alarm. If this error type persists and alarms are not downgraded on this MO due to the value of **set options**, then, after a period of time, a Minor or Major alarm is raised.

3 Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

4 It may take up to one hour for these SYNC alarms to clear due to "leaky bucket" strategy.

Notes:

a. This error indicates a problem with the primary DS1 reference. It is cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:

1. Check if the primary DS1 interface circuit pack is inserted in the carrier via the **list configuration board PCSS** command.
2. Check the connection of the cable supplying the external timing source to the primary DS1 interface circuit pack.
3. Test the primary DS1 interface circuit pack via the **test board PCSS long** command. Check the Error Log for DS1-BD errors and refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation to resolve any errors associated with the primary

DS1 interface circuit pack. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.

4. Test the active Tone-Clock circuit pack in the master port network via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.
5. Execute the **disable synchronization-switch** and the **enable synchronization-switch** commands. These two commands (when executed together) switch the system synchronization reference to the primary DS1 interface circuit pack. Check the Error Log and execute the **status synchronization** command to verify that the primary DS1 interface circuit pack is still the system synchronization reference. If the primary DS1 interface circuit pack is not the system synchronization reference, and this is not a High or Critical Reliability system, escalate the problem. If not, continue with the following step.
6. **High or Critical Reliability system:**

   Switch Tone-Clock circuit packs on the master port network via the **set tone/clock PC** command, and repeat the disable/enable commands described in the previous step. If the problem still persists, follow normal escalation procedures.

b. This error indicates that Synchronization Maintenance has been disabled via the **disable synchronization-switch** command. Execute the **enable synchronization-switch** command to enable Synchronization Maintenance reference switching and to resolve this alarm.

c. This error indicates a problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting **secondary** for **primary** in the preceding resolution steps.

d. This error indicates that the Tone-Clock circuit pack is providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.

e. This error indicates that the external Stratum 3 Clock fails to provide the system timing reference. Refer to Stratum 3 Clock Maintenance document to resolve the defective synchronization reference.

f. **In Generic 1.1**:

   This error indicates excessive switching of system synchronization references has occurred. When this error occurs, synchronization is disabled and the Tone-Clock circuit pack (in the master port network) becomes the synchronization reference for the system. Execute the following steps to resolve this error:

1. Check for timing loops and resolve any loops that exist.
2. Test the active Tone-Clock circuit pack in the master port network via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.
3. **High or Critical Reliability system:** Switch Tone-Clock circuit packs on the master port network via the **set tone/clock PC** command.

   Standard system: Replace the primary and secondary (if administered) DS1 Interface circuit packs.
4. Check for an error logged against the primary or secondary DS1 board. If there is an error, follow the DS1 section to resolve the errors. If there is not, enter **enable sync**, and wait for two to five minutes for the primary sync source to come on-line.
5. If the problem still persists, escalate the problem.

   In Generic 3i: This error indicates that some reference switches have occurred. If there is not a major SYNC alarm, then investigate other SYNC errors. If there is an active major SYNC alarm, and if this is not a Stratum 3 system, then follow the steps for Generic 1.

g. This error indicates that the Expansion Interface Link is experiencing timing slips. The two port networks are not synchronized. This error increases the bit error rates for data transmission between port networks. Verify that all the TDM/LAN Bus cables on the backplane are AT&T Parts number AT&T SK00199-001 rather than flat ribbon cables. Also, check that the bus terminators are the ZAHF V1 TDM/LAN Bus Terminator type. Refer to note (i) for error resolution steps.

   This error is cleared by a leaky bucket strategy and takes one hour to clear (leak away) the error counter once it is alarmed. Therefore, it may take up to one hour to clear the alarm after the problem is cleared.

h. This error indicates that the slave Tone-Clock circuit pack is experiencing loss of signal. Refer to note (i) for error resolution steps.

i. The following steps should be executed to resolve error 2049 and 2305:

1. Check for timing loops, and resolve any loops that exist.
2. Check the Error Log for any active as well as resolved Expansion Interface circuit pack errors and refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation to resolve any errors found.
3. **High or Critical Reliability system:**

- Switch Tone-Clock circuit packs in the slave port network via the **set tone/clock PC** system technician command. The error count for this particular error should start decrementing once the problem is solved—if the count does not decrease in 15 minutes the problem still persists.
- If the problem still persists, switch the Tone-Clock in the slave port network back to the previous configuration. Then, switch Expansion Interface Links via the **set expansion-link PCSS** command.
- If the problem still persists, switch the Expansion Interface Links back to the previous configuration via the **set expansion-link PCSS**. Then, switch the Tone-Clock circuit packs in the master port network.
- If the problem still persists, switch the Tone-Clock circuit packs in the master port network back to the previous configuration. If the system synchronization reference is a Tone-Clock circuit pack, follow normal escalation procedures. If the system synchronization reference is a DS1 interface circuit pack, administer a different DS1 interface circuit pack as the primary synchronization reference. If the problem still is not resolved, follow normal escalation procedures.

4. **Standard system:**—Error 2049:

- Test the Tone-Clock circuit packs in the master and slave port networks via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.
- If the master and slave Tone-Clock circuit packs **do not** fail TDM Bus Clock Test #150 (PPM Inquiry), replace the Expansion Interface circuit packs in the system.
- If the system synchronization reference is a Tone-Clock circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, follow the steps listed in TDM-CLK (TDM Bus Clock) Maintenance documentation to replace the master Tone-Clock circuit pack.
- If the system synchronization reference is a DS1 interface circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, the primary or secondary (if administered) synchronization references are not providing valid timing signals for the system. Check the system synchronization references administered, and follow the steps outlined in note (a) if the primary synchronization

reference is providing timing for the system or note (c) if the secondary synchronization reference is providing timing for the system.

- If the slave Tone-Clock circuit pack fails the TDM Bus Clock Test #150 but the master Tone-Clock **does not** fail this test, the master Tone-Clock circuit pack must be replaced. Follow the Tone-Clock replacement steps listed in the TDM-CLK (TDM Bus Clock) Maintenance documentation.

  If SLIP errors remain follow SLIP ANALYSIS.

5. **Standard system:**—Error 2305:
   - Replace the Expansion Interface circuit pack in this port network and the Expansion Interface circuit pack in the PPN that is connected to this port network.
   - If the problem persists, replace the Tone-Clock circuit pack in the slave port network. Follow the steps listed in the TDM-CLK (TDM Bus Clock) Maintenance documentation to replace the Tone-Clock circuit pack.
   - If the problem still persists, escalate the problem.

j. Noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a synchronization problem occurs causing error types 1, 257, or 513, a WARNING alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MAJOR or MINOR alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Test Synchronization Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Test Synchronization Test (#417)	X	X	ND

1 D = Destructive; ND = Nondestructive

Test Synchronization Test (#417)

This test updates all the Synchronization Maintenance component circuit packs with the correct information regarding their role in providing synchronization for the system. All the Tone-Clock, Expansion Interface, and DS1 Interface circuit packs in the system are updated via this test. This test will either pass or abort.

Table 11-335. TEST #417 Test Synchronization Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	PASS	The Synchronization Maintenance component circuit pack parameters have been successfully updated. The system should be synchronized after successful execution of this test. If synchronization problems still exist, refer to the Error Log to obtain information regarding the source of the problem.

SYS-PRNT (System Printer)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
SYS-PRNT	MINOR	test sp-link l	System Printer
SYS-PRNT	WARNING	release sp-link	System Printer

The Report Scheduler feature provides the capability to schedule selected administration commands to be printed by an asynchronous System Printer (SYS-PRNT) or sent to a Personal Computer (PC). The System Printer Link to this external device can be administered either as a data extension or to the EIA port on the switch Processor (PROCR) circuit pack which provides a standard EIA 232C interface.

System Printer Link Maintenance provides a strategy for maintaining the link between the system and an external SYS-PRNT output device. The strategy includes a set of tests for detection of errors during normal operation, troubleshooting actions, and alarms for serious problems. System Printer Link Maintenance uses a try-and-wait mechanism for maintaining the SYS-PRNT link. If the link set-up fails, a minor alarm is raised for service attention. A warning alarm is raised when the SPE has been busied out. A maximum of two link retry attempts is made. After the second attempt, set-up attempts are only made by the application software (that is, the 15-minute timer fires and jobs are printed unless an immediate job was entered.) After two unsuccessful attempts to establish the link, a MINOR alarm is raised for service attention. If the System Printer Link is torn down due to an error, System Printer Link Maintenance raises a MINOR alarm but does not attempt to bring up the System Printer Link.

In DEFINITY Generic 1, the following physical configurations are supported for the System Printer Link:

a. from the EIA port on the Processor circuit pack to a SYS-PRNT output device via the standard EIA 232C interface
b. from a data channel (DATA-CHL) on the Network Control circuit pack (DATA-BD) to a data extension where the SYS-PRNT output device connects via the standard EIA 232C interface

The data extension can be a(n) PDM, MPDM, DTDM, or ADU. The PDM, MPDM, or DTDM connects to a Digital Line (DIG-LINE) on the TN754 or TN754B Digital Line circuit pack (DIG-BD); the ADU connects to a Data Line (DAT-LINE) of the TN726 Data Line circuit pack (DT-LN-BD).

System Printer Link Maintenance does not cover the elements comprising the SYS-PRNT physical link; that is, the external SYS-PRNT output device, the EIA port on the Processor circuit pack, the Data Module (PDM/MPDM/DTDM) and the Digital Line of TN754 or TN754B Digital Line circuit pack, the ADU and the Data

Line of TN726 Data Line circuit pack, and the data channels on the TN777 Network Control circuit pack. If System Printer Link Maintenance cannot restore the System Printer Link, the maintenance tests of these individual components of the System Printer Link must be executed to diagnose faults.

Procedures for Restoring the System Printer Link

The following procedures should be followed to restore the System Printer Link:

1. Determine the status of the System Printer Link via the **status sp-link** command. Verify that the System Printer Link is not busied out for maintenance. On the System Printer Link Status Form, this is indicated by a "no" in the "Maintenance Busy?" field. If the System Printer Link has been busied out, issue the **release sp-link** command. If the link is "down," proceed to Step 2.
2. Issue the **display system feature** command to determine the destination of the System Printer Link.

   If the destination is an *extension number*, enter the **status data-module <extension>** command and verify that the data extension is in-service/idle. If the data extension is NOT available, refer to the "Port/Channel Number" field on the "Data-Module Status" Form. Look for errors and/or alarms on the circuit pack with which this extension is associated. Refer to the appropriate MO documentation for recommended repair strategy. Continue with Step 3.

   If the destination is *eia*, look for PR-MAINT errors in the Hardware Error Log. If errors are present, refer to Maintenance/Tape Processor Maintenance documentation, and continue with Step 5.
3. Determine if a data channel on the Network Control circuit pack is in-service/idle as follows:
   a. Use the **list data-module** command to find out the extension numbers of the data channels on the Network Control circuit pack. (There is a maximum of 4. They are listed as "netcon" on the Active SPE. Ignore the Standby data channels.)
   b. Enter the **status data-module <extension>** command to verify that at least one Active data channel is in-service/idle.
4. If four data channels are administered and none are available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If errors are present, refer to these MO sections for recommended maintenance strategy. When problems (if any) with DATA-CHL/DATA-CON/DATA-BD have been resolved, continue with Step 5.

   If fewer than four data channels are administered, then use the **add data-module** command to add a network control data module to the system.
5. Verify the availability of the external SYS-PRNT output device as follows:

Make sure that the SYS-PRNT output device is *on-line* and ready-for-service. Check the physical connectivity between the Data Module and the SYS-PRNT output device or between the EIA port on the backplane of the switch and the SYS-PRNT output device.

6. Verify that there are less than three active logins to the system. If this condition exists, a login session must be terminated before the System Printer Link can be established.
7. If the System Printer Link still cannot be restored, escalate the problem.

NOTE:
It is recommended that the System Printer Link be busied out before executing maintenance tests over objects which compose the System Printer Link. If the System Printer Link is busied out, then all System Printer Link maintenance actions are deactivated.

Hardware Error Log Entries and Test to Clear Values

SYS-PRNT Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test sp-link
18 (a)	0	busyout sp-link	WARNING	OFF	release sp-link
257 (b)	1 to 6	Link Retry Test (#215)	MINOR/ WARNING[2]	OFF	test sp-link l
513 (c)	0	None	MINOR	OFF	test sp-link

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. System Technician has busied out the System Printer Link.

b. A failure was encountered while attempting to set up the System Printer Link. This attempt could have been initiated by either the Report Scheduler software or link maintenance [automatic link retry or the as the result of a Link Retry Test (#215) request]. The Aux Data field contains the following diagnostic information to aid in the correction of the failure:

   1. unavailability of system resources (too many active logins to the system).
   2. no data channels (DATA-CHLs) available on the Network Control circuit pack (DATA-BD).
   3. 4- time-out during setup attempt. Most likely due to problem with physical link or printer status.
   4. internal system error. Most likely temporary/sporadic failure.
   5. the data module the printer is trying to use is busy with another call. Use the **Status data module** command to determine when the port is available for testing.

   Refer to the "Procedures for Restoring the System Printer Link" section for recommended maintenance strategy.

c. The SYS-PRNT was interrupted because of one of the following reasons:

   1. the cable to the SYS-PRNT output device is disconnected;
   2. the SYS-PRNT output device is powered off;

3. the data extension to which the SYS-PRNT output device connects has been busied out;
4. internal software error.

Check the connectivity of the wires and cables among the wall jacket, data module, and SYS-PRNT output device. Follow the instructions provided in the "Procedures for Restoring the System Printer Link" section.

System Technician-Demanded Tests: Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the table below. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Link Tear Down Test (#213)		X	D
Link Retry Test (#215)	X	X	ND
Link Tear Down Test (#213)	X	X	ND

1 D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

The Link Tear Down Test disconnects the existing link between DEFINITY Generic 1 and the external SYS-PRNT output device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a System Printer Link are released after this test.

Table 11-336. TEST #213 Link Tear Down Test

Error Code	Test Result	Description/ Recommendation
40, 50	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of two times. 2. If the test continues to abort, escalate the problem.
1010	ABORT	The System Printer Link has been busied out. 1. Enter the **release sp-link** command to release the System Printer Link from the busyout state. 2. Reissue the **test sp-link long** command to execute the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of two times. 2. If the test continues to abort, escalate the problem.
	PASS	The System Printer Link is torn down or a Short Test Sequence was executed and the link was not torn down.

Link Retry Test (#215)

The Link Retry Test sends a message to the SYS-PRNT software process either (1) to make a data call to the extension to which the SYS-PRNT output device connects OR (2) to open the EIA port to the SYS-PRNT output device. If the System Printer Link is already up, this test passes without making a data call or opening the EIA port.

Table 11-337. TEST #215 Link Retry Test

Error Code	Test Result	Description/ Recommendation
10, 20	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of two times. 2. If the test continues to abort, escalate the problem.
30	ABORT	Internal System Error. 1. Refer to the "Procedures for Restoring the System Printer Link" section for recommended maintenance strategy.
1010	ABORT	The System Printer Link has been busied out. 1. Enter the **release sp-link** command to release the System Printer Link from the busyout state. 2. Reissue the **test sp-link long** command to execute the test.
	FAIL	The System Printer Link CANNOT be established. 1. Refer to the "Procedures for Restoring the System Printer Link" section for recommended maintenance strategy.
	PASS	The System Printer Link is up.

SYSTEM (System)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
SYSTEM	None	None	SYSTEM

1 SYSTEM only has errors associated with it and thus only appears in the Error Log and not in the Alarm Log. There are no tests that can be run with SYSTEM.

SYSTEM is generally used for two purposes:

1. When software encounters a problem with either hardware or itself and requests a restart to clear the problem, an error is logged under SYSTEM. For example, if there is a loss of clock in a Generic 1 system with High or Critical Reliability, the system asks for a Reset 2 to switch to the other clock.
2. To log errors that cannot be associated with any single process.

   These errors are more for use by software developers in debugging restarts than in pointing to current problems.

   This should not be considered a problem with the system. The initcauses log should also confirm that a software-requested restart was performed.

Hardware Error Log Entries and Test to Clear Values

The Aux Data field may be 0 or the return code from a bad software call, and the following examples in no way exhaust the possibilities. Often, two errors are logged at the same time for each problem.

System Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	None
8 (a)	0	None			
9 (b)	Any	None			
10 (c)	Any	None			
21 (d)		None			
355 (e)	Any	None			
356 (f)	Any	None			
601 (g)		None			
602 (h)		None			
603 (i)		None			
9012 (j)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. A System Restart Level 3 was requested.

b. A System Restart Level 2 was requested. This can happen due to a loss of tones (due to a faulty Tone-Clock circuit pack).

c. A System Restart Level 1 was requested.

d. A process trapped.

e. A Restart Level 2 occurred due to a power loss.

f. A Restart Level 2 occurred due to a tone clock loss.

g. An error occurred during initialization.

h. An error occurred while loading translations and the system requested a Restart Level 3.

i. A process was reset.

j. In a Generic 1 system configured with High or Critical Reliability, a scheduled SPE-interchange was blocked because a tape operation was in progress.

TAPE (Tape Unit) [G3iV1.1-286]

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TAPE	MAJOR	test tape long[1]	Tape Unit
TAPE	MINOR	test tape long	Tape Unit
TAPE	WARNING	test tape long	Tape Unit

1 This alarm occurs only at power-up time or on a Reset System 3, 4, or 5 when the system cannot load **all** translations from tape. Refer to the footnote associated with Error Type 3329 in the "Hardware Error Log Entries and "Test to Clear Values" section.

NOTE:
Alarms on the TAPE, PROCR, and PR-MAINT MOs are indicated by the red LED on the Processor circuit pack.

The Tape Unit consists of a Wangtek FAD3500 series tape drive mounted on the TN774 Tape Drive circuit pack, which is controlled by the TN773 Processor circuit pack. For tape controller functions, the processor uses memory on the TN770 Memory circuit pack.

The Tape Unit is used to:

- Boot the system
- Save or load translations and announcements
- Save the Error Logs
- Save core dumps

There are two versions of the **test tape** system technician command that can be used to initiate maintenance tests on the Tape Unit: one for Standard systems and one for High and Critical Reliability systems. In a Standard system, the command line entry to test the TAPE (Tape) MO is **test tape [short/long] [repeat n/clear]**. In a High or Critical Reliability Option system, the command line entry to test the TAPE (Tape) MO is **test tape [short/long] [a/b] [repeat n/clear]**.

In a High or Critical Reliability system, if an alarm is raised against the Tape Unit, the alarm also indicates the carrier (either 1A or 1B), depending on which SPE has the problem.

NOTE:
CLEANING THE TAPE DRIVE HEAD IS VERY IMPORTANT because a tape drive head with abrasive particles can permanently damage a new tape. In

addition, a worn tape may leave abrasive particles in the tape drive head. Before implementing any of the following repair procedures, the tape head of all the tape drive units in the system should be cleaned. Follow the directions given in the "Tape Drive Head Cleaning Procedure" section.

Hardware Error Log Entries and Test to Clear Values

Tape Unit Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 (a)	0	Any	Any	Any	test tape
1 (b)	Any	Tape Status Test (#69)	MINOR	OFF	test tape r 2
257 (c)	Any	Tape Status Test (#69)	WARNING	OFF	test tape r 2
513	Any	Tape Reset Test (#67)	MINOR	OFF	test tape l r 2
1025	Any	Tape Diagnostic Test (#66)	MINOR	OFF	test tape r 2
1281	Any	Tape Diagnostic Test (#66)	MINOR	OFF	test tape r 3
1537	Any	Tape Diagnostic Test (#66)	MINOR	OFF	test tape r 3
1793 (d)	Any	None	MINOR	OFF	see (d)
1828 (e)	Any	None	MINOR	OFF	see (e)
2049 (f)	Any	None	WARNING	OFF	see (f)
2051 (o)	Any	Tape Read/Write Test (#65)	WARNING	OFF	see (o)
2084 (g)	Any	None	WARNING	OFF	see (g)
2561	Any	Tape DMA Latch Test (#230)	MINOR	ON	test tape r 3
2817 (h)	Any	Tape Read/Write Test (#65)	MINOR	OFF	test tape l r 2
3329 (i)	Any	Save the Translations	MINOR	OFF	see (i)
3841 (j)	Any	Save the Translations	MINOR	OFF	save translation
3842 (k)	Any	Save the Translations	MINOR	OFF	save translation
3843 (l)	Any	Save the Translations	MINOR	OFF	save translation

Tape Unit Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3984(m)	Any	Save Translations	MINOR	OFF	save translation
10498 (n)	0	Save the Translations			
10508 (o)	0	Save the Translations			

Notes:

a. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

b. Error 1 indicates that the tape unit does not recognize that a cartridge is inserted into the tape drive. If, in fact, there is no cartridge in the drive, the problem can be corrected by simply inserting a cartridge. Follow the directions given in "Error Type #1 - Repair Procedure."

   If there is a tape cartridge inserted into the tape drive, the problem is that certain tape or tape drive failures may cause the tape drive to erroneously report "missing tape" errors (tape Error Type #1 OR Aux Data value 9024). Since this error may be the result of a problem with either the tape or the tape drive unit, the tape cartridge should be replaced first. If the problem persists, the tape unit should be replaced. When this error is first detected, follow "Error Type #1 - Repair Procedure."

   Error Type #1 - Repair Procedure:

   1. Replace the tape cartridge (if one exists) in the tape unit associated with this error with a new tape cartridge.
   2. Issue the **test tape [a/b] repeat 2** command for the tape drive unit that has the error.
   3. If all the tests pass, assume that the problem has been resolved.

      If some of the tests fail, resolve the corresponding errors, and repeat step #2.
   4. If translations have not already been saved onto the new tape, issue the **save translations** command.
   5. If the system contains recorded announcements, issue the **save announcements** command.

   If Error Type #1 reappears and becomes a chronic problem, the fault may be with the tape drive unit, and it could be intermittent in nature. In this case, replace the tape drive unit with a new tape drive unit and repeat "Error 1 - Repair Procedure." Refer to Step 5 of the "Tape Maintenance and Repair Procedures" section for directions on how to replace the tape drive unit.

c. Error Type #257 indicates that the tape cartridge is write-protected. To disable the tape write-protect feature, move the sliding write-protect switch (which is labeled RECORD) on the tape cartridge away from the RECORD position. The RECORD position is indicated by an arrow pointing to the left. Error Type #257 can then be cleared by issuing the **test tape [a/b] repeat 2** command for the tape drive unit that has the error.

d. Error Type #1793 is reported whenever the system software detects an uncorrectable tape block error during a read or write operation on the tape.

   An **uncorrectable tape error** is one in which a block error persists during a read or write operation to the tape. Errors of this type were unable to be corrected by several attempts at rereading or rewriting the block on the tape. This type of error is most likely the result of one or more hard errors on the tape (for example, a scratch or a hole in the tape that spans multiple sectors).

   The auxiliary data field indicates the file on the tape in which the error was detected. Refer to Table C for a list of possible auxiliary data field values and the corresponding tape file.

   Since this error may be the result of a problem with either the tape or the tape drive unit, the tape cartridge should be changed first. If the problem persists, the tape unit should be changed. When this error is first detected, follow "Error Type #1793 - Repair Procedure."

   Error Type #1793 - Repair Procedure:

   1. Replace the tape cartridge in the tape unit on which the error occurred with a new tape cartridge.
   2. [G1.2, G3iV1.1-286] Issue the **test tape [a/b] long clear** command for the associated tape drive unit.

      [G1.1] Issue the **test tape [a/b] long repeat 3** command for the associated tape drive unit. If the system release is earlier than G1.1, refer to Note (o) also.
   3. If all tests pass, assume that the problem has been resolved.

      If some tests fail, resolve those errors and repeat Step #2.
   4. If translations have not already been saved onto the new tape, issue the **save translations** command.
   5. If the system contains recorded announcements, issue the **save announcements** command.

   If this error reappears and becomes a chronic problem, the fault may be with the tape drive unit, and it could be intermittent in nature. In this case, replace the tape drive unit with a new tape drive unit and repeat "Error Type #1793 - Repair Procedure." Refer to Step 5 of the "Tape Maintenance and Repair Procedures" section for directions on how to replace the tape drive unit.

e. Error Type #1828 is reported under the following conditions;

- [G3iV1, EDI 7.0 and earlier] This error is never reported.
- [G3iV1, EDI 6.0 and earlier] Whenever Test #692 (Tape Block Error Test) fails due to an uncorrectable tape block error.
- [G1.1] Whenever any maintenance test fails due to an uncorrectable tape block error.

To clear Error Type #1828, follow the procedures given in the footnotes for Error Type #1793.

f. Error Type #2049 is reported under the following conditions;

- [G3iV1 EDI 7.0 and later] This error is never reported.
- [G1.1, G3iV1 EDI 6.0 and earlier] Error Type #2049 is reported whenever the software detects a correctable tape block error during a read or write operation on the tape.

  A **correctable tape error** is one in which a block error is detected but corrected during a read or write to the tape. This type of error may be caused by either a soft tape error (for example, the tape head is jiggled while reading or writing data), or by a hard tape error (for example, a scratch or a hole in the tape that affects only a single sector of the tape).

  The auxiliary data field indicates the file on the tape in which the error was detected. Refer to Table C for a list of possible auxiliary data field values and the corresponding tape file.

  With this error, the tape is fully functional but is in danger of developing an uncorrectable tape error. The tape cartridge should be changed when it is convenient to do so.

  To clear Error Type #2049, follow the procedures given in the footnotes for Error Type #1793.

g. Error Type #2084 is reported under the following conditions;

- [G3iV1 EDI 7.0 and later] This error is never reported.
- [G3iV1 EDI 6.0 and earlier] Whenever Test #692 (Tape Block Error Test) fails due to a correctable tape block error.
- [G1.1] Whenever any maintenance test fails due to an correctable tape block error.

To clear Error Type #2084, follow the procedures given in the footnotes for Error Type #1793.

h. [G1.1, G3iV1 EDI 6.0 and earlier] Error Type #2817 is reported whenever the tape read/write test fails. The auxiliary data field indicates the cause of the test failure as follows:

9032 –	Significant portion of the scratch area on the tape cannot be read.
9033 –	Significant portion of the scratch area on tape cannot be written.
9034 –	Significant portion of the scratch area on the tape cannot be read or written.

i. Error Type #3329 indicates that an error occurred while loading translations. This error and the corresponding alarm occurs at power-up or on a Reset System 3, 4, or 5 if the system cannot load translations. This error results in a MAJOR alarm if translations are not already loaded and in a MINOR alarm otherwise. If the system does not contain valid translations, this alarm will invoke Emergency Transfer.

Standard System

NOTE:
The following repair procedure assumes that no major alarms exist on the PROCR (Processor) or MEM-BD (Memory) circuit packs. If any of these alarms exists, resolve them before trying to resolve this alarm.

Error Type #3329—Repair Procedure (Standard System):

1. Look in the Hardware Error Log for Error Type #1793. If this error exists, replace the tape cartridge with a backup cartridge that has valid system translations.
2. [G1.2, G3iV1.1-286] Issue the **test tape long clear** command.
3. [G1.1] Issue the **test tape long repeat 3** command.
4. If all tests except for Test #505 pass, assume that the problem has been resolved. Test #505 will fail if a successful load translations has not occurred.

   If some other tests besides Test #505 fail, resolve those errors, and repeat Step #2.
5. Issue the **reset system 3** command.
6. Issue the **list configuration software** command.
7. If the tape resident translations date is "none," insert a backup tape cartridge and go back to Step #2 (try up to 2 backup tapes).
8. If the problem is *not* resolved, follow normal escalation procedures.

High and Critical Reliability Systems

NOTE:
In a High or Critical Reliability system, the following repair procedure assumes that no major alarms exist on the PROCR (Processor), MEM-BD (Memory), or DUPINT (Duplication Interface) circuit packs or on the STBY-SPE (Standby SPE) MO. If any of these alarms exists, resolve them before trying to resolve this alarm.

Both Active and Standby SPE Tapes alarmed

This situation arises whenever translations cannot be loaded on either SPE. If the system was powered up, both tapes were alarmed at almost the same time as a result of this error. It is very possible that no SPE-Interchange occurred. However, if the system was restarted as a result of a **reset system [3 | 4 | 5]** command, and when an alarm was raised against the Active SPE as a result of Error Type #3329, a Level 3 SPE-Interchange automatically occurred, and the "new" Active SPE attempted to load translations. When this SPE failed to load translations, its tape was alarmed as well.

Error Type #3329 - Repair Procedure #1 (High or Critical Reliability System):

1. Issue the **status system** command to determine which SPE

   (A or B), is the Active SPE. It is labeled as "active."

2. Use "Error Type #3329—Repair Procedure (Standard System)" to ensure that the tape and tape unit in the Active SPE are functioning properly and to read in translations.

3. Log into the Manager I terminal again and issue the **display alarms** command to see if any alarms were raised against the Active SPE tape.

   a. If a major alarm against the Active SPE tape now exists, escalate the problem.

   b. If minor alarms against the Active SPE tape now exist, resolve those alarms before continuing with Step #5.

   c. If no alarm exists against the Active SPE tape, continue with Step #4.

4. Replace the tape in the Standby SPE. If a new tape is used, translations must have been successfully saved in order to clear Error Type #3329.

5. Issue the **refresh spe-standby** command. It may be necessary to issue this command multiple times. However, if you have issued the **refresh spe-standby** command five times, and if the Standby SPE is still not labeled "Standby" on the Status System Form, escalate the problem.

6. The Standby SPE must be in Standby Mode before issuing the **test tape [a|b] long** command. If the Standby SPE is not in Standby Mode, the additional tests needed to clear Error Type #3329 are not run. These additional tests also cause the **test tape [a|b] long** command to take longer to execute.
7. Test the Standby tape by issuing the **test tape [a|b] long** command. Issuing this command whenever the SPE contains an active Error Type #3329 causes the SPE to undergo a COLD 1 restart. This restart attempts to load translations and, if successful, it clears the error.
8. If the problem is not resolved, follow normal escalation procedures.

Only one SPE Tape alarmed

A typical scenario that results in a single minor TAPE alarm follows: The system boots up on an SPE and cannot read in translations. As a result, a major alarm against TAPE is raised. The system performs a Level 3 SPE-interchange and then reads in translations from the tape on the "new" Active SPE. At this point, the major TAPE alarm is downgraded to a minor TAPE alarm.

Error Type #3329 - Repair Procedure #2 (High or Critical Reliability System):

1. The tape against which Error Type #3329 has been logged should reside in the Standby SPE. Issue the **status system** command to determine which SPE is active.

   If Error Type #3329 is logged against the Active SPE, follow Steps 1 through 3 of "Error Type #3329—Repair Procedure #1 (High and Critical Reliability Systems)."

   If Error Type #3329 is logged against the Standby SPE, follow Steps 4 through 7 of "Error Type 3329 - Repair Procedure #1 (High and Critical Reliability Systems)."
2. Error while saving translations. Resolve other tape errors, and reissue the **save translations** command.

j. Error Type #3841 indicates that a save translations operation failed because the tape was in use. Wait two minutes, then issue the **save translations** command. Try this a maximum of five times.

k. Error Type #3842 indicates a save translation failure due to a tape-related problem. The following procedure is recommended to clear this error.

   Error Type 3842 - Repair Procedure:

   1. Look in the Hardware Error Log for Error Type #1793. If this error exists, replace the tape cartridge in the tape unit on which the error occurred with a new cartridge.
   2. [G1.2 and later] Issue the **test tape [a/b] long clear** command for the associated tape drive unit.

[G1.1 and earlier] Issue the **test tape [a/b] long repeat 3** command for the associated tape drive unit.

3. If all tests up to Test #505 pass, assume that the problem has been resolved. Test #505 will fail if a successful save translations has not occurred since the original failure.

   If any tests other than Test #505 fail, resolve those errors and repeat Step #3.

4. Issue the **save translations** command.
5. If the system contains recorded announcements, issue the **save announcements** command.

l. Error Type #3843 indicates that during daily scheduled maintenance, the automatic save translation failed. The failure occurred most likely as a result of a hardware problem rather than a tape problem.

   To clear Error Type #3843, follow the procedures given in the footnotes for Error Type #3842.

m. [G1.1 and earlier] Translations were not saved on the tape(s) corresponding to the port field(s) indicated. In this case, the port field points to the Standby SPE at the time the error occurred. Resolve other tape errors, and then issue the **test tape long** and **save translations** commands, respectively.

n. [G1.1 and earlier] If these errors occur in conjunction with Error Type #3329, a major alarm is logged against the error type. To resolve this alarm, follow the instructions for Error Type #3329.

o. [G1.1 and earlier] "Leaky Bucket" strategy for Error Types #1793, #1828, #2049, #2051, and #2084 on the Active SPE. Whenever any of these errors appear in the Error Log, they will be automatically resolved within 48 hours if the errors do not recur within that period. In G1.0, this is the only way these errors can be cleared (without resetting the system).

System Technician Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tape DMA Latch Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tape Reset Test (#67)		X	ND
Tape DMA Latch Test (#230)	X	X	ND
Tape Diagnostic Test (#66)	X	X	ND
Tape Read/Write Test (#65) (a)		X	ND
Tape Block Error Test (#692) (b)		X	ND
Tape Status Test (#69)	X	X	ND
Tape Translation Status Test (#505)		X	ND
TAPE-DAT Tape Consistency Test (#421) (c)		X	ND

1 D = Destructive; ND = Nondestructive

a. The Tape Read/Write Test only runs in the following software releases;
   - G1
   - G3iV1, EDI 6.0 and earlier.
b. The Tape Block Error Test runs only in software release G3iV1, EDI 15.0 and earlier.
c. Refer to TAPE-DAT (Tape Consistency) Maintenance documentation for the description of this test.

Tape Read/Write Test (#65)

The purpose of this test is to exercise the hardware read/write circuitry and the basic functionality of the tape cartridge. This test is done by reading 22 blocks of data and by then writing 22 blocks of data into reserved space on the tape cartridge.

NOTE:
This test does not check for tape cartridge data consistency, nor does it check the integrity of every block on tape.

Table 11-338. TEST #65 Tape Read/Write Test

Error Code	Test Result	Description/ Recommendation
1029 to 1030 and 2011 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9000's	ABORT or FAIL	Refer to Table A in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
Any Others	ABORT or FAIL	Refer to Table B in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
	PASS	All tape hardware is in good working order. Passing this test does not guarantee that every single data block on the tape cartridge can be read or written to.

Tape Diagnostic Test (#66)

This test activates the diagnostic tests built into the Maintenance/Tape Processor (MTP) firmware on the TN773 Processor circuit pack. The test verifies the basic read/write capability of the tape drive and tape cartridge. Also, the test performs controller/MTP hardware diagnostics.

The test reads from the tape and performs write verification testing by writing data into a maintenance block and reading it back. It also performs a tape drive head step check by advancing the tape drive head through all even streams on the tape (streams 0 through 18) to make sure the head is operational.

The test does not test every data block on the tape.

Table 11-339. TEST #66 Tape Diagnostic Test

Error Code	Test Result	Description/ Recommendation
1029 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9000’s	ABORT or FAIL	Refer to Table A in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
Any Others	ABORT or FAIL	Refer to Table B in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
	PASS	This is a comprehensive test of the Tape Unit. The test verifies that the tape drive is in good working order.

Tape Reset Test (#67)

This test resets the tape portion of the Processor on the Maintenance/Tape Processor (PR-MAINT), and it resets the shared RAM on the Processor circuit pack (TN770). The test can pass when no drive is present because it never accesses the tape drive.

Table 11-340. TEST #67 Tape Reset Test

Error Code	Test Result	Description/ Recommendation
1029 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9000's	FAIL	Refer to Table A in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
Any Others	FAIL	Refer to Table B in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
	PASS	Communication with the tape processor is possible at a very basic level.

Status Request Test (#69)

This test requests the Maintenance/Tape Processor (MTP) firmware on the TN773 Processor circuit pack for the current Tape Unit status and displays the results.

Table 11-341. TEST #69 Status Request Test

Error Code	Test Result	Description/ Recommendation
1029 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9000's	ABORT	Refer to Table A in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
Any Others	FAIL	Refer to Table B in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.
	PASS	This test verifies the basic communication between the Processor and the Tape Drive circuit pack.

Tape DMA Latch Test (#230)

Also known as the *Tape Interface Test*, this test checks the shared RAM on the TN770 Memory circuit pack. The test also checks the communication paths on the TN773 Processor circuit pack.

Table 11-342. TEST #230 DMA Latch Test

Error Code	Test Result	Description/ Recommendation
1029 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
23001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
23002 to 23005	FAIL	Hardware not responding. 1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section.
23006	FAIL	Could not send a test message to MTP. 1. Repeat the same test again. 2. Look for PROCR and MEM-BD errors in the Error Log. If such errors are present, refer to PROCR (80286 Processor circuit pack) and MEM-BD (Memory) Maintenance documentation. 3. If no tests on the Memory circuit pack or Processor circuit pack fail, escalate the problem.

Continued on next page

Table 11-342. TEST #230 DMA Latch Test — *Continued*

Error Code	Test Result	Description/ Recommendation
23007	FAIL	Operation timed out. 1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Issue the **test tape long** command. 3. If the test fails, make sure tape is fully inserted. 4. If the test continues to fail, clean the tape head and retest. 5. If fail, swap tape and retest. 6. If the test still fails, swap tape unit, *use original tape* and retest. 7. If the problem still exists, escalate the problem.
23008	FAIL	MTP indicates a test failure. 1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
23009 to 23017	FAIL	Hardware problem. Problem accessing test Memory locations #1, #2, and #3. 1. Follow the procedures provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
9000's	ABORT	Refer to Table A, "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for the specific error code.
Any Others	ABORT	Refer to Table B, "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for the specific error code.
	PASS	If this test passes, the TN770 Memory and the TN773 Processor circuit packs are in good working order. This is not a test of the tape cartridge or of the TN774 Tape Drive circuit pack.

Tape Translation Status Test (#505)

This test checks whether the TAPE is currently alarmed due to the failure of a load translation or save translation attempt on the TAPE.

Table 11-343. TEST #505 Tape Save Translation Status Test

Error Code	Test Result	Description/ Recommendation
1029 to 1030 and 2011, 2013 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
2012	ABORT	1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Issue the **test tape long** command. If the test passes, issue the **save translations** command to verify condition is clear. 3. If the test fails, make sure tape is fully inserted. 4. If the test continues to fail, clean the tape head and retest. 5. If fail, swap tape and retest. 6. If the test still fails, swap tape unit, *use original tape* and retest. 7. If the problem still exists, escalate the problem.
	FAIL	The tape is currently alarmed because a save translation or a load translation attempt failed on this tape. Look for Errors Types #3329, #3841, #3842, and #3843 in the Hardware Error Log and resolve these errors by following the procedures provided in the "Hardware Error Log Entries and Test to Clear Values" section.
	PASS	The last load translation and (if any) save translation attempts were successful on this tape.

Tape Block Error Test (#692)

This test is performed by rereading the list of tape blocks that have been reported by the software to contain correctable (Error Type #2049) or uncorrectable (Error Type #1793) block errors.

A **correctable tape error** is one in which a block error is detected but corrected during a read or write to the tape. This type of error may be caused by either a soft tape error (for example, the tape head is jiggled while reading or writing data) or by a hard tape error (for example, a scratch or a hole in the tape that affects only a single sector of the tape).

An **uncorrectable tape error** is one in which a block error persists during a read or write operation to the tape. Errors of this type are unable to be corrected by several attempts at rereading or rewriting the block on the tape. This type of error is most likely the result of one or more hard errors on the tape (for example, a scratch or a hole in the tape that spans multiple sectors).

This test passes only if no block errors of any type are detected after the test completes. Otherwise, the test fails and returns an error code of the form "x0y," where:

> **x** indicates the number of uncorrectable block errors detected by the test [0-5]
> **y** indicates the number of correctable block errors detected by the test [0-5]

The software stores the block location for at most five errors of each type.

Table 11-344. TEST #692 Tape Block Error Test

Error Code	Test Result	Description/ Recommendation
1029 to 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9000's	ABORT	Refer to Table A in "Tape Unit Aux Data/Error Codes Tables" and follow the recommended repair strategy for specific Aux Data.

Continued on next page

Table 11-344. TEST #692 Tape Block Error Test — *Continued*

Error Code	Test Result	Description/ Recommendation
x0y	FAIL	"x" indicates the number of uncorrectable block errors detected by the test [0-5]. "y" indicates the number of correctable block errors detected by the test [0-5]. Look for Error Types #1793, #1828, #2049, and #2084 in the Hardware Error Log and resolve these errors by following the procedures provided in the "Hardware Error Log Entries and Test to Clear Values" section. **NOTE:** If the value of "x" is "0," only the value of "y" is displayed.
100	FAIL	1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Issue the **test tape long** command. 3. If the test fails, make sure tape is fully inserted. 4. If the test continues to fail, clean the tape head and retest. 5. If fail, swap tape and retest. 6. If the test still fails, swap tape unit, *use original tape* and retest. 7. If the problem still exists, escalate the problem.
	PASS	No block errors are detected.

Tape Unit Aux Data/Error Codes Tables

Table 11-345. Table A: Tape Unit Aux Data Table

Aux Data/ Error Codes	Explanation	Strategy
9002	Internal system error.	Escalate the problem.
9003	Hardware not responding.	1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
9004 9005	Internal system error.	Escalate the problem.
9009 9010	Operation timed out. Hardware not responding.	1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
9011	Internal system error.	Escalate the problem.
9012	Tape already in use.	1. If the Tape Unit is in use (that is, the yellow LED on the tape drive is on and there is tape cartridge motion), wait until the first request is complete. **If there does not appear to be tape motion and/or the yellow LED on the tape drive is not on, go to next step**. 2. Retry the **test tape** command at one-minute intervals a maximum of five times. **If the command continues to abort, escalate the problem.**

Continued on next page

Table 11-345. Table A: Tape Unit Aux Data Table — *Continued*

Aux Data/ Error Codes	Explanation	Strategy
9013	Tape drive self-test failed.	1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
9015	Test detected hardware failure.	
9017	Could **NOT** reset the tape drive.	
9020	⚠ **WARNING:** *The tape cartridge is starting to wear, but it is still functional.*	
9023	Write-protected tape.	1. Disable the write-protect switch on the tape cartridge. 2. Check the power by performing Step 1 of the "Tape Maintenance and Repair Procedures" section. 3. If the problem still exists, escalate the problem.
9024	No tape cartridge in tape drive.	1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Issue the **test tape long** command. 3. If the test fails, make sure tape is fully inserted. 4. If the test continues to fail, clean the tape head and retest. 5. If fail, swap tape and retest. 6. If the test still fails, swap tape unit, *use original tape* and retest. 7. If the problem still exists, escalate the problem.

Continued on next page

Table 11-345. Table A: Tape Unit Aux Data Table — *Continued*

Aux Data/ Error Codes	Explanation	Strategy
9025	Tape cartridge is worn, and it is **NOT** functional.	1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Clean the tape head. 3. If still fail, check tape insertion, swap tape if necessary, and retest. 4. Replace tape unit as a last resort. 5. If the problem still exists, escalate the problem.
9026	Hardware error detected.	1. Do the steps below following the directions in the "Tape Maintenance and Repair Procedures" section. 2. Issue the **test tape long** commnd.dispatch with tape unit. 3. If the test fails, make sure tape is fully inserted. 4. If the test continues to fail, clean the tape head. *Use original tape* and retest. 5. If the test still fails, swap tape unit, *use original tape* and retest. **NOTE:** It is very important that hardware problems are resolved *before* using backup tape. 6. If fails again, swap tape and restest. 7. If the problem still exists, escalate the problem.
9027	The test failed because the software could not access the tape hardware.	

Continued on next page

Table 11-345. Table A: Tape Unit Aux Data Table — *Continued*

Aux Data/ Error Codes	Explanation	Strategy
9030	Internal system error.	1. Follow the steps provided in the "Tape Maintenance and Repair Procedures" section. 2. If problem still exists then escalate.
9032	Inability to read a significant portion of the scratch area on the tape.	1. Follow the steps provided in the "Tape Maintenance and Repair Procedures" section. 2. If problem still exists then escalate.
9033	Inability to write a significant portion of the scratch area on the tape.	1. Follow the steps provided in the "Tape Maintenance and Repair Procedures" section. 2. If problem still exists then escalate.
9034	Inability to both read and write a significant portion of the scratch area on the tape.	1. Follow the steps provided in the "Tape Maintenance and Repair Procedures" section. 2. If problem still exists then escalate.

How to Use Table B to Determine Aux Data Values

In this table, the numbers can have one to five digits. If the first or leftmost digit is "1," the number has five digits. If the first digit or leftmost digit is "2," the number has four digits. If the first or leftmost digit is "3," the number has three digits. If the first or leftmost digit is "4," the number has two digits. If the first or leftmost digit is "5," the number has one digit. For example, if the number is "2300," "2" indicates that the tape cartridge should be replaced soon. "3" indicates that the Tape Drive could not read or write at least one block of data from the tape.

Table 11-346. Table B. Tape Unit Aux Data Table

Digit	Aux Data/ Error Code (a)	Explanation	Strategy
0	0	Exact cause of error is not determined.	1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the tape alarm still exists, escalate the problem. If this is the only error and there is no alarm, ignore this error.
1	1xxxx	If the aux data is "10000," the error is non-fatal.	Ignore the "10000" case.
		Each of the last four digits of the Aux Data "1xxxx" is a non-zero value.	Follow the steps in the appropriate aux data section.
2	2xxx	The tape cartridge should be replaced soon.	1. Follow the instructions provided in the "Tape Maintenance and Repair Procedures" section. 2. If the problem still exists, escalate the problem.
3	3xx	Cannot read or write at least one block of data from the tape.	
4	4x	A problem was found reading the Shared Memory.	
5	5	Tape drive self-test failed.	

Aux Data Values Indicating the Tape File Type

This table translates Aux Data values to the corresponding tape file type.

Table 11-347. Table C. Tape File Types

Aux Data Value	File Type
0	Primary Translation File
1	Backup Translation File
2	Core Dump File
3	Program Update File
4	Boot Image File
6	Error Log File (not including scratch area)
12	Stored Announcement File
16	Processor Interface Firmware File
17	Header Block
19	Packet Control Firmware File
20	NIPM File
21	X25 File
22	Primary Directory File
23	Backup Directory File

Tape Drive Head Cleaning Procedure

The tape drive head (also called the tape head) should be cleaned at least once a year. **However, as part of the preventive maintenance strategy, it is recommended that you inspect the tape head during each maintenance visit and that you clean the tape head several times a year**. In addition, a dated label should be placed on the tape drive unit after the tape head is cleaned. You should also complete the "AT&T Preventive Maintenance Log" sheet. (Refer to Chapter 5, "Routine Maintenance Procedures".)

New tapes leave more abrasive particles on the tape head. Therefore, if a new tape is used, issue the **test tape long repeat 3** command, and then clean the tape head.

The tape head can be accessed for cleaning from the front of the drive by opening the tape access door with your finger. See Figure 11-100.

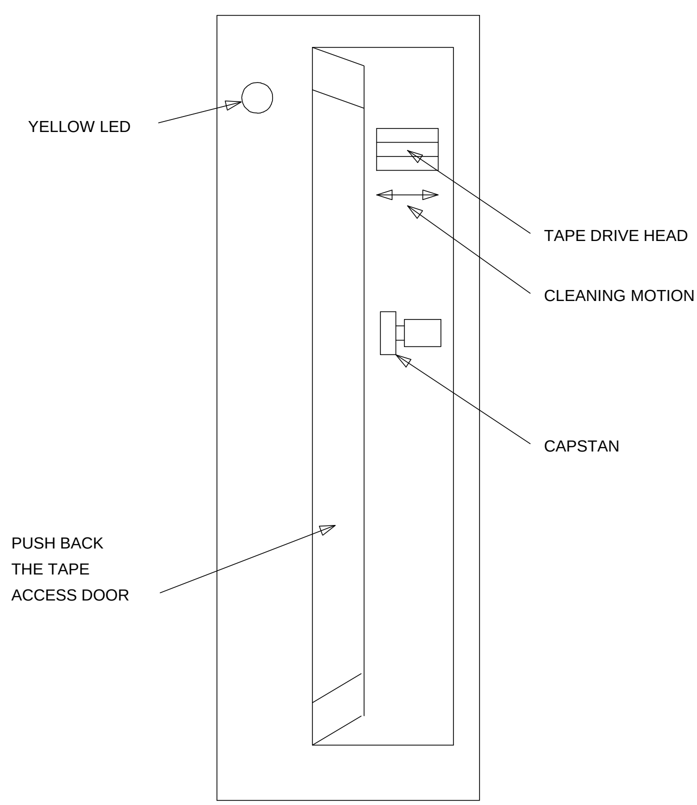

Figure 11-100. Front View of the Tape Drive

To position the tape drive head properly for cleaning, do the following:

1. Install a tape cartridge into the drive with the power on.
2. Wait 10 seconds or until the spinning of the tape stops.
3. Remove the tape cartridge.

CAUTION:
The tape drive head should be cleaned by using only Freon TF and polyurethane swabs. These products are usually available in VCR head cleaning kits sold in video stores.

4. Wet the swab with the Freon TF solution.
5. Using a "side-to-side" motion, wipe the tape drive head.

WARNING:
DO NOT GET TAPE HEAD CLEANING SOLUTION ON THE CAPSTAN.

6. With a dry swab, wipe away any remaining residue from the tape head.

Tape Maintenance and Repair Procedures

This section contains commonly used procedures to resolve tape alarms. The following equipment may be needed to complete these procedures:

- Tape Cartridges (3)
- TN774 Tape Drive Circuit Pack (1)
- TN773 Processor Circuit Pack (1)
- TN770 Memory Circuit Pack (1)

NOTE:
In the following repair procedures, the term "main tape(s)" is used to refer to the tape(s) that were physically present in the tape drive(s) at the time the problem occurred. The "main tape(s)" should not be confused with the term "backup tape(s)" Backup tapes are physically stored outside of the tape drive(s). The term "new tape(s)" refers to the three new tapes that you should bring with you to the customer's site; these tapes may be needed to complete the tape maintenance procedures. The new tapes should not have been used previously in the customer's system. **It is very important to keep track of these tapes.**

1. Check the Error Log for power-related problems and refer to the POWER, DC-POWER, and CARR-POW Maintenance documentation sections. If no power errors exist, check the tape drive for power as follows:

- If there is a problem with the 12V supplied to the tape drive, its yellow LED will be in a blinking mode. The 12V is supplied by the 631DB or 676B power unit in a multicarrier cabinet system and by a WP91153 in the single-carrier cabinet system. This problem can also be caused by a failure in the 984D DC power converter on TN774 Tape Drive circuit pack.
- If there is a problem with the five volts supplied to the tape drive, there is no visible way to determine this except by using the TN2036 Voltage Range circuit pack (see the "Troubleshooting Backplane Voltage Problems" section in Chapter 5, "Routine Maintenance Procedures" or by using the following procedure:

  Insert a tape cartridge into the tape drive. There should be a spinning noise indicating that the tape drive is doing a short retension pass. If there is no noise, the power may be disconnected.

2. Check for a dirty tape drive head.
   - Clean the tape drive head (refer to the "Tape Drive Head Cleaning Procedure" section, which immediately precedes this section).
   - Reinsert the main tape cartridge (for example, the tape that was in the tape drive). Make sure the tape is not write-protected.
   - Issue the **test tape long repeat 3** or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

   If all tests pass:

   The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was a dirty tape drive head.

   If any of the tests failed, proceed to Step 3.

3. Check the health of the main tape cartridge.
   - Clean the tape drive head again since the main tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
   - Insert the backup tape cartridge. **Make sure it is not write-protected.**
   - Issue the **test tape long repeat 3** command or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

   If all tests pass:

   The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was a defective main tape. Mark the defective tape and follow the standard disposal procedures.

   If any of the tests failed, proceed to Step 4.

4. Check for the health of the backup tape.

   - Clean the tape drive head again since the backup tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
   - Insert a new tape cartridge.

     CAUTION:
     Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.

   - Issue the **test tape long repeat 3** command or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

   If all tests pass:

   The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that both the main tape and backup tape became defective. Mark the defective tape and follow the standard disposal procedures.

   Use the following procedure to save translations and announcements on the new tape:

   - On a High or Critical Reliability system, issue the **refresh spe-standby** command. It may be necessary to issue this command multiple times. However, if you have issued the **refresh spe-standby** command five times and the Standby SPE is still not labeled "Standby" on the Status System Form, escalate the problem.
   - Issue the **save translations** command. If there is a TN750 Announcement circuit pack in the system, issue the **save announcements** command. Saving announcements may take longer than 30 minutes to complete.
   - If this is a High or Critical Reliability system, run the Tape Consistency Test (#421) by issuing the **test tape [a|b] long** command. Refer to the TAPE-DAT Maintenance documentation to resolve any errors.
   - Clean the tape head since new tapes leave more abrasive particles on the tape head (refer to the "Tape Drive Head Cleaning Procedure" section).

     If any of the tests fail, proceed to Step 5.

5. Check the health of the tape drive.

   WARNING:
   Vintage 6 and Vintage 8 of the TN773 Processor circuit pack in a Medium Cabinet use 12V DC power supplied from the Tape Drive

circuit pack and thus may cause severe service disruption when the Tape Drive circuit pack is unseated from its slot. Therefore, when repairing a High or Critical Reliability system with this configuration, make the carrier with tape errors/alarms the Standby carrier before proceeding. For a Standard system with this configuration, arrange to do the work in off-hours before proceeding.

- Replace the tape drive. **DO NOT TURN OFF THE POWER**.
- Clean the tape drive head of the new tape drive.
- Insert the main tape cartridge.
- Issue the **test tape long repeat 3** command, or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

  If all tests pass:

  The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that the original tape drive was defective. (To see the hardware errors against the TAPE MO, issue the **display errors** command. Enter "a" in the Interval field and "tape" in the Category field.)

  If any of the tests fail, proceed to Step 6.

6. Determine if the defective tape drive has damaged the tapes.

   - Clean the tape drive head again since the main tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
   - Insert a new tape (not the one used in Step 4).

     CAUTION:

     Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.

   - Issue the **test tape long repeat 3** command, or for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that the original drive is defective and that it damages any tape you put in it. (To see the hardware errors against the TAPE MO, issue the **display errors** command. Enter "a" in the Interval field and "tape" in the Category field.)

If the alarm persists, the cause of the problem is either the Maintenance/Tape Processor (MTP) residing on the TN773 Processor circuit pack or the Shared Memory (SRAM) on the TN770 Memory circuit pack. **Replacement of either of these two circuit packs in a Standard system requires powering down of the control carrier.** Therefore, use the following procedures to determine that there is a good (bootable) tape with the customer's translations (since the main and backup tapes may have been corrupted and, as a result, would then prevent the successful reading in of translations during power-up).

NOTE:
Follow Steps 7 through 10 for Standard systems and Steps 11 through 13 for High or Critical Reliability systems.

For Standard Systems

NOTE:
Before performing the following repair procedures, refer to the "Handling Control Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures" for instructions on how to replace a circuit pack in a Standard system.

7. **Make sure that there is a good tape drive and a good tape with the customer's translations before powering down the system.**
   - Insert a new tape cartridge. **Recall that a "new tape" is a tape that has not been used previously in the customer's system**.

     CAUTION:
     Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.

   - Try to make a tape with the customer's translations by issuing the **save translations** command. If successful, proceed to Step 8. If the translations were not saved successfully, request that the TSC remotely make a copy of the customer's tape by saving the translations and announcements. When you receive this tape from the TSC, continue with Step 8.
8. With the tape that has the customer's translations set aside, replace the TN770 Memory circuit pack.

   CAUTION:
   Make sure that you are using the customer's existing tape drive and tape and not the tape made in Step 7.

   - Power down the system.
   - Replace the TN770 Memory circuit pack.

- Power up the system.
- If the existing tape cannot bring up the system with the customer's translations, replace the tape drive and tape with a new tape drive and the tape made in Step 7. Reboot the system again.
- If the tape made in Step 7 cannot bring up the system with the customer's translations, proceed to Step 9.
- If the system comes up with the customer's translations, enter the **test tape long repeat 3** command.

If all tests pass:

The problem was a defective Memory circuit pack. If the tape was replaced, the Memory circuit pack and the tape may be defective.

If any test failed, proceed to Step 9.

9. Replace the TN773 Processor circuit pack.
   - Power down the system.
   - Reinsert the original TN770 Memory circuit pack.
   - Replace the TN773 Processor circuit pack.
   - Power up the system.
   - If the system boots up with the customer's translations, enter the **test tape long repeat 3** command.

   If all tests pass:

   The problem was a defective TN773 Processor circuit pack. The TN770 Memory circuit pack is working fine.

   If any test failed or if the system cannot be brought back into service successfully, proceed to Step 10.

10. Replace the TN770 Memory circuit pack. Use both the new Memory circuit pack and the new Processor circuit pack.
    - Power down the system.
    - Replace the TN770 Memory circuit pack.
    - Power up the system.
    - If the system comes up with the customer's translations, issue the **test tape long repeat 3** command.

    If all tests pass:

    The problem was a defective Memory circuit pack and a defective Processor circuit pack.

    If any test still fails, escalate the problem.

For High or Critical Reliability Systems

NOTE:
Before performing the following repair procedures, refer to the "Circuit Pack Replacement Procedure" section in Chapter 8, "Reliability Systems: A Maintenance Aid" for instructions on how to replace a circuit pack in a High or Critical Reliability System.

Make sure that the SPE that has the alarmed tape/tape drive is the Standby SPE before replacing the Processor circuit pack or the Memory circuit pack.

11. Replace the TN770 Memory circuit pack on the STANDBY control carrier.
    - Replace the TN770 Memory circuit pack (see the previous Note).
    - Test the tape in the Standby control carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

    If all tests pass:

    The problem was a defective Memory circuit pack.

    If any test failed, proceed to Step 12.

12. Replace the TN773 Processor circuit pack on the STANDBY control carrier.
    - Reinsert the original TN770 Memory circuit pack.
    - Replace the TN773 Processor circuit pack (see the previous Note).
    - Test the tape in the Standby Control Carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

    If all tests pass:

    The problem was with the TN773 Processor circuit pack.

    If any test failed, proceed to Step 13.

13. Replace the TN770 Memory circuit pack on the STANDBY control carrier. Use both the new Memory circuit pack and the new Processor circuit pack.
    - Replace the Memory circuit pack (see the previous Note).
    - Test the tape in the Standby Control Carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

    If all tests pass:

    The problem was a defective Memory circuit pack and a defective Processor circuit pack.

    If any test still fails, the problem could be with other control carrier circuit packs. Replace each circuit pack, one at a time, until all the tape tests pass. If the problem persists, escalate the problem.

TAPE-DAT (Tape Consistency)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TAPE-DAT	MINOR	test tape a|b l	Tape Consistency

In High and Critical Reliability systems, the system software translations, as well as other information, can be stored on two tapes: one in the Active SPE and one in the Standby SPE. In order to flag a problem when these tapes become mismatched, Tape Consistency monitors the translations, announcements, update files, and software vintage number on both tapes in a High or Critical Reliability PPN system. If the translation time stamp, announcement time stamp, and update file time stamp and identifiers on the two tapes are not the same and/or if the software vintage numbers do not match, an alarm is raised. The software vintage can be displayed via the **list configuration software-vintage** command. The Tape Consistency Test is run on system technician command and once a week as part of daily Standby SPE maintenance. Tape Consistency does not apply and does not exist in Standard systems.

Hardware Error Log Entries and Test to Clear Values

Tape Consistency Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tape a/b l
8 or 16	8 or 16	Tape Consistency Test (#421)	WARNING	OFF	test tape a/b l
1-7, 9-15, 17-86	8 or 16	Tape Consistency Test (#421)	MINOR	OFF	test tape a/b l

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

a. An "8" in the log refers to carrier A and a "16" refers to carrier B. The Aux Data field records which SPE was active at the time the Tape Consistency Test failed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tape Diagnostic Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Tape Reset Test (#67) (a)		X	ND
Tape DMA Latch Test (#230) (a)	X	X	ND
Tape Diagnostic Test (#66) (a)	X	X	ND
Tape Read/Write Test (#65) (a) (b)		X	ND
Tape Block Error Test (#692) (a) (b)		X	ND
Tape Status Test (#69) (a)	X	X	ND
Tape Translation Status Test (#505) (a)		X	ND
TAPE-DAT Tape Consistency Test (#421) (c)		X	ND

1 D = Destructive; ND = Nondestructive

a. See TAPE (Tape Unit) Maintenance documentation for this test description.

b. This test does not run in release G3iV1 EDI 7.0 or later.

c. The Tape Consistency Test does not run in a Standard system.

Tape Data Consistency Check Test (#421)

The software vintage number, translation time stamps, announcement time stamps, and update file time stamps and identifiers are read off both tapes and compared. If the comparison shows any discrepancy, TAPE-DAT is alarmed. This test is run in a High or Critical Reliability Option system. The test is run as part of the **test tape long** and as part of weekly TAPE maintenance.

Table 11-348. TEST #421 Tape Data Consistency Check Test

Error Code	Test Result	Description/ Recommendation
0	ABORT	The test timed out without completing. This error can occur when the system is heavily loaded and the test is not allocated sufficient time to run. 1. Rerun the test when the system is less busy and is not running standby maintenance. 2. If the test continues to abort, escalate the problem.
1029 1030 2011 2012 2013 2014 2015 2016 2017 2018 2019 2020 2021 2022 2023 2024 2025 2051	ABORT	Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
9005	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
35498	ABORT	Difficulty was encountered trying to send information between the SPEs.
35512	ABORT	The Standby SPE cannot be put into maintenance mode. 1. Check for and resolve all DUPINT (Duplication Interface Circuit Pack), SHDW-LNK (Memory Shadowing Link), SHDW-CIR (Common Shadow Circuit), and STBY-SPE (Standby SPE) alarms. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
35514	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
35534	ABORT	Could not allocate the tape drive (could be active or standby) because another tape operation was in progress. 1. Wait 10 minutes, and retry the command.
35535	ABORT	Could not access the tape (could be active or standby). 1. The tape may be damaged or missing. Resolve all problems with all tape tests in the Long Test Sequence for both tapes. 2. Repeat the test.
1	FAIL	The standby translations are out-of-date. The translations on the Standby SPE (tape) are older than those on the Active SPE (tape).
2	FAIL	The Active SPE translations are out-of-date. 1. Issue the **save translations** command. If the translation save passes on both SPEs, proceed to Step 2. 2. Run **test tape long** again to resolve the alarms.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
3	FAIL	The load vintages are different in both SPEs.
4	FAIL	The load vintages are different in both SPEs.
5	FAIL	The load vintages and translations are different in both SPEs. The Active SPE has the most current translations.
6	FAIL	The load vintages and translations are different in both SPEs. The Standby SPE has the most current translations. 1. Determine which tape contains the desired software release by issuing a **list configuration software long** command. Obtain another tape of the same software release. Install both tapes, and issue the **save translations** command. If there is a TN750 Announcement circuit pack in the system, issue the **save announcements** command. If the translation (and announcement) save passes on both SPEs, proceed to Step 2. 2. Run **test tape long** again to resolve the alarms.
8	FAIL	The announcements are different in both SPEs. The Active SPE has the most current announcements. 1. Issue the **save announcements** command to save announcements in both SPEs. If the announcement save passes on both SPEs, proceed to Step 2. 2. Issue the **test tape long** command again to resolve the alarms.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
9	FAIL	The translations and announcements are different in both SPEs. The Active SPE is the most current.
10	FAIL	The translations and announcements are different in both SPEs. The Standby SPE has the most current translations, and the Active SPE has the most current announcements. 1. Issue the **save translations** command to save translations in both SPEs. 2. Issue the **save announcements** command to save announcements in both SPEs. 3. If both the translation save and announcement save pass on both SPEs, issue the **test tape long** command again to resolve the alarms.
12	FAIL	Load vintages and announcements are different in both SPEs. The Active SPE has the most current announcements.
13	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Active SPE has the most current translations and announcements.
14	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Standby SPE has the most current translations, and the Active SPE has the most current announcements. 1. Follow the procedures for Error Code 4. Be sure to issue the **save announcements** command.
16	FAIL	Announcements are different in both SPEs. The Standby SPE has the most current announcements. 1. Follow the procedures for Error Code 8.
17	FAIL	The translations and announcements are different in both SPEs. The Active SPE has the most current translations and the Standby SPE has the most current announcements.
18	FAIL	The translations and announcements are different in both SPEs. The standby SPE is the most current. 1. Follow the procedures for Error Code 9.

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
20	FAIL	Load vintages and announcements are different in both SPEs. The Standby SPE has the most current announcements.
21	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Active SPE has the most current translations and the Standby SPE has the most current announcements.
22	FAIL	The translations, announcements, and load vintages are different in both SPEs. The Standby SPE has the most current translations and announcements. 1. Follow the procedures for Error Code 4. Be sure to issue the **save announcements** command.
32	FAIL	The update files are different in both SPEs. The update file on the Active SPE is the more current one. 1. Have INADS issue the **copy update-file** command. If the update file copy passes, proceed to Step 2. 2. Reissue the **test tape long** command to resolve the alarms.
33	FAIL	The update files and translations are different in both SPEs. The Active SPE has the most current update file and translations.
34	FAIL	The update files and translations are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current translations. 1. Issue the **save translations** command to save translations on both SPEs. 2. Have INADS issue the **copy update-file** command to copy the update file from the Active SPE to the Standby SPE. 3. Reissue the **test tape long** command to resolve the alarms.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
36	FAIL	The update files and load vintages are different in both SPEs. The Active SPE has the most current update file.
37	FAIL	The update files, load vintages, and translations are different in both SPEs. The Active SPE has the most current update file and translations.
38	FAIL	The update files, load vintages, and translations are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE had the most current translations. 1. Follow the procedures for Error Code 4 to get the correct load vintage. After running the **test tape long** command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.
40	FAIL	The update files and announcements are different in both SPEs. The Active SPE has the most current update file and announcements. 1. Issue the **save announcements** command to save announcements on both SPEs. 2. Have INADS issue the **copy update-file** command to copy the update file from the Active to the Standby SPE. 3. Issue the **test tape long** command again to resolve the alarms.

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
41	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, translations, and announcements.
42	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and announcements, and the Standby SPE has the most current translations. 1. Issue the **save translations** command. 2. Issue the **save announcements** command. 3. Have INADS issue the **copy update-file** command to copy the update file from the Active to the Standby SPE. 4. Reissue the **test tape long** command to resolve the alarms.
44	FAIL	The update files, load vintages, and announcements are different in both SPEs. The Active SPE has the most current update file and announcements.
45	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, translations, and announcements.
46	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and announcements, and the Standby SPE has the most current translations. 1. Follow the procedures for Error Code 4 to get the correct load vintage. Be sure to save announcements. After running the **test tape long** command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
48	FAIL	The update files and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current announcements. 1. Follow the procedures for Error Code 40.
49	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and translations, and the Standby SPE has the most current announcements.
50	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current translations and announcements. 1. Follow the procedures for Error Code #41.
52	FAIL	The update files, load vintages, and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current announcements.
53	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, and translations, and the Standby SPE has the most current announcements.
54	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and the Standby SPE has the most current translations and announcements. 1. Follow the procedures for Error Code 4 to get the correct load vintage. After running the **test tape long** command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
64	FAIL	The update files are different in both SPEs. The update file on the Standby SPE is most current. 1. If you are on site with the switch, interchange the Active SPE tape with the Standby SPE tape. If you are not on site with the switch, issue the **reset system interchange** command. This action causes the Standby SPE to become the Active SPE. Refer to the "Reset Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for information on the side effects of a processor interchange. 2. Have INADS issue the **copy update-file** command. If the update file copy passes, proceed to Step 3. 3. Reissue the **test tape long** command to resolve the alarms.
65	FAIL	The update files and translations are different in both SPEs. The Standby SPE has the most current update file, and the Active SPE has the most current translations.
66	FAIL	The update files and translations are different in both SPEs. The Standby SPE has the most current update file and translations. 1. Issue the **save translations** command to save translations on both SPEs. 2. Follow the procedures for Error Code #64.

Continued on next page

Table 11-348. TEST #421 Tape Data Consistency Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
68	FAIL	The update files and load vintages are different in both SPEs. The Standby SPE has the most current update file.
69	FAIL	The update files, load vintages, and translations are different in both SPEs. The Standby SPE has the most current update file, and the Active SPE has the most current translations.
70	FAIL	The update files, load vintages, and translations are different in both SPEs. The Standby SPE has the most current update file and translations. 1. Follow the procedures for Error Code #4 to get the correct load vintage. After running the **test tape long** command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.
72	FAIL	The update files and announcements are different in both SPEs. The Standby SPE has the most current update file and the Active SPE has the most current announcements. 1. Issue the **save announcements** command to save announcements on both SPEs. 2. Follow the procedures for Error Code #64.
73	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current translations and announcements, and the Standby SPE has the most current update file.
74	FAIL	The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current announcements, and the Standby SPE has the most current update file and translations. 1. Issue the **save translations** command. 2. Issue the **save announcements** command. 3. Follow the procedures for Error Code #64.

85	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current translations, and the Standby SPE has the most current update file and announcements.
86	FAIL	The update files, load vintages, translations, and announcements are different in both SPEs. The Standby SPE has the most current update file, translations, and announcements. 1. Follow the procedures for Error Code #4 to get the correct load vintage. After running the **test tape long** command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.
	PASS	The load vintages, translations, announcements, and update files are the same.

TDMODULE (Trunk Data Module)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TDMODULE[1]	MINOR	test port PCSSpp l	Trunk Data Module
TDMODULE (a)	WARNING	test port PCSSpp l	Trunk Data Module

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...,etc.); and pp is the 2-digit port number (for example, 01).

The TDMODULE (Trunk Data Module) Maintenance documentation is covered in the PDMODULE (Processor Data Module) Maintenance documentation.

TDM-BUS (TDM Bus)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TDM-BUS	MAJOR	test tdm P	TDM Bus
TDM-BUS	MINOR	test tdm P	TDM Bus
TDM-BUS	WARNING	test tdm P	TDM Bus

The TDM Bus consists of a duplicated TDM Bus on each port network (PPN and EPN): TDM Bus A and TDM Bus B. Each TDM Bus consists of 256 time slots. The first five time slots on each bus are called the Control Channel. The Control Channel is active on only one bus at a time in each Port Network. The next 17 time slots are reserved for dedicated tones (that is, dial tone). These time slots are called the dedicated tone time slots and only one bus at a time carries the dedicated tones. The rest of the time slots on each bus are for general system use (that is, phone call).

On system initialization, the Control Channel is on TDM Bus A and the dedicated tones on TDM Bus B in each Port Network.

Systems with High or Critical Reliability have the ability to set the Control Channel and Tone Bus to a specific TDM Bus via the **set tdm PC** command, where **P** stands for the Port Network Number and **C** stands for the TDM Bus A or B (A for TDM Bus A or B for TDM Bus B). Throughout this document, PC is used to refer to a TDM Bus.

Terminology:

- Control Channel Bus - The TDM Bus control channel is on.
- Non-Control Channel Bus - The TDM Bus control channel is NOT on.
- Tone Bus - The TDM Bus dedicated tone time slots are on.
- Non-Tone Bus - The TDM Bus dedicated tone time slots are NOT on.

TDM Bus Fault Detection and Isolation Procedure

TDM Bus faults are most likely caused by a defective circuit pack connected to the backplane or bent pins on the backplane. It is possible that a circuit pack can cause a TDM Bus fault but still exhibit trouble-free operation. For example, the insertion of an MBUS (Memory Bus) only circuit pack can bend the TDM Bus pins on the backplane and short two leads together. The four circuit packs that may cause this problem are the TN770 Memory circuit pack, the TN777 80286 Processor circuit pack, the TN772 Duplication Interface circuit pack, and the TN777 Network Control circuit pack. The latter exists only on High and Critical

Reliability systems. Since the TDM Bus is a shared resource, automatic identification of the cause of a TDM Bus fault is difficult. If a TDM Bus problem is suspected, the system technician should run the **test tdm P** system technician command. If any of the resulting tests fail, then the system technician must manually perform a TDM Bus isolation procedure to identify the cause of the problem.

WARNING:

Since the TDM Bus fault isolation procedure involves removing circuit packs and possibly disconnecting entire carriers, the procedure is extremely destructive to the port network that contains the TDM Bus being tested. If possible, this procedure should be used after hours or during hours with minimum system use.

As circuit packs are removed or entire carriers are disconnected, any active calls terminating on those circuit packs or carriers are dropped. If the system technician has any hints about a particular circuit pack that may be causing the TDM Bus problem (for example, a new circuit pack was inserted into the Port Network just before the TDM Bus problem appeared), then those hints should be investigated before performing this procedure.

For this procedure, make sure at least one Tone Detector circuit pack is in the same Port Network in which the TDM Bus fault is being isolated. The Tone Detector circuit pack is needed by maintenance to test the TDM Bus.

Procedure 1

This procedure is an attempt to isolate the TDM Bus fault to circuit packs that are essential to the system operation. For each of the following circuit packs, perform Procedure 1.

Circuit Pack	Error Log Names
Tone-Clock	TONE-BD, TONE-PT, and TDM-CLK
Network Control	SW-CTL
Tone Detector	DETR-BD, GPTD-PT, and DTMR-PT
Processor Interface	PI-BD and PI-PT
Duplication Interface—only for systems with High or Critical Reliability	DUPINT
Expansion Interface	EXP-INTF

1. Display the Hardware Error and Alarm Logs for the circuit pack via the **display errors** and **display alarms** commands.

2. If there are errors for the circuit pack, refer to its Maintenance documentation and try to resolve the errors.
3. Whether or not all the errors can be cleared, test the TDM Bus again via the **test tdm P** command.
4. If some TDM Bus tests fail, continue with the next circuit pack.
5. If there are no more circuit packs in the list, go to Procedure 2.
6. If all the TDM Bus tests pass, the problem has been fixed.

Procedure 2

This procedure removes and re-inserts port circuit packs (purple slot); one or several at a time.

If all of the TDM Bus tests pass when the circuit pack is removed, but some of the tests fail when the circuit pack is inserted, the circuit pack is the cause of the problem and should be replaced. If some of the tests fail regardless of whether the circuit pack is inserted or removed, the circuit pack is not the cause of the problem (see Note). Repeat this procedure for each purple slot circuit pack in the Port Network.

NOTE:
Of course, in a multiple failure situation, the circuit pack may be one cause of the TDM Bus problem and there may be other failures that are causing TDM Bus faults. Also, the circuit pack itself may not be the cause of the problem, but the backplane pins may have been bent when the circuit pack was inserted.

1. Remove port circuit packs which have failed the NPE Crosstalk Test (#6) first. To find which circuit packs failed this test, display the Hardware Error Log via the **display errors** command. Refer to the Maintenance documentation of each port circuit pack that has port errors to check if any error indicates the failure of the NPE Crosstalk Test.
2. If no circuit pack failed the NPE Crosstalk Test (#6), remove one or several purple slot circuit packs.
3. Run the **test tdm P** command.
4. If any of the TDM Bus tests fail:
   - Check if the backplane pins in the removed circuit pack's slot appear to be bent.
   - If the backplane pins are bent, straighten or replace the pins, re-insert the circuit pack, and do this procedure again for the same circuit pack.
   - If the backplane pins are not bent, re-insert the circuit pack and do this procedure for the next set of circuit packs.
5. If none of the TDM Bus tests fail:

- Re-insert the circuit pack.
- Run the **test tdm** system technician command.
- If any of the TDM Bus tests fail, the re-inserted circuit pack is faulty. Replace the circuit pack and do this procedure again for the new circuit pack.
- If none of the TDM Bus tests fail, then the problem has been fixed.

Procedure 3

This procedure removes and re-inserts control carrier circuit packs one at a time. The Network Control circuit pack and the Processor Interface circuit pack are the only processor complex circuit packs that communicate on the TDM Bus, and thus are the only processor complex circuit packs likely to cause a TDM Bus problem in a stable system. This procedure should be performed for the Processor Interface circuit pack before it is attempted for any other processor complex circuit packs.

In a System Without High or Critical Reliability

To perform this procedure for the Network Control circuit pack, this circuit pack must be replaced. The system cannot operate without the Network Control circuit pack.

1. Power down the control carrier.
2. Remove the suspected circuit pack.
3. Check if the backplane pins in the removed circuit pack's slot appear to be bent.
4. If the backplane pins are bent:
   - Straighten or replace the pins.
   - Insert the same circuit pack.
   - Repeat from Step 2 with the same circuit pack.
5. If the backplane pins are not bent, insert or replace the circuit pack.
6. Turn the power back on to reboot the system.
7. Run the **test tdm P** command.
8. If any of the TDM Bus tests fail:
   - If the circuit pack in Step 5 was inserted, do this step again replacing the circuit pack.
   - If the circuit pack in Step 5 was replaced, do this step again with the next circuit pack.
9. If none of the TDM Bus tests fail, the problem has been fixed.
10. If this step fails to identify the cause of the problem, go to Procedure 4.

In a High or Critical Reliability System

In a High or Critical Reliability system, a less destructive procedure for processor complex circuit packs can be used rather than the one described for standard systems. Once again, the procedure should be performed on the Processor Interface circuit pack and Network Control circuit pack before it is attempted for any other processor complex circuit packs.

Pulling out processor complex circuit packs from the Standby SPE does not require powering down the carrier and does not require starting the system again. See Chapter 8, "Reliability Systems: A Maintenance Aid" for more details.

1. Perform Procedure 2 for the suspected processor complex circuit pack in the Standby SPE to determine if it is causing the TDM Bus problem (see Note). The **status system** command indicates which SPE is in standby mode. If the suspected circuit pack is the Tone-Clock circuit pack, make sure the Tone-Clock circuit pack is in standby mode via the **status system** command or its LED state. The SYSTEM CLOCKS and SYSTEM TONES fields of the status system form should read "standby" or the yellow LED of the circuit pack should be off.

   NOTE:
   When doing Procedure 2 as a request of Procedure 3, pull out processor circuit packs instead of purple slot port circuit packs.

2. If it fails to identify the processor complex circuit pack as the cause of the problem, perform an SPE switch via the **reset system i** command (see Note).

   NOTE:
   Make sure that the current Standby SPE is in the standby mode via the **status system** command before performing the SPE switch.

3. Perform Procedure 2 for the suspected processor complex circuit pack in the new Standby SPE to determine if it is causing the TDM Bus problem.
4. If it fails again to identify the processor complex circuit pack as the cause of the problem, perform Procedure 2 for the remaining processor complex circuit packs.
5. If this procedure fails to identify the cause of the problem, go to Procedure 4.

Procedure 4

Procedure 4 attempts to isolate the failure to a particular set of carriers, and then checks only the circuit packs in those carriers. This procedure involves terminating the TDM Bus so that certain carriers are disconnected from the TDM Bus. This is done by moving the TDM Bus terminators (AHF1) on the carrier backplane. To terminate a TDM Bus at the end of a particular carrier, the TDM Bus cable that connects the carrier to the next carrier should be unplugged and replaced with the TDM Bus terminator. The TDM Bus terminators can be taken from one carrier to the other. To get to the TDM Bus cables, remove the back cover of the cabinet. When the length of the TDM Bus is modified via this procedure, the circuit packs that are essential to system operation and TDM Bus maintenance (for example, Network Control circuit pack, Tone-Clock circuit pack, Tone Detector circuit pack) must still be connected to the new *shortened* TDM Bus.

For the Processor Port Network (PPN)

1. Terminate the TDM Bus so that it extends within the active control carrier.
2. Run the **test tdm** system technician command. If any of the TDM Bus tests fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers connected to the *shortened* TDM Bus. Procedure 2 is performed for port circuit packs (purple slots) and Procedure 3 for control carrier circuit packs.
3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier and repeat this procedure. When a carrier is added that causes some of the TDM Bus tests to fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.

For the Expansion Port Network (EPN)

1. Terminate the TDM Bus so that it only extends within the carrier containing the active Expansion Interface (EXP-INTF) circuit pack.
2. Run the **test tdm** system technician command. If any of the TDM Bus tests fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers connected to the shortened TDM Bus.
3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier and repeat this procedure. When a carrier is added that causes some of the TDM Bus tests to fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.

If the above steps fail to identify a particular circuit pack or slot, the problem may be caused by a TDM Bus common component such as the termination resistors on the ends of the bus.

Restarting Nonfunctioning Port Circuit Packs

A defective TDM Bus Control Channel or system timing reference on one of the networks can result in port circuit packs (that is non-control carrier circuit packs) on this defective network entering the reset state. When this situation occurs, the circuit pack stops functioning and its red LED lights. The system does not detect the presence of a circuit pack when the circuit pack is in the reset state. Hence, executing the **list config board PCSS** command indicates that the circuit pack is not present.

If a circuit pack enters the reset state when the control channel is on TDM Bus PT (where network P contains the circuit pack), this circuit pack stops functioning until it receives a restart message when the control channel is on the same TDM Bus PT or when this circuit pack is powered up again.

To force the system to send a restart message to all circuit packs on a network, try one of the following methods depending on the circumstances:

NOTE:
A circuit pack functioning normally (that is, not in the reset state) ignores the restart message.

Procedure 1 (Nondestructive)

Execute the Idle Time Slot Test (#294) by issuing the command **test tdm P** when the control channel is on the same TDM Bus as it was when the circuit pack entered the reset state. If using this method is not feasible, try the other procedures in this section.

Procedure 2 (Non-Destructive)

if you are at the site: Reseat the circuit pack. This action causes the circuit pack that was in the reset state to begin functioning on the *current* Control Channel bus.

Procedure 2 (Nondestructive)

Execute the Idle Time Slot Test (#294) by issuing the command **test tdm P** when the control channel is on the same TDM Bus as it was when the circuit pack entered the reset state. If using this method is not feasible, try the other procedures in the section.

Procedure 3 (Destructive)

Reset the port network that contains the circuit pack that is in the reset state. When a network is reset, two restart messages, one on the control channel of each TDM Bus, are sent to each circuit pack on the network. Executing the **reset system L** command (where L=2, 3, 4, or 5) resets all networks in the system. *To reset an EPN only*, busyout all links to the EPN via the **busyout board PCSS** command and then release them via the **release board PCSS** command.

WARNING:
*The **reset system** command disrupts all calls in the system. Resetting the EPN only disrupts all calls going to and originating from the EPN.*

Procedure 4 (Destructive)

Execute the **recycle carrier PC** command where P is the Port Network Number of the network containing the circuit pack and C is the designation of the carrier containing the circuit pack.

WARNING:

This command removes power and returns power to the designated Medium cabinet port carrier. Thus, any other circuit packs on this carrier is also temporarily taken out-of-service.

Hardware Error Log Entries and Test to Clear Values

TDM Bus Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tdm
1	0	Control Channel Test (#296)	MINOR	ON	test tdm P r 3
18 (a)	0	busyout tdm PC	WARNING	ON	release tdm PC
35 (b)	0-1	TDM Bus Corruption	MINOR	ON	set tdm PC
257 (c)	0	none	MAJOR	ON	
513 (d)	Any	Idle Time Slot Test (#294)	MINOR	ON	test tdm P r 3
769 (e)	Any	Idle Time Slot Test (#294)	WARNING	ON	test tdm P r 3
769 (f)	Any	Idle Time Slot Test (#294)			(see Notes)
1025	Any				
3872 (g)	Any	none			
3873 (g)	Any	none			
3874 (g)	Any	none			
3877 (g)	Any	none			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

NOTE:
For TDM-BUS, an ON-BOARD alarm refers to a problem with the TDM-BUS itself.

Notes:

a. The TDM Bus has been busied out by the technician. The error retires when the technician releases the TDM Bus.

b. This error indicates the TDM Bus is corrupted. If the corruption was on the Control Channel bus and this system has High or Critical Reliability, TDM Bus maintenance automatically switches the control channel and/or tones to the other bus. The same strategy applies if the corruption was on the bus carrying the tones.

An aux data value of 0 indicates the last reported TDM Bus corruption was on the Control channel bus.

An aux data value of 1 indicates the last reported TDM Bus corruption was on the Non-Control channel bus.

If this error is logged on both TDM Buses (A and B) on the PPN within two or three minutes, the red LED of several circuit packs may or may not be lit and there could be Switch Control errors. Under these circumstances do the following:

- Display the Hardware Error Log via the **display errors** command and look for SW-CTL (Switch Control) errors.
- If there are any errors logged against the Switch Control, try to resolve them.
- Test the TDM Bus via the **test tdm P** command.
- If all the TDM Bus tests pass, the problem has been fixed.
- If some of the TDM Bus tests fail, replace the Duplication Interface circuit pack in the A carrier (see Chapter 8, 'Reliability Systems: A Maintenance Aid" for details). None of the Duplication Interface circuit pack tests detect this particular type of failure. Therefore, all its tests may still pass.
- Test the TDM Bus via the **test tdm P** command.
- If all the TDM Bus tests pass, the problem has been fixed.
- If not all the TDM Bus tests pass, escalate the problem.

c. This error indicates the TDM Bus was switched to the other bus due to TDM Bus corruption. The aux data value is not meaningful and no action is required.

d. This error indicates that some time slots are corrupted in the specified TDM Bus. The Minor alarm is raised when there are more than 50 bad time slots in the bus. The aux data indicates the number of bad time slots found by the test.

e. This error indicates that some time slots are corrupted in the specified TDM Bus. The Warning alarm is raised when there are more than 10 bad time slots but less than or up to 50 bad ones in the bus. The aux data value indicates the number of bad time slots found by the test.

f. This error indicates the idle time slot test found less than 10 bad time slots in the TDM Bus. The aux data value indicates the number of bad time slots found by the test. There is no alarm associated with this error.

g. These errors indicate communication problems. On a High or Critical Reliability system, TDM Bus maintenance may switch the Control Channel bus and/or Tone bus to the other bus. Test the TDM Bus via the **test tdm P** command and follow the procedures according to the error codes reported from the test.

The aux data value shows the Angel ID number for which a downlink message was lost.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
Control Channel Test on the Control			
Channel Bus (#296)	X	X	ND
Digit Detection Test on the Non-Control			
Channel Bus (#297)	X	X	ND
Idle Time Slot Test on TDM Bus A (#294)	X	X	ND

1 D = Destructive; ND = Nondestructive

Idle Time Slot Test on TDM Bus A or B (#294)

The Idle Time Slot Test detects noisy time slots on the bus and takes them out-of-service. The Tone Detector circuit pack is told to listen to idle time slots and if it detects any noise on a time slot, it returns a failure. At the end of the test, any out-of-service time slots are retested to see if they are still noisy and restored to service if they are idle. After all the time slots have been tested, maintenance counts the number of bad time slots and reports the number to the technician in the error code field. No more than 220 time slots are taken out-of-service on one bus, and no more than 300 are taken out-of-service on both buses at one time.

Table 11-349. TEST #294 or #295 Idle Time Slot Test on TDM Bus A or TDM Bus B

Error Code	Test Result	Description/ Recommendation
none	ABORT	Could not allocate the necessary system resources to run this test. For example, maintenance could be running on the Tone Detector circuit pack and it is using the CPTRs.
1115	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
number	FAIL	The error code indicates the number of bad time slots that were detected. The cause of this failure is most likely due to a bad port circuit pack and not the TDM Bus itself. 1. Execute the command again. 2. If the error persists, check the Error and Alarm Logs for alarms on port circuit packs from the NPE Crosstalk Test. 3. Refer to the appropriate circuit pack's documentation to clear the circuit pack's problem. 4. Test the TDM Bus again. If the error continues, refer to the "TDM Bus Fault Detection and Isolation Procedure" described earlier.
	PASS	The success of this test indicates all the idle time slots that are supposed to be idle are indeed idle. There is no noise on any of the idle time slots.

Control Channel Test (#296)

This test tests the integrity of the Control Channel bus. It ensures that communication through the TDM Bus is operational.

Table 11-350. TEST #296 Control Channel Test

Error Code	Test Result	Description/ Recommendation
any code other than 1005	ABORT	Internal System Error. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Since this test is valid only on the control channel bus, it aborts execution when run on the non-control channel bus. This is a valid response. Use the **status system** command to verify which bus is the control channel bus.
none	FAIL	Communication through the Control Channel is not working. The problem is not necessarily the TDM Bus itself. 1. Display the hardware error and alarm log for the Tone-Clock circuit pack. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation. 2. Resolve the errors for the Tone-Clock circuit pack. 3. Display the hardware error and alarm log for the Network Control circuit pack. Refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 4. If this error is on the EPN, display the hardware error and alarm log for the Expansion Interface. Refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation and resolve its errors. 5. Execute the **test tdm P** command again. 6. If the test still fails, refer to the "TDM Bus Fault Detection and Isolation Procedure" described earlier.
	PASS	Communication through the TDM Bus is operational.

Digit Detection Test (#297)

This test is executed on the Non-Control Channel bus. The Tone-Clock circuit pack is told to put a tone on the Non-Control Channel bus and the Tone Detector circuit pack is told to listen to it. The test passes if the tone is successfully transmitted on the Non-Control Channel bus.

Table 11-351. TEST #297 Digit Detection Test

Error Code	Test Result	Description/ Recommendation
none, 1001 2100	ABORT	Could not allocate the necessary system resources to run this test.
1005	ABORT	Since this test is valid only on the non-control channel bus, it aborts execution when run on the control channel bus. This is a valid response. Use the **status system** command to verify which bus is the control channel bus.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
none	FAIL	This failure indicates that communication on the Non-Control Channel is not reliable. 1. Execute the command again. 2. If the problem persists, test the Tone-Clock circuit pack and Tone Detector circuit pack to make sure they are healthy. Refer to TONE-BD (Tone-Clock Circuit Pack), TONE-PT (Tone Generator), GPTD-PT (General Purpose Tone Detector Port), and DTMR-PT (Dual Tone Multifrequency Port). 3. Execute the command again. 4. If the problems persists, refer to the "TDM Bus Fault Detection and Isolation Procedure" described earlier.
	PASS	The non-control channel bus is operational.

TDM-CLK (TDM Bus Clock)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
TDM-CLK	MAJOR	test tone-clock PC short	TDM Bus Clock
TDM-CLK	MINOR	test tone-clock PC short	TDM Bus Clock
TDM-CLK	WARNING	release tone-clock PC	TDM Bus Clock

1 P is the port network number (1 for PPN, 2 -3 for EPNs). C is the carrier designation (A, B, C, D, or E).

NOTE:
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The Time Division Multiplex (TDM) Bus Clock resides on the Tone-Clock circuit pack, providing clocking signals both for the TDM Bus and the LAN Bus. The Tone-Clock circuit pack is a critical component in the system and is necessary to ensure the operation of all port circuit packs in the system. The TDM busses of the Processor Port Network (PPN) and any Expansion Port Networks (EPNs) are synchronized together. The system timing reference can be derived internally from the Tone-Clock circuit pack in any PN, or from an external (off-board) timing reference. Currently, the TDM Bus Clock supports synchronizing the TDM Bus with interface rates from Digital Signal 1 (DS1) facilities as primary or primary and secondary references, and from Stratum 3 Clock (STRAT-3) facilities. Only the TN780 tone-clock supports a Stratum 3 clock.

The Tone-Clock circuit pack aids in monitoring and selecting synchronization references. The Tone-Clock circuit pack, after detecting that the external source of timing is not valid, will automatically begin its escalation procedure, according to the facilities administered. In the following table, successive losses of signal cause escalation from left to right.

NOTE:
Switching back to a DS1 source is handled by synchronization maintenance, once any problems with it have been corrected and tested. However, once synchronization has been switched to the internal timing source of the master Tone-Clock circuit pack, *switching back to a Stratum 3 Clock must be initiated by a technician* after the external reference has been repaired.

Synchronization Source Escalation Strategy

Tone-Clock Role	Synchronization Facilities	Initial External Synchronization Source	Backup External Synchronization Source	Internal Source
MASTER	Stratum 3 Clock	Source "A"	Source "B"	Local oscillator
	DS1 Primary and Secondary	DS1 Primary	DS1 Secondary	
	DS1 Primary Only	DS1 Primary	None	
	No External Source	None	None	
SLAVE	PNC Duplication	Active EI	Standby EI	
	No PNC Duplication	Active EI	None	

See Synchronization (SYNC) Maintenance documentation for more details of the escalation plan. *There exists a strong interdependency among the DS1 Interface circuit pack Maintenance, Synchronization Maintenance, and TDM Bus Clock Maintenance MOs*.

See the section on TONE-BD Maintenance in this manual for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Hardware Error Log Entries and Test to Clear Values

TDM Bus Clock Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tone-clock PC sh r 1
1 (a)	0	None	MINOR	OFF	
18 (b)	0	busyout tone-clock PC	WARNING	OFF	release tone-clock PC
130 (c)		None			
257 (d)		None	WARNING	ON	
513 (e)	Any	Clock Circuit Status Inquiry (#148)	MINOR[2]	OFF	test tone-clock PC
769 (f)	Any	Clock Circuit Status Inquiry (#148)	MAJOR	ON	test tone-clock PC sh r 10
1025 (g)	Any	Clock Slip Inquiry (#149)			test tone-clock PC sh
1281(h) 1282(h)	Any	None	MINOR	OFF	
1537	Any	Clock PPM Inquiry (#150)			test tone-clock PC sh
2049(i)	Any	Standby Reference Health Check Test (#651)	MAJOR[2]	ON	test tone-clock PC
2305(j)	0	None	WARNING	OFF	

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Major or MINOR alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. The Tone-Clock circuit pack may have a clock at the edge of its specified frequency. This can cause Expansion Interface circuit packs and SNI circuit packs to go out-of-frame or report no-neighbor conditions. This can is turn cause EPNs, Expansion Archangel Links (EALs), Remote Neighbor Links (RNLs), and/or Local Neighbor Links LNLs) to go down. When this error is alarmed, Clock Health Inquiry Test (#46) will fail with an error code of 1.

1. Replace the Tone-Clock circuit pack identified in the error log. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.
2. If the error persists, follow normal escalation procedures.

b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. It only applies to systems which have the High or Critical Reliability Option, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock PC** command for the alarmed circuit pack.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. The Tone-Clock circuit pack in the PPN is not a TN780 while a Stratum 3 synchronization is administered. Replace the Tone-Clock in the PPN with a TN780, or change synchronization administration to Stratum 4 if a Stratum 3 clock is not being used.

e. The TN2182 tone-clock has reported an out-of-lock condition. A aux value of 1 indicates this error is an out-of-lock with the primary reference. A aux value of 2 indicates this error is an out-of-lock with the secondary reference. It could not lock onto the frequency of that synchronization reference. This will lead to a change in the synchronization reference if the condition continues.

f. This error indicates that the Tone-Clock circuit pack may be defective.

1. If this error was logged against the Active Tone-Clock circuit pack, then test the Active Tone-Clock circuit pack via the **test tone-clock PC**. If there are any error codes from any tests, follow the recommended maintenance procedures for the error code(s) to resolve the problem(s). If the problem(s) persists, follow normal escalation procedures.
2. If this error was logged against the Standby Tone-Clock circuit pack, and if the Aux Data value was 18369, Synchronization maintenance acts on this error. No corrective action is required. For all the other Aux Data values, replace the Standby Tone-Clock circuit pack. Refer to the TONE-BD section on "How to Replace a Tone-Clock Circuit Pack".
3. If the error persists, follow normal escalation procedures.

g. Tone-Clock circuit pack on-board maintenance has detected one or more clock slips, timing differences between its internal reference source and the synchronization signal provided by the master Tone-Clock. Although no clock slip errors are expected during normal operation, both manual and automatic interchanges of Tone-Clock circuit packs, synchronization references, and EI link switches, may result in clock slip counts.

If error 1281 is also logged for the same Tone-Clock circuit pack, it is related to this problem and should be corrected first. Otherwise, continue with the procedure below.

1. Use **test tone-clock PC** and examine the results of test #149 to see if slip errors are still occurring. If no new slip errors are reported, and if these errors are not causing a TDM-CLK alarm, they may be ignored. Use **test tone-clock PC long clear** to clear the errors.
2. Otherwise, enter the **display errors** command and follow corrective procedures for any other TDM-CLK, TONE-BD, SYNC, and EXP-INTF errors logged, except for those in the following table.

Circuit Pack Name	Error Log Name	Error Log Entry for Slips
DS1 Interface	DS1-BD	3073 to 3160
Expansion Interface	EXP-INTF	2305
Tone-Clock	TDM-CLK	1025
UDS1 Interface	UDS1-BD	3073 to 3160

3. If 1025 errors persist, refer to SYNC Maintenance in this manual. If this still does not resolve the error, follow normal escalation procedures.

h. Error Type 1281—This error is an indication that the Tone-Clock circuit pack has detected a loss of timing signal from the system synchronization reference. The Tone-Clock circuit pack has switched synchronization references, according to the strategy described in the preceding table on Synchronization Escalation.

1. Resolve any errors logged against the SYNC or STRAT-13 maintenance objects.
2. Refer to SYNC maintenance, in the “Approach to Troubleshooting” section, if the error is not resolved by step 1
3. If the error persists, follow normal escalation procedures.

Error Type 1282—Indicates that the TN2182 tone-clock was synchronized to a DS1 facility and that the reference frequency provided by the DS1 drifted beyond a range that could be tracked by the TN2182. Therefore the TN2182 is no longer synchronized to that DS1 reference. If a second DS1 is available, the tone-clock may be synchronized to that reference. If no secondary DS1 reference is available, the tone-clock will run off of its internal clock. This may result in slips being reported by the tone-clock and all DS1 facilities.

i. The tone-clock circuit pack in the master port network was unable to detect the incoming synchronization signal, but the other tone-clock was able to detect the references. If the aux data is 0, the problem is with the signal on the primary. If the aux data is 1, the problem is with the signal on the secondary. The system should switch clocks in this situation.

1. If this error is against a PPN clock board and the system is using a Stratum 3 clock, check the cabling that brings the stratum 3 signal to this clock board.
2. Replace the current standby Tone-Clock circuit pack. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.
3. If the error persists, follow normal escalation procedures.

j. The indicated active Tone-Clock circuit pack, which is on a port network that does not contain the system synchronization reference (a **slave** Tone-Clock), has detected a loss of timing signal from its EXP-INTF synchronization source.

1. Enter **display errors** and **display alarms**, and follow the associated repair procedures for EXP-INTF, TDM-CLK, and TONE-BD error log entries that have on-board alarms.
2. If the 2305 errors persist, follow the repair procedures for EXP-INTF error log entries 257, 769, or 770.
3. If the 2305 errors persist:

    d. *For Port Networks with more than one Tone-Clock circuit pack*, execute the command **test synchronization r 10**, and check to see if new 2305 errors against TDM-CLK were reported. If not, execute **set expansion-interface** and then **test synchronization r 10** again, and recheck for new 2305 errors against TDM-CLK.

    e. *For Port Networks with a single Tone-Clock circuit pack*, execute the command **test synchronization r 10**, and check to see if new 2305 errors were reported.

    If no new instances of the 2305 errors were logged for either test, then enter **test tone-clock PC long clear** to clear the TDM-CLK errors and the procedure is complete.

4. **For Port Networks with more than one Tone-Clock circuit pack**, interchange Tone-Clocks with the **set tone-clock PC**, then run **test synchronization r 10**, and check to see if new 2305 errors are reported against the new active Tone-Clock circuit pack. If not, replace the standby Tone-Clock circuit pack. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section. If this clears the error, the problem has been resolved.
5. Replace the EI circuit pack for the active EXP-LNK.
6. If the problem is still not cleared, and the Tone-Clock circuit pack reported in the error log has not been replaced up to now, replace it. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.
7. If the problem persists, follow normal escalation procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Use the **list configuration control** command to find the Tone-Clock circuit pack code of the system, and then proceed to look for the Short and Long Test Sequences according to the Tone-Clock circuit pack code.

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For a system with a TN756 Tone-Clock Circuit Pack:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X	D
Clock Health Test (#46) (b)	X	X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Tone Detection Verification Test (#42) (c)	X	X	ND
Tone Detector Audit/Update Test (#43) (c)	X	X	ND
Tone Generator Crosstalk Test (#90) (d)		X	ND
Tone Generator Transmission Test (#40) (d)	X	X	ND
Tone Generator Audit/Update Test (#41) (d)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) documentation for a description of this test.

c. Refer to Dual Tone Multifrequency Receiver Port (TTR) (DTMR-PT) or General Purpose Tone Detector Port (CPTR) (GPTD-PT) Maintenance documentation for descriptions of this test.

d. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

For a system with a TN768,TN780 or TN2182 Tone-Clock Circuit Pack:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X	D
Clock Health Test (#46) (b)	X	X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Tone Generator Crosstalk Test (#90) (c)		X	ND
Tone Generator Transmission Test (#40) (c)	X	X	ND
Tone Generator Audit/Update Test (#41) (c)	X	X	ND
TDM Bus Clock Circuit Status Inquiry Test (#148)	X	X	ND
TDM Bus Clock Slip Inquiry Test (#149) (e)	X	X	ND
TDM Bus Clock PPM Inquiry Test (#150)	X	X	ND
TDM Clock Board Type (#574)		X	ND
TDM Bus Clock Parameter Update Test (#151)	X	X	ND
Standby Reference Health Check Test (#651) (d)		X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) documentation for a description of this test.

c. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above or be a TN2182.

e. Test #149 is not run on a TN2182.

TDM Bus Clock Circuit Status Inquiry Test (#148)

The TDM Bus Clock circuitry is checked for sanity. Any problems that are found are reported via error codes.

Table 11-352. TEST #148 TDM Bus Clock Circuit Status Inquiry Test

Error Code	Test Result	Description/ Recommendation
None 1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait 1 minute, and retry the test. 2. If the test continues to abort, follow normal escalation procedures.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
1	FAIL	This error means the Tone-Clock circuit pack framing verification firmware reports an error in the clock synchronization signal coming into this Port Network. 1. If the Tone-Clock circuit pack reporting the problem is a master clock, then the system synchronization reference is providing a bad timing source. Refer to SYNC (Synchronization) or STRAT-3 (Stratum 3 Clock) Maintenance documentation to change the system synchronization reference. 2. If the Tone-Clock circuit pack is a slave clock, then the EI to which it is listening is providing a bad timing source. Follow the diagnostic procedures specified for TDM-CLK Error Code 2305. 3. If no problem can be found with the incoming synchronization signal, replace the Tone-Clock circuit pack. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.

Continued on next page

Table 11-352. TEST #148 TDM Bus Clock Circuit Status Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	This error indicates that the Tone-Clock circuit pack has inaccurately detected loss of signal on the incoming synchronization timing source.
4 8	FAIL	The local oscillator on the Tone-Clock circuit pack has failed.
16 32	FAIL	The circuitry on the Tone-Clock circuit pack used to detect synchronization timing errors has failed. 1. Errors 2, 4, 8, 16, and 32 indicate that there is poor synchronization between port networks and external facilities. It may be noticeable to the customer in the form of errors in data communications. The Tone-Clock circuit pack is defective. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.
64	FAIL	This message is only sent when an uplink message has reported the loss of valid synchronization timing information coming into this Port Network. It has been reported in TDM-CLK Error Log entries; one or more of 1025, 1281, 1537, 2049 and 2305. 1. Resolve the errors indicated. No separate corrective action is required.

Continued on next page

Table 11-352. TEST #148 TDM Bus Clock Circuit Status Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
65	FAIL	The tone-clock is currently not able to lock on to the current synchronization reference. If this tone-clock is in the master port networK: 1. Examine the error log for any DS1-BD, SYNC or other TDM-CLK errors and resolve as applicable. 2. Run this test again via the test tone-clock PC command. 3. Examine the DS1 measurements to determine if the facility is healthy. 4. Adminsiter a new synchronization reference. 5. Replace the DS1 board currently supplying the reference. If this tone-clock is in the slave port networK: 1. Examine the error log for any SYNC, EXP-INTF or other TDM-CLK errors. 2. Run this test again via the test tone-clock PC command.
66	FAIL	There is an on-board failure of TDM clock hardware. 1. Replace this faulty tone-clock circuit pack.
	PASS	TDM Bus Clock Circuit Status is sane. There are no clock-detection circuit problems on the Tone-Clock circuit pack.

TDM Bus Clock Slip Inquiry Test (#149)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack. This test does not apply to the TN2182.

Table 11-353. TEST #149 TDM Bus Clock Slip Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system could not allocate the necessary resources for the test.
1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait one minute, and retry the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
ANY	FAIL	This error represents the number of timing slips detected on the incoming synchronization source since the last slip inquiry was sent to the Tone-Clock circuit pack. The incoming synchronization source can be from one of three sources: (1) a DS1 Interface circuit pack, (2) an EXP-INTF circuit pack if the port network on which the test was executed does not contain the current system synchronization reference; (3) a local oscillator on an Active Tone-Clock circuit pack. The error code is a variable amount ranging from 1 to 255. 1. If there are errors against synchronization (SYNC), refer to the Synchronization Maintenance documentation to change the system synchronization reference. 2. If there are errors against DS1 Interface circuit pack (DS1-BD), refer to the DS1 Interface circuit pack Maintenance documentation to resolve the errors.

Continued on next page

Table 11-353. TEST #149 TDM Bus Clock Slip Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY *(cont'd.)*	FAIL	3. If there are no SYNC or DS1-BD errors and a. this error was logged against the Tone-Clock circuit pack that was the current system synchronization reference at the time (use the command **status synchronization** to determine this), replace this Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section. **NOTE:** Disruption may occur when executing the following procedures. If the system does not return to normal after these procedures are completed, escalate the problem. b. the Tone-Clock circuit pack you are testing is in Active mode but does not contain the current system synchronization reference, switch the synchronization reference to the Tone-Clock circuit pack under test via the **set synchronization PC** command. Retry the command. If the error is still present, replace this Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section. c. the Tone-Clock circuit pack under test is in Standby mode, make it active via the **set tone-clock PC** command and switch the synchronization reference to it. Reissue the command. If the error is still present, replace this Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section. If the problem persists, escalate the problem.
	PASS	The Tone-Clock circuit pack does not detect any timing slips. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The **status synchronization** command should be used to verify that the desired synchronization reference is providing timing for the system.

TDM Bus Clock PPM Inquiry Test (#150)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack.

Table 11-354. TEST #150 TDM Bus Clock PPM Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system could not allocate the necessary resources for the test.
1001	ABORT	The system could not allocate the necessary resources for the test. 1. Wait 1 minute, and retry the test. 2. If the test continues to abort, follow normal escalation procedures.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
255	ABORT	The test was not executed because the Tone-Clock circuit pack was using its local oscillator rather than synchronizing to an external source. 1. Verify that this Tone-Clock circuit pack is expected to be the synchronization source. If not, correct the synchronization information and re-execute the test.

Continued on next page

Table 11-354. TEST #150 TDM Bus Clock PPM Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	This error represents the number of PPM errors detected on the external synchronization source since the last PPM inquiry was sent to the Tone-Clock circuit pack. A failure of this test indicates that we are outside of Stratum 4 or Stratum 3 timing specifications on the external timing source. This error produces an invalid timing signal for any system that uses this source for a synchronization reference. The error code is a variable amount ranging from 1 to 254. 1. If there are errors against SYNC (Synchronization), refer to SYNC (Synchronization) Maintenance documentation to change the system synchronization reference, OR 2. If there are errors against STRAT-3 (Stratum 3 Clock), refer to the STRAT-3 (Stratum 3 Clock) Maintenance documentation to resolve the errors, OR 3. If there are errors against DS1-BD (DS1 Interface circuit pack), refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation to resolve the errors, OR

Continued on next page

Table 11-354. TEST #150 TDM Bus Clock PPM Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
ANY *(cont'd.)*	FAIL	4. If there are no other errors besides Error Type 1537 against TDM-CLK and if this error was logged against the Tone-Clock circuit pack that provided the current system synchronization reference (use the **status synchronization** command to determine this), replace the defective Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section in this Maintenance documentation. **WARNING:** *Since service may be disrupted when the following procedures are carried out, try to perform the following steps when it is convenient for the customer.* 5. If the Tone-Clock circuit pack under test is in the Active mode but is not providing the current system synchronization reference, switch the synchronization reference to the Tone-Clock circuit pack under test using the **set synchronization PC** command. Rerun the test. If the test still fails, replace the defective Tone-Clock circuit pack (refer to the "How to Replace a Tone-Clock Circuit Pack" section in this Maintenance documentation). 6. If the Tone-Clock circuit pack under test is in the Standby mode place it in the Active mode via the command **set tone-clock PC**. Switch the synchronization reference to the Tone-Clock circuit pack under test using the **set synchronization PC** command. Rerun the test. If the test still fails, replace the defective Tone-Clock circuit pack (refer to the "How to Replace a Tone-Clock Circuit Pack" section in this Maintenance documentation). If problems persist, follow normal escalation procedures.

Continued on next page

Table 11-354. TEST #150 TDM Bus Clock PPM Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Tone-Clock circuit pack does not detect timing any PPM errors. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The **status synchronization** command should be used to verify that the desired synchronization reference is providing timing for the system.

TDM Bus Clock Parameter Update Test (#151)

This action updates the Tone-Clock internal circuit pack parameters. Tone-Clock circuit pack:

- Disable in-line duplication status messages.
- Disable in-line subrate frame maintenance messages (TN768, TN780 only).
- Set the PPM threshold at 60 PPM for TN768 and TN780. Set the PPM threshold at 85 PPM for TN2182.
- Enable PPM threshold switching
- Set the number of slips to trigger *loss of signal* - currently 30 per 5 millisecond period
- Enable the on-board synchronization switching algorithm (see above)
- Enable holdover operation (TN2182 only).

This is not a test and will always pass without identifying or reporting any Tone-Clock circuit pack errors.

Table 11-355. TEST #151 TDM Bus Clock Parameter Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow normal escalation procedures.
	PASS	The Tone-Clock circuit pack parameters have been successfully updated.

TDM-Clock Circuit Pack Type Test (#574)

The purpose of this query is to check if the required type of Tone-Clock circuit pack (TN780) is present when the Stratum 3 clock is administered.

Table 11-356. TEST #574 TDM Clock Circuit Pack Type Test

Error Code	Test Result	Description/ Recommendation
	ABORT	The system could not allocate the necessary resources to run the test. 1. Wait one minute and retry the test.
	FAIL	The Tone-Clock circuit pack in the system is not a TN780. The Stratum 3 clock requires a TN780 Tone-Clock circuit pack. 1. Replace the Tone-Clock circuit pack with a TN780. The old circuit pack may still be good, and need not be discarded.
	PASS	The required TN780 circuit pack is present.

Standby Reference Health Check Test (#651)

This test evaluates the quality of the external synchronization timing source for the Standby Tone-Clock circuit pack.

Table 11-357. TEST #651 Standby Reference Health Check Test

Error Code	Test Result	Description/ Recommendation
	ABORT	This test may already be running due to a tone-clock installation, scheduled maintenance, alarm activity, or a technician-demand test from another terminal. This abort can also occur due to an internal system error. 1. Try the command again at 1-minute intervals up to five times. 2. If the test continues to aboft, escalate the procedure.
1184	ABORT	This test requires an external synchronization source to be administered (DS1 primary, DS1 primary and secondary, or Stratum 3 Clock). 1. Administer the external synchronization source and retry the test.
2500	ABORT	Internal System Error 1. Try the command again at 1-minute intervals up to 5 times. 2. If the test continues to abort, follow normal escalation procedures.
0	FAIL	**If the Tone-Clock circuit pack is in the PPN**, the external synchronization timing source for side A of the Stratum 3 clock, or for the Primary DS1 reference is either absent or invalid. **If the Tone-Clock circuit pack is in an EPN**, the synchronization reference from the active EI circuit pack is either absent or invalid.

Continued on next page

Table 11-357. TEST #651 Standby Reference Health Check Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	**If the Tone-Clock circuit pack is in the PPN**, both external synchronization timing sources are either absent or invalid. **If the Tone-Clock circuit pack is in an EPN**, the synchronization references from both EI circuit packs are either absent or invalid. 1. Correct the synchronization source problem. Refer to the Synchronization (SYNC) maintenance section of this manual. 2. If the error still exists, replace the Tone-Clock circuit pack reported in the error log. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section. 3. If the problem has not been corrected, follow normal escalation procedures.
	PASS	The external synchronization timing source is valid.

TIE-BD (Tie Trunk Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
TIE-BD	MIN	test board PCSS sh	Tie Trunk Circuit Pack
TIE-BD	WRN	test board PCSS sh	Tie Trunk Circuit Pack

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also TIE-TRK (Tie Trunk).

TIE-DS1 (DS1 Tie Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TIE-DS1[1]	MAJOR[2]	test trunk <grp/mbr> l	DS1 Tie Trunk
TIE-DS1	MINOR	test trunk <grp/mbr> l	DS1 Tie Trunk
TIE-DS1	WARNING	test trunk <grp/mbr>	DS1 Tie Trunk

1 For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.

2 A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

The DS1 tie trunk provides both voice and data inter-PBX communication. A 24 channel DS1 Interface circuit pack can support up to 24 digital tie trunks through a 1.544 Mbps DS1 link. A 32 channel DS1 Interface circuit pack can support up to 30 digital tie trunks through a 2.048 Mbps DS1 link. DS1 Interface circuit packs are described in DS1-BD. DS1 Tie Trunks are used widely in the DCS and Central Attendant Service (CAS) features of the system.

A DS1 tie trunk can also be used as an access endpoint which is a non-signaling channel with a bandwidth of voice-grade-data, 56K-data or 64K-data.

DS1 tie trunk maintenance provides a strategy to maintain a DS1 tie trunk via a port on the DS1 Interface circuit pack. The maintenance strategy covers logging DS1 tie trunk hardware errors, running tests for trunk initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution. Three different trunk service states are specified in the DS1 tie trunk maintenance. They are: *out-of-service* in which the trunk is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the trunk is in an activated state and can be used for both incoming and outgoing calls; *disconnect* (ready-for-service) in which the trunk is in an activated state but can only be used for an incoming call. If the DS1 Interface circuit pack is out-of-service, all trunks on the DS1 Interface circuit pack are placed into out-of-service state, and a Warning alarm is raised.

Hardware Error Log Entries and Test to Clear Values

DS1 Tie Trunk Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value

DS1 Tie Trunk Maintenance Error Log Entries

2562(j)	16665				
2817(k)	52992				
3840 (j)	Any	Port Audit and Update (Test #36)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.

3 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the MINOR alarm is not downgraded by the **set options** values, the MINOR alarm is upgraded to a MAJOR alarm if 75 percent of the trunks in this trunk group are alarmed.

a. Error Type 1—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error can be caused by incompatible translations. Make sure the parameters administered on the DS1 circuit pack form match those administered on the far-end switch. See *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107, for details.

   The Aux Data field indicates the following hardware error types:

57476	On-hook before wink
57477	On-hook before ready to receive digits
57485	Wink too short for valid signal
57487	The timer expired while waiting for an off-hook signal from the far end as a response at end of digits dialing. Check the far-end switch for related problems.

   If all administration errors between the switch and the far-end match, and these errors continue to recur, follow normal escalation procedures.

b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).

c. Error Type 18—The DS1 tie trunk has been busied out by a **busyout trunk** grp/mbr command. No calls can be made on this trunk except for the Facility Access Test Call. Facility Access Test Calls are describe in Chapter 6, "Accessing Alarms and Errors" and in *DEFINITY Communications System Generic 3 Feature Description,* 555-230-204.

d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

e. Error Type 257—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk cannot communicate with the far end because it is unable to interpret digits sent from the far-end switch. The Aux Data field indicates the following:

57473	The rotary dial rate is below 8 pulses per second.
57474	The rotary dial rate is above 12 pulses per second.

Check with the far-end switch or operating company for proper trunk connection.

f. Error Type 513—DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk is in-service/active and waiting for an ‘‘on-hook’’ from the far-end switch. No calls can be routed over the trunk while it is in this state. Aux Data 57392 indicates no external release on PBX disconnect. Check with the far-end switch or operating company for proper trunk connection.

g. Error Type 769—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error usually occurs after one or more occurrences of error type 513. The trunk has received the belated ‘‘on-hook’’ that it has been waiting for from the far-end switch. The trunk is restored to in-service/idle and can be used for calls. Aux Data 57393 indicates delayed external release on PBX disconnect. This error can be ignored.

h. Error Type 1793—The DS1 Interface circuit pack is out-of-service. See the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation for details.

i. Error Type 2305—Reorder message. The trunk could not be seized. This error will cause the Trunk Seizure Test (#136) to run and is only considered a problem if the Seizure Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in “Ready-for-Service’’ state (shown as ‘‘disconnected’’ by the status command), which allows only incoming calls. Run the Trunk Seizure Test (#136) and follow its outlined procedures.

j. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

k. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the DS1 Tie Trunk Seizure Test (#136) and follow its outlined procedures.

l. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command and verify the status of the trunk. If the trunk is out-of-service, then enter **release trunk** command to put it back to in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the

NPE Crosstalk Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 Tie Trunk Seizure Test (#136)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes on the order of 20 to 30 seconds to complete.

Table 11-358. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Table 11-358. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) Maintenance Documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the **list measurements tone-receiver** command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at 1 minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-358. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run because of a previously existing error on the specific port or a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Table 11-358. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-PN and/or EXP-INTF errors in the error log. If present, refer to the EXP-PN Maintenance documentation and the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Retest when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 11-358. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 11-359. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. Table 11-359. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the far-end PBX. Make sure that the near-end and far-end switches and any NTCE equipment (the CSU's) have the correct administration.

Continued on next page

Table 11-359. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(con't.)*	6. Replace the circuit pack. **NOTE:** If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Table 11-359. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to ensure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk kept by the DS1 Interface circuit pack and the switch software.

Table 11-360. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1006	ABORT	The test was aborted because the trunk is out of service. 1. Use the **status trunk** command to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. If it is OK to put the trunk back in service, issue the **release trunk** command to put the trunk back in service, and then retry the test. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-360. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but it does return PASS. To verify that the trunk is in-service: 1. Enter **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release trunk** command to put trunk back into in-service. 3. Retry the test command.

Table 11-360. TEST #36 Audit and Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

DS1 Tie Trunk Seizure Test (#136)

The DS1 Tie Trunk Seizure Test is run to verify the trunk's signaling capability. The test is composed of two parts. The first part queries the circuit pack for the following errors: Loss of Signal, Red Alarm, Blue Alarm, Yellow Alarm, and Hyperactivity Alarm. The second part of the test is performed by sending a seizure message to the DS1 Interface circuit pack and expecting an active reply by the DS1 Interface circuit pack. If maintenance software does not receive any reply and the timer expires, the test is aborted. Once the active message is received, a dial pause message is sent to the DS1 Interface circuit pack. If the DS1 Interface circuit pack replies with a dial pulse tone message when the far end responds to the seizure, then the DS1 tie trunk Seizure Test passes. If the far end does not respond to the seizure and the timer expires, and the DS1 Interface circuit pack sends a reorder message back to the maintenance software, then the test fails.

This second part of this test **CANNOT** be run on a trunk if one of the following cases is true:

1. The trunk direction is administered as an incoming only trunk.
2. The trunk is the 24th port on a DS1 Interface circuit pack which is administered using 24th Common Channel Signaling.
3. The trunk has been seized by a normal trunk call.
4. The trunk is administered with maintenance test disabled.
5. The outgoing signal type of the trunk is either automatic or immediate-start.

Table 11-361. TEST #136 DS1 Tie Trunk Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1004	ABORT	Far end is seizing the trunk while the test is ongoing. A glare situation is detected. Current test is designed to be aborted. Use the **display port UUCSSpp** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-361. TEST #136 DS1 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Verify the following fields on the trunk group administration screen: a. Is trunk direction incoming only? b. Is trunk outgoing type either automatic or immediate-start? c. Is trunk the 24th port of the DS1 Interface circuit pack while common control channel signaling is specified? 2. If the trunk has been administered using the above information, then this test should abort.
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n.' To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.
1020	ABORT	The test did not run due to an already existing error on the specific port or due to a more general circuit pack error. 1. Examine the error log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error. 2. Retry the test. 3. If the test continues to abort, escalate the problem.
1040	ABORT	This test is not performed for trunk ports administered as access endpoints. 1. Verify this port is an access endpoint by using the **display port** command. 2. If the port has been administered as an access endpoint, this test should abort.

Continued on next page

Table 11-361. TEST #136 DS1 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT/ FAIL(1)	At least one of the following errors is found on the circuit pack: 1281: Loss of Signal, 1793: Blue Alarm, 2049: Red Alarm, 2305: Yellow Alarm, 1537: Hyperactivity. 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the DS1-BD tests for the listed error types.

Continued on next page

Table 11-361. TEST #136 DS1 Tie Trunk Seizure Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The far-end trunk did not respond to the seizure of the near-end trunk within the allowable time period. This test could have associated in-line errors in the error log. 1. 1) Enter the **list configuration board UUCSS** command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 136 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the 'Trunk Type' field on the 'Trunk Administration' screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) Maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) Maintenance documentation. 4. Retry the test at 1 minute intervals for a maximum of 5 times. 5. If the test continues to fail, escalate the problem.

Continued on next page

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the **list config** command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

(1) Earlier G1 Software Versions reported Error Code 2053 as a FAIL

TIE-TRK (Tie Trunk)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
TIE-TRK[2]	MAJOR[3]	test port PCSSpp l	Tie Trunk
TIE-TRK	MINOR	test port PCSSpp l	Tie Trunk
TIE-TRK	WARNING	test port PCSSpp sh	Tie Trunk

1 Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

2 Not relevant to the TN497 circuit pack.

3 A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. (This is not relevant to the TN497 circuit pack.

NOTE:
If ATMS testing is enabled, check the error log for ATMS Errors #3840 and #3841. If the error log indicates that measurements exceeded acceptable thresholds, and if no other trouble is found with the **test trunk** command, run the ATMS test call with the **test analog-testcall port PCCSSpp full** command.

The following circuit packs are covered by this section of TIE-TRK (Tie Trunk):

- TN760 series
- TN437 [G3iV2-386]
- TN439 [G3iV2-386]
- TN458 [G3iV2-386]
- TN497 [G3iV2-386]
- TN2140 [G3iV2-386]

The Tie Trunk circuit pack fits into a port slot and contains four trunk circuits (see Figure 11-101). Each of these circuits interface a digital PBX to an analog tie trunk going to another PBX across one-way dedicated circuits (except for the TN497 circuit pack) or across two-way dedicated circuits. Except for the TN439 and TN497 circuit packs, each tie trunk has a 4-wire audio connection and may have two signaling leads (E and M). Each tie trunk for the TN439 and TN497 circuit packs has 2-wire audio connection/signal leads (A and B).

In G3iV1.1-286 or G3iV2-386, a tie trunk port can also be administered as an access endpoint, which is a non-signaling channel with a voice-grade data bandwidth.

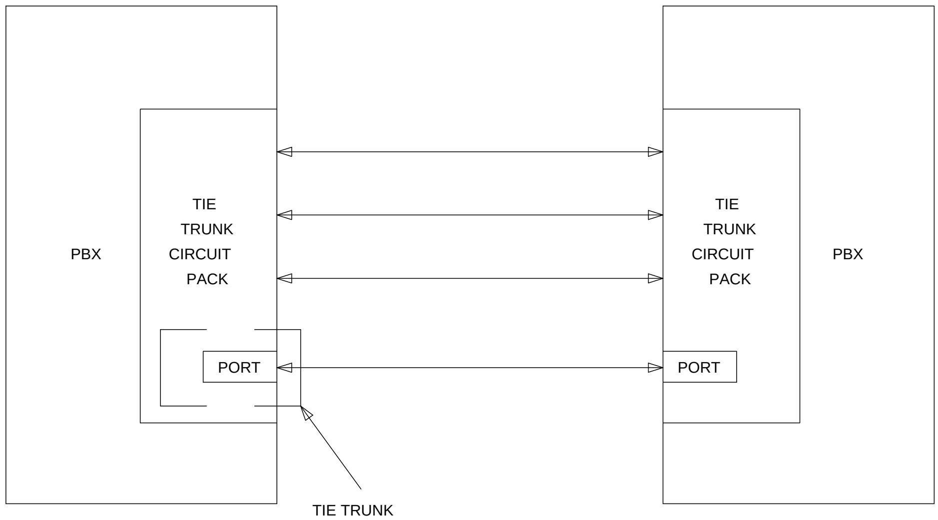

Figure 11-101. Tie Trunk Interactions

The number of tests to be implemented for Tie Trunk maintenance depends upon the TIE-TRK circuit packs involved. The test are as follows:

1. NPE Crosstalk Test—Verifies the switch connection operation of the circuit pack. It verifies that the trunk circuitry talks only on the selected time slot on the TDM Bus and that it never crosses over to time slots reserved for other connections.
2. Loop Around and Conference Circuit Test—Verifies the transmission operation of the circuit pack. It verifies that signals are transmitted to and from each port (Loop Around within the port), and it tests the conference capabilities of all ports.

   This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration test field.
3. Several seizure tests, including the following:
   - Tie Trunk Seizure Test (not relevant to the TN439 and TN497 circuit packs)—Verifies the seizure capabilities of the circuit pack. For wink start and delay dial outgoing trunks only, (and, for the TN2140

[G3iV2-386] circuit pack, also for continuous-seize-ack and discontinuous-seize-ack), this test activates the M lead and checks for a response from the distant end within 10 seconds. For G3iV1.1-286 or G3iV2-386, this test ABORTS on trunk ports administered as access endpoints.

— Seizure Test (for TN497 circuit packs only)—Verifies the seizure capabilities of the circuit pack. This test seizes the trunk and outpulses a "pause." The port reports the result of the seizure attempt uplink. The test can be disabled via Trunk Group Administration.

— Tie Trunk Dial Test (for TN439 circuit packs only)—Verifies the seizure and dialing capabilities of the circuit pack. **This test ABORTS on trunk ports administered as access endpoints.**

4. EPF, M, and E Lead Test [G3iV1.1-286 and G3iV2-386 only]—ABORTS on trunk ports administered as access endpoints. This test consists of two parts:

   - E lead test—Checks for the proper activation and deactivation of the port's E lead.
   - M lead test—Checks the M lead EPF current flow. The results of this test allow for distinguishing between circuit pack and external facility failures.

5. Port Audit Update Test (Audit & Update Test for the TN497 circuit pack)—Sends non-disruptive administrative updates to the circuit pack with no expected response. The test updates the translation information on individual ports of the Tie Trunk. Except for the TN497 circuit pack, these updates include:

   - Immediate, automatic, wink start, or delay dial and for the TN2140 [G3iV2-386], continuous-seize-ack
   - For the TN2140 [G3iV2-386], continuous or discontinuous.
   - Rotary or DTMF senderization in or out
   - Disconnect timing
   - DMTF time slot

Additional in-line testing is performed while a call is in progress. Thus, many in-line errors may occur during operation. See the Error Log table for a description of these errors. These errors may be reproduced by using the trunk (making a call), and checking their occurrence in the Hardware Error Log.

Before a maintenance test can be run on a port, the port is required to be idle. Except for a TN497 circuit pack, if an incoming call seizes the port which is being tested by maintenance, the test is aborted, and the incoming call proceeds.

Non-TN497 circuit packs can be configured for back-to-back testing (also known as connectivity testing) by making translation and cross-connect changes. This testing configuration allows for the connection of Tie Trunks back-to-back in the same switch to verify the operation of Tie Trunk ports. The tests can be performed in either the E&M or simplex modes. For details, refer to the "Analog Tie Trunk Back-to-Back Testing" section in Chapter 5, "Routine Maintenance Procedures"

Hardware Error Log Entries and Test to Clear Values

Table 11-362. TIE Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value

1 Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the MINOR alarm is not downgraded by the **set options** values, the MINOR alarm is upgraded to a MAJOR alarm if 75 percent of the trunks in this trunk group are alarmed.

2 Non-TN497 circuit packs only.

3 TN439 circuit packs only.

4 Non-TN439 and non-TN497 circuit packs only

5 TN497 circuit packs only.

6 TN439 and TN497 circuit packs only.

Notes:

a. Digit time-out. This occurs when the far-end PBX begins transmitting digits too late (10 seconds) after receiving the signal indicating ready to receive digits (if any). This can occur on an incoming immediate, wink, or delay dial line. Check the far-end PBX to ensure a translation match at both ends.

b. Rotary dial before wink. This occurs when the far-end PBX starts dialing before the PBX sends the wink on a wink-start or (for non-TN439 circuit packs) on a delay-dial line. Check the far-end PBX to ensure a translation match at both ends.

c. Rotary dial too early. This occurs when the far-end PBX starts dialing too soon (about 50ms) after seizure on a wink start or (for non-TN439 circuit packs) on a delay-dial line. Check the far-end PBX to ensure a translation match at both ends.

d. On hook before wink. This occurs when the far end goes on hook before a wink. Check the far-end PBX to ensure a translation match at both ends.

e. On an outgoing wink-start or delay-dial trunk, the wink time was too short (less than 80ms) for a valid signal. Check the far-end PBX to ensure a translation match at both ends.

f. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).

g. This indicates that the trunk in question has been busied-out by maintenance personnel.

h. This indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

i. The rotary dial rate was too slow (less than eight pulses per second.) Check the far-end PBX to ensure a translation match at both ends.

j. The rotary dial rate was too fast (more than 12 pulses per second.) Check the far-end PBX to ensure a translation match at both ends.

k. The time between digits was too short (less than 300ms). Check the far-end PBX to ensure a translation match at both ends.

l. This indicates that the trunk is still seized with an incoming call. The far-end PBX is not releasing the trunk after the call is dropped. A Minor alarm is generated every four minutes until the far-end PBX releases the trunk. Check the far-end PBX for problems.

   Once the trunk is released from the call, the severity of this problem is decreased. If Error Type 1025 does not appear again, this means that the problem has been corrected. Verify that Error Type 1025 does not reappear in the Error Log.

m. Reorder message. Trunk could not be seized. This error causes the Tie Trunk Seizure Test (#73) to run, and it is considered a problem only if the Seizure Test fails (in which case Error Type 1793 also shows up). In this case, the trunk may be placed in the "Ready-for-Service" state (shown as "disconnected" by the status command), which allows only incoming calls. Run the Tie Trunk Seizure Test and follow its outlined procedures.

n. Test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements that were outside the acceptable limits. Use the **list testcall detail** command to examine specific transmission parameters that are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, the limits administered on the "change trunk" screen should be changed.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Loop Around and Conference Circuit Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Loop Around and Conference Circuit Test (#33)		X	ND
Tie Trunk Seizure Test (#73)([2]), Tie Trunk Dial Test (#747)([3]), Seizure Test (#73)([4])	X	X	ND
Tie Trunk EPF Test (#74)([5])	X	X	ND
Port Audit and Update Test (#36)([6]), Audit and Update Test (#36)([4])	X	X	ND
Analog Transmission Test (#844-848)	(a)	(a)	

1 D = Destructive; ND = Nondestructive
2 Non-TN439 and non-TN497 circuit packs only
3 TN439 circuit pack only
4 TN497 circuit pack only
5 G3iV1.1-286 and G3iV2-386 only
6 Non-TN497 circuit packs only

Notes:

a. ATMS test are not part of either sequence. They are run either on demand with the **test analog-testcall** command or via the ATMS schedule.

NPE Crosstalk Test (#6)

One or more NPE reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes 20 to 30 seconds to complete.

Table 11-363. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no connected ports), check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-363. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1001	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	(Non-TN497 circuit packs only) The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting.

Continued on next page

Table 11-363. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.

Continued on next page

Table 11-363. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop around, and conference capabilities of a tie trunk port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. This is an on-board test only, and each tone is transmitted through the loop and checked upon return.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from the trunk administration Test field.

Table 11-364. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
7	ABORT	The conference circuit test was aborted. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
129	ABORT	The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
131		The 1004-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
133		The 2804-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Table 11-364. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	(Non-TN497 circuit packs only.) The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** command to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting.
1018	ABORT	The test has been disabled via administration. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the 'change trunk-group x' command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'.

Continued on next page

Table 11-364. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
7,	FAIL	The conference capabilities of the port failed (Error Code 7).
129,		The reflective 404-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 129).
131, or		The reflective 1004-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 131).
133		The reflective 2804-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 133). FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see notes on the next page). 1. To make sure the problem is on-board, disconnect the port from the CO and retry the test. Coordinate this with the CO, or do it after busy hours; otherwise, the CO may put the connection out of service. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test. If the retry passes and troubles have been reported, refer the problem to the CO. *More information continues on the next page.*

Continued on next page

Table 11-364. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
7, 129, 131, or 133 *(cont'd.)*	FAIL *(cont'd.)*	**NOTE:** If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above.
	PASS	Tie trunk Loop Around and Conference Test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port.

Continued on next page

Table 11-364. TEST #33 Loop Around and Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Audit Update Test (#36)

This test sends updates of the Tie Trunk port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the board. No response message is expected from the circuit pack once it receives translation updates. The port translation data for non-TN439 and non-TN497 circuit packs includes the following: Immediate, automatic, wink-start or delay dial trunk, rotary or DTMF senderization in or out, disconnect timing from 10 to 2550ms in 10ms increments, and DMTF time slot. (Continuous-seize-ack is also included for the TN2140 [G3iV2-386] circuit pack.) The port translation data for the TN439 circuit pack includes the following: Immediate or wink-start trunk, rotary or DTMF senderization in or out, disconnect timing from 10 to 2550ms in 10ms increments, and DMTF time slot.

Table 11-365. TEST #36 Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	(TN439 and TN497 circuit packs only.) The port is in the out-of-service state. The test cannot be run. 1. Retry the command once the port is in service.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to fail, escalate the problem.
	FAIL	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-365. TEST #36 Audit Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	This test passed. Translation information was successfully updated on the circuit pack. 1. If signaling troubles are reported, verify translation information for this port. (Non-TN439 and non-TN497 circuit packs only.) If the trunk is busied out, the test does not run, but it does return PASS. To verify that the trunk is in-service: 1. Enter **status trunk** command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter **release trunk** command to put trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Tie Trunk Seizure Test (#73), Tie Trunk Dial Test (#747). Seizure Test(#73)

The Tie Trunk Seizure Test activates the M lead and checks for a response from the external end within 10 seconds. This test is applicable only to wink start and delay dial outgoing trunks. (For the TN2140 [G3iV2-386] circuit pack, the trunk must also be continuous-seize-ack and discontinuous-seize-ack).

The Tie Trunk Dial Test seizes the trunk and outpulses a pause digit.

For a port administered as TGU or a TGE, the Seizure Test internally seizes the trunk and outpulses a "pause." The report reports the result of the seizure attempt uplink.

Table 11-366. Seizure Tests (#73, #747, #73)

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no calls), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. The far-end PBX may not be releasing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-366. Seizure Tests (#73, #747, #73) — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	(Non-TN497 circuit packs only.) The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1005	ABORT	(Non-TN439 circuit packs only.) This test is not valid for this trunk translation. For this test to run, a delay dial trunk (or, for non-TN497 circuit packs, a wink-start trunk) must be in effect, and the trunk must be outgoing or two-way. Also, for the TN2140 [G3iV2-386], the trunk must be continuous-seize-ack or discontinuous-seize-ack. 1. Check trunk translation. If it is not a wink-start or delay dial trunk, this abort message should be ignored. (For the TN2140 [G3iV2-386], disregard this abort on a trunk that is not continuous-seize-ack or discontinuous-seize-ack.)
1018	ABORT	Test disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the **change trunk-group x** command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."

Table 11-366. Seizure Tests (#73, #747, #73) — *Continued*

Error Code	Test Result	Description/ Recommendation
1040	ABORT	(Non-TN497 circuit packs only.) This test is not performed for trunk ports administered as access endpoints. 1. Verify this port is an access endpoint by using the **display port** command. 2. If the port has been administered as an access endpoint, this test should abort.
2000	ABORT	Seizure message is not received back within 10 seconds. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, check the far-end PBX to ensure a translation match at both ends. 3. Check the facility.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
3	FAIL	(TN439 circuit packs only.) No dial tone detected from the other end. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to fail, check the far-end PBX to ensure a translation match at both ends. 3. Check the facility.
	PASS	The relevant seizure test passes. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port, wiring, and stations.

Table 11-366. Seizure Tests (#73, #747, #73) — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Tie Trunk EPF Test (#74)

This test consists of an E lead and M lead test. The E lead test checks for the proper activation and deactivation of the port's E lead. The M lead test checks the M lead EPF current flow. The processor sends an M lead test request to the circuit pack and receives the results. The returned results are measured to see if a port or external tie trunk line fails.

Table 11-367. TEST #74 Tie Trunk EPF Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The trunk may be busy with a valid call. Use the **display trunk xx** to determine trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active, but the port is not in use (no calls), then check the Error Log for Error Type 1025 (see Error Log table for description of this error and required actions). The port may be locked up. The far-end PBX may not be releasing. 2. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-367. TEST #74 Tie Trunk EPF Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display trunk xx** to determine the trunk group/member number of the port. Use the **status trunk** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this trunk translation. Must be a Type-1 standard trunk for this test to run. 1. Check trunk configuration. If it is not a Type-1 standard trunk, this abort message should be ignored.
1014	ABORT	The test was aborted because the circuit pack has not been inserted into the system. 1. Use the **list configuration board** command to make sure the circuit pack is inserted in the carrier. 2. If the board is not inserted, make sure the circuit pack is inserted in the carrier and fully seated. 3. If the test continues to fail, escalate problem.
1040	ABORT	This test is not performed for trunk ports administered as "access endpoints." 1. Verify this port is an access endpoint by using the **display port** command. 2. If the port has been administered as an access endpoint, this test should abort.

Continued on next page

Table 11-367. TEST #74 Tie Trunk EPF Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The E lead test failed due to an on-board port problem. 1. Replace the circuit pack.
2	FAIL	The M lead test failed. The EPF has experienced an overcurrent condition, perhaps due to the external M lead. 1. To make sure the problem is on-board, disconnect the facility from the pack and retry the test. 2. If the test fails, replace the circuit pack. Otherwise, check the external wiring toward the far-end PBX.
	PASS	Tie Trunk EPF test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the **busyout board** command. 3. Issue the **reset board** command. 4. Issue the **release busy board** command. 5. Issue the **test board** command. This should re-establish the linkage between the internal ID and the port.

Transmission Test (#844-848)

This test is non-destructive.

NOTE:
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of ''marginal'' or ''unacceptable'' thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 11-368. TEST #844-848 Transmission Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use **display port PCSSpp** to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the service state indicates that the port is in use, then the port unavailable for this test. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-368. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM bus errors. Refer to TDM Bus Maintenance to diagnose any active TDM bus errors. 1. If system has no TDM bus errors and is not handling heavy traffic, repeat test at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use status trunk to determine when the port is available for testing. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	Trunk has been administered as incoming-only; transmission tests can only be run on outgoing trunks.
1115	ABORT	The near end test line on the TN771 circuit pack could not be allocated. 1. Verify that the TN771 circuit pack is in service and that port 1 is administered and in service with the **status port** command. 2. retry the command at 1 minute intervals for a maximum of 5 retries. 3. If the test continues to abort escalate the problem.
1900	ABORT	The test completion message was not received from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-368. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1901	ABORT	This error occurs when the TN771 circuit pack uplinks a message that is not the proper response for this test. The anticipated uplink messages are seize, ring or answer. 1. Verify that the Trunk is administered properly. 2. If the test continues to abort, escalate the problem.
1905	ABORT	Intercept tone detected from far end. 1. Get the test line data from theand verify it with the far end. Dial the test number manually to see if the TTL is reached. If it is not, then either the number is wrong, or the far end is administered incorrectly. 2. If the test continues to abort escalate the problem.
1906	ABORT	Reorder tone detected from far end. 1. See actions for error code 1905.
1907	ABORT	Other unexpected tone detected from far end. 1. See actions for error code 1905.
1913	ABORT	Audible Ring detected from far end. 1. See actions for error code 1905.
1914	ABORT	Unidentified interrupted tone detected from far end. 1. See actions for error code 1905
1915	ABORT	Busy tone detected from far end. 1. Since the test line at the far end was busy. Try the test again. 2. If the test continues to abort, the problem is with the far end system.
1918	ABORT	Test progress tone not removed from far end (type 105 test line only). 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 11-368. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1919	ABORT	Unexpected far end release 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1920	ABORT	No response from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1921	ABORT	No data returned from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1922	ABORT	Steady, unidentifiable tone from far end 1. See actions for error code 1905.
1923	ABORT	Broadband energy detected from far end (such as voice or announcement). 1. See actions for error code 1905.
1924	ABORT	No test tone from far end 1. See actions for error code 1905.
1938	ABORT	Near-end self test failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1939	ABORT	Loss self check at 0dBm at 1004 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1940	ABORT	Far end noise self check failed. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 11-368. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1941	ABORT	High frequency singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1942	ABORT	Echo return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1943	ABORT	Singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1944	ABORT	Loss self check at -16 dBm at 1004 Hz failed. 1. Test the TN771 circuit packs 2. If the test continues to abort escalate the problem.
1945	ABORT	Loss self check at -16 dBm at 404 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1946	ABORT	Loss self check at -16 dBm at 2804 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1947	ABORT	Noise with tone self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
2000	ABORT	The test timed out while waiting for a response from the TN771 circuit pack. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Continued on next page

Table 11-368. TEST #844-848 Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2012	ABORT	An internal software error occurred. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2053	ABORT	The test call could not be established, but no information on why is available. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2056	ABORT	An error occurred while trying to obtain results from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
	FAIL	Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.
8000	FAIL	Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the **list testcalls** command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form.

TONE-BD (Tone-Clock Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run[1]	Full Name of MO
	MAJOR	test tone-clock PC	Tone-Clock Circuit Pack
TONE-BD	MINOR	test tone-clock PC	Tone-Clock Circuit Pack
TONE-BD	WARNING	release tone-clock PC	Tone-Clock Circuit Pack

1 P is the port network number (1 for PPN, 2-3 for EPNs). C is the carrier designation (A, B, C, D, or E).

The Tone-Clock circuit pack functionality is provided by two independent objects in the same circuit pack. The tone generator provides all the tones needed by the system and the clock generates the system clocks for the Time Division Multiplex (TDM) Bus and aids in monitoring and selecting internal synchronization references.

When resolving errors/alarms on the Tone-Clock circuit pack, the following should be used also:

- TONE-PT (Tone Generator) Maintenance documentation.
- TDM-CLK (TDM Bus Clock) Maintenance documentation.
- SYNC (Synchronization) Maintenance documentation.

The TN2182 is a combined Tone-Clock-Detector circuit pack which contains a third independent function not available on the TN768 or TN780. The TN2182 contains 8 ports used for all-purpose tone detection. These ports are called Enhanced Tone Receiver ports (ETR-PT) and are described in the documentation for ETR-PT.

Tone-Clock Circuit Packs and System Reliability Options

The following sections describe the relationship between the various System Reliability Options and Tone-Clock circuit pack configurations.

Standard Reliability Option

Systems with the Standard Reliability Option (no duplication options) have one Tone-Clock circuit pack in each port network (PPN and EPN). For the PPN or the EPN this is in the A carrier. This Tone-Clock circuit pack generates clocks and provides system tones for all carriers of the port network it resides on.

High Reliability Option

Systems with the High Reliability Option (duplicated SPE, simplex PNC) have one Tone-Clock circuit pack in each PPN control carrier, A and B. One Tone-Clock circuit pack will be actively generating system clock signals for PPN components, while the other will be in standby mode, ready to take over in the event of a Tone-Clock interchange. Similarly, one Tone-Clock circuit pack will be actively providing system tones for the PPN, while the other will be in standby mode. Normally, the same Tone-Clock circuit pack will be active for both tones and clock signals, but these responsibilities may be divided if neither circuit pack is able to perform both functions. The **status port-network** command will indicate which Tone-Clock circuit pack is actively performing each function.

For systems using the TN2182 Tone-Clock-Detector circuit pack, tone generation and clock generation behaves the same as other clock boards with one being active and one being standby. But the tone detector ports (ETR-PTs) of the TN2182 are always considered available and in-service regardless of the active/standby state of the tones or clock for a specific circuit pack.

EPN Tone-Clock circuit pack configuration is the same as for the Standard Reliability Option. Each EPN Tone-Clock circuit pack will be active for both tones and clock signals for its port network.

Critical Reliability Option

Systems with the Critical Reliability Option (SPE duplication and PNC duplication) have two Tone-Clock circuit packs associated with the PPN, as in the High Reliability Option case, and two more Tone-Clock circuit packs for each EPN. For the EPN, these are in carriers A and B. As in the previous case, one Tone-Clock in each Port Network is active, supplying system clocks and tones, and the other is in standby mode.

Tone-Clock Interchange Strategy

The Tone-Clock circuit pack interchanges are controlled both by manual intervention and by maintenance software strategies.

The manual interchange strategy for Tone-Clock circuit packs differs slightly between the PPN and any EPNs on a system.

Manual PPN Tone-Clock Interchange

In a PPN with more than one Tone-Clock circuit pack, the intention is to assure that the one considered most healthy is active at any given time. *This is independent of the SPE Duplication strategy*, in the sense that the active Tone-Clock circuit pack need not change with an interchange of SPE carriers. Rather, except for the effect of the manual intervention discussed earlier, Tone-Clock interchanges occur only as a result of changes in the health of Tone-Clock circuit packs, as perceived by maintenance software. When both Tone-Clock circuit packs are equally healthy, no preference is given to one over the other, regardless of which SPE carrier is active.

It is possible to manually control Tone-Clock interchanges in three ways.

1. The **standby** Tone-Clock circuit pack may be made unavailable for most purposes by using the **busyout tone-clock PC** command. Such a Tone-Clock may not be selected with console commands, nor with normal maintenance software activities, until it has been made available again with the **restore tone-clock PC** command.

   NOTE:
   busyout tone-clock is not allowed for active Tone-Clock circuit packs.

2. The SPE processor lock switches may be used to force a particular SPE to be active. *This method overrides all other Tone-Clock interchange controls*. If there is a Tone-Clock circuit pack in the same carrier as the active SPE, it will become active, regardless of its health. If the Tone-Clock circuit pack in the selected SPE was in the *busyout* state (see item 1 above), it will automatically be released and made active. While the lock switches are set for a particular carrier, *no manual intervention or software error detection* will cause an interchange of Tone-Clocks; the Tone-Clock circuit pack in the standby SPE carrier can never become active. If there is no Tone-Clock circuit pack in the selected SPE at the time the switches are set, but one is later installed, the system will interchange to it regardless of its health. If the Tone-Clock circuit pack is removed from an SPE while the switches are set, *no interchange will occur*; the system will have no active tone-clock. When the lock switches are restored to the neutral position, a tone clock interchange will occur only if the standby Tone-Clock circuit pack is healthier than the active one.

3. A particular Tone-Clock circuit pack can be made active by issuing the **set tone-clock PC [override]** command. If the Tone-Clock to be made active is less healthy than the currently active one, no interchange will occur unless the **override** option is specified; without it a message will inform the user that it is required.

   Once a Tone-Clock circuit pack is made active by the **set tone-clock PC** command, it will stay active until either the **set tone-clock PC** command is issued again to make the other circuit pack active, or until a fault occurs in the active Tone-Clock circuit pack, which causes the system to interchange Tone-Clocks.

Manual EPN Tone-Clock Interchange

In an EPN with duplicated Tone-Clock circuit packs, one circuit pack is always *preferred* over the other. This is the Tone-Clock circuit pack in carrier **A**. The intention is that the preferred circuit pack be active whenever it is healthy. Once a failing preferred Tone-Clock circuit pack has been replaced or repaired, the system will make it active as soon as possible.

Control over interchanges for an EPN is accomplished in essentially the same ways as items 1 and 3 in the PPN case above. In addition, when the non-preferred Tone-Clock circuit pack in an EPN is active, and the preferred circuit pack is repaired and proven capable of filling its roles, the system will automatically interchange back to it as soon as possible.

Software Maintenance Interchange

Interchanges may be instigated by software Tone-Clock maintenance in two ways.

1. A scheduled Tone-Clock circuit pack interchange occurs according to the parameters set by the **change system-parameters maintenance** command. This can be disabled or set to run weekly, but the standard (default) situation is for it to occur daily, at the time specified in the system-parameters list for scheduled maintenance to begin. This interchange will be blocked if the lock switches are set, if the non-preferred Tone-Clock circuit pack in an EPN has been selected with the **set tone-clock** command, if the standby Tone-Clock has been set to the busyout state, or if the clock generation capability of the standby Tone-Clock circuit pack is known to be impaired. When this scheduled interchange occurs, the standby Tone-Clock circuit pack becomes active for a period of 20 seconds to test its ability to generate clock signals, and then is returned to standby mode.
2. Unscheduled interchanges occur when on-board Tone-Clock circuit pack maintenance, or ongoing switch maintenance tests of **TONE-BD, TONE-PT**, or **TDM-CLK** uncover failures serious enough to raise any MAJOR or MINOR alarm against the active Tone-Clock circuit pack.

International Settings [G3i V2]

The TN780 Tone-Clock circuit pack uses three firmware configuration parameters for international support [G3i V2]. The following two are automatically set by the software load for the targeted country:

- The circuit pack’s country-code (USA, ITALY, AUSTRALIA, etc.)
- The circuit pack’s companding mode (mu-Law or A-Law)

The third configuration parameter is used only for Italy (country code: ITALY), and selects whether *new* versus *old* ISPT (Istituto Superiore Poste Telegrafi) tones will be used for dial and confirmation tones. Values for dial confirmation tone can be set independently on the **change system-parameters miscellaneous** form. Whenever such changes are made, the effects are immediately enforced on all TN780 Tone-Clock circuit packs without disrupting tone or timing services.

Italian Tone Settings (New ISPT Value)

Tone	Default	Old ISPT Value
Dial	Continuous	Cadenced
Confirmation	Cadenced	Continuous

In addition the TN780 allows customization of up to six system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

The TN2182 allows the same International changes as the TN780 but allows the customization of up to 24 system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

How to Replace a Tone-Clock Circuit Pack

Replacing the Tone-Clock circuit pack is a service-disrupting procedure on Port Networks with a single Tone-Clock, because the Tone-Clock circuit pack is always needed to generate clocks for its network. For EPN Tone-Clock replacement where no second Tone-Clock circuit pack exists, only that EPN is affected. When the circuit pack is removed, all calls are dropped immediately, the EPN enters emergency transfer within one minute, and no calls can be set up from or to that EPN. However, if the PPN Tone-Clock is removed for replacement in a Standard Reliability Option system, the System Emergency Transfer feature is activated within milliseconds, and the entire system is disrupted; no calls can be placed, and existing calls are dropped.

When replacing the Tone-Clock circuit pack, always replace it with a comparable Tone-Clock circuit pack for the system. See the following table:

System Type	Tone-Clock Circuit Pack Code
One-port network single-carrier cabinet system without High or Critical Reliability.	TN756, TN768, TN780 TN2182 [G3iV4-386]

System Type	Tone-Clock Circuit Pack Code
One-port network system without High or Critical Reliability (multicarrier cabinet).	TN768, TN780
Two-port network single-carrier cabinet system without High or Critical Reliability.	TN768, TN780 TN2182 [G3iV4-386]
One- or two-port network without High or Critical Reliability.	TN768, TN780 TN2182 [G3iV4-386]

- **TN768**—This is the general purpose Tone-Clock circuit pack for port networks on a G3i switch. It can be used in every situation except as the Master Tone-Clock circuit pack when a Stratum 3 Clock is administered.
- **TN780**—The Stratum 3 Clock feature requires the use of this circuit pack code for the PPN (in both carriers of High and Critical Reliability systems). The Stratum 3 Clock will operate only with this code as the Master Tone-Clock circuit pack. The TN780 circuit pack is upward compatible with the TN768 code, and can be used in any place a TN768 would be allowed. The TN780 is used in many countries outside the U.S. where the TN768 does not provide local tones.
- **TN2182**—This Tone-Clock-Detector may be used anywhere a TN768 or TN780 is used with the exception of configurations requiring Stratum 3 Clock. The TN2182 may be used in all country configurations.

Port Networks with a Single Tone-Clock Circuit Pack

This procedure is destructive.

1. Pull out the defective Tone-Clock circuit pack. This will remove the clocks and cause the system to activate emergency measures:
   - For the PPN Tone-Clock, the system will immediately go into the Emergency Transfer state.
   - For an EPN Tone-Clock, all calls to and from the EPN will drop and the EPN will activate Emergency Transfer within about one minute, but the rest of the system should operate normally.
2. Insert a new Tone-Clock circuit pack. The system will detect the return of the clocks and will automatically recover as follows:
   - If the Tone-Clock circuit pack being replaced is in the Processor Port Network, the system will perform a **reset system 2 (system cold 2 restart)** automatically. First, all red LEDs of the PPN will come on and off wi thin 30 seconds. Then, all red LEDs of any Expansion Port Networks will come on and go off within the next 30 seconds.

- If the Tone-Clock circuit pack being replaced is in an Expansion Port Network, the system will reset the EPN **(EPN cold restart)** and all the red LEDs of the EPN will come on and go off within 30 seconds.

3. If the red LEDs come on but do not go off within 30 seconds, pull the circuit pack out and reseat it. If the LEDs perform as expected this time, continue with step 6. Otherwise, there may be a problem with the TDM Bus; possibly a bent pin in the Tone-Clock circuit pack slot. Follow the directions in the TDM-BUS maintenance section.
4. If the red LEDs did light, as explained above, then go to Step 6. If the red LEDs do NOT light, as explained above, then go on to Step 5.
5. Restart the affected Port Network:
   - In the PPN, restart the system via the **reset system 2** command.
   - In an EPN, restart the EPN by resetting its Expansion Interface circuit pack via the **reset board** command, using the board address 1a01 for EPN1 and 1a02 for EPN2.

   If this step should fail, follow normal escalation procedures.
6. Test the new Tone-Clock circuit pack to verify that it is functioning properly, using the **test tone-clock PC long** command, and verify that the system is operational by placing several phone calls. Where possible, try calls into, out from, and within the affected Port Network.

   If the system is not operating properly, follow normal escalation procedures.

Port Networks with Two Tone-Clock Circuit Packs:

1. If both Tone-Clock circuit packs in a Port Network need to be replaced, first replace and test the one that is in standby mode. Make sure that it is healthy and active before replacing the second one. Make sure the Tone-Clock circuit pack to be replaced is in Standby Mode by displaying its status via the **status port-network** command or making sure its yellow LED is off.

   The active/standby state of a Tone-Clock circuit pack may also be determined by looking at its LED. A continuously lit red LED on the Tone-Clock circuit pack indicates a reported fault on one or more of the maintenance objects on the circuit pack. Flashing patterns of the yellow and green LEDs correspond to the following service states: **Tone-Clock LED Flashing Codes**

Condition	Tone-Clock Circuit State	Explanation
"flashing yellow" 2.7 seconds on, .3 seconds off	active	An external timing source is being used as a synchronization reference.[1]
"flashing yellow" .3 seconds on, 2.7 seconds off	active	The local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference.
"yellow" on continuously	active	The circuit pack has been reset but has not been told which synchronization source to use.
"yellow" LED off	standby	The circuit pack is in standby mode, (neither generating tones nor supplying clocks).
"jingle bells" green and yellow .1 sec on, .2 sec off, .1 sec on, .4 sec off, .4 sec on, .4 sec off	standby	Maintenance software is testing the standby circuit pack (the standby Tone-Clock is providing tones).
"double blink yellow" .3 sec on, .3 sec off, .3 sec on, 2.4 sec off	active	TN2182 has lost all external references and is in holdover mode.
"other green and yellow patterns"	active	Maintenance software is testing the active circuit pack.
random yellow	standby	If the circuit pack is a TN2182, the yellow LED may come on and off intermittently as ETR-PTs on the board are used for tone detection services.

1 For a Tone-Clock in the master port network, the external source is the primary or secondary DS1 source, or a Stratum 3 clock. For a Tone-Clzteock in a slave port network, the external source is the Expansion Interface circuit pack.

2. If the Tone-Clock circuit pack to be replaced is active, then switch to the other Tone-Clock circuit pack by doing the following:
   - **set tone-clock PC**—where PC is the Standby Tone-Clock circuit pack. Since the system is designed to operate primarily on the preferred tone clock, the set tone-clock PC command should be

used to make the preferred tone board active when maintenance activity is completed. There is no preferred tone clock for the PPN, but carrier A is preferred for EPNs.

- **status system**—verify the Tone-Clock circuit pack switched to the other Tone-Clock circuit pack or check the LEDs. The yellow LED of the new Standby Tone-Clock circuit pack should be off (provided maintenance is not running on it) and the yellow LED of the active Tone-Clock circuit pack should be blinking.
- If the interchange was not successful, the standby Tone-Clock circuit pack may be defective. In particular, if the error message "must use override" is displayed, fix the standby Tone-Clock circuit pack before attempting to replace the active one.

3. If the Tone-Clock circuit pack to be replaced is in the PPN, it is recommended, but not required, that the SPE carrier containing it be locked in standby mode by executing an interchange if necessary, and locking the SPE-Select switches. This protects you from disrupting service in case of inadvertent errors in replacing the circuit pack.

   NOTE:
   If the SPE-Select switches are locked, be sure to release them at the conclusion of the replacement procedure.

4. Pull out the defective Tone-Clock circuit pack. No calls should be affected. If this is a TN2182 circuit pack, some ETR-PTs may be in use and removal of the pack will affect some individual users. It may be less disruptive to busyout the standby TN2182 before removing it.
5. Insert a new Tone-Clock circuit pack of the appropriate code in the same slot where the defective Tone-Clock circuit pack was removed.
6. Test the new Tone-Clock circuit pack via the **test tone-clock PC** command to make sure it is functioning properly. If the Tone-Clock circuit pack is being replaced due to loss of clocks, the Clock Health Inquiry (#46) will still report a failure, proceed with the next step.
7. To verify that the new Tone-Clock circuit pack is able to generate clocks for the system, switch to the new Tone-Clock circuit pack via the **set tone-clock PC override** command, and execute **test tone-clock PC**. (In a PPN, the SPE-Select switches must be in the auto position.)

   CAUTION:
   If the new Tone-Clock circuit pack is not able to generate system clocks, this procedure becomes destructive. The system will detect a loss of clock and recover accordingly.

   In this case if the Tone-Clock circuit pack being replaced is in the PPN the system will perform a reset system 2 (cold 2 restart) automatically. If the Tone-Clock circuit pack being replaced is in an EPN, the system will reset the EPN (EPN cold restart). After either type of restart, the faulty

Tone-Clock circuit pack will be in standby mode. Since the replacement procedure was not successful, follow normal escalation procedures. **If the new Tone-Clock circuit pack is able to generate system clocks, there will be no system disruption.**

8. Place several phone calls.

9. After replacing a Tone-Clock circuit pack in an SPE, if the SPE lock switches were set during the procedure, they should be released. Additionally, after repairs in an EPN, the **set tone-clock PC** command should be used if required to make the preferred Tone-Clock circuit pack active.

Hardware Error Log Entries and Test to Clear Values

Tone-Clock Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tone-clock PC sh
1(a)	0	Circuit pack removed or SAKI Sanity Test (#53)	MINOR	ON	
18(b)	0	busyout tone-clock PC	WARNING	OFF	release tone-clock PC
23(c)	0	None	WARNING	OFF	
125(d)		None	MINOR	ON	
126(e)		None	MINOR	ON	
257	65535	Control Channel Test (#52)	MINOR	ON	test tone-clock PC r 20
257(f)	Any	None			
513(g)	Any	None			
769(h)	4358	None			
1025(i)	4363	NPE Audit Test (50)			test tone-clock PC sh
1538(j)	Any	None	MINOR	ON	
2049(k)	0	Clock Health Inquiry Test (#46)	MAJOR	ON	set tone-clock PC override
2305(k)	0	Clock Health Inquiry Test (#46)	MAJOR	ON	set tone-clock PC override
2561(l)	Any	None	MAJOR	ON	
3329(m)	0	None	MINOR/ WARNING[2]	OFF	set tone-clock PC
3840(n)	Any	None			
3848(o)	0	Clock Health Inquiry Test (#46)			set tone-clock PC override
3872(p)	0	None			set tone-clock PC override
3999 (q)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

a. Error Type 1—This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

> **NOTE:**
> The alarm is logged approximately 11 minutes after the circuit pack is removed/SAKI Sanity Test (#53) fails.

If the circuit pack is not present in the system, insert a circuit pack in the slot indicated by the error to resolve the error.

If the circuit pack is present in the system, it is faulty and must be replaced. See the preceding section, "How to Replace a Tone-Clock Circuit Pack".

If the faulty circuit pack is in standby mode, a MINOR alarm is raised, but no other system action is taken. If the circuit pack is the active Tone-Clock, further effects of this error depend on the Reliability Option for the switch.

Table 11-369. Effect of Error Type 1 on an Active Tone-Clock Circuit Pack

	Location of Tone-Clock Circuit Pack	
Reliability Option	**PPN**	**EPN**
Standard	System Emergency Transfer (entire system affected)	Emergency Transfer in the affected EPN
High	Interchange to standby Tone-Clock in the PPN	Emergency Transfer in the affected EPN
Critical	Interchange to standby Tone-Clock in the PPN	Interchange to standby Tone-Clock in the affected EPN

If an interchange is attempted and the system is unable to activate the standby Tone-Clock, Emergency Transfer is activated. If the problem is in the PPN the entire system is affected. Otherwise only the EPN in question is affected. When this happens, both circuit packs are faulty and must be replaced. See the preceding section, "How to Replace a Tone-Clock Circuit Pack".

If a successful interchange occurs in response to a failure of the active Tone-Clock, or if a standby Tone-Clock fails, the faulty Tone-Clock should be replaced.

b. Error Type 18—The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. This error applies only to High or Critical Reliability systems (an active Tone-Clock may not be busied out). To resolve this error, execute **release tone-clock PC**.

c. Error Type 23—The circuit pack has been logically administered but not physically installed. Installing the circuit pack will resolve the alarm.

d. Error Type 125—A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

e. Error Type 126—The port network specified in the PORT field of the error log entry booted up without a Tone-Clock circuit pack, or with a one that cannot communicate at all with the system. The error is logged five minutes after the port network is restarted. If no circuit pack is present, install one of the proper code. If there is a circuit pack present, replace it. See the preceding section, "How to Replace a Tone-Clock Circuit Pack". If replacement does not solve the problem, follow normal escalation procedures.

f. Error Type 257—This error indicates transient communication problems with this circuit pack . This error is not service-affecting and no action is required.

g. Error Type 513—This circuit pack has an on-board hardware failure. Replace the circuit pack using the procedure described in preceding section, "How to Replace a Tone-Clock Circuit Pack".

h. Error Type 769—This error can be ignored, but look for other errors on this circuit pack.

i. Error Type 1025—This error is not service-affecting and no action is required.

j. Error Type 1538—The circuit pack was taken out of service because of an excessive rate of uplink messages. Use **test tone-clock PC long** to reset the circuit pack and put it back into service. If the command is not successful, replace the circuit pack using the procedure described in the preceding section, "How to Replace a Tone-Clock Circuit Pack". If the alarmed circuit pack is the active Tone-Clock of a duplicated pair, first interchange Tone-Clocks via the **set tone-clock PC** command to avoid a service outage. If the error occurs again within 15 minutes, follow normal escalation procedures.

k. Error Type 2049 or 2305—These errors indicate the loss of one or more clock signals from the reported Tone-Clock circuit pack, which was active at the time of the error. The effect of any of these errors is described in the table for error type 1. Diagnosis of the problem is the same for all four error types, with the exception noted below.

   1. Examine the Hardware Error Log for errors reported against circuit packs in the same Port Network, especially TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the repair or replacement procedures indicated for any such errors found.

2. If the error is not corrected by resolving errors found in step 1, the Tone-Clock circuit pack should be replaced. See the preceding section, "How to Replace a Tone-Clock Circuit Pack".

   NOTE:
   Replacing the circuit pack and retesting it with the **test tone-clock** command is not adequate to retire this alarm and return the Tone-Clock Circuit Pack to full service; the Clock Health Inquiry test (#46) will continue to fail. Because the ability to generate clocks was considered lost, once any repairs have been made it is necessary to execute the **set tone-clock PC override** command, forcing the circuit pack to become active. If the problem has not actually been corrected, this action may cause a disruption in service for active digital facilities users.

3. If error 2305 or 3848 persists, all clock signals from the indicated board were lost. If the reported Tone-Clock circuit pack is in a Port Network with duplicated Tone-Clocks, the problem may lie with the circuit pack responsible for selecting the active Tone-Clock circuit pack (the *t/c selector*).

   - For a PPN, the t/c selector is the DUPINT circuit pack on carrier A.
   - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

   The t/c selector circuit pack of interest is the one which was active at the time the error was logged. This is the currently active t/c selector unless there has been an SPE interchange for PPN problem, or an EXP-INTF link switch for EPN problem, In order to determine whether an interchange has occurred since the TONE-BD error, examine the **display initcauses** log for SPE interchanges, and EXP-LNK entries in the hardware error log for expansion link interchanges.

   If the t/c selector circuit pack was not replaced as part of the previous step, replace it now. Follow procedures described in "Replacing Defective SPE Circuit Packs" in Chapter 8, "Reliability Systems: A Maintenance Aid" for the DUPINT circuit pack, or in the EXP-INTF section of this chapter for the Expansion Interface.

4. If the error has not been corrected at this point, there is a problem with the TDM Bus within the Port Network containing the reported Tone-Clock circuit pack. This may include TDM Bus intercarrier cables, Bus terminators, bent pins on the backplane, and errors on any circuit pack plugged into the same Port Network. Refer to the TDM-BUS section.

5. If the problem persists, follow normal escalation procedures.

l. Error Type 2561—This error indicates that a Tone-Clock circuit pack, with a different circuit pack code as required for this system, has been inserted in the port slot as shown in the Hardware Error Log. To resolve this error, refer to the "How to Replace a Tone-Clock Circuit Pack" section for an appropriate circuit pack code and replace the Tone-Clock circuit pack according to the procedures indicated for this system. The meanings of the aux data values are as follows:

1001	A TN756 Tone-Clock circuit pack is in the PPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1002	A TN756 Tone-Clock circuit pack is in the EPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1003	Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a one port network system without High or Critical Reliability (Multicarrier Cabinet).
1004	Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a High or Critical Reliability system.
1005	Same as for aux value 1004.

m. Error Type 3329—The system attempted but failed to interchange Tone-Clock circuit packs. (This error occurs only in Port Networks with duplicated Tone-Clocks.) The fault may lie in the standby Tone-Clock or in the circuit pack that controls selection of the active Tone-Clock (the *t/c selector*). The goal of the following procedure is to ensure that both Tone-Clocks can be interchanged into while either t/c-selector circuit pack is active.

1. Examine the Error Log for errors reported against circuit packs in the same Port Network, paying special attention to TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the procedures indicated for any such errors found. After eliminating the above potential problem sources, proceed with the following steps.
2. Determine which circuit pack was controlling the choice of Tone-Clock at the time the error occurred.
   - For a PPN, the t/c selector is the DUPINT circuit pack on the A-carrier.
   - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

   The t/c-selector circuit pack of interest is the one which was active at the time the error was logged. An EXP-LNK interchange since the time of the error may have made that circuit pack the current standby. Determine whether an interchange affecting the t/c selector has occurred since the TONE-BD error. When investigation an EPN Tone-Clock, look for EXP-LNK entries in the hardware error log for PNC interchanges, which would affect the EXP-INTF.

3. If the t/c selector has not undergone an interchange since the error occurred, go to the next step. If such an interchange has taken place, interchange back to the formerly active t/c selector. Use the **set expansion-interface** command when investigating an EPN Tone-Clock.) If the interchange attempt fails due to other errors, resolve those problems first.
4. Interchange the Tone-Clock circuit packs using the **set tone-clock PC** command. If the command succeeds, the interchange which previously failed has been accomplished and the problem has been satisfactorily resolved. If it fails, proceed to the next step. (You may want to proceed in any case to definitively test all relevant components.)
5. Interchange the t/c selector using **set expansion-interface** if investigating an EPN. If errors prevent this interchange, resolve them first.
6. Attempt again to interchange Tone-Clocks with the **set tone-clock PC** command.
   — If the Tone-Clock interchange failed for both t/c selectors:

   Replace the standby Tone-Clock circuit pack which could not be interchanged into and return to this step. (See "How to Replace a Tone-Clock Circuit Pack".) Test the new circuit pack as follows:

   a. Execute the set tone-clock PC command.
   b. Execute a set expansion-interface, if this is an EPN Tone-Clock.
   c. Execute the set tone-clock PC command again.

   If these commands successfully complete, the problem has been resolved.

   — If these commands successfully complete, the problem has been resolved.

   — If the Tone-Clock circuit packs successfully interchange when one EXP-INTF is active, but not when the other one is:

   The t/c-selector circuit pack on the failing side is suspect.

   a. Replace the A carrier DUPINT or EXP-INTF board that is active when the Tone-Clock interchange fails. (Follow procedures in "Replacing Defective SPE Circuit Packs" in Chapter 8, "Reliability Systems: A Maintenance Aid" for the DUPINT circuit pack; for the Expansion Interface, see EXP-INTF.)

b. Make sure the new t/c selector is active and execute the set tone-clock PC command.

— If both Tone-Clocks can be interchanged into, and interchanges succeed when either t/c selector is active, the problem has been resolved. If the problem persists after following the above steps, follow normal escalation procedures.

n. Error Type 3840—This error is not service-affecting and can be ignored. It indicates that the circuit pack has received a bad control message from the switch.

o. Error Type 3848—This error indicates that the Tone/Clock circuit pack had a loss of clock. If error 2305 is also logged, see note (j).

p. Error Type 3872—These errors indicate this Tone/Clock circuit pack had a loss of Data Clocks. This error will impact mainly users on station connected to Digital circuit packs. These users could be with out service. If error 2049 is also logged see note (i).

q. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Use the **list configuration control** command to find the Tone-Clock Circuit Pack Code of the system. Look for the Short and Long Test Sequences according to the Tone-Clock Circuit Pack Code.

For a system with a TN756 Tone-Clock Circuit Pack:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Sanity Test (#53) (a)		X	D
Clock Health Inquiry Test (#46)	X	X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Tone Detection Verification Test (#42) (b)	X	X	ND
Tone Detection Audit/Update Test (#43) (b)	X	X	ND
Tone Generator Crosstalk Test (#90) (b)		X	ND
Tone Generator Transmission Test (#40) (b)	X	X	ND
Tone Generator Audit/Update (#41) (b)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to XXX-BD (Common Port Circuit Pack) documentation for descriptions of these tests.

b. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

For a system with a TN768, TN780 or TN2182 Tone-Clock Circuit Pack:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X	
Clock Health Inquiry Test (#46)	X	X	
Control Channel Loop Around Test (#52) (a)	X	X	
Tone Generator Crosstalk Test (#90) (b)		X	
Tone Generator Transmission Test (#40) (b)	X	X	
Tone Generator Audit/Update (#41) (b)	X	X	
TDM Bus Clock Circuit Status Inquiry Test (#148) (c)	X	X	
TDM Bus Clock Slip Inquiry (#149) (c) (e)	X	X	
TDM Bus Clock PPM Inquiry Test (#150) (c)	X	X	
TDM Bus Clock Parameter Update Test (#151) (c)	X	X	
Board Type Check Test (#574) (c)	X	X	
Standby Reference Health Check Test (#651) (c,d)		X	

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to XXX-BD for descriptions of these tests.

b. Refer to TONE-PT for descriptions of these tests.

c. Refer to TDM-CLK for descriptions of these tests.

d. This test runs only on the standby Tone-Clock circuit pack in a Port Network with duplicated Tone-Clocks (High or Critical Reliability systems). The circuit pack must be a TN780 with firmware version 2 or above or a TN2182.

Clock Health Inquiry Test (#46)

This inquiry reads special data stored in memory to determine if this Tone-Clock circuit pack had a loss of any of three clock types:

- SYSCLK
- SYSFM
- SYSDCLK

If this data indicates this Tone-Clock circuit pack had a loss of any of these clocks, the inquiry reports FAIL. In addition, if TDM-CLK error 1 is at threshold, this test will FAIL. TDM-CLK error 1 indicates a suspect clock is at the edge of its specified frequency. If the circuit pack did not have a loss of clock or TDM-CLK error 1 at threshold, the inquiry reports PASS.

This is not really a test, in the sense that it simply reports status held by the system, and does not generate new information or raise alarms. If this test fails with no error code, there is at least one Major alarm against a Tone-Clock circuit pack. If this test fails with an error code of 1, there is at least one Minor off-board alarm against a TDM-CLK.

Table 11-370. TEST #46 Clock Health Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at 11-minute intervals for a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
none	FAIL	This Tone-Clock circuit pack had an apparent loss of clock. One or more of error types 2049, 2305, 3834, and 3872 will appear in the error log. Correct the problem according to the appropriate error log entries. Once this test fails, the only way to make it pass, and to retire the associated alarm, is to repair the problem and to execute the **set tone-clock P[illegible]verride** command against the indicated Tone-Clock circuit pack. **NOTE:** If power is removed from a carrier in a duplicated system, and that SPE has the active TONE-CLK, a MAJOR alarm is raised for the TONE-BD. The TONE-BD will be out of service and when running Test 46 (Clock Health Test) it will fail, indicating a loss of any of these three clocks, SYSCLK, SYSFM, and SYSDCLK. To restore the TONE-BD to service you must execute the **set tone spe health-override** command.

Continued on next page

Table 11-370. TEST #46 Clock Health Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1	FAIL	This Tone-Clock circuit pack is suspect of having a clock at the edge of its specified frequency. A Tone-Clock circuit pack with this problem can cause Expansion Interface circuit packs to go out-of-frame or report no neighbor conditions, thus causing EPNs to go down 1. Replace the Tone-Clock circuit pack identified in the error log. Refer to the "How to Replace a Tone-Clock Circuit Pack" section. 2. If the error persists, follow normal escalation procedures.
	PASS	This Tone-Clock circuit pack has not reported a loss of clock.

TONE-PT (Tone Generator)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TONE-PT	MAJOR	test tone-clock PC sh	Tone Generator
TONE-PT	MINOR	test tone-clock PC sh	Tone Generator
TONE-PT	WARNING	release tone-clock PC sh	Tone Generator

NOTE:
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The tone generator resides on the Tone/Clock circuit pack and provides all system tones such as dial tone, busy tone, and so on. If an active tone generator fails, its port network may not have tones (see the Tone Generator Transmission Test #40). For instance, a user may go off-hook and hear no dial tone. This problem will affect only users on the same port network in which the faulty Tone-Clock circuit pack resides. The system will be able to process certain type of calls (that is, internal calls will succeed while outgoing calls will not).

The Tone-Clock circuit pack also provides the clocks for the system and can serve as the synchronization reference. Therefore, when resolving alarms on the Tone-Clock circuit pack, the TDM-CLK (TDM Bus Clock) and SYNC (Synchronization) Maintenance documentation should be utilized as well as the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation.

See the section on TONE-BD Maintenance in this manual for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Hardware Error Log Entries and Test to Clear Values

Tone Generator Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test tone-clock PC r 1
1(a)	17664	Tone Generator Audit/ Update Test (#41)	MAJOR/ MINOR	ON	test tone-clock PC r 2
18(b)	0	busyout tone-clock PC	WARNING	OFF	release tone-clock PC
130(c)		None	MINOR	ON	test tone-clock PC Sh
257(d,f)	17667	None	MINOR	ON	
513(e,f)	17666	Tone Generator Audit/ Update Test (#41)	MINOR	ON	test tone-clock PC r 3
769	Any	Transmission Test (#40)	MAJOR/ MINOR	ON	test tone-clock PC r 3
1025		Crosstalk Test (#90)	MAJOR/ MINOR	ON	test tone-clock PC l r 2
1281(g)	Any	Tone Generator Audit/ Update Test (#41)	MINOR	ON	test tone-clock PC r 3

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. A failure in the tone generation facility on the indicated circuit pack has been detected. Replace the circuit pack. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.

b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. It only applies to systems which have the High or Critical Reliability Option administered, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock PC** command for the alarmed circuit pack.

c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

d. The tone generation facility is having problems verifying that tones have been connected as requested.

e. The tone generation facility may or may not be able to generate tones.

f. Infrequent errors, at a rate which does not bring up an alarm, probably do not affect service, unless there are customer complaints of no tones, or incorrect tones which can not be explained in any other way. However, if an alarm is raised because this error is being repeatedly logged, then the circuit pack should be replaced. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.

g. The system-parameters country-options administration are setup such that a TN780 or TN2182 are required and the existing tone-clock circuit pack will not provide the needed functionality. The Base Tone Generation Set on page 1 or the custom tones beginning on page 2 of the system-parameters country options form may have values not supported by the existing tone-clock.

This error (1281) indicates that the system parameters country-options form has custom tones translated and that the alarmed tone board does not support the customized tones. TN768 tone boards do not support any customized tones. TN780 tone boards support up to 6 customized tones using the following frequencies/levels only:

Silence

350Hz at 17.25 dB

425Hz at 4.0 dB

425Hz at 11.0 dB

425Hz at 17.25 dB

440Hz at 17.25 dB

350Hz+425Hz at 4.0 dB

350Hz+440Hz at 13.75 dB

480Hz at 17.25 dB

620Hz at 17.25 dB

440Hz+480Hz at 19.0 dB

404Hz at 11.0 dB

404Hz at 16.0 dB

480Hz+620Hz at 24.0 dB

404Hz+425Hz at 11.0 dB

375Hz+425Hz at 15.0 dB

404Hz+450Hz at 11.0 dB

1000Hz at 0.0 dB

1000Hz at +3.0 dB

525Hz at 11.0 dB

1400Hz at 11.0 dB

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Use the **list configuration control** command to find the Tone-Clock Circuit Pack Code of the system. Then look for the Short and Long Test Sequences according to the Tone-Clock Circuit Pack Code.

For a system with a TN756 Tone-Clock Circuit Pack

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Sanity Test (#53) (a)		X	D
Clock Health Inquiry Test (#46) (b)	X	X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Tone Detection Verification Test (#42) (c)	X	X	ND
Tone Detector Audit/Update Test (#43) (c)	X	X	ND
Tone Generator Crosstalk Test (#90)		X	ND
Tone Generator Transmission Test (#40)	X	X	ND
Tone Generator Audit/Update Test (#41)	X	X	ND

1 D = Destructive; ND = Nondestructive

a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for descriptions of these tests.

c. Refer to Dual Tone Multifrequency Receiver Port (TTR) (DTMR-PT) or General Purpose Tone Detector (CPTR) (GPTD-PT) Maintenance documentation for descriptions of this test.

For a system with a TN768, TN780 or TN2182 Tone-Clock Circuit Pack:

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
SAKI Reset Test (#53) (a)		X	D
Clock Health Test (#46) (b)	X	X	ND
Control Channel Loop Around Test (#52) (a)	X	X	ND
Tone Generator Crosstalk Test (#90)		X	ND
Tone Generator Transmission Test (#40)	X	X	ND
Tone Generator Audit/Update Test (#41)	X	X	ND
TDM Bus Clock Circuit Status Inquiry Test (#148) (c)	X	X	ND
TDM Bus Clock Slip Inquiry Test (#149)(e)(c)	X	X	ND
TDM Bus Clock PPM Inquiry Test (#150) (c)	X	X	ND
TDM Bus Clock Parameter Update Test (#151) (c)	X	X	
Board Type Check Test (#574) (c)	X	X	
Standby Reference Health Check Test (#651) (c,d)		X	

1 D = Destructive; ND = Nondestructive

Notes:

a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.

b. Refer to TONE-BD (Tone-Clock Circuit Pack) section for descriptions of these tests.

c. Refer to TDM-CLK (TDM Bus Clock) section for descriptions of these tests.

d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above, or a TN2182.

Tone Generator Transmission Test (#40)

The purpose of this test is to verify that the tone generation hardware on the tone-clock circuit pack is capable of generating a subset of system tones and a set of test tones. This test does not verify all system tones the tone generator produces during normal system operation.

The test is performed in two parts. For the first part, the Tone Generator is told to generate the touch-tone digits. The digits are received and checked by a Tone Detector touch-tone detector. If any of the digits fail, the test is repeated using a touch-tone detector in another Tone Detector circuit pack.

For the second part, the Tone Generator is told to generate call progress tones that are detected and identified by a tone detector. These tones are:

- 440 Hz
- 2225 Hz
- Digital Count

The tone generator is then told to generate a sequence of test tones whose output levels are measured by a tone detector. These tones are:

- 404 Hz at 0 dB
- 1004 Hz at -16 dB
- 1004 Hz at 0 dB
- 2804 Hz at 0 dB

A Tone Detector general purpose tone detector listens for the tones and measures the quality of the tone. If any of the measured values are not within limits, the test is repeated using a general purpose tone detector in a different Tone Detector circuit pack. If the values are still out of the limits, the test will fail.

For all the failure cases of Test #40, do the following:

1. Check that all Tone Detector circuit packs have the same companding mode as that administered for the system. Correct the situation if there is a mismatch.
2. Run the long test sequence: **test tone-clock PC long repeat 1**.
3. If the problem persists, replace the Tone-Clock circuit pack by following the steps outlined in the "How to Replace a Tone-Clock Circuit Pack" section.

Table 11-371. TEST #40 Tone Generator Transmission Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	The system was not able to allocate all the resources needed for this test or there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the DTMF tones.
1001	ABORT	The system was not able to put the tone generation facility in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM Bus via the **test tdm port-network PN#** command. Refer to TDM-BUS section for details. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
1003	ABORT	The system could not allocate a tone receiver for the test connection. This can happen when the system is heavily loaded or there is not a Tone Detector circuit pack in the port network where this test is being executed. 1. Make sure there is a Tone Detector circuit pack in the same port network. 2. If a Tone Detector circuit pack is missing, install one in the same port network. 3. Allow approximately 1 minute for Tone Detector maintenance to run on the newly inserted Tone Detector circuit pack. 4. Retry the command at 1-minute intervals a maximum of 5 times. 5. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-371. TEST #40 Tone Generator Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1022	ABORT	[G3r V2] Tone detection for the system is administered as wide broadband (tone detection mode 5), and the Tone Detector used for this test was not a TN420C or TN2182 (the only circuit packs with this capability). GPTD ports on other types of Tone Detector circuit packs are taken out of service since they cannot provide the administered function. 1. Change the tone-detection mode administered on the system-parameters country-options form (see *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, Or 2. Remove all non-TN420C and non-TN2182 circuit packs from the system.
2000	ABORT	Response to the test request was not received within the allowable time period. System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
1 (a)	FAIL	DTMF generation failed for the active tone generator.
105 (a)	FAIL	Generation of 440-Hz failed.
109 (a)	FAIL	Generation of 2225-Hz failed.
110 (b)	FAIL	Generation of 404-Hz level invalid.
111 (b)	FAIL	Generation of 1004-Hz low level invalid.
112 (b)	FAIL	Generation of 1004-Hz high level invalid.
113 (b)	FAIL	Generation of 2804-Hz level invalid.

Continued on next page

Table 11-371. TEST #40 Tone Generator Transmission Test — *Continued*

Error Code	Test Result	Description/ Recommendation
115 (b,c)	FAIL	Generation of digital count sequence invalid.
120 (a)	FAIL	Generation of quiet tone failed.
1044 (a)	FAIL	DTMF generation failed to generate Digit 1 for the standby tone generator.
1045 (a)	FAIL	DTMF generation failed to generate Digit 5 for the standby tone generator.
1046 (a)	FAIL	DTMF generation failed to generate Digit 9 for the standby tone generator.
1047 (a)	FAIL	DTMF generation failed to generate Digit D for the standby tone generator.
	PASS	The tone generation facility is able to generate and transmit all the tones.

Notes:

Except in Port Networks containing more than one Tone-Clock circuit pack, replacing the circuit pack is a service disrupting procedure. The test should be run several times with more than one failure before the replacement policy specified in the following notes is executed. Use the procedure described in "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.

a. All the failure error codes marked with (a) may affect users if the failure is on the active tone generator. When this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. When the tone generation facility fails in this way, especially in a Port Network without duplicated Tone-Clock circuit packs, the faulty Tone-Clock should be replaced promptly.

b. All the failure error codes marked with (b) are almost transparent to the user. Again, when this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. Users may or may not hear any noisy tones. This type of failure affects maintenance on other objects. Maintenance may not be able to run on other objects which use the tone generation facility (that is, Tone Detector Circuit Pack maintenance). In this case, the Tone-Clock circuit pack can be replaced as suitable to the customer.

c. Error code 115 may also be caused by TDM Bus corruption. This normally means a physical problem with bent backplane pins, TDM/LAN Bus cabling, or TDM/LAN Bus terminators. Such physical problems should especially be suspected if board replacement or other physical activity has occurred just before this error is observed.

   Use **display errors** to look for errors on other circuit packs in the carriers of the same Port Network as the indicated Tone-Clock. If any are found, they should be resolved if possible, and the Tone-Clock circuit pack retested. If this does not clear the problem, the Tone-Clock circuit pack should be replaced and the new one tested. If the problem persists, follow instructions for TDM Bus maintenance in this manual.

Tone Generator Update/Audit Test (#41)

The active tone generation facility is refreshed with all the time slot tone information. This test also triggers in-line error messages the Tone-Clock circuit pack generates when it detects problems by itself.

A check is also made between the type of tone-clock being tested and the type of tone-clock needed based on system administration. The administration on the system-parameters country-options form may imply that a TN780 or TN2182 is required.

Table 11-372. TEST #41 Tone Generator Update/Audit Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test.
2100	ABORT	System resources required for this test are not available.
1	FAIL	The system requires a TN780 TN2182 tone-clocks to support the currently administered country-options tone generation parameters. 1. Check the administration on the system-parameters country-option form. Specifically, the Base Tone Generation Set on page 1 and any custom tone administration beginning on page 2. 2. Replace existing tone-clock circuit packs with a TN780 or TN2182.

Continued on next page

Table 11-372. TEST #41 Tone Generator Update/Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The system requires TN2182 tone-clocks to support the currently administered country-options tone generation parameters. 1. Check the administration on the system-parameters country-option form. Specifically, the Base Tone Generation Set on page 1 and any custom tone administration beginning on page 2. 2. Replace existing tone-clock circuit packs with TN2182s.
	PASS	The tone generation facility has been successfully refreshed with its time-slot translation and system administration is consistent with this type of tone-clock. 1. Display the Hardware Error Log via the **display errors** command to make sure this circuit pack did not generate new errors. 2. If errors persist, follow normal escalation procedures.

Tone Generator Crosstalk Test (#90)

This test checks the ability of the Tone Generator to talk on a specific time slot. The tone generator is told to talk on a specific time slot. The other idle time slots are checked to make sure the Tone Generator put the tone on only the specified time slot.

Table 11-373. TEST #90 Tone Generator Crosstalk Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.
1001	ABORT	The system was not able to put the tone generation facility in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the **test tdm port-network PN#** command. Refer to TDM-BUS section for details.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, follow normal escalation procedures.

Continued on next page

Table 11-373. TEST #90 Tone Generator Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The Tone Generator could be defective. In a Port Network with more than one Tone-Clock circuit pack, the system will attempt to move the tone generation function to the alternate one. 1. Test the Tone-Clock circuit pack again via the **test tone-clock PC** command 2. If the test fails again, look at the Hardware Error Log for Tone Detector circuit pack errors. 3. If there are Tone Detector circuit pack errors, refer to Tone Detector Maintenance documentation (DTMR-PT, GPTD-PT, CLAS-PT, ETR-PT) to resolve these errors first. 4. If there are no Tone Detector circuit pack errors, then the Tone-Clock circuit pack should be replaced. See "How to Replace a Tone-Clock Circuit Pack" in the TONE-BD section.
	PASS	The tone generation facility is able to put tones out.

TSC-ADM (Administered Temporary Signaling Connections)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TSC-ADM	none	none	Administered Temporary Signaling Connections
TSC-ADM	none	none	Administered Temporary Signaling Connections

No alarms are generated for the TSC-ADM (Administered Temporary Signaling Connections) MO. Due to the unusual length of the full name of this MO (that is, Administered Temporary Signaling Connections), the abbreviation Administered TSC is used often in this Maintenance documentation.

In general, administered temporary signaling connections provide a path through ISDN-PRI switches for supplementary D-channel messages. ISDN-PRI applications [that is, Distributed Communications System (DCS)] use temporary signaling connections to exchange user information across an ISDN-PRI network. What makes Administered Temporary Signaling Connection unique is that these particular Temporary Signaling Connections stay active for an extended period time (that is, similar to a permanent data connection). These ADM Temporary Signaling Connections are used for DCS features that require a NCATSC, and the ADM TSC serves as the logical channel function in a DCS network.

A Non-Call Associated Temporary Signaling Connection (NCATSC) is a virtual connection established within a D-channel. The NCATSC connection provides user to user service by exchanging USER INFORMATION messages through the virtual connection in a D-channel without associating any B-channel connections.

An *Administered TSC* is a special NCA Administered TSC defined for the DCS over the ISDN-PRI D-channel application of G3iV1.1-286 or G3iV2-386. The Administered TSC connection is a special type of NCATSC that has an administratively defined endpoint and is established for an extended period of time.

There are two types of ADMTSCs:

- Permanent

  TSCs are established by the originating PBX (that is *Near-end* ADM TSC) or by the terminating PBX (that is, *Far-end* ADM TSC). Once these ADMTSCs are established, they remain active.

- As-Needed

TSCs are established on an as-needed basis. In this case, the ADMTSC is established whenever it is needed, and not before.

ADMTSC maintenance provides a strategy to verify that a far-end can respond to an ISDN-PRI USER INFORMATION TSC heartbeat message, thereby indicating that user to user signaling is functioning. In addition, maintenance can retrieve the status of the ADMTSC's connection state.

Since ADMTSCs are administered on a per signaling group basis, the health of an ADMTSC also depends on the state of the D-channel or D-channel pair administered per signaling group. Refer to ISDN-SGR (ISDN-PRI Signaling Group) Maintenance documentation for details on ISDN-PRI NFAS and D-channel Backup maintenance. The two administration commands for ADMTSCs are as follows:

- **add signaling group #**
- **change signaling group #**

The two maintenance commands for ADMTSCs are as follows:

- **test tsc-administered signaling group #[/tsc index]**
- **status tsc-administered signaling group #/tsc index**

Hardware Error Log Entries and Test to Clear Values

ADM TSC Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3840-3967(a)	tsc index #	test tsc-administered			

Notes:

a. There is no Test to Clear Value for error types 3840-3967. The error types provides the following additional data that may prove useful when tracking down problems.

   This error indicates that a TSC Heartbeat Inquiry Test was run on an Active far-end Administered TSC from the switch. Upon receiving the heartbeat message, the network communicated to the switch that the call reference value is not currently in use on the ISDN interface. As a result, the error was logged. Check the signaling group status of the D-channel or D-channel pair via the **status signaling-group <group>** command for the Administered TSC. Check the status of the Administered TSC via the **status tsc-administered** command. Also check the administration of the Administered TSC on the switch.

   This error may only be affecting service for some DCS customers. Upon receipt of this error condition, the switch tears down and re-establishes the ADMTSC within 20 minutes.

b. The port field in the error log contains the signaling group number for TSC-ADM errors.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *TSC Heartbeat Inquiry Test,* for example, you may also clear errors generated

from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
TSC Heartbeat Inquiry Test (#604)			ND

1 D = Destructive; ND = Nondestructive

TSC Heartbeat Inquiry Test(#604)

This test can be invoked by system technician personnel for any ADMTSC administered in the switch. The following table indicates the possible error conditions that might be encountered when the test is invoked. Most of the error conditions do not log an error, but switched services may take some type of recovery action in certain instances.

This test sends a USER INFORMATION TSC heartbeat message inquiry across an Administered TSC to determine if the far-end can respond to a USER INFORMATION TSC heartbeat message.

Table 11-374. TEST #604 TSC Hartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Reissue the **test tsc-administered** command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	The Administered TSC does not exist. 1. Display the administration for the Administered TSC. 2. If an Administered TSC is exists, reissue the **test tsc-administered** command. 3. If the test continues to abort, escalate problem.
1113	ABORT	The D-channel is out-of-service. 1. Refer to the ISDN-LNK (ISDN-PRI Signaling Link Port) Maintenance documentation.

Continued on next page

Table 11-374. TEST #604 TSC Hartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
1145	ABORT	There is congestion in the network. 1. Issue the **status tsc-administered** command at one-minute intervals a maximum of five times. 2. If the congestion does not clear, disable and enable the Administered TSC via the **change sig-group <group>** command. To disable the Administered TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where **<group>** refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADMTSC, change the "Enable" field to "y." 3. If the congestion still does not clear, check other nodes in the network. If congestion persists, then escalate the problem.
1146	ABORT	The congestion just occurred in the network. 1. Issue the **status tsc-administered** command at one-minute intervals a maximum of three times. 2. If congestion does not clear, disable and enable the Administered TSC via the **change sig-group <group>** command. To disable the Administered TSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where **<group>** refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADMTSC, change the "Enable" field to "y." 3. If congestion still does not clear, check the other nodes in the network. If the congestion persists, escalate the problem.

Continued on next page

Table 11-374. TEST #604 TSC Hartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
1147	ABORT	The ADMTSC is being torn down. 1. Issue the **status tsc-administered** command at one-minute intervals a maximum of three times. 2. If ADMTSC is still down, disable and enable the ADM TSC via the **change sig-group <group>** command. **NOTE:** To disable the ADMTSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where **<group>** refers to the number of the signaling group under which the suspect TSC is administered. Change the Enable field to "n." To enable the ADMTSC, change the "Enable" field to "y." 3. If the ADMTSC is still down, check the other nodes in the network. If the ADMTSC is still down, escalate the problem.
1148	ABORT	The ADMTSC is enabled, but inactive (near-end). 1. Disable and enable the ADMTSC. 2. Reissue the **test tsc-administered** command. 3. If the ADMTSC is still inactive, check the other nodes in the network.
1149	ABORT	The ADMTSC is disabled. 1. Enable the TSC, and see if the status indicates "active." 2. Reissue the **test tsc-administered** command. 3. If the TSC still disabled, remove the ADMTSC from the system.
1181	ABORT	Ran out of ADMTSC resources. 1. Reissue the **test tsc-administered** command at one-minute intervals a maximum of three times. 2. If test continues to abort, escalate the problem.

Continued on next page

Table 11-374. TEST #604 TSC Hartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
1182	ABORT	The BX.25 link is down at the gateway. 1. Disable the ADMTSC. 2. Check the status of the gateway link via the **status link link-no** command. 3. Once the gateway link indicates an "in-service" state, enable the Administered TSC. 4. Reissue the **test tsc-administered** command. 5. If the test still aborts, escalate the problem.
2000	ABORT	The Administered TSC is not responding to a TSC heartbeat inquiry. 1. Retry the **test tsc-administered** command at one-minute intervals a maximum of three times. 2. If the problem continues to fail, obtain the status of the D-channel or D-channel pair associated with the ADMTSC via the **status sig-group <group>** command. If the D-channel is INS (that is, in-service) and the status of the ADMTSC appears to be active, disable and enable the ADMTSC through administration. **NOTE:** To disable the ADMTSC, display the (administration) Signaling Group Form via the **change sig-group <group>** command where **<group>** refers to the number of the signaling group under which the suspect TSC is administered. Change the "Enable" field to "n." To enable the ADMTSC, change the "Enable" field to "y." 3. Reissue the **test tsc-administered** command. 4. If the test fails, check the ADMTSC node on the other side of the network to verify that the ADM TSC is indeed active. 5. Escalate the problem.
2012	ABORT	Internal System Error. 1. Reissue the **test tsc-administered** command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-374. TEST #604 TSC Hartbeat Inquiry Test

Error Code	Test Result	Description/ Recommendation
1	FAIL	The Administered TSC is not active (far-end). 1. Reissue the **test tsc-administered** command. 2. Verify that the Administered TSC node on the other side of the network is active. 3. Disable and enable the Administered TSC. 4. Retry the **test tsc-administered** command. 5. If test fails, escalate the problem.
2	FAIL	Facility IE (Information Element) reject. 1. Check all other nodes in the network, and make sure Administered TSC is active. 2. Escalate the problem.
	PASS	The Administered TSC responded to a heartbeat.

TTR-LEV (TTR Level)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
TTR-LEV	WARNING	See Note[1]	TTR Level

1 See the "Repair Procedure for the TTR Level Maintenance Object" section.

A TN748 Tone Detector circuit pack and the TN744 Call Classifier circuit pack provides touch tone receivers (TTRs or DTMR-PTs)) which are devices used to interpret touch tone calling signals and to translate the dual tones into the following valid digits: 0 through 9, *, and #. A Tone Detector circuit pack is a resource shared by all PBX users. The term "touch tone" formerly bore an AT&T trademark while the term "dual tone multifrequency receiver" has been the generic term used for this kind of device. A Tone Detector circuit pack also has general purpose tone detector ports (GPTD-PTs) to detect call progress tones, modem answer tones, and transmission test tones. In G3iV1.1-286 or G3iV2-386, Call Classifier Ports (CLSFY-PTs) have also been added to detect voice or network intercept tones. A Call Classifier Port (CLSFY-PT) can function as either a DTMR-PT or as a GPTD-PT.

When a user places a call from a digital or analog voice terminal on the switch, a TTR is needed to interpret the dual tone multifrequency signals sent from the voice terminal. The TTR is in use until the total number of digits needed is collected or until a time-out occurs. Dial tone is supplied to a user after receipt of an off-hook signal which signifies that a TTR is connected and ready to receive digits. For example, if there are 20 TTRs in the system being used simultaneously by 20 users at a given time, then the 21st user would not receive dial tone until a TTR becomes available. It is for this reason that it is necessary to have sufficient tone detectors in the system to prevent delay in receiving dial tone. The TTR-LEV errors can be used to determine a shortage of tone detectors. Use the **list measurements tone-receiver** command to determine tone detector usage. For more information on this command, refer to the *DEFINITY. Communications System Generic 1—Administration and Measurement Reports,* 555-200-500. The minimum threshold values assigned on the Maintenance-Related System Parameters Form for TTRs (DTMR-PTs), CPTRs (GPTD-PTs), and CCRs (CLSFY-PTs) should match the number of touch tone receivers (TTR) and tone detectors (GPTD-PT) in the system. The numbers are four TTRs and two GPTDs for each Tone Detector circuit pack [TN748, TN748B, and TN748C, and (the TN756 Combined Tone Detector/Tone-Clock in a single-carrier cabinet system)] used in the switch and 8 CCRs for each Call Classifier Port (TN744) circuit pack. The threshold values are administered via the **change system-parameters maintenance** command on the Maintenance-Related System Parameters Form. The desired numbers are entered in the "TTR" (DTMR-PT), "CPTR" (GPTD-PT), and "Call Classifier" (CLSFY-PT) fields, respectively.

The TTR Level (Touch Tone Receiver Level) MO is used to represent the following possible events:

1. The total number of General Purpose Tone Detector Ports (GPTD-PTs), [also known as Call Progress Tone Receivers (CPTRs)], currently in service is less than the administered threshold number.
2. The total number of Dual Tone Multifrequency Receiver Ports (DTMR-PTs) [(also known as Touch Tone Receiver (TTRs)], currently in service is less than the administered threshold number.

The TTR Level maintenance performs a monitoring function. When one of the above events occurs, the switch reports it. At this point, the system is still operating properly, but the system capacity is reduced.

The above events can occur if:

1. The threshold number of General Purpose Tone Detector Ports (GPTD-PTs) for service or the threshold number of Dual Tone Multifrequency Receiver Ports (DTMR-PTs) for service is administered incorrectly on a Tone Detector circuit pack.
2. Too many General Purpose Tone Detector Ports (GPTD-PTs) or Dual Tone Multifrequency Receiver Ports (DTMR-PTs) have been taken out-of-service for a Tone Detector circuit pack (that is, the ports have been either busied-out by system technician or maintenance has taken them out-of-service).
3. Too many ports have been taken out-of-service for a Call Classifier circuit pack (that is, the ports have been busied-out by system technician or maintenance has taken them out-of-service).
4. There is an insufficient number of General Purpose Tone Detector Ports (GPTD-PTs) or Dual Tone Multifrequency Receiver Ports (DTMR-PTs) in the system for a Tone Detector circuit pack. Or there is an insufficient number of ports in the system for a Call Classifier circuit pack.

Repair Procedure for the TTR Level Maintenance Object

The following is a step-by-step approach to resolve the TTR Level maintenance alarm.

1. Execute the **display error** command. Determine if the TTR-LEV warning alarm is raised against the GPTD-PT level, the DTMR-PT level, or the CLSFY-PT level. In the Hardware Error Log Table, the error type field of the TTR-LEV MO has a value of 2 for DTMR-PT level, a value of 4 for GPTD-PT level, or a value of 6 for CLSFY-PT level.

   Perform the actions described in Step 2 for the DTMR-PT, the GPTD-PT, or the CLSFY-PT.

2. Issue the **change system-parameters maintenance** command. Check the administered value(s) for TTRs and CPTRs for service on the Tone Detector circuit packs or for CCRs on the Call Classifier Port (CLSFY-PT) circuit pack. If a threshold value is set too high, change it to a lower value via the **change system-parameters maintenance** command and wait one minute for the alarm to clear.

   To determine the correct TTR, CPTR, and Call Classifier port values, check the total number of Tone Detector and Tone-Clock circuit pack and Call Classifier circuit packs (TN744) currently in the system. A Tone Detector circuit pack has two GPTD ports and four DTMR ports. A Call Classifier circuit pack has eight ports. Verify that the total number of GPTD-PTs, DTMR-PTs, and/or CLSFY-PTs in the system is greater than or equal to their respective administered threshold values. If not, then you must either (1) add more Tone Detector circuit packs and/or Call Classifier circuit packs to the system as required or (2) reduce the threshold to match the number in the system. If after (1) adding more Tone Detector circuit packs and/or Call Classifier circuit packs or (2) reducing the threshold, the TTR Level alarm is still present, then proceed to Step 3.

3. Execute the **display error** command. Look for a GPTD-PT, DTMR-PT, or CLSFY-PT that has been busied out. A port that has been busied out has a value of 18 in the error type field of the Hardware Error Log.

   For each of the busied-out ports, use the following procedure:

   - Determine why the port was busied out.
   - If the port can be placed back into service, test the port via the **test port PCSSpp** command.
   - If all the tests pass, release the port via the **release port PCSSpp** command. Then wait one minute for the TTR Level alarm to clear.

   If this does not clear the TTR Level alarm, proceed to Step 4.

4. Execute the **display alarm** command. Determine the address of the Tone Detector circuit pack which contains the defective (alarmed) GPTD-PT or DTMR-PT.

   Execute the **test board PCSS long rep 3** command where PCSS is the address (that is, port network number, carrier designation, and slot address) of the Tone Detector circuit pack or Call Classifier circuit pack containing the defective (alarmed) GPTD-PT or DTMR-PT.

   If this does not clear the TTR Level alarm, proceed to Step 5.

5. At this point, the only way to clear the alarm is to replace the Tone Detector circuit pack or Call Classifier circuit pack containing the defective (alarmed) GPTD-PT, DTMR-PT or CLSFY-PT.

Hardware Error Log Entries and Test to Clear Values

TTR Level Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	1	None			
2 (b)	2		WARNING (See the WARNING message below)	OFF	
3 (c)	3	None			
4 (d)	4		WARNING	OFF	
5 (e)	5	None			
6 (f)	6		WARNING	OFF	
7 (g)	7		MAJOR	OFF	
8 (h)	8		MINOR	OFF	
9 (i)	9		MINOR	OFF	

WARNING:
The Alarm is upgraded to MAJOR if the Base Tone Generator is set to 12 (France).

Notes:

a. Error code 1 does not indicate a current error condition. It indicates that the number of DTMR ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

b. The total number of DTMR ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.

c. Error code 3 does not indicate a current error condition. It indicates that the number of GPTD ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

d. The total number of GPTD ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure describe above.

e. Error code 5 does not indicate a current error condition. It indicates that the number of Call Classifier ports (CLSFY-PT) in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

f. The total number of Call Classifier ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.

g. There are currently no DTMR ports in service. To clear the alarm, refer to the repair procedure described above.

h. There are currently no GPTD ports in service. To clear the alarm, refer to the repair procedure described above.

i. There are currently no Call Classifier ports in service. To clear the alarm, refer to the repair procedure described above.

UDS1-BD (UDS1 Interface Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
UDS1-BD	MAJOR	test board PCSSpp sh	UDS1 Interface Circuit Pack
UDS1-BD	MINOR	test board PCSSpp l	UDS1 Interface Circuit Pack
UDS1-BD	WARNING	test board PCSSpp sh	UDS1 Interface Circuit Pack

The UDS1 Interface circuit pack provides an interface to the DS1 facility. UDS1 Interface circuit packs include the TN464B circuit pack and the TN464C circuit pack.

The TN464B circuit pack is designed to support 32 DS0 channels on a 2.048 Mbps DS1 link, and the TN464C (or greater vintage) circuit pack is designed to support either 24 DS0 channels on a 1.544 Mbps DS1 link or 32 DS0 channels on a 2.048 Mbps DS1 link. The TN464C (or greater vintage) circuit pack is optioned via a removable strap on the circuit pack. The 2 strap positions are labeled "24CHNL" or "32CHNL."

The DS0 channels can be administered either as trunks to other switches, lines to off-premises stations, ports to line-side PRI terminating devices, or as ports to other line-side non-PRI terminating devices.

NOTE:
DS0 channels on the TN464B circuit pack can be administered only as trunks to other switches.

UDS1 Interface Circuit Pack Maintenance documentation provides a strategy for maintaining the UDS1 Interface circuit pack. The maintenance strategy deals with logging the in-line errors reported by the UDS1 Interface circuit pack, running tests for error diagnosis and recovery, and raising or clearing maintenance alarms.

The TN464B and TN464C circuit packs support Tie trunks, CO trunks, DID trunks, OPS lines, narrowband access endpoint ports, the ISDN-PRI signaling channel (D-channel), and ISDN-PRI trunks (B-channels). The TN464C circuit pack can also support wideband access endpoint ports and PRI endpoint ports (B-channels).

The signaling (that is, the call setup) for the Tie trunks, CO trunks, DID trunks and OPS lines is done on the circuit pack by the UDS1 firmware. Signaling for the B-channels (ISDN-PRI trunks and PRI endpoint ports) is routed over the D-channel. ISDN-PRI Trunk and PRI endpoint port signaling (Q.921, Q.931), however, is not provided by the UDS1 Interface circuit pack. For the MIPS version of D92, the system software generates and/or receives the actual ISDN-PRI signaling messages (Q.931). The system software sends and/or receives these ISDN-PRI messages via the TN1655 Packet Interface circuit pack. The Packet Interface circuit pack, in turn, communicates with the UDS1 circuit pack's D-channel via the Packet Bus. For the INTEL version of D92, the system software generates and/or receives the actual ISDN-PRI signaling messages (Q.931). The system software sends and/or receives these ISDN-PRI messages via the TN765 Processor Interface circuit pack. The Processor Interface circuit pack, in turn, communicates with the UDS1 circuit pack's D-channel via the TDM Bus.

The signaling over the DS1 link must be synchronized between the transmitting end and the receiving end to ensure error-free communication. Refer to SYNC (Synchronization) Maintenance documentation for details.

Each trunk, line, and port has its own maintenance strategy. However, each trunk, line, or port is dependent upon the health of the UDS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1 documentation for a DS1 Tie Trunk, CO-DS1 documentation for a DS1 CO Trunk, DID-DS1 documentation for a DS1 DID Trunk, OPS-LINE documentation for a DS1 OPS Line, WAE-PORT documentation for a Wideband Access Endpoint, ISDN-TRK documentation for a DS1 ISDN Trunk, PE-BCHL documentation for a PRI Endpoint Port, and ISDN-LNK documentation for an ISDN-PRI Signaling Link Port.

The maintenance strategy for the TN464 UDS1 Interface circuit pack (UDS1-BD) is very similar to the maintenance strategy for the TN767 DS1 Interface circuit pack (DS1-BD). The same commands are used for administering and testing the boards. The differences in maintenance strategy between the boards are due to the UDS1 circuit pack's direct interface to the Packet Bus which is used for ISDN-PRI signaling (ISDN-LNK). While both the TN464 and TN767 can support ISDN-PRI B-channels, ISDN-PRI D-channel signaling applications require a TN464 UDS1 circuit pack.

The TN464F (or later suffix) circuit pack combined with AT&T's new 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN464F hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The 120A1 CSU Module connects to the TN464F circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation*, 555-230-193, Issue 1, December 1993.

The TN464F and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN464F circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises

Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this UDS1-BD section, but Figure 11-102 gives a high level overview of the loopback points.

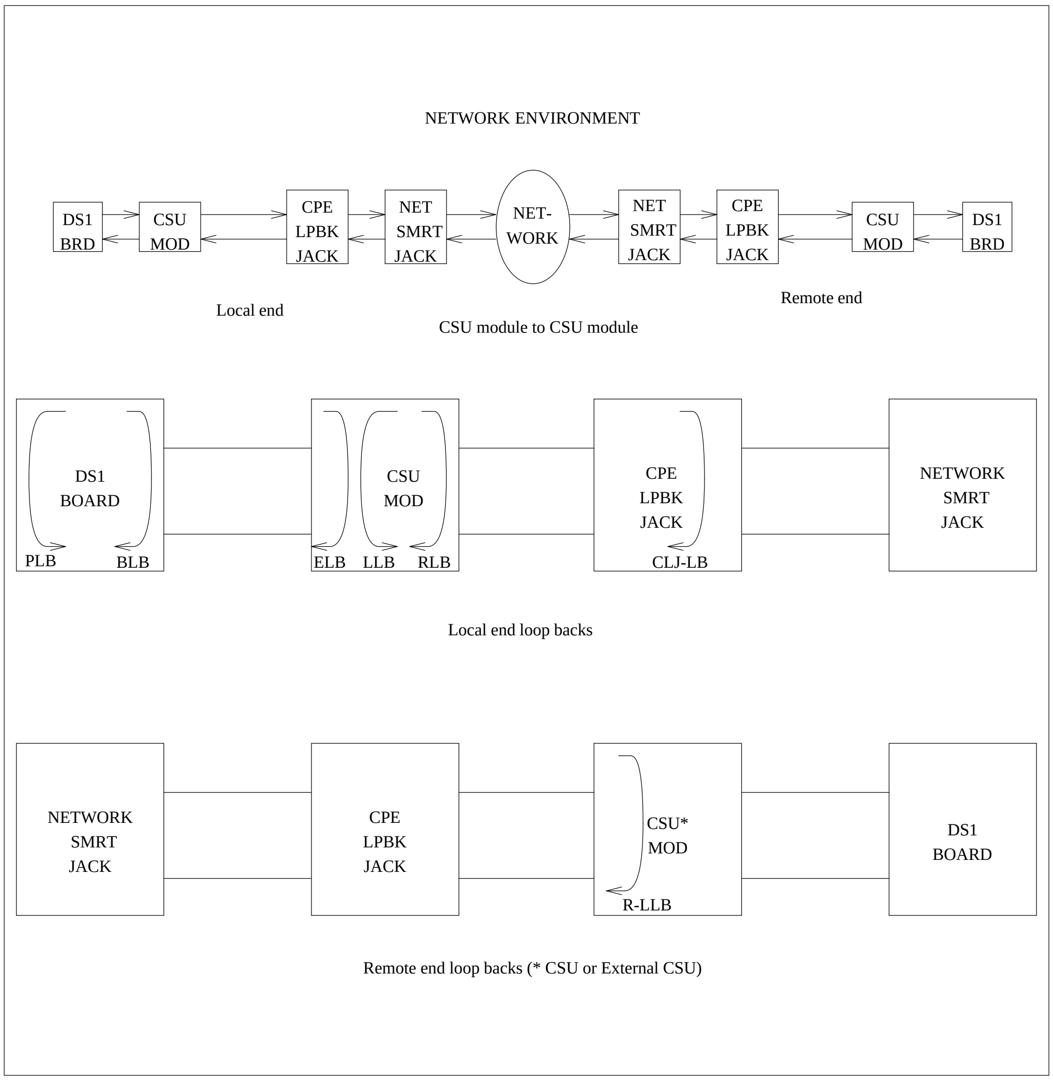

Figure 11-102. High Level Overview Of Loopback Points

Circuit Pack Administration and Options

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack form. *Bit Rate* is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. *Country Protocol* is used to drive layer 3 protocol decisions based on PRI specifications specific to a given country (not those related to specific features). This Country Protocol is independent of the *Country* parameter administered on the country-options system-parameters form. Different UDS1 circuit packs may be administered with different Country Protocols, allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations (for example, between two different countries). US systems use country protocol 1. *Near-End CSU Type* is set to *other* for no CSU installed, *or* for an external CSU such as an AT&T ESF T1 CSU, or *integrated* for the 120A1 CSU Module. Answering *integrated* will cause additional fields to be displayed for administering the Enhanced Integrated CSU Module. In addition to the above there are numerous other fields defining such parameters as framing modes, line coding companding mode and so on. For details, see *DEFINITY Communications System Generic 3 V2 Implementation,* 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107.

Figure 11-103 through Figure 11-105 show how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

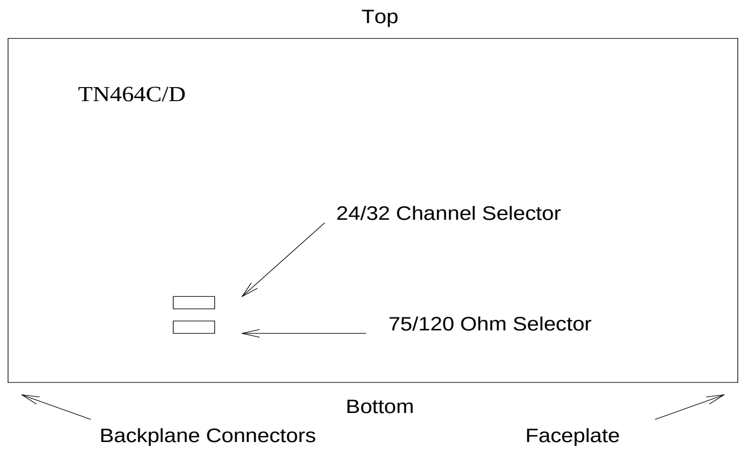

Figure 11-103. TN464C/D DS1 Option Jumpers

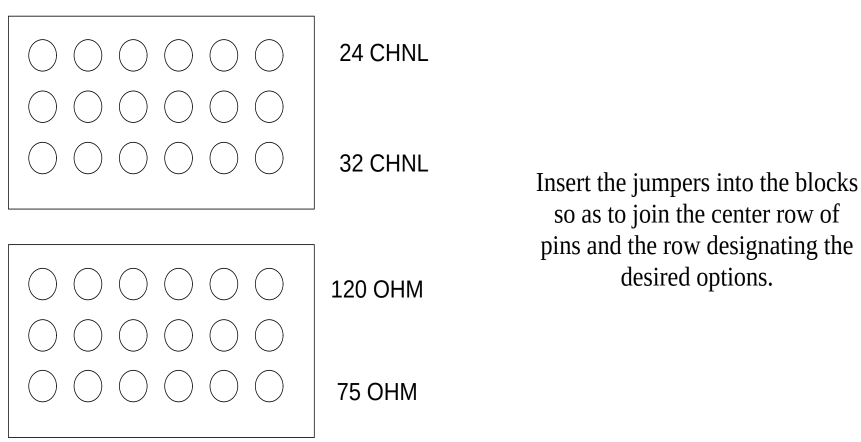

Figure 11-104. TN464C/D DS1 Option Jumpers

The option switch located on the component side of the TN464E/F circuit pack must be set correctly. Figure 11-105 shows how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

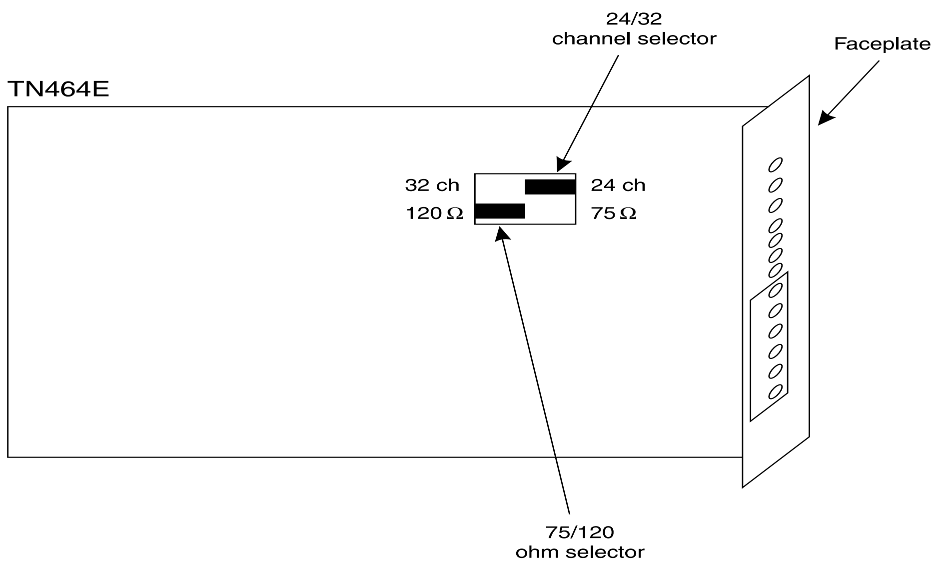

Figure 11-105. TN464E/F DS1 Option switches

Continued on next page

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.

3 Minor alarms on this MO may be downgraded to warning alarms based on values set in the **set options** command.

4 Major alarms on this MO may be downgraded to minor or warning alarms based on values set in the **set options** command.

Notes:

a. Error 1 indicates that the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

To be fully administered, a UDS1 circuit pack must meet all of these 3 conditions:

1. Have an entry in the circuit plan via the **change circuit pack** command
2. Be administered via the **add ds1** PCSS command
3. Be physically inserted into the correct slot

If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning UDS1 circuit pack is inserted in the correct slot, or
2. Completely remove the UDS1-BD from the system using the following steps:
   a. Remove any administered DS1 trunks, access endpoints or PRI endpoints associated with the circuit pack from their trunk groups.
   b. Execute the **remove ds1** PCSS and **change circuit pack** PCSS commands.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for LED Alarms with Error Type 1 in Chapter 7, "LED Interpretation".

b. The UDS1 Interface circuit pack has been busied out by a **busyout board PCSS** command.

c. The UDS1-BD circuit pack is not completely administered. To be fully administered, the UDS1 circuit pack must:
   1. Have an entry in the circuit plan via the **change circuit pack** command,
   2. Be administered via the **add ds1** PCSS command, and
   3. Be physically inserted into the correct slot.

   A DS1 (UDS1-BD and DS1-BD) differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered with the **add ds1** command.

d. No Aux Data: A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

   Aux Data 3: The 24/32-channel option jumper setting on the circuit pack does not match the option set on the DS1 circuit pack administration form. The circuit pack must be physically removed to see the setting of the jumper.

e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.

f. The UDS1 Interface circuit pack has detected a transient hardware problem. The value in the Aux Data field indicates the type of hardware problem.

4352	External RAM failure
4353	Internal RAM failure
4355	Internal ROM failure

If the UDS1 board detects only one of these hardware problems, then the error will disappear when none of these faults are detected for 10 minutes. If the same Aux Data value is logged more than once in a 24 hour period, the circuit pack should be replaced.

g. LAN External RAM Error. This error occurs when there is a hardware fault in the PPE external RAM. The RAM is used for message buffering to and from the Packet Bus. This error should not occur regularly. If this error is seen quite frequently (10 times within 30 minutes), the circuit pack should be replaced.

h. Transmit FIFO Underflow Error. This error occurs when the circuit pack cannot find the "end of frame" bit when transmitting a frame to Packet Bus. An alarm will be raised if this error occurs three times within 10 minutes. Clear the alarm via the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS long**, **release board PCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

i. Unable to Write LAN Translation RAM Error. This error occurs when a call is aborted because there are no available translation RAM locations for the call connection attempt. An alarm will be raised if this error occurs two times within 10 minutes. Clear the alarm via the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS long**, **release board PCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

j. CSU Module missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module is not physically connected (or is improperly connected) to the TN464F board on the back of the port carrier.

   If using the 120A1 CSU Module, plug (or replug) the CSU Module into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*.

   If this error remains after plugging the CSU Module into the board's connector, there could be a problem with the I/O connector panel.

k. CSU Module not expected. The 120A1 CSU Module is physically connected to the TN464F board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*.

   If the 120A1 CSU Module is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier.

l. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN464F circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.

m. DS1 circuit pack suffix incorrect for CSU Module. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the DS1 circuit pack is not a TN464F or later suffix UDS1 board.

   If the 120A1 CSU Module is to be used, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise, use the ***change ds1*** command to change the *Near-End CSU Type* field to *other*.

n. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: ***busyout board PCSS***, ***test ds1-loop PCSS ds1/csu-loopback-tests***, ***release board PCSS***. If the BLB test continues to fail, then the TN464F circuit pack needs to be replaced.

o. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS ds1/csu-loopback-tests*, *release board PCSS*. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by reexecuting the test by replacing one piece of hardware at a time.

p. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS ds1/csu-loopback-tests*, *release board PCSS*. If the RLB test continues to fail, then the CSU Module needs to be replaced.

q. CPE Loopback Jack deactivation error. This error occurs when the TN464F circuit pack could not deactivate a CPE Loopback Jack loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS end-loopback/span-test*, *release board PCSS*. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

r. Far CSU Loopback deactivation error. This error occurs when the TN464F circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

   Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS end-loopback/span-test*, *release board PCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

s. LAN Bus Timeout Error. This error occurs when the circuit pack transmits too many bytes on the LAN bus for a single frame. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.

   If the error occurs three times within 10 minutes, the board will be isolated from the Packet Bus and the board will be alarmed. To clear the alarm and restore the board to the Packet Bus, use the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS long**, **release board PCSS**.

   If the problem persists, and there are no PKT-BUS alarms or port alarms, then replace the circuit pack.

t. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #50 and/or Test #52 are aborting with error code 2000.
   2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
   3. A busyout/release of the circuit pack has no affect on test results.
   4. A **list configuration** command shows that the circuit pack and ports are properly installed.

   The circuit pack is isolated from the system and all trunks or ports on this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 20-30 minutes. When no faults are detected for 20-30 minutes, the UDS1 Interface circuit pack is restored to normal operation. All trunks or ports of the UDS1 Interface circuit pack are then returned to the in-service state. If the board is not restored to normal operation, or the error recurs after the board was restored to normal operation, escalate the problem.

u. LAN Critical Error. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to an on-board fault or a Packet Bus fault. If the Packet Bus is alarmed, refer to the PKT-BUS Maintenance documentation for recommended repair procedures.

This error will isolate the board from the Packet Bus and raise an alarm. If the Packet Bus is not alarmed, enter the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS**, **release board PCSS**. This should clear the alarm and restore the board to the Packet Bus.

If the problem persists, and there are no PKT-BUS alarms, then replace the circuit pack.

v. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving slips and the AUX data shows the last slip count that was reported.

w. These errors are not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Bad logical link

x. For later releases of G3V4 and beyond, only error 3585 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.

y. The UDS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.

z. Bad Translation RAM Location Found Error. This error is not service-affecting. No action is required. A Bad Translation RAM is detected, but the call continues by using another translation location.

aa. LAN Receive Parity Error. This error occurs when the circuit pack detects an error in a received frame from the Packet Bus. These errors are most likely caused by a Packet Bus problem, but may be due to a circuit pack fault.

Refer to the PKT-BUS Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

ab. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

ac. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

ad. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.

1 — Test is currently running.

2 — Test has failed because test could not be activated.

3 — Test pattern was not received from the far end.

4 — Test has been terminated.

ae. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Connection Audit Test,* for example, you may also clear errors generated from other tests in the testing sequence.

Table 11-376. System Technician-Demanded Tests: Descriptions and Error Codes

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop Command	D/ND[1]
NPE Connection Audit Test (#50)		X			ND
Control Channel Loop Test (#52)		X			ND
Loss of Signal Alarm Inquiry Test (#138)	X	X			ND
Blue Alarm Inquiry Test (#139)	X	X			ND
Red Alarm Inquiry Test (#140)	X	X			ND
Yellow Alarm Inquiry Test (#141)	X	X			ND
Major Alarm Inquiry Test (#142)	X	X			ND
Minor Alarm Inquiry Test (#143)	X	X			ND
Slip Alarm Inquiry Test (#144)	X	X			ND
Misframe Alarm Inquiry Test (#145)	X	X			ND
Translation Update Test (#146)	X	X			ND
ICSU Status LEDs Test (#1227)	X	X			ND
SAKI Sanity Test (#53)			X		D
Internal Loop Around Test (#135)			X		D

CPE Loopback Jack Test (#1212)				X	D
Far CSU Loopback Test (#1213)				X	D
One-Way Span Test (#1214)				X	D
Inject Single Bit Error (#1215)				X	D
End Loopback/Span Test (#1216)				X	D

1 D = Destructive; ND = Nondestructive

NPE Connection Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for the SCOTCH-NPE chip on the circuit pack.

Table 11-377. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1019	ABORT	The test aborted because a test was already running on the port. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort/fail, escalate the problem.
	PASS	The circuit pack's SCOTCH-NPE chip have been updated with its translation.

Continued on next page

Table 11-377. TEST #50 NPE Connection Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Control Channel Loop Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 11-378. TEST #52 Control Channel Loop Around Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	The circuit pack failed to return the circuit pack code or vintage. 1. Retry the command a maximum of 5 times. 2. If the problem continues, and if the circuit pack is one of the Port circuit packs, replace the circuit pack. Otherwise, if the circuit pack is part of the SPE, use the procedure described in "Replacing Defective SPE Circuit Packs" in Chapter 8, "Reliability Systems: A Maintenance Aid". 3. Retry the command a few times a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
	PASS	Communication with this circuit pack is successful.

Continued on next page

Table 11-378. TEST #52 Control Channel Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

Table 11-379. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to SYNC (Synchronization) Maintenance documentation.
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute the **reset board** command again. 3. If the test aborts with this error code again, escalate the problem.
2100	ABORT	System resources required for this test are not available. 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute the **reset board** command again. 2. If the problem persists, replace the circuit pack.

Continued on next page

Table 11-379. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Internal Loop Around Test (#135)

This test is destructive.

The Internal Loop Around Test is run by looping the transmitted DS1 bit stream back into the UDS1's board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Internal Loop Around Test. When the Internal Loop Around Test is initiated, maintenance software sends appropriate messages to the UDS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk or port are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the UDS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks or ports of the UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-380. TEST #135 Internal Loop Around Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-380. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the **reset board** command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	Received an incoming call on a port of the UDS1 circuit pack during the test. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack to out-of-service state. 2. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the **reset board** command. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-380. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization PCSS** command. 3. Lastly, issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this error type.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the **reset board** command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-380. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The UDS1 Interface circuit pack failed in the Internal Loop Around Test. If the UDS1 connects to a T1 network facility or another switch: 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. Enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connectivity of DS1 Interface circuit packs and cable. 5. Replace the local UDS1 Interface circuit pack and repeat the test. 6. Contact T1 Network Service to diagnose the remote DS1 endpoint. 7. If the test still fails, then escalate the problem. *More information continues on the next page.*

Continued on next page

Table 11-380. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter: 1. Retry the **reset board** command at 1-minute intervals a maximum of 5 times. 2. Enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. 3. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 4. Investigate the maintenance status of the line-side terminating device. Obtain the error seconds measurement on the terminating device (if possible). Refer to the line-side terminating device operating manual for information. 5. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If the error seconds measurement is severe, investigate premise distribution system wiring for noise and distance limitation. 6. Replace the local UDS1 Interface circuit pack and repeat the test. 7. Contact the vendor of the line-side terminating device to diagnose the equipment. 8. If the test still fails, then escalate the problem.
	PASS	All administered trunks or ports of the UDS1 Interface circuit pack pass the Internal Loop Around Test. The bit pattern consistency test is executed successfully over the path that covers a DS1 port, cable, and the external NCTE device.

Continued on next page

Table 11-380. TEST #135 Internal Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the UDS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the UDS1 Interface circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored.

The UDS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 3 seconds. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the new AT&T 120A1 CSU Module. This CSU Module, when combined with the functionality provided by the TN464F circuit pack, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The combination of the TN464F and 120A1 CSU Module is known as an Enhanced Integrated CSU (I-CSU).

If a TN464F circuit pack detects certain I-CSU hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN464F board to confirm the I-CSU error. A Minor or Warning alarm will be raised depending on the severity of the I-CSU error. The trunks on the board may be taken out of service if the I-CSU error is deemed serious.

If a Loss Of Signal alarm and an I-CSU error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the I-CSU hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other I-CSU errors or Loss Of Signal alarm exist).

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	UDS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this UDS1 interface circuit pack are out-of-service. If the UDS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to the SYNC section in this chapter for details. If the UDS1 connects to a T1 network facility: 1. Check the physical connection of the UDS1 Interface circuit pack and the cable. If a 120A1 CSU Module is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack. 2. If the UDS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the UDS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter: 1. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If a 120A1 CSU Module is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack. 2. Contact the vendor of the line-side terminating device to diagnose the equipment.

Continued on next page

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1300		The CSU Module is missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module is not physically connected to the TN464F board on the back of the port carrier. 1. If using the 120A1 CSU Module, plug the CSU Module into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*. 2. Run the test again.
1301	FAIL	The 120A1 CSU Module is physically connected to the TN464F board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*. 1. If the 120A1 CSU Module is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier. 2. Run the test again.
1302	FAIL	Attempting to use the 120A1 CSU Module with a TN464F circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America. 1. If the 120A1 CSU Module is to be used, physically remove the TN464F circuit pack and reconfigure for 24-channel (1.544 Mbps) operation. 2. Reinsert the circuit pack and run the test again.

Continued on next page

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1303	FAIL	The DS1 circuit pack Suffix is incorrect for CSU Module administration. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the DS1 circuit pack is not a TN464F or later suffix UDS1 board. 1. If the CSU Module is to be used, and the *Near-End CSU* type field is set to *intergrated* to allow for CSU Module administration, remove the circuit pack and replace with a TN464F or later suffix board. Otherwise, use the ***change ds1*** command to change the *Near-End CSU Type* field to *other*.
1310	FAIL	The DS1 Board Loopback (BLB) demand test (#1209) failed. 1. Repeat the test using the ***test ds1-loop PCSS ds1/csu-loopback-tests*** command. 2. If the BLB test continues to fail, then replace the TN464F circuit pack. 3) Run this test again.

Continued on next page

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1311	FAIL	The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*. 1. Execute the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module and running the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 3. If the ELB test continues to fail, then replace the TN464F board and run the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module.
1312	FAIL	The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*. 1. Execute the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the RLB test continues to fail, then replace the CSU Module. 3. Run this test again.

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1313	FAIL	The TN464F circuit pack could not deactivate a CPE Loopback Jack loopback. 1. Execute the ***test ds1-loop PCSS end-loopback/span-test*** command. 2. If the attempt to deactivate the CPE Loopback Jack loopback is not successful, check the cabling and investigate the problem at the CPE Loopback Jack. 3. Run the test again.
1314	FAIL	The TN464F circuit pack could not deactivate a far-end CSU loopback. 1. Execute the *test ds1-loop PCSS end-loopback/span-test* command. 2. If the attempt to deactivate the far-end CSU loopback continues to fail, then escalate the problem.
1320	FAIL	A 120A1 CSU module hardware failure or an ICSU serial interface audit failure was detected by the TN464F UDS1 circuit pack. 1. Replace the CSU module, and then run the test again. 2. If the test continues to fail with this error code, replace the TN464F and run the test again. 3. If the test continues to fail with this error code, then the problem could be in the I/O cable between the backplane and the CSU module.

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1321	FAIL	DTE LOS (loss of signal) was detected between the TN464F UDS1 board and the 120A1 CSU Module. Either the TN464F board, the 120A1 CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. 1. Replace the CSU Module and run the test again. 2. If the test continues to fail with this error code, then replace the TN464F board and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1322	FAIL	No 5 volts power detected from the TN464F circuit pack to the 120A1 CSU Module. Problem probably due to an open fuse on the DS1 board or a faulty ICSU. **NOTE:** Do not immediately swap DS1 boards as this may blow the fuse on the new board. 1. If the test continues to fail with this error code, then replace the CSU Module and run the test again. 2. Remove the TN464F from the system and reinsert. 3. Run the test again once the board has finished its reset. 4. If the test continues to fail with this error code, then replace the TN464F board and run the test again. 5. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1323	FAIL	A service affecting CSU Module audit failure was detected by the TN464F UDS1 circuit pack. All administered ports on the UDS1 circuit pack are affected and maintenance software will place the ports into the out-of-service state. 1. Replace the 120A1 CSU Module.

Continued on next page

Table 11-381. TEST #138 Loss of Signal Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1324	FAIL	A non-service affecting CSU Module audit failure was detected by the TN464F UDS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.
	PASS	DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the UDS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The UDS1 Interface circuit pack takes 3 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the UDS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks or ports back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. When the switch DS1 is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Table 11-382. TEST #139 Blue Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Red Alarm Inquiry Test (#140)

A UDS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a UDS1 Interface circuit pack. A UDS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the UDS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks or ports of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the UDS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks or ports of the UDS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm

If the UDS1 Interface circuit pack is administered using DMI-BOS signaling, the UDS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once the UDS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

Table 11-383. TEST #140 Red Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Red alarm is detected on the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The UDS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks or ports on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks or ports on the UDS1 Interface circuit pack back to their previous service state before the Yellow alarm was raised.

This Yellow alarm corresponds to the yellow F2 state documented in CCITT Recommendation I.431.

Remote Multiframe Alarm

Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the UDS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 Fault Alarm

For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

Table 11-384. TEST #141 Yellow Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A 'busyout' or a 'release' command has no affect on the test results. 4. A 'list config' command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 11-384. TEST #141 Yellow Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Neither a Yellow alarm nor a Remote Multiframe Alarm nor a F5 state alarm is being received from the remote DS1 endpoint.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Major Alarm Inquiry Test (#142)

The Major alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. The UDS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. (32-channel interfaces send a YELLOW alarm to the far end). After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the UDS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks or ports on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks or ports on the circuit pack to their previous service state before a Major alarm occurs.

Table 11-385. TEST #142 Major Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The performance of the DS1 link between the UDS1 interface circuit pack and the remote DS1 endpoint is very poor. If the UDS1 connects to a T1 network facility or to another switch, do the following: 1. Enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. 2. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 3. Contact T1 Network Service or the technician at the remote switch to diagnose the equipment. 4. Check the physical connectivity of the UDS1 interface circuit packs and the cable. 5. Replace the local UDS1 interface circuit pack, and repeat the test. 6. If the test still fails, escalate the problem. *Information continues on the next page.*

Continued on next page

Table 11-385. TEST #142 Major Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL *(cont'd.)*	If the UDS1 connects to a line-side terminating device (for example, a PRI terminal adapter), do the following: 1. The performance of the DS1 link between the UDS1 interface circuit pack and the line-side terminating device is very poor. Enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. 2. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding. 3. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information. 4. Contact the vendor of the line-side terminating device to diagnose the equipment. 5. Check the physical connection of the UDS1 interface circuit pack to the terminating device, and check the premise distribution system (or the intra-premise wiring) for physical connection failures. 6. Replace the local UDS1 interface circuit pack and repeat the test. 7. If the test still fails, escalate the problem.
	PASS	No Major alarm is detected in the UDS1 Interface circuit pack.

Continued on next page

Table 11-385. TEST #142 Major Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the UDS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition has cleared. If ESF framing mode is selected, the UDS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition has cleared.

When the UDS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks or ports on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

Table 11-386. TEST #143 Minor Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Slip Alarm Inquiry Test (#144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The UDS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips that have occurred on a DS1 link.

When the UDS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on a UDS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the UDS1 Interface circuit pack. All trunks or ports of the UDS1 Interface circuit pack remain in the in-service state. If the UDS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See TDM-BUS (TDM Bus) and SYNC (Synchronization) Maintenance documentation for details.

Table 11-387. TEST #144 Slip Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. Table 11-387. TEST #144 Slip Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	No Slip alarm is detected on the UDS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a UDS1 Interface circuit pack are in error. The Misframe Alarm Inquiry Test queries the total number of misframes that have occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches a specified threshold (i.e.- 17), a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the UDS1 Interface circuit pack.

When the threshold of misframes is reached, if the UDS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the UDS1 Interface circuit pack is raised, but all trunks or ports of the UDS1 Interface circuit pack remain in the in-service state.

Table 11-388. TEST #145 Misframe Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-388. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1 to 17	FAIL	The test failed because the UDS1 interface circuit pack detected errors in the received framing bits pattern. The error code equals the number of misframes detected by the UDS1 interface circuit pack since the last misframe alarm inquiry test. Major bit and minor bit error rate (error types 2561 and 2817) error logs often accompany misframe alarms. Clearing the cause of these error logs may clear the misframes which are occurring. If the UDS1 connects to a T1 network facility or to another switch, do the following: 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN464C, enter the **list measurement ds1-log PCSS** command to read the error seconds measurement. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 5. Contact T1 Network Service or the technician at the remote switch to diagnose the remote DS1 endpoint. 6. Check the physical connectivity of the UDS1 interface circuit packs and the cable. 7. Replace the local UDS1 interface circuit pack, and repeat the test. *More information continues on the next page.*

Table 11-388. TEST #145 Misframe Alarm Inquiry Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the UDS1 Interface circuit pack. Translation includes the following data administered for a UDS1 Interface circuit pack (see output of **display ds1 PCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

In G3V3, if a TN464F or later UDS1 circuit pack is combined with an AT&T 120A1 CSU Module to form and Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, etc.

Table 11-389. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal system software error. 1. Enter the **display ds1 PCSS** command to verify the UDS1 Interface circuit pack translation. 2. If the test continues to fail, escalate the problem.
	PASS	Translation data has been downloaded to the UDS1 Interface circuit pack successfully.

Continued on next page

Table 11-389. TEST #146 Translation Update Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN464F DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-390. TEST #1209 DS1 Board Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	DS1 Board Loopback Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.

Continued on next page

Table 11-390. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Next, issue the **set synchronization PCSS** command. 3. Lastly, issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.
1950	ABORT	Another loopback/span test is already executing on the DS1 boardor the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop PCSS end-loopback/span-test* command in order to execute this test.

Table 11-390. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-390. TEST #1209 DS1 Board Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	UDS1 Interface circuit pack failed the DS1 Board Loopback Test. 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the BLB test continues to fail, then replace the UDS1 circuit pack.
	PASS	The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN464F DS1 board edge.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local AT&T 120A1 CSU Module and tests the connection from the TN464F DS1 board to the CSU Module (DS1 board edge, connection, and CSU Module edge). This test will only be performed if the AT&T 120A1 CSU Module is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern itself.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 11-391. TEST #1210 CSU Equipment Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-391. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1005	ABORT	CSU Equipment Loopback Test cannot be executed in the current configuration. To run this test, the *Near-End CSU Type* field on the DS1 circuit pack administration form must be set to *integrated* and the "Bit Rate" field must be set to "1.544" (24-channel operation). 1. Use the **change ds1 PCSS** command to set the *Near-End CSU Type* field on the DS1 circuit pack administration form to *integrated*, and/or change the "Bit Rate" field to "1.544" if the board is to be used in 24-channel configuration. 2. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 3. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-391. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. 1. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: ■ Issue the **disable synchronization-switch** command. ■ Next, issue the **set synchronization PCSS** command. ■ Lastly, issue the **enable synchronization-switch** command. Then rerun the test. 2. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.
1950	ABORT	Another loopback/span test is already executing on the DS1 boardor the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span tests can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop PCSS end-loopback/span-test* command in order to execute this test.
1951	ABORT	The CSU Equipment Loopback Test could not be executed because the 120A1 CSU Module was not physically installed. Physically connect the 120A1 CSU Module to the TN464F board on the back of the port carrier.

Continued on next page

Table 11-391. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-391. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	UDS1 Interface circuit pack failed the CSU Equipment Loopback Test. 1. Retry the *test ds1-loop PCSS ds1/csu-loopback-tests* command. 2. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module and running the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 3. If the ELB test continues to fail, then replace the TN464F board and run the *test ds1-loop PCSS ds1/csu-loopback-tests* command again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module.
	PASS	The ELB test executed successfully. The test pattern was transmitted and received successfully over the connection from the TN464F DS1 board to the near-edge of the 120A1 CSU Module.

Continued on next page

Table 11-391. TEST #1210 CSU Equipment Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local AT&T 120A1 CSU Module and tests the connection from the TN464F DS1 board to and including the CSU Module circuitry. This test will only be performed if the AT&T 120A1 CSU Module is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern itself.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN464F DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded ***test ds1-loop PCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]*** command. The system technician has the choice of entering a loopback activation code on the command line or using the default code (0x47F).

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CSJ Loopback Test.

The CPE Loopback Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field),and whether the pattern(*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 11-393. TEST #1212 CPE Loopback Jack Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS cpe-loopback-jack-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	CPE Loopback Jack Test cannot be executed in the current configuration. To run this test, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

Table 11-393. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The CLJ-LB test failed because it was not set up properly. The UDS1 interface pack could not successfully put the CPE loopback jack into loopback mode. 1. Rerun the **test ds1-loop PCSS cpe-loopback-jack-test-begin** command. 2. If the test continues to fail, the problem could be with the TN464F board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop PCSS ds1/csu-loopback-tests** command to determine if the loopback tests that are closer to the TN464F board are successful. If any of these tests fail, follow the maintenance strategy that is associated with the test that fails; otherwise, escalate the problem.
3	FAIL	The CPE Loopback Jack Test was not set up properly. The framed 3-in-24 test pattern, generated by the UDS1 Interface circuit pack and looped back through the CPE Loopback Jack, could not be detected properly by the UDS1 circuit pack. 1. Retry the *test ds1-loop PCSS cpe-loopback-jack-test-begin* command. 2. If the CPE Loopback test continues to fail, the problem could be with the TN464F board, the CPE Loopback Jack equipment, or somewhere in between. Run the *test ds1-loop PCSS ds1/csu-loopback-tests* command to see if the loopback tests closer to the TN464F board are successful. If any of those loopback tests fail, follow the maintenance strategy associated with those loopbacks. Otherwise, escalate the problem.
	PASS	The CSJ Loopback test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop PCSS end-loopback/span-test* command or the *release board PCSS* command.

Continued on next page

Table 11-393. TEST #1212 CPE Loopback Jack Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Far CSU Loopback Test (#1213)

This test is destructive.

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN464F DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS far-csu-loopback-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not an AT&T 120A1 CSU Module, and the UDS1 is administered for ami-zcs line coding, one's density protection must be disabled on the CSU during the test due to the large number of zero's in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field),and whether the pattern(*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 11-394. TEST #1213 Far CSU Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS far-csu-loopback-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Far CSU Loopback Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Issue the **set synchronization PCSS** command. 3. Issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.

Table 11-394. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-394. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The test failed because it was not set up properly. The UDS1 pack could not successfully put the far-end CSU into loopback mode. 1. Rerun the **test ds1-loop PCSS far-csu-loopback-test-begin** command. 2. If the test continues to fail, the problem could be with the TN464F board, the CPE loopback jack equipment, or somewhere between. Run the **test ds1-loop PCSS cpe-loopback-jack-test-begin** command to determine if the CPE loopback jack loopback test is successful. If a CPE loopback jack device is not being used, issue the **test ds1-loop PCSS ds1/csu-loopback-tests** command instead. If the closer loopback test fails, follow the maintenance strategy that is associated with that test; otherwise, escalate the problem.
3	FAIL	The Far CSU Loopback Test was not set up properly. The framed 3-in-24 test pattern, generated by the UDS1 Interface circuit pack and looped back through the far-end CSU, could not be detected properly by the UDS1 circuit pack. 1. Retry the ***test ds1-loop PCSS far-csu-loopback-test-begin*** command. 2. If the Far CSU Loopback test continues to fail with this error code, the problem could be with the TN464F board, the far-end CSU equipment, or somewhere in between. Run the ***test ds1-loop PCSS cpe-loopback-jack-test-begin*** command to see if the CPE Loopback Jack test which is closer to the TN464F board is successful. (If a CPE Loopback Jack device is not being used, then run the ***test ds1-loop PCSS ds1/csu-loopback-tests*** command to see if these even closer loopback tests succeed). If the closer loopback test fails, follow the maintenance strategy associated with that loopback. Otherwise, escalate the problem.

Table 11-394. TEST #1213 Far CSU Loopback Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters the *test ds1-loop PCSS end-loopback/span-test* command or the *release board PCSS* command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN464F DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS one-way-span-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN464F UDS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN464F board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show *0* until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the type of Loopback/Span test executing (*Test Field*), the type of pattern generated for the Loopback/Span test (*Pattern Field*),and whether the pattern(*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized Field*).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

Table 11-395. TEST #1214 One-Way Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS one-way-span-test-begin* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	One-Way Span Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1039	ABORT	The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the **disable synchronization-switch** command. 2. Issue the **set synchronization PCSS** command. 3. Issue the **enable synchronization-switch** command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.

Continued on next page

Table 11-395. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the *test ds1-loop PCSS end-loopback/span-test* command in order to execute this test.

Continued on next page

Table 11-395. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A **busyout** or a **release** command has no affect on the test results. 4. A **list config** command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	The One-Way Span test has successfully began transmitting a framed 3-in-24 test pattern. The test will continue to run until the system technician enters the *test ds1-loop PCSS end-loopback/span-test* command or the *release board PCSS* command.

Continued on next page

Table 11-395. TEST #1214 One-Way Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

Inject Single Bit Error Test (#1215)

This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, One-Way Span Test) are active on a TN464F circuit pack.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Table 11-396. TEST #1215 Inject Single Bit Error Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS inject-single-bit-error* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1015	ABORT	Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the **busyout board PCSS** command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. 2. Retry the command. 3. If the test continues to abort, escalate the problem.

2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	A single bit error has been successfully injected into an active framed 3-in-24 test pattern.

Continued on next page

Table 11-396. TEST #1215 Inject Single Bit Error Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN464F UDS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded Since only one of these three different long-duration loopback/span tests can be active at a time, the TN464F circuit pack knows which loopback/span test to terminate.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state, execute the **release board** command

Table 11-397. TEST #1216 End Loopback/Span Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	End Loopback/Span Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.

Table 11-397. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1313	FAIL	The TN464F UDS1 circuit pack could not deactivate the loopback through the Customer Loopback Jack. 1. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail with this error code, escalate the problem.
1314	FAIL	The TN464F UDS1 circuit pack could not deactivate the loopback through the far-end CSU. 1. Make sure that the far-end DS1 is installed if the far-end CSU is a 120A AT&T CSU Module. 2. Retry the *test ds1-loop PCSS end-loopback/span-test* command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to fail with this error code, escalate the problem.
	PASS	The active long-duration loopback or span test on the TN464F circuit pack was successfully terminated.

Continued on next page

Table 11-397. TEST #1216 End Loopback/Span Test — *Continued*

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Ensure that the board translations are correct. Execute the **add ds1 PCSS** command to administer the UDS1 interface if it is not already administered. 2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, then issue the **busyout board** command. 4. Issue the **reset board** command. 5. Issue the **release busy board** command. 6. Issue the **test board long** command. This should re-establish the linkage between the internal ID and the port.

ICSU Status LEDs Test (#1227)

The TN464F UDS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN464F board via the I/O connector panel on the back of the port carrier. The TN464F circuit pack combined with AT&T's new 120A1 CSU Module forms an Integrated CSU (ICSU).

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off and returns control of the status LEDs to the circuit pack.

This test will only be executed on a TN464F or later suffix UDS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 120A1 CSU Module is not physically installed, the status LEDs are always off and this test will abort.

Table 11-398. TEST #1227 ICSU Status LEDs Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	The ICSU Status LEDs test can not be executed for the current configuration. The test applies only to TN464F or later UDS1 circuit packs administered for 24-channel operation (1.544 bit rate). 1. If the circuit pack is a TN464F or later suffix UDS1 circuit pack, then retry the command. 2. If the test continues to abort, escalate the problem.
1951	ABORT	The ICSU Status LEDs Test can not be executed because a 120A1 or later suffix CSU Module is not physically installed. If using a 120A1 CSU Module, physically connect it to the TN464F board on the back of the port carrier. Otherwise, ignore this abort.

Continued on next page

Table 11-398. TEST #1227 ICSU Status LEDs Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2500	ABORT	Internal System Error 1. Retry the command. 2. If the test continues to abort, follow normal escalation procedures.
	PASS	The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, the board should be replaced at the customer's convenience.

WAE-PORT (Wideband Access Endpoint Port)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run	Full Name of MO
WAE-PORT[1]	MINOR	test access-endpoint <extension> l	Wideband Access Endpoint Port
WAE-PORT	WARNING	test access-endpoint <extension>	Wideband Access Endpoint Port

1 For additional repair information, see also UDS1-BD (UDS1 Interface Circuit Pack) Maintenance documentation.

The Wideband Switching capability supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

The Wideband Switching capability extends the DEFINITY G3 Administered Connections feature to include non-signaling Wideband Access Endpoints. Endpoint application equipment with direct T1 or E1 interfaces may connect directly to the switch’s line-side facilities. Application equipment without T1 or E1 interfaces requires a Terminal Adapter, such as a DSU/CSU. The terminal adapter or endpoint application equipment is connected to the Universal DS1 circuit pack (TN464C). These endpoints are administered as Access Endpoints, and they have no signaling interface to the switch. Instead, they simply transmit and receive data. (Some applications detect and respond to the presence or absence of data.) Calls are initiated from these endpoints using the Administered Connections feature.

Multiple Access Endpoints on one line-side UDS1 circuit pack (TN464C) facility are separate and distinct within the facility, and the endpoint application equipment must be administered to send and receive the correct data rate over the correct DS0s. All Administered Connections originating from Access Endpoints use the entire bandwidth administered for the Access Endpoint. An incoming call of a different data rate then that administered for the Access Endpoint cannot be routed to the Access Endpoint.

Although Wideband Access Endpoints are used primarily for line-side facilities, these endpoints can also be administered on network DS1 facilities to connect DEFINITY to non-switched network services, such as the AT&T fractional T-1 service. An example of this is the AT&T Static Integrated Network Access, where a trunk group to AT&T 4Ess Switched Services shares an access T-1 facility with a Wideband Access Endpoint. In this case, the Wideband Access Endpoint is connected to the AT&T fractional T-1 service, and it does not terminate on local endpoint equipment but is connected to a far-end CPE (for example, another DEFINITY PBX) via the dedicated fractional T-1. All Wideband Access Endpoint functionality and operation is identical on both line-side and network facilities. However, because maintenance capabilities are limited to the Wideband Access Endpoint interface, and because faults can occur end-to-end, troubleshooting procedures based on an end-to-end view of the network is required.

Wideband Access Endpoint Port maintenance provides a strategy for maintaining a Wideband Access Endpoint Port via a port on the Universal DS1 interface circuit pack hardware. The maintenance strategy involves logging Wideband Access Endpoint Port hardware errors, running tests for port initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution. Two different port service states are specified in the Wideband Access Endpoint Port maintenance. These states include *out-of-service*, where the port is in a deactivated state and cannot be used for calls, and *in-service*, where the port is in an activated state and can be used for calls. If the Universal DS1 Interface circuit pack (TN464C) is out-of-service, all ports on the Universal DS1 Interface circuit pack (TN464C) are placed into the out-of-service state.

Hardware Error Log Entries and Test to Clear Values

Wideband Access Endpoint Maintenance Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0[1]	0	Any	Any	Any	test access-endpoint <extension> sh r 1
18 (a)	0	busyout access-endpoint	WARNING	OFF	release access-endpoint <extension>
130 (b)		None	WARNING	ON	test access-endpoint <extension>
1281 (c)		Conference Circuit (Test #7)	MINOR	ON	test access-endpoint <extension> l r 4
1537 (d)		NPE Crosstalk Test (#6)	MINOR	ON	test access-endpoint <extension> l r 3
1793 (e)		None			test board PCSS long
3840 (f)	Any	Port Audit and Update (Test #36)			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

a. The wideband access endpoint has been busied out by a **busyout access-endpoint <extension>** command. No calls can be made to this extension.

b. The circuit pack has been removed, or it has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

c. The Conference Circuit Test (#7) failed on this port. See Test #7 for repair procedures.

d. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for repair procedures.

e. There was a failure of the TN464C UDS1 Interface circuit pack. See UDS1-BD Maintenance documentation for details.

f. The Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status access-endpoint <extension>** command and verify the status of the port. If the wideband access endpoint is out-of-service, enter the **release access-endpoint <extension>** command to put it back to in-service. Retry the test command. If the test continues to fail, escalate the problem.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND[1]
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit and Update Test (#36)	X	X	ND

1 D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and it provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence, and it takes between 20 and 30 seconds to complete.

Table 11-399. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status access-endpoint <extension>** command to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and if the port is not in use, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 11-399. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots that are out-of-service due to TDM-BUS errors. The **status health** command can be used to determine if the system is experiencing heavy traffic. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors, and if it is not handling heavy traffic, repeat the test at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. The **list measurement tone-receiver** command displays information on the system's tone receivers. 1. Look for TTR-LEV errors in the Error Log. If errors are present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If errors are present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status access-endpoint <extension>** command to determine when the port is available for testing. The port is available when it is in the **in-service/idle** state. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and if the port is not in use, escalate the problem.

Continued on next page

Table 11-399. TEST #6 NPE Crosstalk Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due either to a previously existing error on the specific port or to a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or the circuit pack, and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. User-reported troubles on this port should be investigated by using other port tests and by examining the terminal adapter or the external wiring.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and it provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and to conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 11-400. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the **status access-endpoint <extension>** command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the **status access-endpoint <extension>** command to determine when the port is available for testing. The port is available when it is in the **in-service/idle** state. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, and if the port is not in use, escalate the problem.
1020	ABORT	The test did not run due either to a previously existing error on the specific port or to a more general circuit pack error. 1. Examine the Error Log for existing errors against this port or circuit pack, and attempt to diagnose the previously existing error.

Continued on next page

Table 11-400. TEST #7 Conference Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. Although wideband calls do not use the conferencing feature on the NPE, this failure indicates problems with the circuit pack hardware. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. 1. User-reported troubles on this port should be investigated by using other port tests and by examining the terminal adapter or the external wiring.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the UDS1 Interface circuit pack to ensure that the wideband access endpoint port's translation is correct.

Table 11-401. TEST #36 Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	The port is out-of-service. If the port is busied out: 1. Issue **release access-endpoint <extension>** command to put the port back into in-service. 2. Retry the test command. If the port is not busied out: 1. Check the error and alarm logs for WAE-PORT and UDS1-BD errors and alarms. Follow the recommended repair procedures.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal system error. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	Port translation has been updated successfully.

XXX-BD (Common Port Circuit Pack)

MO Name As It Appears in Alarm Log	Alarm Level	Initial System Technician Command to Run (a)	Full Name of MO
XXX-BD[1]	MAJOR	test board PCSS	Common Port Circuit Pack Maintenance
XXX-BD[1]	MINOR	test board PCSS	Common Port Circuit Pack Maintenance
XXX-BD[1]	WARNING	test board PCSS	Common Port Circuit Pack Maintenance

1 Refer to the appropriate circuit pack documentation to get the correct MO name displayed in this field. It usually ends with BD.

a. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02,...etc.)

The Common Port Circuit Pack Maintenance is a set of common tests used by all the circuit packs with the generic hardware that interfaces with the TDM bus. Circuit packs included in this category are listed on the following pages.

Notes:

a. All circuit pack suffixes (B,C, D, etc.) are also supported by the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

b. The XXX-BD designation is also used in the SAT display in the case where a **reset board command** is issued to a circuit pack type which is in conflict to the actual circuit pack type administered for that slot or when a **reset board** command is issued to an empty circuit pack slot.

When any of the Common Port Circuit Packs (except the TN754 Digital Line and TN758 Pooled Modem circuit packs) are physically removed from the backplane, no alarm is logged for approximately 11 minutes. In the case of the Digital Line and Pooled Modem circuit packs, approximately 21 minutes elapse before an alarm is logged. When a circuit pack that has been removed is alarmed, the alarm type is minor and is classified as an on-board alarm. The time delay permits maintenance activity to be performed without triggering an additional alarm. **An alarm is logged only against a Common Port Circuit Pack on which ports have been administered.** See the next Note.

NOTE:
In a heavily loaded system, the interval between the removal of a Common Port Circuit Pack and the logging of the alarm may be several minutes longer.

XXX-BD Common Circuit Packs

The following list of circuit packs are listed by apparatus code, including circuit packs used in non-United States installations. .

Table 402. XXX-BD Common Circuit Packs

Apparatus Code	Name	Type
(TN566) (TN567)	DEFINITY AUDIX R3 System	Port Assembly

1793 (m)		Neon Test (#220)	MINOR	ON	test board PCSS r 2
3840 (n)	Any	None			
3999 (o)	Any	None			

1 Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2 G3iV1-1.286 or G3iV2-386 only

Notes:

a. This error indicates the circuit pack totally stopped functioning or it was physically removed from the system. This error type is not applicable to ANN-BD, DETR-BD, S-SYN-BD, M/T-BD, or CLSFY-BD.

> **NOTE:**
> The alarm is logged approximately 11 minutes after the circuit pack has been removed and/or SAKI Sanity Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, follow the instructions for "Red (alarm)" in the "Control and Port Circuit Pack Status LEDs" section in Chapter 7, "LED Interpretation" (See also the "Handling Port Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures")

b. This error indicates the circuit pack has been busied out. Release the circuit pack via **release board PCSS**.

c. The circuit pack has been logically administered but not physically installed. The alarm should clear when the circuit pact is installed.

If the circuit pack is already installed:

1. Run **test board PCSS long** and look at any test failures or error codes generated.
2. If the test does not clear error 23, then execute **reset board PCSS** and run the long test again.
3. If the reset/test does not clear error 23, replace the circuit pack.

d. This error applies only to the Maintenance/Test circuit pack (TN771B or TN771C). The error indicates that the hardware associated with the Analog Trunk Testing port of the circuit pack failed to initialize. This port is **not** used in G3iV1.1-286 or G3iV2-386. Note, however, that when this error occurs, the Maintenance/Test circuit pack may report an invalid vintage. Although this error is not service-affecting, the Maintenance/Test circuit pack should be replaced.

e. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

f. This error applies to the Maintenance/Test circuit pack (TN771D), Tone Detector (TN748B, TN748C, or TN748D), and Call Classifier (TN748) circuit packs. For the Maintenance/Test circuit pack, the error indicates that there is more than one Maintenance/Test circuit pack in the port network. For the Tone Detector or Call Classifier packs, the error indicates that there are more than 10 circuit packs in the system. Remove the circuit pack against which the error is logged.

g. This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

h. This error, when reported with Aux data in the range of 4352 to 4358, indicates that the circuit pack has reported an on-board hardware failure. The circuit pack continuously tests the hardware and report the results approximately every 10 minutes. If the hardware problem is resolved, the "leaky bucket" strategy should clear the alarm in approximately 30 minutes. However, if the alarm does NOT clear in 30 minutes, the circuit pack should be replaced.

i. This error can be ignored, but look for other errors on this circuit pack.

j. This error is not service-affecting and no action is required.

k. This error indicates that no ringing current is detected. Run Test #51, Ringing Application Test, and follow the procedures for Test #51. This error is only applicable to Analog Line circuit packs.

l. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

   1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
   2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
   3. A busyout/release of the circuit pack has no affect on test results.
   4. A **list configuration** command shows that the circuit pack and ports are properly installed.

   If the XXX-BD is not a TN754 Digital Line Circuit Pack (DIG-BD), and if this error happens again within 15 minutes, replace the circuit pack. If the XXX-BD is a TN754 Digital Line Circuit Pack (DIG-BD), check the alarm level. If the alarm level is a WARNING, this indicates that users are probably causing the hyperactivity by playing with their digital stations. If the circuit pack is really hyperactive, this alarm is upgraded to a MINOR alarm within one hour. If the alarm level is a MINOR alarm, replace the circuit pack. (Refer to the "Handling Port Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures".)

m. This error indicates that no neon current is detected. Run Test #220, Neon Test, and follow the procedures for Test #220. This error is applicable only to TN769 and TN746 Analog Line circuit packs.

n. This error is not service-affecting and no action is required.

o. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND[1]
NPE Audit Test (#50)		X		ND
Ringing Application Test (#51) (a)	X	X		ND
Control Channel Loop Around Test (#52)	X	X		ND
SAKI Sanity Test (#53)		X	D	
Neon Test (#220) (b)	X	X		ND

1 D = Destructive; ND = Nondestructive

a. Only applicable to Analog Line circuit packs.

b. Only applicable to TN746 and TN769 Analog Line circuit packs.

NPE Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 11-403. TEST #50 NPE Audit Test

Error Code	Test Result	Description/ Recommendation
none or 2100	ABORT	System resources required for this test are not available.
1019	ABORT	Test already in progress.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The circuit pack's NPEs have been updated with their translation.

Continued on next page

Table 11-403. TEST #50 NPE Audit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	EXTRA BD	Certain circuit packs have limitations on how many circuit packs can be in the system or port network such as the Maintenance/Test circuit pack (TN771B or TN771C), the Tone Detector circuit pack (TN748B, TN748C or TN748D) and the Call Classifier (TN744). The Maintenance/Test circuit pack allows only one circuit pack per port network. The Tone Detector and Call Classifier allow only 10 circuit packs in each system. All additional circuit packs return EXTRA-BD and should be removed.
any	NO BOARD	This is normal if the test is being done when (a) the circuit pack is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the circuit pack is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at one-minute intervals for a maximum of five times. 4. If the test continues to return NO BOARD, escalate the problem.

Ringing Application Test (#51)

This test checks the ringing application circuitry common to all ports on an Analog Line circuit pack.

Table 11-404. TEST #51 Ringing Application Circuit Test

Error Code	Test Result	Description/ Recommendation
1000 or 2100	ABORT	Could not allocate the necessary system resources to run test.
	ABORT	Could not allocate the necessary system resources to run test. The circuit pack is not installed. Internal System Error.
2000	ABORT	There was no response from the board. 1. If error type 1538 (hyperactivity) is present in the error log, follow the maintenance strategy that is recommended for this error type. 2. Run the **busyout board**, **reset board**, and **release busy board** commands,and then retest. 3. If the test still aborts, dispatch with the circuit pack. 4. Check the off-board wiring and the terminal, and, if there are no problems found, replace the circuit pack.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is idle, escalate the problem.

Continued on next page

Table 11-404. TEST #51 Ringing Application Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1008	ABORT	Could not allocate a ringing circuit for one of the following reasons: all the ringing circuits are in use; the ringing generator is defective; ringing generator is not wired correctly. 1. If the test continues to abort, look for RING-GEN error in Error Log. a. If there are RING-GEN errors, refer to RING-GEN Maintenance documentation and try to resolve any problem(s). Go to Step 2. b. If there are no RING-GEN errors, and the test continues to abort, issue the **test board PCSS** command on other TN742, TN769, or TN746 Analog circuit packs. If an ABORT with error code 1008 occurs for this test on other circuit packs as well, the ringing generator may be defective or may not be wired properly. Refer to RING-GEN Maintenance documentation for details. If an ABORT with error code 1008 does NOT occur on the other ports, then all four ring generators are in use. Exit from this documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
	FAIL	No ringing current is detected. The ringing application circuitry on this circuit pack probably is not healthy. 1. Retry the command again. 2. If the test continues to fail, look for RING-GEN error in Error Log. a. If there are RING-GEN errors, refer to the RING-GEN Maintenance documentation and try to resolve any problem(s). b. If there are no RING-GEN errors, replace the circuit pack. 3. Retry the command again. 4. If the test continues to fail, escalate the problem.

Continued on next page

Table 11-404. TEST #51 Ringing Application Circuit Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	PASS	Ringing current is detected or this vintage of the Analog Line circuit pack does not support the Ringing Application Circuit Test. Analog Line circuit packs that DO NOT support Test #51 include TN712 Vintage 13 and earlier and TN742 Vintage 3 and earlier.
any	NO BOARD	This is normal if the test is being done when (a) the circuit pack is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the circuit pack is physically in the system. Verify that the system is not in a stage of booting up. Retry the command at one-minute intervals for a maximum of five times. If the test continues to return NO BOARD, escalate the problem.

Control Channel Loop Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 11-405. TEST #52 Control Channel Loop Around Test

Error Code	Test Result	Description/ Recommendation
none or 2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	The test failed because the circuit pack failed to return the circuit pack code or vintage. 1. Retry the command for a maximum of 5 times. 2. If the test still fails, issue the **busyout board**, **reset board**, and **release busy board** commands, and then retest. 3. If the problem continues, replace the circuit pack. 4. Run the test again. 5. If the test continues to fail, escalate the problem.
	PASS	Communication with this circuit pack is successful.

Continued on next page

Table 11-405. TEST #52 Control Channel Loop Around Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	EXTRA BD	This result should only appear for the TN771B or TN771C Maintenance/Test circuit pack. More than one circuit pack has been installed in this port network. Remove this circuit pack.
any	NO BOARD	This is normal if the test is being done when (a) the circuit pack is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the circuit pack is physically in the system. 2. Verify that the system is not in a stage of booting up. 3.) Retry the command at one-minute intervals for a maximum of five times. 4. If the test continues to return NO BOARD, escalate the problem.

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack.

This test is executed as part of the long test sequence only for the Tone-Clock circuit pack and DS1 interface circuit packs. All other common circuit packs can be reset via the **reset board PCSS** command. The **reset** command executes this test.

Table 11-406. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 interface circuit packs. It means the DS1 interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, set synchronization to another DS1 interface circuit pack or the Tone-Clock circuit pack and try again. Refer to SYNC (Synchronization) Maintenance documentation.
1015	ABORT	Port is not out-of-service. 1. Busy out the circuit pack. 2. Execute command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The circuit pack failed to reset.

Continued on next page

Table 11-406. TEST #53 SAKI Sanity Test — *Continued*

Error Code	Test Result	Description/ Recommendation
2	FAIL	The circuit pack failed to restart. 1. Execute command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
any	NO BOARD	This is normal if the test is being done when (a) the circuit pack is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the circuit pack is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at one-minute intervals for a maximum of five times. 4. If the test continues to return NO BOARD, escalate the problem.

Neon Test (#220)

This test checks the voltage required to light the neon lamp on an analog terminal. A relay connects a 150V DC source from the backplane of the circuit pack onto the voltage bus, and another relay connects a 2K shunt from the bus to ground. Current in the line is then monitored to determine if the voltage is present.

The neon test runs only for TN746 and TN769 Analog circuit packs. If the circuit pack is not a TN746 or TN769, the test returns PASS, but there is no testing done to the circuit pack.

Table 11-407. TEST #220 Neon Test

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the **display port PCSSpp** command to determine the station extension. Use the **status station** command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1008	ABORT	Could not allocate a ringing circuit. Either all the ringing circuits are in use, or the ringing generator is defective or is not wired correctly. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly (see errors for RING-GEN). If it doesn’t occur on port test 48 for ANL-16-L, then all four ring phases are in use. 3. If the test to continues to abort, escalate the problem.

Continued on next page

Table 11-407. TEST #220 Neon Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT	There are not any translated ports on the circuit pack, or if there are ports, then none are administered to have "neon." 1. Verify that there are ports administered on the circuit pack. If no ports are administered, no further action is required. 2. Make sure a TN755 or TN752 power unit circuit pack is installed. 3. Verify that you have neon sets connected (AT&T sets that may be neon sets are 500 and 2500 series, also some non-AT&T may also be neon sets). If no neon sets are connected to the circuit pack, the test continues to abort, but no further action is required. 4. If there are no neon sets connected to the circuit pack, at least one port needs to be translated with neon. To check if a port is translated with neon, use the **display port PCSSpp** command to determine the station extension of any station on this circuit pack. Use the **display station <extension>** to determine if the port is administered with neon. The field "Message Waiting Indicator:" must be set to "neon" for at least one of the administered ports. If this field is not administered to "neon" the test continues to abort. This is acceptable because not all stations have neon lamps on their analog terminals. If none of the terminals have neon lamps, the the test continues to abort, but no further action is required.

Continued on next page

Table 11-407. TEST #220 Neon Test — *Continued*

Error Code	Test Result	Description/ Recommendation
1018	ABORT *(cont'd.)*	5. Retry the command again. 6. If the test continues to abort with neon translated ports, escalate the problem. 7. Retry the command at one-minute intervals a maximum of five times. 8. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly (see errors for RING-GEN). If it doesn't occur on port test 48 for ANL-16-L, all four ring phases are in use. 9. If the test to continues to abort, escalate the problem. 10. Retry the command again. 11. If the test continues to abort with neon translated ports, escalate the problem.
2000	ABORT	Response to the request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Could not allocate the necessary system resources to run this test. Internal System Error. 1. If Error Type 1538 is present in the Error Log, follow the recommended maintenance strategy.

Continued on next page

Table 11-407. TEST #220 Neon Test — *Continued*

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because no neon current was detected. 1. Determine if there is a TN755 or TN752 power unit circuit pack installed in the same carrier as the TN746 or TN769 analog line circuit pack that failed the test. Look for the failure of test 220 on other TN746 or TN769 circuit packs in the carrier. If test 220 fails on the other circuit packs, replace the TN755 or TN752 power unit circuit pack. 2. Retry the command again. 3. If the test continues to fail, replace the circuit pack. 4. Retry the command again. 5. If the test continues to fail, escalate the problem.
	PASS	This circuit pack is a TN746 or TN769 Analog Line circuit pack and the neon current is detected. This test also returns PASS for circuit packs that are not TN746 or TN769 circuit packs, but the test is not run on the circuit pack and the results of this test can be ignored.
any	NO BOARD	This is normal if the test is being done when (a) the circuit pack is not physically in the system or (b) the system is booting up. Otherwise, there is some inconsistency between the physical configuration and the data kept in the system. 1. Verify that the circuit pack is physically in the system. 2. Verify that the system is not in a stage of booting up. 3. Retry the command at one-minute intervals for a maximum of five times. 4. If the test continues to return NO BOARD, escalate the problem.

References

A

The following is a list of DEFINITY Enterprise Communications Server (ECS) Release 5 documents, including a brief description of each document.

To order these or other DEFINITY documents, contact the Lucent Technologies Publications Center at the address and phone number on the back of this document's title page. A complete list of Business Communications Systems (BCS) documents, including previous issues of the documents listed here, is provided in *BCS Publications Catalog,* 555-000-010.

Basic DEFINITY ECS Documents

The following are basic documents for anyone using DEFINITY ECS.

***DEFINITY Enterprise Communications Server Release 5 — Pocket Reference, Issue 1,* 555-230-207**

A compact reference containing hardware descriptions, system parameters, and listings of features and system configurations.

***DEFINITY Enterprise Communications Server Release 5 — Feature Description, Issue 1*, 555-230-301**

Provides comprehensive technical descriptions of system features and parameters. Includes the applications and benefits, feature interactions, administration requirements, hardware and software requirements, and a brief discussion of data communications and private networking configurations.

***DEFINITY Enterprise Communications Server Release 5 — Implementation, Issue 1*, 555-230-302**

Provides step-by-step procedures for preparing the hardcopy forms that correspond to the screens and are required to implement the features, functions, and services of the system. Includes procedures for completing a communications survey. Includes an initial set of blank forms (555-230-655B, 555-230-653B).

***DEFINITY Enterprise Communications Server Release 5 — Implementation Blank Forms, Issue 1*, 555-230-303**

Provides additional blank hardcopy forms that correspond to the screens that are required to implement the features, functions, and services of the system.

Copies of these forms are automatically included with the *DEFINITY Enterprise Communications Server Release 5 Implementation, Issue 1*, 555-230-302. Use this order number to purchase additional forms.

***DEFINITY Enterprise Communications Server Release 5 — System Description and Specifications, Issue 1*, 555-230-203**

Provides a technical description of the systems and is intended for service personnel, sales personnel, and customers. Includes descriptions of hardware, technical specifications, environmental requirements, and maintenance requirements.

***DEFINITY Enterprise Communications Server Release 5 — System Monitoring and Reporting, Issue 3*, 555-230-511**

Provides detailed descriptions of all the measurement, status, and security reports available in the system and is intended for administrators who validate traffic reports and evaluate system performance. This document was titled *Traffic Reports* for earlier systems. It includes corrective actions for potential problems.

***DEFINITY Communications System Generic 1 and Generic 3 — Installation and Test, Issue 5*, 555-230-104**

Provides descriptions of the procedures for installing and testing the system's common equipment and adjuncts. Includes setup procedures for the system management terminal, power and grounding requirements, and testing steps. Includes compete details on system wiring. Provides both domestic and international information.

***DEFINITY Enterprise Communications Server Release 5 — Installation and Test for Single-Carrier Cabinets, Issue 2*, 555-230-894**

Provides procedures and information for hardware installation and initial testing of single-carrier cabinets. This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Castillian Spanish (SP), and Japanese (JA).

To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

***DEFINITY Enterprise Communications Server Release 5 — Installation and Test for Multi-Carrier Cabinets, Issue 1,* 555-230-112**

Provides procedures and information for hardware installation and initial testing of multi-carrier cabinets.

***DEFINITY Communications System Generic 3 Version 1.1 - Version 4 Upgrades and Additions, Issue 2*, 555-230-107**

Provides procedures for an installation technician to convert an existing DEFINITY Communications System earlier than Generic 3 Version 4 to Generic 3 Version 4.

***DEFINITY Enterprise Communications Server Release 5 — Upgrades and Additions for R5r, Issue 1,* 555-230-121**

***DEFINITY Enterprise Communications Server Release 5 — Upgrades and Additions for R5vs/si, Issue 1*, 555-230-120**

Provides procedures for an installation technician to convert an existing DEFINITY Communications System Generic 3 Version 4 to DEFINITY ECS.

Included are upgrade considerations, lists of required hardware, and step-by-step upgrade procedures. Also included are procedures to add control carriers, switch node carriers, port carriers, circuit packs, auxiliary cabinets, and other equipment.

***DEFINITY Enterprise Communications Server* Release 5 — *Maintenance for R5r, Issue 5*, 555-230-105**

***DEFINITY Enterprise Communications Server Release 5 — Maintenance for R5vs/si, Issue 9*, 555-204-105**

Provides detailed descriptions of the procedures for monitoring, testing, and maintaining the systems. Included are maintenance commands, step-by-step trouble-clearing procedures, the procedures for using all tests, and explanations of the system’s error codes.

DEFINITY Enterprise Communications Server Release 5 — Overview, Issue 2, **555-230-024**

Provides a detailed overview of the system including descriptions of many of the major features, applications, hardware, system capabilities, and the support provided with the system.

DEFINITY Communications System Generic 3 Planning and Configuration, Issue 2, **555-230-601**

Provides step-by-step procedures for the account team in determining the customer's equipment and hardware requirements to configure a system according to the customer specifications. Includes detailed requirements and block diagrams. This document reflects Generic 3 Version 2 software, but still contains relevant information.

BCS Products Security Handbook, Issue 5, **555-025-600**

Provides information about the risks of telecommunications fraud and measures for addressing those risks and preventing unauthorized use of BCS products. This document is intended for telecommunications managers, console operators, and security organizations within companies.

DEFINITY Communications System and System 75 and System 85 Terminals and Adjuncts Reference, Issue 7, **555-015-201**

Provides descriptions of the peripheral equipment that can be used with System 75, System 85, DEFINITY Communications System, and DEFINITY ECS. This document is intended for customers and Lucent Technologies account teams for selecting the correct peripherals to accompany a system.

DEFINITY Communications System Generic 1, Generic 3, and System 75 Voice Terminal Guide Builder, Issue 3, **555-230-755**

Provides capability to produce laser-printed documentation for specific voice terminals. The software is supported by a comprehensive user's guide and on-line help. This product requires a 386 PC, minimum of 6MB disk space, minimum of 4MB RAM, a printer supported by Microsoft GDI printer drive, and Microsoft Windows 3.1 or higher. A mouse is recommended.

Call Center

The following list of documents are Call-Center specific.

DEFINITY

***DEFINITY Enterprise Communications Server Release 5 — Call Vectoring/EAS Guide, Issue 1*, 585-230-521**

Provides information on how to write, use, and troubleshoot vectors, which are command sequences that process telephone calls in an Automatic Call Distribution (ACD) environment. It is provided in two parts: tutorial and reference.

The tutorial provides step-by-step procedures for writing and implementing basic call vector scripts.

The reference includes detailed descriptions of the call vectoring features, vector management, vector administration, adjunct routing, troubleshooting, and interactions with management information systems (including the Call Management System).

***DEFINITY Enterprise Communications Server Release 5 — Basic Call Management System (BCMS) Operations, Issue 1*, 555-230-706**

Provides detailed instructions on how to generate reports and manage the system and is intended for telecommunications managers who wish to use Basic Call Management System (BCMS) reports and system managers responsible for maintaining the system.

CentreVu CMS

***CentreVu Call Management System Release 3 Version 5 — Administration, Issue 1,* 585-215-820**

***CentreVu Call Management System Release 3 Version 5 — Reports, Issue 1,* 585-215-821**

***CentreVu Call Management System Release 3 Version 5 — Custom Reports, Issue 1,* 585-215-822**

***CentreVu Call Management System Release 3 Version 5 — Upgrades and Migrations, Issue 1,* 585-215-826**

***CentreVu Call Management System Release 3 Version 5 — External Call History Reference, Issue 1,* 585-215-824**

***CentreVu Call Management System Release 3 Version 5 — Forecast, Issue 1,* 585-215-825**

Networks

The following list of documents are network-specific.

***DEFINITY Communications System Generic 3 Wideband Technical Reference, Issue 1*, 555-230-230**

Provides detailed information regarding the Wideband Switching feature for the system and is intended for users and technical support personnel involved with the installation, administration, and operation of this feature. This feature provides high speed end-to-end connectivity between customer endpoints where dedicated facilities are not economical or appropriate. The primary function is to support high speed video-conferencing and data applications.

***DEFINITY Communications System Generic 2.2 and Generic 3 Version 2 DS1/CEPT1/ISDN PRI Reference Manual, Issue 1*, 555-025-107**

Provides a detailed technical description of digital trunks in the DEFINITY Communications Systems. This includes trunks conforming to the DS1 standard (1.544 Mbps) and the CEPT1 standard and all other methods of signalling, including bit-oriented signalling as well as ISDN-PRI signalling. This document includes background information on these topics, information on how digital trunk capabilities have been designed into the DEFINITY Communications System and information for field personnel and customers on how to provision and administer digital trunk capabilities and features. Provides both domestic and international information.

Application Specific Documents

The following list of documents are application-specific.

***DEFINITY Enterprise Communications Server Generic 2 to Release 5 — Transition Reference, Issue 1,* 555-230-622**

Provides information on the differences in features and administration between the old and new systems when upgrading from a Generic 2 system to DEFINITY ECS.

ASAI

***DEFINITY Enterprise Communications Server Release 5 — CallVisor ASAI Planning Guide, Issue 5*, 555-230-222**

Provides procedures and directions for the account team and customer personnel for effectively planning and implementing the CallVisor Adjunct/Switch Application Interface (ASAI) PBX-Host environment. The CallVisor ASAI is a communications interface that allows adjunct processors to access switch features and to control switch calls. It is implemented using an Integrated Services Digital Network (ISDN) Basic Rate Interface (BRI). Included are hardware and software requirements.

***DEFINITY Enterprise Communications Server Release 5 — CallVisor ASAI Protocol Reference, Issue 5*, 555-230-221**

Provides detailed layer 3 protocol information regarding the CallVisor Adjunct/Switch Application Interface (ASAI) for the systems and is intended for the library or driver programmer of an adjunct processor to create the library of commands used by the applications programmers. Describes the ISDN message, facility information elements, and information elements.

***DEFINITY Enterprise Communications Server Release 5 — CallVisor ASAI Technical Reference, Issue 5*, 555-230-220**

Provides detailed information regarding the CallVisor Adjunct/Switch Application Interface (ASAI) for the systems and is intended for the application designer responsible for building and/or programming custom applications and features.

***DEFINITY Enterprise Communications Server Release 5 — Installation, Administration, and Maintenance of CallVisor ASAI Over the DEFINITY LAN Gateway, Issue 2*, 555-230-223**

Provides procedures for installation, administration, and maintenance of the CallVisor Adjunct/Switch Application Interface (ASAI) Ethernet application over the DEFINITY LAN Gateway and is intended for system administrators, telecommunications managers, Management Information System (MIS) managers, LAN managers, and Lucent personnel. The ASAI-Ethernet application provides ASAI functionality using 10Base-T Ethernet rather than BRI as a transport media.

DEFINITY Enterprise Communications Server Release 5 — Overview, Issue 2, **555-230-225**

DEFINITY Enterprise Communications Server Release 5 — CallVisor PC ASAI Installation and Reference, Issue 3, **555-246-205**

ACD

DEFINITY Enterprise Communications Server Release 5 — Automatic Call Distribution (ACD) Agent Instructions, Issue 5, **555-230-722**

Provides information for use by agents after they have completed ACD training. Includes descriptions of ACD features and the procedures for using them.

DEFINITY Enterprise Communications Server Release 5 — Automatic Call Distribution (ACD) Supervisor Instructions, Issue 4, **555-230-724**

Provides information for use by supervisors after they have completed ACD training. Includes descriptions of ACD features and the procedures for using them.

Console Operations

DEFINITY Communications System Generic 1 and Generic 3 Console Operations, Issue 2, **555-230-700**

Provides operating instructions for the attendant console. Included are descriptions of the console control keys and functions, call-handling procedures, basic system troubleshooting information, and routine maintenance procedures.

DEFINITY Enterprise Communications Server Release 5 — Console Operations Quick Reference, Issue 2, **555-230-890**

Provides operating instructions for the attendant console. Included are descriptions of the console control keys and functions, call handling, basic system-troubleshooting information, and routine maintenance procedures. This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Colombian Spanish (SPL), and Japanese (JA).

To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

Hospitality

***An Introduction to DEFINITY Communications System Generic 3 Hospitality Services, Issue 1*, 555-230-021**

Provides an overview of the features available for use by the lodging and health industries to improve their property management and to provide assistance to their employees and clients. Included are brief definitions of many of the system features, descriptions of the hardware, planning considerations, and list of the system capabilities.

***DEFINITY Communications System Generic 1 and Generic 3 Hospitality Operations, Issue 2*, 555-230-723**

Provides step-by-step procedures for using the features available for use by the lodging and health industries to improve their property management and to provide assistance to their employees and clients. Includes detailed descriptions of reports.

PAD
Packet Assembly/Disassembly

PBX
Private Branch Exchange

PC
Personal Computer

PCM
Pulse Code Modulation

PCOL
Personal Central Office Line

PCOLG
Personal Central Office Line Group

PCS
Permanent Switched Calls

PDM
Processor Data Module

PDS
Premises Distribution System

PE
Processing Element

PEC
Price Element Codes

PEI
Processor Element Interchange

PGATE
Packet Gateway

PGN
Partitioned Group Number

PI
Processor Interface

PIB
Processor Interface Board

PIDB
Product Image Database

PKTINT
Packet Interface

PL
Private Line

PLS
Premises Lightwave System

PMS
Property Management System

PN
Port Network

PNA
Private Network Access

POE
Processor Occupancy Evaluation

POP
Point Of Presence

PPM
Parts Per Million or Periodic Pulse Metering

PPN
Processor Port Network

PRI
Primary Rate Interface

PROCR
Processor

PSC
Premises Service Consultant

PSDN
Packet Switch Public Data Network

PT
Personal Terminal

PTC
Positive Temperature Coefficient

PTT
Postal Telephone and Telegraph

R

RAM
Random Access Memory

RBS
Robbed-Bit Signaling

RC
Radio Controller

RCL
Restricted Call List

REN
Ringer Equivalency Number

RFP
Request For Proposal

RHNPA
Remote Home Numbering Plan Area

RINL
Remote Indirect Neighbor Link

RISC
Reduced Instruction Set Computer

RLT
Release Link Trunk

RMATS
Remote Maintenance, Administration, and Traffic System

RNX
Route Number Index (Private Network Office Code)

ROM
Read-Only Memory

RPN
Routing Plan Number

RS-232C
Recommended Standard 232C

RS-449
Recommended Standard 449

RSC
Regional Support Center

S

SABM
Set Asynchronous Balance Mode

SAC
Send All Calls

SAKI
Sanity and Control Interface

SAT
System Access Terminal

SCC
Single Carrier Cabinet or Serial Communications Controller

SCD
Switch-Control Driver

SCI
Switch Communications Interface

SCO
System Control Office

SCOTCH
Switch Conferencing for TDM Bus in Concentration Highway

SCSI
Small Computer System Interface

SDDN
Software Defined Data Network

SDI
Switched Digital International

SDLC
Synchronous Data Link Control

SDN
Software Defined Network

SFRL
Single-Frequency Return Loss

SID
Station Identification Number

SIT
Special Information Tones

SMDR

#36 Port Audit and Update Test, 11-380, 11-597
#36 Station Status and Translation Audits and Updates Test, 11-119
#36 Station Status and Translation Audits and Updates Test (#36), 11-92
#40 Tone Generator Transmission Test, 11-1804
#42 Tone Detection Verification Test, 11-360
#46 Clock Health Inquiry Test, 11-1796
#47 Loop Around and Conference Test, 11-123
#48 Station Present Test, 11-95, 11-131
#50 NPE Connection Audit Test, 11-1845
#52 Control Channel Loop Around Test, 11-629
#53 SAKI Sanity Test, 11-1849
#595 LANBIC Receive Parity Error Counter Test, 11-194
#6 NPE Crosstalk Test, 11-51, 11-52, 11-80, 11-109, 11-371, 11-592
#618 BRI Port Local LAN Loop Around, 11-208
#619 BRI Port Local TDM Loop Around, 11-211
#620 Electronic Power Feed Restoral, 11-215
#621 Level 1 Status Inquiry, 11-217
#622 Electronic Power Feed Inquiry, 11-221
#624 Layer 1 Transmission Error Counter Test, 11-223
#625 Receive FIFO Overflow Error Counter Test, 11-225
#626 Signaling Link Status Test, 11-243
#627 BRI Remote Loop Back, 11-248
#628 BRI XID, 11-253
#629 BRI Layer 3 Query, 11-257
#630 BRI Set Audits, 11-261
#693 Memory Card Erase-Write-Read Test, 11-298
#694 Memory Card Translation Data Integrity Test, 11-302
#695 Memory Card Insertion Test, 11-304
#696 Memory Card Format and Read Test, 11-306
#697 Memory Card Match Test, 11-308
#698 Memory Card Write-Protected Test, 11-312
#699 Memory Card Directory Recovery Test, 11-314
#7 Conference Circuit Test, 11-55, 11-85, 11-375, 11-595
#78 AC Power Query Test, 11-17, 11-26
#844-848 Transmission Test, 11-418, 11-1771
#9 Digital Line NPE Crosstalk Test, 11-568
#9 NPE Crosstalk Test, 11-39, 11-66
Time Slot Test Call, 5-74
TN2036 circuit packs, 5-98
TN2182 circuit packs
international settings, 11-1780
TN464 circuit packs
option jumpers, 11-1830
TN765 circuit packs, 2-8
TN768 circuit packs
international settings, 11-1780
TN770 circuit packs, 2-8
TN772 circuit packs, 2-8, 2-9
TN777 circuit packs, 2-8
TN777 network control circuit packs, 5-10
TN777B circuit packs, 2-8
TN777B network control circuit packs, 5-10
TN778 circuit packs, 2-8
TN780 circuit packs
international settings, 11-1780
TN790, 4-6, 4-11, 8-24, 8-30
TN790 Release 5 systems, 8-21
tone-clock circuit packs
international settings, 11-1780
tones
Italian, 11-1780
Touch-Tone (DTMF) Receiver Test Call, 5-73
transaction keys, 3-3
trouble-clearing, 11-1
troubleshooting
backplane voltage problems, 5-98
control carrier power units, 5-25
ISDN-PRI problems, 5-90
ISDN-PRI test call problems, 5-94
PRI endpoint problems, 5-92
Trunk Group Busy/Warning Indicators to Attendant, 5-71
Trunk Group form, 5-81
Trunk Identification by Attendant, 5-71
Trunk Test Call, 5-72
trunks
port carriers, 2-6
TTT, see Terminating Trunk Transmission (TTT)

U

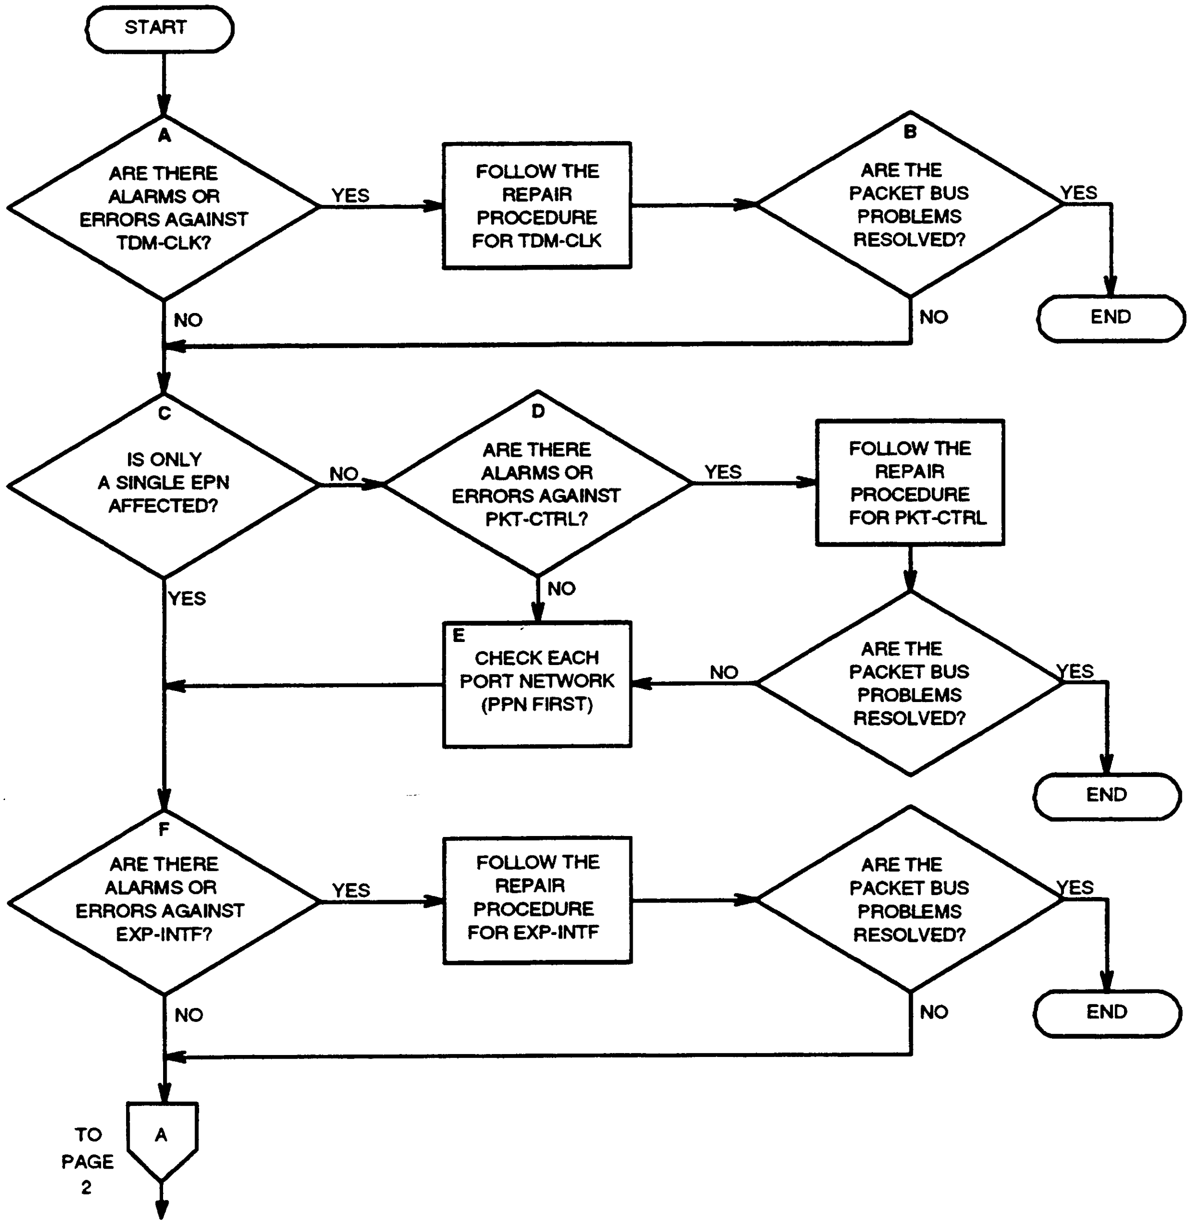
universal DS1 (UDS1) circuit packs
option jumpers, 11-1830
upgrade software commands, 10-25, 10-771

V

voice terminals
trunk troubles, 11-2
voltages, 5-98

W

warm starts, 4-2
wiring harnesses
expansion port network (EPN) cabinets, 2-7
processor port networks (PPNs) cabinets, 2-7



Processing of Packet Bus Problems (Page 1 of 2)
